**Role of Glomerular Proteoglycans in IgA Nephropathy** Kerstin Ebefors,[1] Anna Granqvist,[1] Madeleine Ingelsten,[1] Johan C. Molne,[2] Jenny C. Nystrom,[1] Borje Haraldsson.[1] *[1]Clinical and Molecular Medicine, University of Gothenburg, Gothenburg, Sweden; [2]Pathology, University of Gothenburg, Gothenburg, Sweden.*

**Purpose:** IgA nephropathy (IgAN) is the most common glomerulonephritis, still the mechanisms behind the disease are relatively unknown. To find molecular markers and improve the understanding of the disease, the expression of proteoglycans was investigated in biopsies from patients with IgAN and correlated to clinical data. Proteoglycans are negatively charged matrix molecules also acting as binding sites and signaling molecules.

**Methods:** We collected and microdissected biopsies from patients with IgAN (n=19) and from healthy kidney donors (n=14). Gene expression of proteoglycans and related genes were separately investigated in glomerular and tubular parts. Paraffin embedded sections of the biopsies were used for protein staining. Gene expression levels were correlated to morphological and clinical data.

**Results:** Patients were followed for an average time of 4 years and blood pressure was according to target guidelines. Three of the proteoglycans investigated were found to be of special interest and upregulated in glomeruli; perlecan (x1.9, p<0.01), decorin (x1.4, p<0.05) and biglycan (x2.4,p<0.001). Perlecan gene expression negatively correlated to albumin excretion (r=-0.58, p<0.05) and progress (r=-0.52, p<0.05) of the disease. Abundant decorin protein expression was found in sclerotic glomeruli, but not in normal glomeruli from IgAN patients or controls. Also, the decorin and biglycan-binding protein, transforming growth factor beta (TGF-β) was upregulated in IgAN both on gene (x2.5, p<0.001) and protein (p<0.05) level.

The tubular gene expression differed from the glomerular compartment, with a down regulation of perlecan (x0.6, p<0.01), and unchanged expression of decorin, biglycan and TGF-β.

**Conclusion**: We found that a high perlecan expression correlates to a slow progress of the disease, and may thus be used as a predictor for patient outcome. Also, the upregulation of the TGF-β associated proteoglycans biglycan and decorin, as well as TGF-β itself, in IgAN patients indicate that regulation of TGF-β, and other profibrotic markers may play a role in IgAN pathology.

**Clearance of Renal IgA1 Deposits Using a Bacterial Protease: A Treatment Option under Investigation for IgA-Nephropathy** Elaine Phan, Shinong Long, Rajeev Mahimkar, Amanda N. Kovach, Andreas Taylor, Sherron Bullens, Paul A. Fitzpatrick. *BioMarin Pharmaceutical Inc., Novato, CA.*

This poster describes the development of a mouse model for IgA Nephropathy (IgAN) using human IgA1 as well as ability of the *H. Influenzae* IgA1 protease to clear IgA1 deposits in the model.

Previous studies by Hiki *et. al.* (1999), showed that IgAN patients have aberrantly undergalactosylated IgA1. High levels of this aberrant IgA1, both circulating freely and in immune complexes, lead to deposition and accumulation within the kidney glomerulus. Accumulation is causally linked to pathological development including hematuria, proteinuria and progression to end stage renal failure.

The mouse model was developed by injecting different doses of human IgA1 and assessing the renal deposition. IgA1 from plasma of normal human subjects was purified to near homogeneity by a series of enrichment and chromatographic steps including ammonium sulfate precipitation and by column chromatography including ion exchange, Jacalin lectin and size exclusion. Purified normal IgA1 was modified with specific deglycosidases to confer properties similar to undergalactosylated IgA1 (degly-IgA1). The mouse model developed renal IgA1 deposits.

The pathogenic bacterium, *H. Influenzae*, expresses an endogenous IgA1 protease that is specific to human IgA1 but is not suited for large scale IgA1 protease production. A recombinant form of IgA1 protease was produced in *E. coli* as inactive and insoluble inclusion bodies (IBs). The IBs were solubilized by 8M urea and refolded by dilution into an arginine-containing buffer. The refolded recombinant protein was purified by metal chelating chromatography, ion exchange chromatography, and size exclusion chromatography.

The IgA1 protease produced in *E. coli* was tested for its ability to clear renal IgA1 deposits in the mouse model. A two week study was conducted to treat the degly-IgA1 deposits in mice by injecting them with IgA1 protease intravenously, resulting in clearance of the degly-IgA1 deposits. Thus, the mouse IgAN model and clearance of deposits via the IgA1-Protease provide a platform for development of protease therapeutics for treatment of IgA Nephropathy.

**Renal Klotho Expression May Be Modulated by Recombinant Human Erythropoietin in Experimental Chronic Kidney Disease** Hidekazu Sugiura, Takumi Yoshida, Junko Kohei, Shunji Shiohira, Michihiro Mitobe, Ken Tsuchiya, Kosaku Nitta. *Fourth Department of Internal Medicine, Tokyo Women's Medical University, Tokyo, Japan.*

Erythropoietin (EPO) and Klotho expression have both been detected in the kidney. Klotho is well known as an anti-aging gene, which protein is essential for the functioning of endogenous fibroblast growth factor 23. Since a recent study suggested that both erythropoietin and Klotho mitigate kidney damage, we explored the relation between erythropoietin and Klotho in a doxorubicin hydrochloride (DXR)-induced rat nephropathy model treated with recombinant human erythropoietin (rhEPO). Male Sprague-Dawley (SD) rats were subjected to DXR-induced nephropathy. The rhEPO group was intracutaneously injected with rhEPO twice weekly at 4 to 16 weeks after the DXR injection. On the other hand, to examine the direct effects of rhEPO on Klotho expression, SD rats were pretreated with rhEPO (200 U/kg s.c. three times every other day). Expression of renal Klotho and heat shock protein 70 (HSP70) were assessed using real-time PCR or Western blotting. The hematocrit, serum creatinine (SCr) and phosphate (iP) levels were also determined. Histological assessment was performed by immunohistochemical and Masson-trichrome staining. Renal Klotho expressions was significantly reduced (0.5-fold, p<0.05) in the DXR nephropathy group. Treatment with rhEPO improved the SCr, iP level and histological changes observed in the DXR nephropathy group. The reduction in Klotho expression induced by DXR nephropathy was mitigated by rhEPO administration. Normal rats with rhEPO treatment showed slight but significant increase in Klotho and HSP70 (1.2-fold, p<0.05), which was heat shock protein family and could be expected anti-oxidant activity, nevertheless the levels of hematocrit, hemoglobin, SCr, iP were not significantly alternated in this group. The precise mechanism of cross-talk between Klotho and EPO could not be clarified in this study, however, both of them, being expressed in the renal interstitium, may have interaction between them. In conclusion, favorable effects of rhEPO against renal damage are likely, in part, mediated via the expession of Klotho.

**Detection of Calcineurin Expression in Podocytes of Patients with Membranous Nephropathy** Zhao-Hong Chen, Yongchun Ge, Xi Tang, Ming-Chao Zhang, Xiao-Dong Zhu, Ke Zuo, Chun-Xia Zheng, Cai-Hong Zeng, Zhi-Hong Liu. *Research Insitute of Nephrology, Jinling Hospital, Nanjing University of Medcine, Nanjing, Jiangsu, China.*

Calcineurin activity relates with the regulation of podocyte cytoskeleton stability and the development of proteinuria. It is interesting to know the expression of calcineurin in podocyte of patients with membranous nephropathy (MN) and its change after treatment with calcineurin inhibitor (CNI). 49 patients with idiopathic MN were recruited. Repeated renal biopsy tests were performed in 2 idiopathic MN patients with complete remission after tacrolimus treatment. Immunohistochemistry was performed to detect the expression

of calcineurin A alpha subunit (CnAα) and synaptopodin in renal tissue. Furthermore, the expression of CnAα was compared between patients with idiopathic MN, type V lupus nephritis and hepatitis B virus associated MN. The results showed that increased expression of CnAα in podocytes were observed in 20 idiopathic MN patients (40.8%), accompanied by decreased expression and abnormal distribution of synaptopodin. Tacrolimus treatment results in the significant decrease of CnAα expression, with improved expression of synaptopodin in the podocytes. No podocyte CnAα expression was observed in patients with hepatitis B virus associated MN, but the positive rate for CnAα expression was similar between patients with type V lupus nephritis and those with idiopathic MN. Therefore, detection of podocyte calcineurin expression may be used as a diagnostic test to evaluate the efficacy of CNI in the treatment of patients with MN.

**Albumin Overload Impairs Autophagy in Proximal Tubular Cell** Raymond Yan, Jonathan M. Gall, Zhiyong Wang, Steven C. Borkan, John H. Schwartz, Andrea Havasi. *Renal Section, Boston University Medical Center, Boston, MA.*

Proteinuria predicts progressive chronic kidney disease (CKD). Exposure of proximal tubular epithelial cells (PTEC) to albumin promotes tubular atrophy and fibrosis but the mechanism(s) of albumin toxicity have yet to be elucidated. We hypothesize that exposing PTEC to albumin inhibits autophagy, a critical cellular function responsible for turnover of macromolecules and organelles, including dysfunctional mitochondria. Autophagy inhibition is a potential cause of cell stress, tubular dysfunction and atrophy. To test this hypothesis, autophagy was measured in cultured mouse tubular cells exposed to albumin. LC3, an established autophagy protein marker, undergoes LC3-I to LC3-II conversion during autophagy induction and becomes tightly membrane-bound to autophagosomes. To assess autophagy LC3-II content was detected by immunoblot and autophagosomes (AP) were visualized in cells expressing an LC3-GFP fusion protein. Autophagic flux was measured in the presence of bafilomycin, an inhibitor that prevents lysosomal LC3-II degradation. In mouse tubular cells, albumin exposure at concentrations of 0.5-25 mg/ml decreased LC3-II content in a concentration-dependent manner. Similar results were obtained using recombinant human albumin or bovine albumin, and either normal media (basal autophagy) or starvation media (induced autophagy). In the presence of bafilomycin, increasing albumin concentrations caused a stepwise decrease in autophagic flux. In addition, by immunofluorescence, albumin treatment decreased the number of GFP positive punctate structures that represent AP. A few larger GFP positive structures were observed in albumin-treated cells, especially over the first 24 hr, raising the possibility that albumin inhibits fusion between AP and lysosomes.

Taken together, these data show that albumin exposure inhibits PTEC autophagy. As a result, we propose that inhibition of autophagy contributes to CKD progression in proteinuric states.

**F-PO1190**

**A Functional Local Vitamin D System in Human Podocytes: Target for Anti-Proteinuric Therapy?** Katarina Mirkovic, Carolina R. C. Doorenbos, Jacob Van den Born, Wendy Dam, Gerjan Navis, Martin H. De Borst. *Department of Nephrology, University Medical Center Groningen, Groningen, Netherlands.*

**Background:**

Podocytes play a main role in glomerular permselectivity. In patients with chronic kidney disease the synthetic vitamin D receptor agonist paricalcitol has an additional anti-proteinuric effect when given on top of RAAS blockade, but its mechanism is not fully understood. To investigate whether podocytes could be a target for the antiproteinuric effect of vitamin D agonists, we characterized the local vitamin D system in cultured human podocytes.

**Methods:**

In human podocytes from a conditionally immortalized podocyte cell line, the presence of a local vitamin D system was investigated by measuring vitamin D receptor (*VDR*), 1α-hydroxylase and 24-hydroxylase (*CYP24A1*) mRNA expression. Cells were treated with increasing doses of calcidiol, calcitriol or paricalcitol (5 nM to 500 nM) or vehicle, and *VDR* activation (defined as *CYP24A1* gene expression) was determined by qPCR.

**Results:**

Human podocytes expressed *VDR*, 1α-hydroxylase and *CYP24A1* mRNA under basal conditions. Calcitriol dose-dependently induced *VDR* activation, with 100 nM inducing *VDR* activation already at 1 h (5-fold vs vehicle), reaching a plateau at 12 h (33-fold, $p<0.05$ vs vehicle) after stimulation. Similarly, paricalcitol dose-dependently induced *VDR* activation up to 10-fold ($p<0.05$) at 100 nM. Of interest, calcidiol (100 nM) also induced *VDR* activation strongly during the first 6 h after stimulation (up to 30-fold), but a rapid decline was observed thereafter.

**Conclusion:**

Our results support the presence of a functional local vitamin D system in human podocytes. Similar to many extrarenal cell types, also podocytes express 1α-hydroxylase. *VDR* activation by calcidiol suggests local (autocrine/paracrine) conversion to calcitriol or direct *VDR* activation by calcidiol in cultured human podocytes. The podocyte may be a target for direct anti-proteinuric effects by vitamin D analogues.

**F-PO1191**

**A Dynamic Retinoic Acid, Wnt and Hedgehog Signalling Network in Experimental Renal Chronic Damage** Christine Von Toerne,[1] Peter J. Nelson,[1] Elisabeth Groene,[2] Hermann-Josef Groene.[2] *[1]Department for Biological Chemistry, University Hospital LMU Munich, München, Germany; [2]Cellular and Molecular Pathology, German Cancer Research Center, Heidelberg, Germany.*

Chronic renal allograft damage (CAD) is a common feature in transplanted kidneys. CAD is manifested by a smouldering inflammation leading to transplant glomerulopathy, diffuse interstitial fibrosis and tubular atrophy. In this regard, CAD can also be seen as a general model for chronic renal failure. Retinoic acid (RA)is an important regulator of differentiation during vertebrate embryogenesis; it can moderate the damage observed in experimental models of CAD (Adams J. et al. Am J Pathol. 167:285-98, 2005). The Wnt and Hedgehog (Hh) signalling pathways are also relevant for tissue homeostasis and have been shown to interact during embryogenesis. Using a Fischer 344 (RT1lvl) to Lewis (RT1l) rat renal allograft model with analogies to human CAD (Kiss E. Am J Pathol. 176:2150-62, 2010) and enhanced microarray analysis linked to a systems biology approach, we show that Wnt and Hedgehog pathway signalling is dysregulated during CAD where subsets of Hh/Wnt modules can be linked to the pathophysiology of progressive fibrosis, loss of cilia in epithelia and chronic dysfunction. Nuclear accumulation of β catenin protein also strenghthened the finding of the array analysis of canonical Wnt pathway activation in CAD. Amongst other critical components of the Hh pathway, the receptor Ptch1, an indicator for Hh pathway induction was increased with CAD. Nuclear receptors such as the RAR can bind β catenin, compete with TCF/LEF1 for DNA binding and help regulate activation of Wnt target genes.

Treatment with 13cis-retinoic acid selectively ameliorated the dysregulation of the Hh and canonical Wnt pathways associated with CAD and preserved cilia structures. We could verify direct effects of RAR activation on tubular epithelial cells by showing effects of 13CRA on mRNA expression of Ihh, Shh, Gli1, Ptch1, Lrp2, Bmp7, Wnt6 and Wnt7a genes. Thus, the interplay between these pathways helps explain the therapeutic effects of retinoic acid treatment in CAD and may suggest future directions for moderating chronic fibrosing renal damage.

**F-PO1192**

**Improvement in Diabetes Care and Immunization Rates with a Disease Management Program in End-Stage Renal Disease Patients** Tami Deeb, Deborah Murray, Jess Parks, Allen R. Nissenson. *DaVita Inc., Denver, CO.*

Introduction: Both infections and complications from diabetes lead to poor outcomes in ESRD patients. Disease management (DM) programs may be effective ways to administer vaccinations to prevent pulmonary infections and improve diabetes care. We evaluated the impact of a DM program on pneumococcal and influenza vaccine rates and diabetes processes of care.

Methods: The ESRD DM Demonstration, implemented by CMS, studied the impact of DM by DM organizations (DMO) in Medicare Advantage ESRD patients on clinical, patient-centered outcomes. The impact of one participating DMO, VillageHealth (VH), is described. Data from Medicare ESRD pts who voluntarily enrolled in VH were compared to fee-for-service (FFS) data from the 2008 and 2009 United States Renal Data System (USRDS) Annual Data Report.

Results: From 2006-2009, 894 patients enrolled in VH. Immunization rates increased after program initiation, rising to a 95% annual influenza vaccination rate in 2009. For pneumococcal vaccination, the 2007 VH rate exceeded the USRDS FFS comparison of 22% for 2006-2007. In 2009, the pneumococcal vaccination rate was 97%.

Care for diabetic patients was also examined. In 2009, 61% of VH diabetic patients received retinal exams compared to 47% of FFS USRDS patients. Low density lipoprotein levels were tested in 78% of diabetic VH patients compared to 73% of FFS USRDS patients in 2009. Foot exams were received by 98% of diabetic VH patients. Compared to available USRDS FFS comparison rates, 71% of VH pts received ≥4 HbA1c tests in 2009, well above the 60% reported in the FFS population in 2009.

Conclusions: Within the VH program, DM leads to increased rates of influenza and pneumococcal immunizations and improved diabetes care processes. In both categories, the VH DM program exceeded rates in the FFS.

**F-PO1193**

**Characterizing Pre-ESRD Care in the Era of eGFR Reporting** Khaled Abdel-Kader,[1] Gary S. Fischer,[2] James R. Johnston,[1] Chen Gu,[2] Charity G. Moore,[2] Mark L. Unruh.[1] *[1]Renal-Electrolyte Division, University of Pittsburgh, Pittsburgh, PA; [2]Department of General Internal Medicine, University of Pittsburgh, Pittsburgh, PA.*

**Background:** PCPs care for the majority of pre-dialysis CKD patients; however, they often fail to recognize the presence of CKD based on serum creatinine levels. One strategy to improve disease awareness and perhaps treatment is eGFR reporting. We examined practices in PCP-managed and co-managed patients before and after routine eGFR reporting.

**Methods:** We conducted a retrospective cohort study of patients with CKD 3b-4 seen at a university-based, outpatient general internal medicine clinic. We compared co-management rates, CKD documentation, renal protective strategies, and laboratory monitoring in 274 and 266 patients seen in a 6-month period prior to and following eGFR implementation, respectively.

**Results:** Pre-eGFR patients were less likely to be men (29% vs. 39%, P=0.02), black (24% vs. 38%, P<0.001), or have HTN documented at baseline (63% vs. 80%, P<0.001) than post-eGFR patients. Following eGFR use, the prevalence of co-management increased from 23% to 49% (P<0.001). In addition, CKD documentation, NSAID avoidance, and annual monitoring of phosphorus and PTH improved following eGFR use.

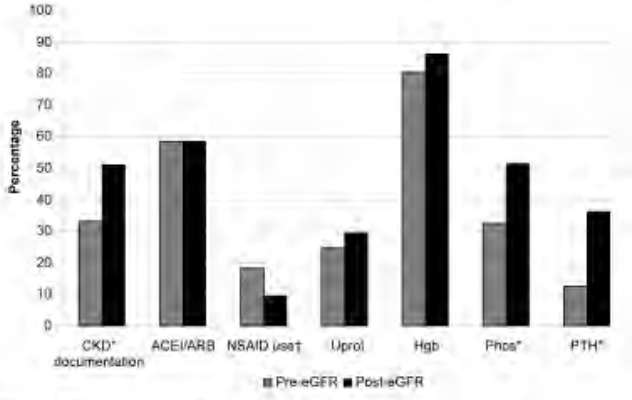

**Figure 1.** Processes of care in CKD 3b-4 patients.
Uprot: annual quantitative urinary albumin/protein testing.
Hgb/Phos/PTH: annual monitoring of respective lab parameter
*P<0.001, † P=0.003.
Pre-eGFR N=274, Post-eGFR N=266.

However, ACEI/ARB use, quantitative urinary protein testing, and Hgb monitoring were unchanged. Despite improvements following eGFR reporting, PCP-managed patients still had significantly lower rates of CKD documentation (31% vs. 81%, P<0.001), NSAID avoidance (86% vs. 97%, P=0.003), and Hgb (81% vs. 94%, P=0.001), Phos (33% vs. 79%, P<0.001), and PTH (17% vs. 65%, P<0.001) monitoring than co-managed patients.

**Conclusions:** Although CKD co-management increased and some CKD processes of care improved following eGFR implementation, overall care remained suboptimal. Further strategies are needed to improve PCP and nephrologist CKD care.

## F-PO1194

**Ten-Site Implementation of the Advanced Chronic Kidney Disease Patient Management Toolkit (ACPMT)** Uptal D. Patel,[1] Jameta N. Barlow,[1] William E. Haley.[2] *[1]Duke Univ, Durham, NC; [2]Mayo Clinic, Jacksonville, FL.*

**Background:** Appropriate management of advanced CKD improves patient outcomes, however, care is often suboptimal. We implemented the Renal Physicians Association's ACPMT in 10 community nephrology practices and evaluated whether adherence to clinical practice guidelines for patients with advanced CKD improved.

**Methods:** Ten willing US sites were selected after stratifying by practice characteristics. Patients with advanced CKD (eGFR 15-30 ml/min) were identified and random samples of 30 charts were abstracted at each site before and after implementation by an independent abstractor. ACPMT implementation was supported by site visits and monthly conference calls with site champions over the 6 month intervention period. Differences in adherence to guidelines between pre- and post-implementation periods were estimated using chi-squared tests.

**Results:** Study sites varied according to practice characteristics, patient compositions, and baseline conformance to practice guidelines. Quantitative analyses demonstrated relatively high (>75%) baseline conformance to routine monitoring guidelines within categories of anemia, metabolic bone disease, hypertension, and nutrition. However, baseline assessment of any abnormalities present (60-80%) and management with treatments (40-60%) were somewhat lower. Documentation for counseling (eg, nutrition, social work, others) and renal replacement preparatory activities (eg, referral for transplant evaluation, vein preservation, vascular access referral, others) was low (<20-40%). Although conformance to various guidelines changed for some measures (increased [n= 2], decreased [n= 4]), most remain unchanged (n= 19) perhaps due to ceiling effects, especially for monitoring guidelines. Median use of tools within the ACPMT was high (13 of 16 available tools), but varied across sites (range, 9-14).

**Conclusion:** There was limited impact on adherence to clinical practice guidelines for patients with advanced CKD during a 6 month implementation of the ACPMT. Consistent tool usage for a longer duration may be required to improve the management of advanced CKD.

**Use of NSAIDS and Awareness of CKD in Patients of Internal Medicine Residency Clinic** Devathi Sreedhar, John E. Prior. *Internal Medicine, Scranton Temple Residency, Scranton, PA.*

Background : Many patients are unaware that they have CKD. In these patients the use of over the counter drugs like NSAIDS is associated with drug related toxicity. It is shown previously the use of NSAIDS is highly prevalent in CKD patients. The aim of this study is to survey the awareness of CKD and the use of NSAIDS in our patients cared for in our internal medicine clinic.

Methods: Patients with CKD (GFR < 60 ) who visited the clinics in a period of of one year ( n=100 ) were identified by EMR and then were interviewed over the telephone to survey their awareness of CKD, education of CKD and to document their use of NSAIDS.

Results: Overall, 60% of the patients with a GFR of <60 were aware of they had CKD, 60% of the patients stated that they were educated by their physicians and 1% of the patients of CKD reported using NSAIDS. Conclusion : In contrast to the results reported by the prior studies, our patients showed a greater awarenss of their diagnosis of CKD ( 60% ) than reported in the literature ( 10% ). This awareness was associated with less use of potentially nephrotoxic drugs such as NSAIDS. The use of EMR, lab reporting of eGFR and education of patients all likely had a positive impact on patients' CKD awareness

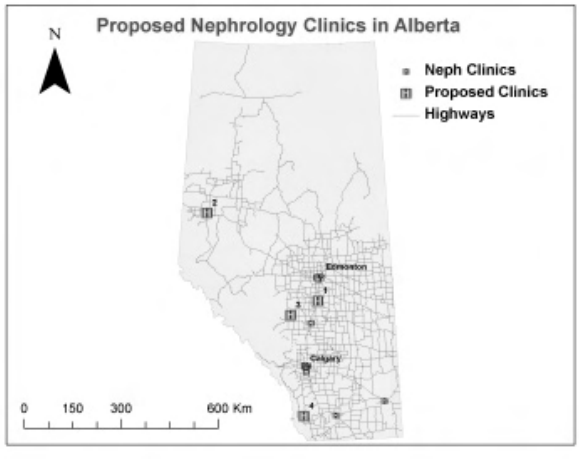
**GIS Techniques To Optimize Locations of New Nephrology Clinics for Remote Areas** Bharati Ayyalasomayajula,[1] Brenda Hemmelgarn,[2] Natasha Wiebe,[1] Marcello Tonelli.[1] *[1]Medicine, U. Alberta; [2]U. Calgary.*

**Background**: The province of Alberta, Canada has a geographic area of 660,000 km$^2$ but only 15 nephrology clinics, which are chiefly located in major cities. Although most CKD patients with eGFR<45 mL/min/1.73m$^2$ live within 30 min (by road) of the closest clinic, a substantial proportion live >2 hours away, which may compromise their care. Given limited resources, a systematic approach to determining the optimal location for 4 new nephrology clinics is required.

**Methods**: GIS techniques such as buffer analysis, network analysis and spatial analysis were used to determine the ideal locations for new clinics. Travel times were calculated using posted speed limits and road network data. Service area polygons for different travel time intervals (0-30 min, 30-60 min, 60-90 min, 90-120 min) were generated and used to determine the best location for the 4 new facilities that would maximize the number of patients travelling < 30 min. Clinical characteristics by travel time category were determined and cartographic techniques used to visualize results.

**Results**: We studied a population-based sample of 31,452 patients with eGFR<45 mL/min/1.73m$^2$, most of who lived <30 min from a nephrology clinic (Table). Adding the 4 new facilities would increase the number of patients living <30 min from a clinic by 1,154 (5.0%) and reduce the number living >120 min away by 960 (35%).

**Conclusion**: GIS techniques facilitate optimum resource allocation and perhaps better patient care. These techniques could be applied in other settings for management of CKD and other non-communicable illnesses.



| Scenario | Total travel time (h) | 0-30min, n(%) | 30-60min | 60-90min | 90-120min | >120min |
|---|---|---|---|---|---|---|
| Status Quo | 19,352 | 23,230(74) | 2,524(8) | 2,041(6) | 903(3) | 2,754(9) |
| 4 New Facilities | 13,783 | 24,384(78) | 2,611(8) | 1,680(5) | 983(3) | 1,794(6) |

**F-PO1197**

**HALT-PKD Clinical Trials, Characteristics of Baseline Liver Cystic Volume** Arlene B. Chapman,[1] Robert W. Schrier,[2] Vicente E. Torres,[3] Ronald D. Perrone,[4] Kyong Tae Bae,[5] Marva M. Moxey-Mims,[6] Theodore I. Steinman,[7] William E. Braun,[8] Franz Winklhofer,[9] Kaleab Z. Abebe,[5] James E. Bost.[5] *[1]Emory U; [2]U Colorado; [3]Mayo Clinic; [4]Tufts; [5]U Pittsburgh; [6]NIH/NIDDK; [7]Beth Israel; [8]Cleveland Clinic; [9]Kansas U; [10]HALT PKD Study Group.*

The HALT-PKD clinical trial network currently has two randomized trials, Study A (548 participants, eGFR >60 ml/min/1.73 m$^2$, 2-by-2 design randomization to ACEi/ARB *vs* ACEi alone and to low *vs* standard BP targets) and Study B (470 participants, eGFR 25-60 ml/min/1.73 m$^2$, randomized to ACEi/ARB *vs* ACEi alone). All Study A patients underwent magnetic resonance imaging to determine total kidney volume (TKV) and liver cyst volume (LCV) to estimate the severity of polycystic liver disease. We ascertained associations of baseline parameters and LCV in Study A participants.

462/558 (83%) of HALT A participants demonstrated liver cysts, similar to the overall CRISP cohort (85%). Mean LCV was 248 ± 762 mLs. LCV were greater in women vs. men (343±801vs.148±706 mL, p=0.006). Those without liver cysts were significantly younger (31.2±10.0 vs. 37.2±7.5 years), more often male (51.5 vs. 48.5%), with greater eGFR (93.8 ±21.4 vs. 84.9±17.1 mLs/min) all P<0.0001. No differences in TKV were found in those with or without liver cysts (1101±660 vs. 1235±732 mLs). LCV significantly correlated with age (r = 0.22**)** and eGFR (-0.11), but not urine albumin excretion or TKV.

Conclusion: Polycystic liver disease is present in the majority of HALT A participants consistent with other cohorts. Female gender, increased age and reduced eGFR associated with larger LCV. Further investigation to determine the factors associated with polycystic liver disease is underway.

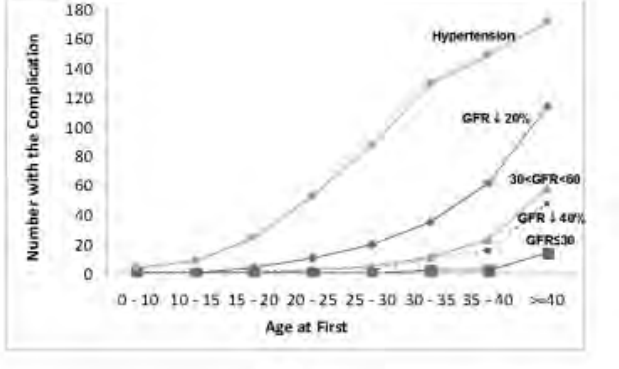
**Cyst-Dependent Renal Complications in Autosomal Dominant Polycystic Kidney Disease** Arlene B. Chapman,[1] James E. Bost,[3] Vicente E. Torres,[2] Michal Mrug,[5] Kyong Tae Bae,[3] Jared J. Grantham.[4] *[1]Emory U; [2]Mayo Clinic; [3]U of Pittsburgh; [4]Kansas U Medical Ctr; [5]U of Alabama, Birmingham.*

Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive kidney enlargement due to expanding cysts, which account for increased kidney volume (TKV). We test the hypothesis that TKV predicts the development of renal complications in ADPKD.

**Methods:** We determined the age of onset of hypertension (HBP), gross hematuria (GH), pain, nephrolithiasis (NL), urinary tract infection (UTI) and renal insufficiency (RI) in 200 CRISP study participants followed from 2001 to 2009. Serial measurements of TKV adjusted for height (htTKV, cc/m) using magnetic resonance images and kidney function assessed by iothalamate clearances (IC) were obtained. HtTKV associations with the occurrence of renal complications in ADPKD were determined.

**Results:** Renal complications began in the first decade of life with eight participants free of complication at end of follow up. The average number of complications excluding RI was 2.7 with > 50% having 3 or more. HtTKV was associated with the number of renal complications experienced independent of age. 50% of CRISP participants had developed HBP by age 30, UTI by age 40, GH by age 45, ≥ 20% reduction in IC by age 45, and K/DOQI stage 3 CKD by age 49. One episode of symptomatic NL had occurred by age 45 in 25%. Plots of cumulative onset curves for HBP and decreased IC were exponential (Figure 1). HtTKV predicted the onset of HBP, GH and RI (p<0.001) in multivariable analysis. Receiver operator curves for baseline htTKV and K/DOQI stage 3 demonstrated an AUC 0.83, with high sensitivity (81.0%) and specificity (72.1%) at htTKV value of 600 c/m.



**Summary:** Major life-altering complications occur early and throughout the course of ADPKD. The development of HBP, GH and RI are predictably related to TKV.

**Effect of Pioglitazone, a PPAR-γAgonist, on Non-Diabetic Chronic Kidney Disease with Proteinuria. A Prospective, Randomized Study** Takashi Oda,[1] Kojiro Yamamoto,[1] Keishi Higashi,[1] Taketoshi Kushiyama,[1] Toshitake Hyodo,[1] Naoki Oshima,[1] Hiroki Sato,[2] Yutaka Sakurai,[3] Soichiro Miura,[1] Hiroo Kumagai.[1] *[1]Nephrology, National Defense Medical College, Tokorozawa, Saitama, Japan; [2]Medical Informatics, National Defense Medical College; [3]Preventive Medicine and Public Health, National Defense Medical College.*

We have reported that pioglitazone (Pio), a PPAR-γ agonist, significantly reduced proteinuria and exerts renoprotective effect in spontaneously hypercholesterolemic (SHC) rats, a model of chronic kidney disease (CKD) with massive proteinuria (Am J Physiol 2007; 293: F1292-8). We therefore conducted a prospective and randomized trial comparing the antiproteinuric effect of Pio with that of dipyridamole (Dip) in nondiabetic CKD patients. Twenty four nondiabetic CKD patients, whose systolic blood pressure have been controlled below 135 mmHg, and who have been receiving a renin-angiotensin system (RAS) inhibitor (4 of them couldn't use it because of low blood pressure or high potassium concentration), were randomly assigned into Pio or Dip group. Pio (at a dose of 15~30 mg/day) or Dip (at a dose of 150~300 mg/day) was added on the regular treatment and continued for 6 month. The primary endpoint was a decrease in the urinary protein to creatinine ratio. One patient in Pio group was eliminated because of the usage of corticosteroid during the study due to the asthmatic attack, and one patient in Dip group stopped continuation of Dip because of severe headache. Thus, 11 patients with Pio and 11 patients with Dip were compared. There was no significant difference in baseline parameters between two groups. In the Pio-treated group, the urinary protein was significantly decreased from 1.41 ± 0.33 to 0.76 ± 0.19 g/gCr (p< 0.01) after the therapy, but it did not change in the Dip-treated group (p=0.873). In both groups, no significant difference was found in other parameters, such as body weight, systolic blood pressure, serum creatinine, estimated GFR, HbA1c, LDL-cholesterol, Total-cholesterol, or uric acid. This study suggests that Pio significantly decrease the proteinuria of non-diabetic CKD and may be useful as a therapeutic option secondary to RAS inhibitors.

**Study of Reduction of Albuminuria with Ramipril Therapy in Obese vs Non-Obese Chronic Albuminuric Kidney Disease Patients** Sanjib Kumar Sharma,[1] Mahesh Bhattarai,[1] Prahlad Karki,[1] Nirmal Baral.[2] *[1]Department of Internal Medicine, B P Koirala Institute of Health Sciences, Dharan, Sunsari, Nepal; [2]Deparment of Biochemistry, B P Koirala Institute of Health Sciences, Dharan, Sunsari, Nepal.*

Background: Obesity increases the risk for chronic kidney disease (CKD). Albuminuria predicts renal disease progression, and its reduction by angiotensin converting enzyme inhibitor is renoprotective.

Objectives: To evaluate the extent of reduction of albuminuria in patients treated with ramipril in chronic albuminuric kidney disease and to compare the reduction of albuminuria in obese vs non-obese.

Methodology: In this prospective, open label, interventional study, the effect of 8 weeks of treatment with ramipril was compared in obese chronic albuminuric kidney disease patients with age and sex matched non-obese chronic albuminuric kidney disease patients.

Results: Despite comparable changes in blood pressure and glomerular filtration rate, 8 weeks of ramipril therapy decreased albuminuria significantly in non obese as compared to obese (50.14% Vs 10.72% p=0.028). Furthermore, in macroalbuminuric patient reduction was significant in non obese (58.16% Vs 7.34% p = 0.038) whereas in microalbuminuric group reduction was (25.48% Vs 18.01%, p = 0.380) not significant.

Conclusion: Eight weeks of ramipril therapy reduced albuminuria more effectively in non obese patients as compared to those of obese patients. Superior anti albuminuric effect in non obese was independent to blood pressure reduction. Reduction of albuminuria is more in macroalbuminuric non obese chronic kidney disease patients.

Disclosure of Financial Relationships: nothing to disclose

**Renal and Cardiovascular Outcomes with Telmisartan, Ramipril or Both in People at High Renal Risk: Results from the ONTARGET and TRANSCEND Studies** Sheldon W. Tobe,[1] Catherine M. Clase,[4] Peggy Gao,[2] Salim Yusuf,[2] Johannes F. Mann.[3] *[1]Medicine, Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [2]Population Health Research Institute, McMaster University, Hamilton, ON, Canada; [3]Medicine, Schwabing General Hospital, and KfH Kidney Center, Erlangen, Germany; [4]Medicine, McMaster University, Hamilton, ON, Canada.*

**Background and Objective:** The relationship between proteinuria reduction, with ACE inhibitors and angiotensin receptor blockers (ARBs) and improved renal and cardiovascular outcomes comes from observational data. Dual therapy with both agents has demonstrated greater proteinuria reduction than either alone but has yet to be shown to also improve renal or cardiovascular outcomes. This analysis was designed to evaluate and compare renal and cardiovascular outcomes in patients with normal and low glomerular filtration rate (GFR) and normal, micro- or macroalbuminuria in the ONTARGET and TRANSCEND studies.

**Methods:** Post-hoc analysis of renal subgroups of ARB versus placebo for the TRANSCEND study and dual therapy versus monotherapy for the ONTARGET study. Hazard ratios of events by subgroups and Cox regression models with factors for treatment, subgroup and interactions. Main renal outcome was the composite of chronic dialysis or doubling of creatinine and the main cardiovascular outcome, the composite of cardiovascular death, MI, stroke or hospitalization for heart failure.

**Results:** No renal or cardiovascular benefit from dual over mono-therapy in any subgroup. In TRANSCEND comparing ARB to placebo, there was a significant interaction (p= 0.01) in the direction of harm for patients with normoalbuminuria (35% greater renal risk from telmisartan) but a benefit for patients with micro- or macroalbuminuria (40% and 29% lower renal risk from telmisartan).

**Conclusions:** This analysis does not support dual over monotherapy even in patients with low GFR and macroalbuminuria. This observation is a post hoc comparison and should be interpreted appropriately.

## F-PO1202

**Tacrolimus Versus Intravenous Pulse Cyclophosphamide Therapy in Adults with Steroid-Resistant Idiopathic Minimal Change Nephropathy: A Nonrandomized Controlled Trial in China** Heng Li,[1] Xiangdong Shi,[2] Hong Shen,[3] Xiayu Li,[1] Jianghua Chen.[1] *[1]Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [2]Department of Nephrology, Huzhou Central Hospital, Huzhou, China; [3]Department of Nephrology, Taizhou Hospital, Taizhou, China.*

**Background:** Treatment of steroid-resistant minimal change nephropathy (SR-MCN) remains a challenge to nephrologists. The aim of this study was to compare the efficacy and safety of tacrolimus (TAC) with that of pulse intravenous cyclophosphamide (CTX) therapy in the management of SR-MCN.

**Methods:** We performed a nonerandomized controlled trial in three Chinese medical centers. Totally 33 Chinese adults with SR-MCN, and serum creatinine level of 133 mmol/L or less, were enrolled. Patients were self assigned to: (1) combination therapy with prednisone and oral TAC or (2) combination therapy with prednisone and intravenous CTX. TAC began at 0.05 mg/kg/day and adjusted to maintain a trough blood level of 5 to 10 ng/mL for 1 year ($n$ = 19). CTX began at 1.0 g/1.73 $m^2$ for a total dosage of 10.0 g/1.73 $m^2$ over 1 year ($n$ = 14). In both groups, oral prednisone began at 0.5 mg/kg/day for 3 months, which was tapered off to complete cessation by 6 months.

**Results.** The remission rate was 57.9%, 73.7%, and 78.9% in TAC group and 14.3%, 42.9%, and 50.0% in CTX group after 2, 4, and 6 months, respectively. The remission rate at 2 months was significantly higher in TAC group ($P < 0.05$). The remission rate during the 1-year therapy and the 1-year follow-up was higher in the TAC group than that in the CTX group (Kaplan-Meier, log-rank test, $P < 0.001$). For patients who achieved remission, the mean time needed for remission was 48.7 ± 36.0 days in the TAC group and was 85.3 ± 40.6 days in the CTX group ($P < 0.05$). During the 1-year therapy and 1-year follow-up periods, 6 of 15 TAC patients and 1 of 7 CTX patients relapsed ($P > 0.05$).

**Conclusions.** TAC therapy is safe and effective for treating adults with SR-MCN and induces remission more rapidly than does pulse intravenous CTX therapy, but it has a high relapse rate after withdrawal.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1203

**Long-Term Outcome of Paediatric Patients with Primary Systemic Vasculitis** Nishkantha Arulkumaran,[1] Helen Doolittle,[1] Susan Jawad,[1] Stuart W. Smith,[3] Lorraine Harper,[3] Paul Brogan,[2] Charles D. Pusey,[1] Alan D. Salama.[1] *[1]Renal Section, Division of Medicine, Imperial College Kidney and Transplant Institute, London, United Kingdom; [2]Institute of Child Health, Great Ormond Street Hospital, London, United Kingdom; [3]Division of Renal Immunobiology, University of Birmingham, Birmingham, United Kingdom.*

Purpose of study

We have described the long-term outcome of patients with primary systemic vasculitides presenting in childhood.

Methods

Retrospective analysis was performed to identify patient demographics and clinical course.

Results

Nine patients were identified- 6 had Wegeners granulomatosis (WG), 2 had Polyarteritis nodosa (PAN), and 1 had Microscopic Polyangiitis (MPA). The mean age at presentation was 11 years. The median follow up is 14 years. Mean presentation creatinine was 0.84mg/dL for 8 patients and one patient presented with end- stage renal failure (ESRF). 2 patients had a renal biopsy, - both were consistent with acute vasculitis. At induction all patients had steroids and 8 had cyclophosphamide. Eight patients achieved complete remission. Maintenance is with azathioprine or mycophenolate mofetil. Biological agents were used in 4 patients in adulthood for relapsing disease. All patients had at least 1 relapse, 5 were infertile and 7 had recurrent infections. Patient 2 died from disease- related complications after 25 years. Mean follow up creatinine is 0.87mg/dL.

Demographics and clinical outcomes of patients

| Patient | Diagnosis | Age at presentation (Years) | Serum Cr at presentation (mg/dL) | Current Cr (mg/dL) | Infertility | Recurrent infections | Relapses |
|---|---|---|---|---|---|---|---|
| 1 | PAN | 14 | 0.85 | 0.70 | + | - | 8 |
| 2 | PAN | 11 | 0.96 | 0.87 | + | + | 4 |
| 3 | MPA | 14 | 0.86 | 1.36 | + | + | 4 |
| 4 | WG | 9 | 0.72 | 0.76 | - | + | 3 |
| 5 | WG | 0.75 | 0.89 | 1.17 | + | + | 6 |
| 6 | WG | 9 | 0.76 | 0.77 | + | + | 8 |
| 7 | WG | 12 | 0.68 | 0.49 | - | + | 2 |
| 8 | WG | 14 | ESRF | ESRF | - | + | 6 |
| 9 | WG | 15 | 0.97 | 0.86 | - | - | 1 |

Abbreviations: Cr= Creatinine

Conclusions

Patients with primary systemic vasculitides presenting in childhood have similar long-term survival to adult cohorts. Renal function is usually preserved, but relapse rates and treatment-related morbidity is high. Close follow-up and identification of new treatment regimes are imperative.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1204

**Quality of Anemia Management and Healthcare Costs in CKD and Other At-Risk Patients** Anthony Staresinic. *Pharmacy Services, Physicians Plus Insurance Corp., Madison, WI.*

**Background:** Adherence to KDOQI, CKD testing, and other guidelines for anemia management in our HMO remains problematic despite ongoing improvement efforts. This study was undertaken at an integrated health system in Madison, WI to evaluate changes in anemia management quality and costs. **Methods:** Members were screened for anemia using administrative claims data. The anemia index date (AID) is the date of the member's first anemia claim. Members had to meet eligibility requirements before and after the AID. Anemia cohorts underwent further analysis: chronic kidney disease (CKD), female 18 to 49 years of age (FEM), diabetes, hypertension or congestive heart failure (DHC) and Other (OTH). To qualify for KDOQI adherence hemoglobin, iron, iron binding capacity and ferritin tests had to be done within 90 days before and 30 days after the AID. This study was reviewed and approved by our local institutional review board. **Results:** Study included 4177 members with anemia. Compared to DHC, the CKD group was more likely to have diabetes but less likely to have hypertension.

| Variable | CKD | DHC | FEM | OTH |
|---|---|---|---|---|
| KDOQI adherent | 25 (19) | 101 (8)* | 125 (11)* | 2 (<1)* |
| SCr, No. (%) | 82 (61) | 398 (33)* | 165 (14)* | 382 (23)* |
| CBC, No. (%) | 111 (83) | 825 (69)* | 668 (58)* | 974 (58)* |
| Ferritin, No. (%) | 22 (16) | 71 (6)* | 77 (7)* | 101 (6)* |
| Fecal occult, No. (%) | 7 (5) | 70 (6) | 22 (2) | 73 (4) |
| ESA Use, No. (%) | 4 (3) | 0 (0) | 0 (0) | 3 (<1) |
| IV Iron, No (%) | 0 (0) | 0 (0) | 0 (0) | 0 (0) |
| ACE Use, No. (%) | 54 (40) | 387 (32) | 3 (<1)* | 63 (4)* |
| *p<0.05 | | | | |

Post AID, there were no differences in rates of myocardial infarction or unstable angina. The CKD cohort had significantly higher rates of emergency room visits post AID. Post AID, CKD and DHC experienced 30% and 75% increases in medical costs. The FEM and OTH group experienced increases of 114% (P< 0.0001) and 138% (P<0.0001) respectively. **Conclusion:** Adherence to anemia testing and management guidelines remain suboptimal. There was no change in the drug management of anemia. Our HMO experienced increased costs post-AID. Interventions are needed to improve anemia-based care in CKD and at-risk member groups.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1205

**SureClick® (Darbepoetin Alfa, DA) Improves Perceived Satisfaction and Competence for Anemia Treatment and Increases Self-Administration in Non-Dialyzed Patients with Chronic Kidney Disease (CKD)** Xavier Bonafont,[1] Ramon Romero,[1] Isabel Martínez,[2] Mª Dolores Del Pino Pino,[3] José Manuel Gil,[4] Pedro Aranda,[5] Ramon Roca,[6] Joana Claverol,[7] Ignacio Arístegui.[7] *[1]H.G.Trias i Pujol, Badalona, Spain; [2]H.Galdakao, Galdakao, Spain; [3]H.Torrecárdenas, Almería, Spain; [4]CH.Jaén, Jaén, Spain; [5]H.Carlos Haya, Málaga, Spain; [6]H.Mollet, Mollet, Spain; [7]Amgen, S.A., Barcelona, Spain.*

Purpose: The SureClick® device is a pre-filled pen for the administration of DA that requires no preparation and is ready to use. The main objective was to evaluate whether the use of SureClick® increases patient satisfaction compared with pre-filled syringes.

Methods: Multicenter, prospective, 6-months, observational study in non-dialyzed patients with CKD treated with DA in pre-filled syringes (≥6 previous months), with stable hemoglobin, who switched to SureClick® as indicated in clinical practice. The primary endpoint was the Anemia Treatment Satisfaction Questionnaire (ATSQ-S). Secondary endpoints included: Perceived Competence for Anemia Scale (PCAS), degree of self-administration and adverse reactions to DA or device.

Results: 132 patients treated with DA every 2 weeks were included. Mean age (SD) was 71.3(14.6) years and 57.6% were women. Median(Q1;Q3) time since diagnosis of CKD was 5.1(2.6; 8.4) years (73.5% stage 4). Approximately half (47.7%) of patients self-administered DA with pre-filled syringes, vs 74.2% at final visit (p<0.001). Mean(SD) ATSQ-S scores at baseline and final visits were 25.5(7.9) and 31.6(4.9) (on a scale from 0 to 36 –maximum satisfaction), respectively (+6.2 points, 95%CI:4.6-7.8, p<0.05). The

patients' perceived competence (PCAS) also increased significantly (4.3(2.0) vs 5.6(1.6), on a scale from 1 to 7 – maximum competence, +1.3 points, 95%CI:1.0-1.6, p<0.05). Two patients (1.5%) had adverse reactions related to the device (pain on application) which led to discontinuation.

Conclusions: The change from pre-filled syringes to SureClick® for the administration of DA is associated to an increase in satisfaction and competence for anemia treatment in non-dialyzed patients with CKD. The use of SureClick® also achieves self-administration in 3 of 4 patients.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1206

**Predictors of Baseline and *Changes* in Quality of Life among Patients with Diabetes, Chronic Kidney Disease, and Moderate Anemia in TREAT** Eldrin F. Lewis,[1] Marc Pfeffer,[1] Amy Feng,[2] Hajime Uno,[1] John Mcmurray,[2] Robert D. Toto,[2] Shravanthi R. Gandra,[2] Scott D. Solomon,[1] Moustafa Moustafa,[2] Iain C. Macdougall,[2] Francesco Locatelli,[2] Patrick S. Parfrey.[2] *[1]Brigham and Women's Hospital; [2]On Behalf of TREAT Investigators.*

**Background:** Patients (pt) with anemia, diabetes, and kidney disease have variable quality of life (QOL). We aimed to identify *independent* predictors of 1) baseline and 2) changes in QOL.

**Methods:** *Baseline* QOL predictors in pt enrolled in Trial to Reduce Cardiovascular Events with Aranesp Therapy (TREAT) were assessed using 3 pre-specified domains[FACT-Fatigue, SF36 Energy, & SF36 Physical Function (SF36-PF)]. At 25 weeks, predictors of ≥3 point improvement in FACT-Fatigue and ≥5 point improvement in SF36 ("clinically meaningful") were assessed with logistic regression.

**Results:** Baseline QOL was impaired(FACT-Fatigue 30.3±12, SF36 Energy 45.9±22, SF36 PF 47.7±29). Predictors of all 3 baseline QOL domains were identified(*Table*). At 25 weeks, higher physical activity and worse baseline QOL were predictors of *improvements* in all 3 domains. Hospitalizations decreased odds of improved FACT-Fatigue and SF36-PF. Randomization to darbepoetin alfa increased odds of improved FACT-Fatigue and SF36-Energy.

**Conclusion:** Directly assessing QOL may be a useful strategy to determine pt who may benefit from therapy.

**Multivariate Predictors of *Baseline* Quality of Life**

### F-PO1207

**Medication Non-Adherence Predicts Hospitalization Rate and Healthcare Costs in Hemodialysis (HD) Patients** Harold J. Manley, Steven Wang, Allen R. Nissenson. *DaVita Inc., Denver, CO.*

Medication non-adherence is common among HD patients. Adherence can be estimated using the medication possession ratio (MPR). According to the USRDS, an MPR > 0.8 for individual ACEI/ARB, Beta-blocker, Statin, or oral hypoglycemic medications are associated with lower healthcare costs. Information on the relationship between entire-medication-regimen MPR and hospitalization risk and healthcare cost is lacking. We evaluated, in a cohort of HD patients, the hypothesis that overall non-adherence is directly related to both hospitalization risk and healthcare costs as part of a CMS ESRD Demonstration.

METHODS: We estimated medication adherence through a retrospective review of all pharmacy and medical claims for 663 HD patients from 1/06 to 6/09. We calculated MPR: MPR = Σ Medication Day's Supply/(# Days between the first fill & the last refill + Day's supply last refill). We used logistic regression models to determine the odds ratio of hospitalization (OR-hosp) for MPR ranges above and below 0.8-0.99, the reference range. We determined patient medication and hospital per member per month (PMPM) costs and hospitalization rate (per member per thousand days, PMPT) for each MPR range.

RESULTS: Risk of hospitalization, PMPM costs and hospitalization rate each increased significantly as overall adherence decreased. MPR values < 0.8 were associated with a greater hospitalization risk.

| MPR | Member Months | Medical Cost | Rx Cost | Total PMPM Cost | Admits PMPT | OR-hosp (CI) |
|---|---|---|---|---|---|---|
| <0.4 | 1444 | $6,266 | $386 | $6.612 | 1820 | 2.57 (1.1,5.3) |
| 0.4-0.59 | 3184 | $6,392 | $553 | $6,944 | 2080 | 2.2 (1.3,3.8) |
| 0.6-0.79 | 4352 | $5,385 | $670 | $6,056 | 1701 | 1.7 (1.1,2.7) |
| 0.8-0.99 | 3117 | $4,493 | $866 | $5,359 | 1178 | 1.0 (ref) |
| 1.0-1.19 | 1053 | $5,313 | $883 | $6,196 | 1641 | 0.6 (0.4,1.1) |
| >1.2 | 460 | $5,962 | $943 | $6,906 | 1826 | 1.3 (0.6,2.6) |

CONCLUSIONS: In HD patients, both hospitalization risk and total PMPM cost are directly related to medication non-adherence. Methods to improve MPR may help reduce morbidity and cost in this fragile patient population.

Note: This is a DaVita analysis of CMS demonstration experience; CMS will conduct an independent evaluation.

### F-PO1208

**Longitudinal Assessment of Health Related Quality of Life (HRQOL) in Pediatric Dialysis Patients** Shari K. Neul,[1] Stuart Goldstein.[2] *[1]Renal Service / Pediatrics, Texas Children's Hospital, Houston, TX; [2]Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Long-term ESRD pt survival has improved. Optimal pt care now must incorporate HRQOL assessment and management. We developed a pediatric ESRD-specific HRQOL instrument now validated (PedsQL™ 3.0 ESRD Module) in multiple cross sectional analyses. As part of standard clinical care we semiannually assess global (PedsQL™ Generic Scale) and ESRD-specific HRQOL in our dialysis patients. Both measures include patient self-report (5 to 18 yrs) and caregiver-proxy report (caregivers of children 2 to 18 yrs). We now report the first longitudinal assessment of pediatric ESRD HRQOL using these scales.

Eighteen dialysis pts (mean age 14.7 yrs; 14 HD; 4 PD; 61% male) and 15 caregivers had longitudinal data available. Results from the first year of assessment indicate that multiple global and disease-specific indices of HRQOL worsened over time on patient and caregiver-proxy ratings. Caregivers tended to view patients as functioning worse than patients viewed themselves on the global domains whereas patients tended to view themselves as functioning worse than caregivers perceived them to be on the ESRD-specific domains with the exception of communication, worry, and disease knowledge.

Magnitude of change in patient & caregiver-proxy HRQOL ratings over time

| PedsQL™ Generic | Patient | Caregiver |
|---|---|---|
| Physical | -3.65 | -5.74 |
| Emotional | -5.51 | -4.67 |
| Social | -1.39 | -4.67 |
| School | -6.25 | -8.67 |
| Total | -4.39* | -5.94* |
| PedsQL™ 3.0 ESRD Module | | |
| General Fatigue | -17.64 | -12.05 |
| About My Disease | -3.67 | -5.00 |
| Treatment Problems | -5.42 | -1.34 |
| Family & Peers | -8.89 | -3.57 |
| Worry | 3.67 | 0.89 |
| Physical Appearance | -3.89 | 0.00 |
| Communication | -4.33 | -8.57 |
| ESRD Total | -5.74 | -4.23 |
| *Represents a clinically significant change | | |

Our data suggest assessing both pt and caregiver HRQOL perceptions, and using both global and ESRD-specific measures, are key to more aptly understanding HRQOL in dialysis-dependent pts. We now are developing intervention initiatives aimed at patient/family HRQOL treatment planning as well as unit-wide programming based on these longitudinal data to optimally manage HRQOL functioning.

### F-PO1209

**Trends in Hospital Charges, Length of Stay (LOS), and Mortality for Pediatric Nephrotic Syndrome** Rose M. Ayoob, David S. Hains, William E. Smoyer. *Center for Clinical and Translational Research, Nationwide Children's Hospital.*

**Background**: Nephrotic syndrome (NS) is one of the most common types of kidney disease diagnosed in children, and is characterized by edema, hypoalbuminemia, and proteinuria. Children with NS are also at increased risk of developing serious complications such as infections, acute kidney injury, or thrombosis necessitating hospitalization.

**Objective:** To analyze trends in hospital charges, LOS, and mortality for children hospitalized with NS in the US.

**Methods:** Data were collected for patients ages 0-18 years hospitalized with the principal diagnosis of NS (ICD-9 codes 581,582.1, 583.1) during 2000, 2003, and 2006 using the Healthcare Cost and Utilization Project (HCUP) Kids' Inpatient Database (KID). Hospital charges were not corrected for inflation.

**Results:** From 2000-2006, the mean number of children hospitalized annually with a principal diagnosis of NS was 2,682 and the mean LOS was 4.4 days. These admissions resulted in aggregate hospital charges that increased from $35 to $52 million (48%). The mean total hospital charges per admission increased 46% from $13,120 to $19,549. About 75% of all admissions were to children's as opposed to non-children's hospitals. Of note, the mean hospital charges per day averaged 19% more in children's vs. non-children's hospitals, while the mean LOS averaged 67% longer. Importantly, the mortality rate remained <0.4% during the entire study period.

**Conclusions:** No significant trends were found in the total admissions for NS or the mean LOS during the 6 year time period. However, children's hospitals had higher mean hospital charges per day and LOS than non-children's hospitals. Furthermore, 25% of all children with NS were admitted to non-children's hospitals. We speculate that the larger hospital charges and LOS in children's hospitals may be due to referrals of higher acuity patients requiring specialized care.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1210

**Healthcare Utilization and Costs for Children with Lupus Nephritis** Marie Tanzer,[1] Amber Kroeker,[1] Larysa Wickman,[1] Cheryl Tran,[1] Brett Ehrmann,[1] Peter Song,[2] Debbie S. Gipson.[1] *[1]Division of Pediatric Nephrology, University of Michigan, Ann Arbor, MI; [2]School of Public Health, Biostatistics, University of Michigan, Ann Arbor, MI.*

Introduction:

Systemic Lupus Erythematosus (SLE) is a common cause of vasculitis in children and adults. The presence of lupus nephritis can be a life threatening complication which when defined and treated specifically may be controlled.

Study Aim:

We undertook the present study to define the healthcare utilization and cost of SLE Nephritis in the USA.

Methods:

We used the 2006 data from the Healthcare Cost and Utilization Kids Inpatient Database, sponsored by the US Agency for Healthcare Research and Quality, for this study. Hospitalization data were reported from 38 states. SLE was defined by ICD-9 code 710.0, nephritis was defined as Nephritis NOS 583.81, Chronic Nephritis 582.81, Nephrotic Syndrome 581.81.

Results:

Among children age 1 to 17 years, 2,109 hospitalizations for SLE were reported out of 6,578,069 total hospitalizations during this period, accounting for 3 out of every 10,000 hospitalizations. Nephritis or Nephrotic syndrome was present in 1,258 (59%) and ARF in 138 (6.5%) of these pediataric hospitalizations. Hospitalization for lupus nephritis was most common among children age 15 to 17. The median length of stay was 3 days for all SLE, 2 days for SLE with nephritis NOS, 3 days for chronic nephritis, 4 days for nephrotic syndrome and 10 days for SLE with ARF. The median charge per hospitalization ranged from $12, 034 for lupus nephritis NOS to $63,266 for lupus with ARF. The weighted aggregate charge was $38,982,842 for all pediatric hospitalizations with lupus nephritis. When ARF charges were added, the total bill increased to $53,956,117. The aggregate inpatient charges was strongly correlated with admission from the emergency department (r=0.99).

Conclusions:

Although only a portion of the total cost of care for children with SLE, the cost of inpatient healthcare for children with Lupus Nephritis is large. When SLE is complicated by nephrotic syndrome or ARF, the cost of a typical SLE hospitalization increases approximately 2 to 5 fold, respectively.

## F-PO1211

**Health Utility at 60 Days Predicts 12-Month Mortality among AKI Survivors** Mark W. Smith,[1] Kirsten L. Johansen,[2] Mark L. Unruh,[3] Andrew M. Siroka,[1] Theresa Z. O'Connor,[4] Paul M. Palevsky.[3,5] *[1]VA Palo Alto; [2]VA San Francisco; [3]University of Pittsburgh; [4]VA Connecticut; [5]Pittsburgh VA.*

We hypothesized that utility 60 days after AKI onset would predict 12-month all-cause mortality. The VA/NIH Acute Renal Failure Trial Network Study was a multi-center, prospective, randomized trial of intensive vs. less-intensive renal replacement therapy in critically ill patients with AKI. Participants completed the Health Utilities Index (HUI3) at days 60 and 365. The total score and subscores for eight attributes range 0-1 where 1 represents highest functioning. Of 1124 participants there were 415 survivors with analyzable utility data at 60 days and 258 at 365 days. Persons still dialysis-dependent at day 60 were less likely to have usable data (48% vs 84%).

Four HUI3 subscales were hypothesized to be affected by AKI: ambulation, cognition, emotion, and pain. We estimated proportional hazard models of 12-month mortality controlling for demographics, baseline health (Charlson Comorbidity Index, admission from home vs. SNF, SOFA score), hospital stay characteristics (study arm, treating specialty, LOS), and dialysis independence at day 60.

Higher scores on the HUI3 and three subscales (ambulation, cognition, and emotion but not pain) were strongly correlated with lower mortality (hazard ratio < 1). Age, LOS, and comorbidity were also significantly associated with mortality.

Health utility can assist clinicians in predicting medium-term mortality risk among AKI survivors.

Cox Proportional Hazard Models of 12-Month Mortality: Partial Results

| | | | | | |
|---|---|---|---|---|---|
| HUI3 total score | 0.27 (<.01) | | | | |
| -- ambulation | | 0.11 (<.01) | | | |
| -- cognition | | | 0.13 (<.01) | | |
| -- emotion | | | | 0.15 (<.01) | |
| -- pain | | | | | 0.44 (0.14) |
| | | | | | |
| Age 60-74 | 1.46 (.10) | 1.41 (.14) | 1.55 (.06) | 1.50 (.08) | 1.54 (.06) |
| Age 75+ | 2.20 (<.01) | 2.15 (.02) | 2.21 (<.01) | 2.43 (<.01) | 2.66 (<.01) |
| Hospital LOS | 1.02 (<.01) | 1.02 (<.01) | 1.03 (<.01) | 1.03 (<.01) | 1.03 (<.01) |

## F-PO1212

**Unintended Consequences of the Proposed Incident Case Mix Adjuster** Zack Burstein, Mahesh Krishnan, Tracy Jack Mayne, Leanne Zumwalt. *DaVita Inc., Denver, CO.*

**Background**: The CMS Notice of Proposed Rule Making (NPRM) for the dialysis prospective payment system (i.e., 'the bundle') included 18 case mix adjusters (CMAs). The single highest CMA (1.47) is for patients during the first 120 days of dialysis. We modeled the impact of a case mix adjuster of this magnitude on reimbursement.

**Methods**: We calculated mean Medicare dialysis reimbursement for incident patients in calendar years 2007, 2008 and 2009 (N=3,831) at a large US dialysis organization. We compared this to average reimbursement for prevalent patients (N=154,851) and calculated average incremental cost per treatment for the first 120 days. We modeled the population effect of the difference between the CMS incident patient CMA, and the CMA calculated based on actual Medicare reimbursement shown here. The analysis excludes costs of oral drugs and lab tests, which are likely to have a minor impact.

**Results**: The actual increment in Medicare reimbursement for the first 120 days of treatment is 11.7%. We applied the resultant 1.117 CMA to the first 120 days of treatment in the 5.6% of incident patients (estimated in the NPRM). Adding the 2% total payment reduction mandated by MIPPA, but not taking into account other case mix adjusters, a 5% reduction in base payment per treatment is necessary to make the incident patient adjuster 'budget neutral.'

| Year | Mean Cost Per Treatment | | Incident increment |
|---|---|---|---|
| | Incident (1st 120 days) | Prevalent (>120 days) | |
| 2007 | $282.33 | $245.02 | 13.2% |
| 2008 | $270.21 | $239.01 | 11.5% |
| 2009 | $269.97 | $241.26 | 10.6% |
| All | $273.82 | $241.72 | 11.7% |

**Conclusions** The first 120 days of dialysis reimbursement are 11.7% higher than prevalent reimbursement, substantially lower than the 47% proposed in the NPRM. The monies taken out of the base payment for the incident adjuster are excessive. These calculations do not take into consideration the multiplier effect that would result when the 1.117 is multiplied by the other co-morbid CMAs, all of which are also positive. CMS should reduce the incident case mix adjuster weighting in the final rule to correct for this.

## F-PO1213

**Using Genetic Polymorphism as a Strategy To Estimate the Potential Cost-Effectiveness of Pharmacological CCR5 Blockade in Dialysis Patients** Stefan Vegter,[1,2] Friso Muntinghe,[1] Marion Verduijn,[4] Elisabeth W. Boeschoten,[3] Friedo W. Dekker,[4] Gerjan Navis,[2] Maarten J. Postma.[1] *[1]Division of Nephrology, University Medical Centre Groningen (UMCG), Groningen, Netherlands; [2]PharmacoEpidemiology and PharmacoEconomics, University of Groningen, Groningen, Netherlands; [3]Hans Mak Institute, Naarden, Netherlands; [4]Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands.*

Background

Pharmacological interventions that are of benefit in non-dialysis populations have thus far been disappointing in dialysis patients. Since clinical trials are expensive and time-consuming, adjunct strategies are needed to support decision making in prioritization of tracks for drug development. Genetic association studies may provide such a strategy when a genotype is associated with a well-defined molecular and functional phenotype. Previously an association with better survival was found in incident dialysis patients with systemic inflammation and a deletion variant of the CC-chemokine receptor 5 (CCR5Δ32). Thus, we hypothesized that pharmacological CCR5 blockade could protect against inflammation associated mortality and estimated if such a treatment would be cost-effective.

Methods

A screen-and-treat strategy was modelled in which patients were screened for the CCR5Δ32 polymorphism and patients with the wild-type genotype and high inflammation status were treated with pharmacological CCR5 blockade. Univariate and probabilistic sensitivity analyses were performed.

Findings

The cost-effectiveness of the screen-and-treat strategy was €18,557 per life-year gained and €21,896 per quality-adjusted life year (QALY) gained. The main drivers of the cost-effectiveness were the costs of pharmacological CCR5 blockade and the reduction in relative risk of mortality.

Interpretation

Pharmacological blockade of the CCR5 receptor in inflamed dialysis patients can be incorporated in a potential cost-effective genetic screen-and-treat program. This study illustrates the potential of genetic association studies in drug-development programs, as a new source of Mendelian randomized evidence from an observational setting.

**F-PO1214**

**The Cost-Effectiveness of Lanthanum Carbonate in the Treatment of Hyperphosphatemia in Chronic Kidney Disease Patients: Pre-Dialysis and Dialysis** Stefan Vegter,[1,2] Keith H. Tolley,[2] Michael S. Keith,[3] Maarten J. Postma.[1] *[1]Department of Pharmacy, University of Groningen, Groningen, Netherlands; [2]Tolley Health Economics Ltd, Buxton, United Kingdom; [3]Shire Pharmaceuticals, Wayne, PA.*

**Purpose:** Hyperphosphataemia is associated with increased mortality in Chronic Kidney Disease (CKD); in dialysis and before dialysis (CKD-ND). First-line treatment consists primarily of calcium based phosphate binders (CB). We determined the cost-effectiveness of the non-calcium based phosphate binder lanthanum carbonate (LC) as second-line treatment from a UK healthcare perspective. **Methods:** A Markov model was developed to determine the cost-effectiveness of LC for patients not achieving target serum phosphate (SP) levels on CB, compared with continued CB treatment. Patient-level data were obtained from two LC trials in CKD-ND (n=56) and dialysis (n=380) for drug efficacy parameters. Data of CKD-ND and dialysis patients were pooled to calculate the drug efficacy of CKD-ND patients. Two 1,000 patient cohorts were modelled: CKD-ND patients and dialysis patients. **Results:** For the CKD-ND cohort, 544 did not achieve target SP levels (<4.6 mg/dl) on CB; of these, 230 were eligible for second-line LC treatment. Of these 230 CB non-responders, 43 (18.8%) now responded to an 8 week trial of LC. Compared to continued CB treatment, 150 life-years (LY) were gained with LC, corresponding to 101 quality-adjusted life-years (QALYs) and 76 dialysis free years were gained. In the cohort of 1,000 dialysis patients, 378 did not achieve target SP levels (<5.5 mg/dl) on CB and were eligible for LC, with 169 (44.6%) additional responders, resulting in 106 LYs and 65 QALYs gained. In CKD-ND, second-line LC resulted in net healthcare cost-savings compared to continued CB treatment. In dialysis patients, second-line LC treatment incurred incremental costs of £6,816 per QALY gained. **Conclusions:** Second line treatment with lanthanum carbonate is cost-effective compared to continued treatment with calcium based binders in CKD, regardless of dialysis status. These results are in line with current K/DOQI guideline recommendations to treat both predialysis and dialysis CKD patients with hyperphosphataemia.

**Comparative Effectiveness of Intravenous Vitamin D Agents** Carey Colson, Mahesh Krishnan, Tracy Jack Mayne, Allen R. Nissenson. *DaVita Inc., Denver, CO.*

**Background:** The topic of comparative effectiveness research (CER) of therapeutic agents has risen to top of the national healthcare debate with the recent passage of healthcare reform. Dialysis electronic health records provide a unique environment for evaluating CER across multiple categories. We undertook an evaluation of two intravenous vitamin D agents used for in-center end stage renal disease (ESRD). **Methods:** December 2009 data was retrieved from the LDO patient database to find hemodialysis patients meeting the following criteria: over age 18 as of the end of the month, at least one treatment in the month, on dialysis for 90 days or more, at least one of the lab tests below within the last 90 days and receiving a single vitamin D preparation via IV at least once during the month. Patients receiving doxercalciferol (n-9,048) were propensity-score matched to patients receiving paricalcitol; the resultant sample included 18,000 individuals. Percent of patients meeting standard mineral and bone disease (MBD) outcomes were determined (using the latest test within 90 days) and compared by Chi-square test. **Results:** The results of these analyses are listed in the table.

| Vitamin D preparation (IV) | Patient Count | Albumin ≥3.5 g/dl | PTH 150-600 pg/ml | Ca 8.5-10.2 mg/dL | Ca >10.2 mg/dL | Phos ≤5.5 mg/dL |
|---|---|---|---|---|---|---|
| Doxercalciferol | 9,000 | 88.1% | 75.4% | 81.8% | 2.6% | 65.8% |
| Paricalcitol | 9,000 | 88.5% | 76.3% | 82.6% | 2.4% | 65.6% |
| p-value | | NS | NS | NS | NS | NS |

**Discussion:** The predominant medication used was paricalcitol but a sizable number of patients also used doxercalciferol, and in a matched sample of 9,000 patients per group no statistically significant differences were noted between doxercalciferol and paricalcitol with regards to albumin, parathyroid hormone (PTH), calcium, or phosphorus. **Conclusions:** In a changing reimbursement environment, comparative effectiveness between the two predominant vitamin D preparations showed no significant differences with regards to important MBD outcomes.

**F-PO1216**

**Cost-Effectiveness of Lanthanum Carbonate vs Sevelamer Hydrochloride for the Treatment of Hyperphosphatemia in Dialysis Patients** Haesuk Park,[1] Karen L. Rascati,[1] Michael S. Keith,[2] Paul S. Hodgkins,[2] Michael D. L. Smyth,[3] David Goldsmith,[4] Ronald L. Akehurst.[5] *[1]University of Texas, Austin; [2]Shire Pharmaceuticals, Wayne; [3]Shire Pharmaceuticals, Basingstoke, United Kingdom; [4]Guy's Hospital London, London, United Kingdom; [5]The University of Sheffield, Sheffield, United Kingdom.*

**Purpose:** To assess the cost-effectiveness of lanthanum carbonate (LC) vs sevelamer hydrochloride (SH) for treatment of hyperphosphatemia in dialysis patients previously treated with calcium-based phosphate binders. **Methods:** A Markov model was developed to estimate health outcomes; quality-adjusted life years (QALYs), life-years saved (LYS), and associated costs. The base-case model included dialysis patients who received a calcium-based binder prior to being included (ITT population) in a randomized head-to-head crossover clinical trial that compared the reduction of serum phosphorus using fixed doses of LC (2250 to 3000 mg/day, N = 148) and SH (4800 to 6400 mg/day, N = 140). A model was also developed for those who completed this trial (i.e. 'completers'). The baseline risks of cardiovascular disease (CVD), overall mortality, and CVD mortality were derived from a large US renal database. Utilities, costs and relative risks of CVD were taken from published sources. Patient outcomes were modeled for 10 years, and incremental cost-effectiveness ratios (ICERs) were calculated for LC vs SH using a 5% discount rate for both costs and outcomes. Deterministic and probabilistic sensitivity analyses (PSA) were performed to test the robustness of the models. **Results:** In the base case model, the ICERs of LC vs SH were $24,724/QALY and $15,053/LYS. The PSA indicated a 61.9% probability of LC being cost-effective at the $50,000/QALY threshold. For completers, the ICERs of LC vs SH were $15,285/QALY and $9,337/LYS, and the PSA indicated an 85.8% probability of LC being cost-effective at the $50,000/QALY threshold. Sensitivity analyses demonstrated the robustness of the pharmacoeconomic model. **Conclusions:** Compared with SH, LC therapy is more cost-effective in the treatment of hyperphosphatemic dialysis patients previously treated with calcium-based binders.

**Baseline Characteristics in the Paricalcitol Capsules Benefits in Renal Failure Induced Cardiac MOrbidity (PRIMO) Trial in CKD** Ravi I. Thadhani. *On Behalf of the PRIMO Steering Committee.*

Background: In subjects with chronic kidney disease (CKD), left ventricular hypertrophy (LVH) is prevalent and associated with morbidity and mortality. Emerging pre-clinical evidence suggests that vitamin D receptor activators (VDRA) may halt LVH progression in animal models of CKD. We sought to evaluate the efficacy of oral paricalcitol (a selective VDRA) to prevent progression or induce regression of LVH in patients with CKD and mild to moderate LVH.

Methods: The PRIMO study (NCT00497146) is an investigator-initiated industry sponsored (Abbott) multinational randomized double-blinded trial using a adaptive sample size re-estimation design to test the hypothesis that paricalcitol 2 mcg daily improves LVH in ~220 patients with stages 3 and 4 CKD (eGFR 15-60 ml/min/1.73m2) and echocardiographic evidence of LVH (septal thickness in men 12-18 mm, 11-17 mm in women) and ejection fraction ≥ 50%. The intervention will be compared with placebo after 48 weeks of treatment. The primary endpoint is change in LV mass index (LVMI) measured by cardiac magnetic resonance. The main secondary endpoint will be a change in diastolic mitral annular relaxation velocity (E') and changes in additional measures of diastolic function (IVRT, E/E', DT) measured by tissue Doppler echocardiography.

Results: 227 subjects (30% Female, 74% Caucasian, age 65±12) from 11 countries were randomized 1:1 to paricalcitol or placebo. At baseline (BL), eGFR was 34±11 ml/min/1.73m2, LVMI was 32 ± 7 g/m2.7, and early diastolic mitral annular relaxation velocity (E') was 8.1±2.4 cm/s. At BL, LVMI correlated with systolic blood pressure (SBP, r= 0.23), urine albumin creatinine ratio (UACR, r=0.32; figure, by quintiles of LVMI), and plasma brain natriuretic peptide (BNP, r=0.23), all with p<0.01.

Conclusion: In multinational subjects with stages 3 and 4 CKD, LVMI correlates with SBP, UACR, and BNP levels.

**Prospective Evaluation of Pharmacokinetically Guided Dosing of Carboplatin in Japanese Patients with Cancer** Yoshinari Yasuda,[1] Tomoya Shimokata,[2] Yuichi Ando,[2] Shoichi Maruyama,[1] Enyu Imai,[1] Yoshinori Hasegawa,[2] Seiichi Matsuo.[1] *[1]Department of Nephrology/CKD Initiatives, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan; [2]Department of Respiratory Medicine, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan.*

*Background:* Carboplatin, a second-generation platinum-containing compound, is widely used to treat solid tumors, especially lung and gynecologic cancers. Because carboplatin is eliminated primarily through renal excretory mechanisms, the dosage adjustment is generally conducted by using the Calvert formula, i.e., carboplatin dose (mg) = target area under the concentration versus time curve (AUC) x [glomerular filtration rate (GFR) + 25], however it has not yet been validated among Japanese subjects in whom GFR was accurately measured. *Objective*: We prospectively evaluated the validity of this formula for Japanese patients with cancer and modified it for this population. *Methods:* GFR was measured by inulin clearance. The dose of carboplatin was determined by the Calvert formula, using 24-h creatinine clearance (Ccr). The pharmacokinetics of carboplatin was analyzed during the first cycle of chemotherapy. The relationship between GFR and carboplatin clearance was prospectively evaluated. *Results:* Inulin clearance was examined in 28 patients with cancer. The 24-h Ccr was unbiased (mean prediction error [MPE] +- SE = -2.3 +- 4.5%) and acceptably precise (root mean squared error [RMSE] = 23.7%) for GFR assessment. The pharmacokinetics of carboplatin was analyzed in 21 patients with GFRs of 17.2 to 91.4 ml/min. The Calvert formula using GFR overestimated carboplatin clearance, resulting in an MPE of 14.3%. When we revised the Calvert formula for Japanese patients by substituting a nonrenal clearance of 15 for 25, i.e., dose = target AUC x (GFR + 15), the MPE decreased to -0.1% (P<0.001). *Conclusions:* We conclude that 24-h Ccr is acceptably precise for GFR assessment, and the nonrenal clearance of carboplatin is suggested to be lower in Japanese patients with cancer than in their Western counterparts.

**Quantitative Modeling and Simulation To Optimize Dosing in Renally Impaired Patients: Application to Entecavir** Marc Bifano,[1] Frank Lacreta,[1] Alaa Ahmad,[1] Amit Roy,[1] Dennis M. Grasela,[1] Suzanne K. Swan,[2] Marc Pfister.[1] *[1]Discovery Medicine and Clinical Pharmacology, Bristol-Myers Squibb, Princeton, NJ; [2]DaVita Clinical Research, Minneapolis, MN.*

**Background.** Quantitative modeling and simulation can be applied to (i) characterize the relationship between renal function and exposure; in order to maximize the amount of information extracted from single-dose renal impairment studies, and (ii) evaluate different dosing options (dose, schedule) in 'virtual' patients to make dosing recommendations. Such a quantitative approach is presented with an application to entecavir.

**Methods.** Using nonlinear mixed effects modeling, a compartmental model with a function to characterize the effect of 'renal function' on drug clearance was utilized to simulate 'virtual' patients with selected degrees of renal impairment. Simulated steady state exposures were evaluated for alternative dose and schedule regimens with the goal of identifying dosing regimens that achieve target exposures in at least 80% of 'virtual' patients.

**Data and Results.** Consistent with prior knowledge that entecavir is eliminated primarily via renal excretion, trial simulation indicated that (i) patients with mild renal (CrCL ≥ 50 ml/min) impairment do not need a dose adjustment (0.5 mg Q 24h usual dose, 1 mg Q 24h for refractory patients), (ii) patients with moderate renal impairment (CrCL 30 to <50 ml/min) need a 50% dose reduction (0.25/ 0.5 mg Q 24h) or a change in schedule to 0.5/1 mg Q 48h, (iii) patients with severe renal impairment (10 to <30 ml/min) need a 70% dose reduction (0.15/ 0.3 mg Q 24h or a change in schedule to 0.5/1 mg Q 72h, and (iv) patients on hemodialysis or CAPD (< 10 ml/min) need a dose reduction of 90% (0.05/ 0.1 mg Q 24h) or a change in schedule to 0.5/1 mg Q 168h.

**Conclusions.** Quantitative modeling and simulation was successfully applied to entecavir and the dosing information is reflected in the product label. Such a quantitative approach maximizes the amount of information extracted from single-dose renal impairment studies and allows for virtual clinical trials that optimize dosing in renally impaired patients while saving cost and time.

**Obesity, Disease Progression and Ramipril Renoprotective Effects in Proteinuric Chronic Nephropathy: A Post-Hoc Analyses of the REIN Study** Francesca Mallamaci,[1] Piero Ruggenenti,[2] Annalisa Perna,[2] Daniela Leonardis,[1] Rocco Tripepi,[1] Giovanni Tripepi,[1] Giuseppe Remuzzi,[2] Carmine Zoccali,[1] Rein Study Group.[3] *[1]CNR-IBIM, Clin. Epid. and Physiopath. of Renal Diseases and Hypertension, Reggio Calabria, Italy; [2]Mario Negri Institute, Bergamo, Italy; [3]Rein Study Group, Italy.*

In observational studies, obesity has been associated with accelerated renal disease progression in CKD patients. The effect of established pharmacological treatment (such as ACE inhibition) has been never specifically tested in overweight and obese CKD patients. We undertook a secondary analysis in the REIN study cohort (n=337) to investigate whether overweight and obesity influence renal events rate and the response to Ramipril.

In the study cohort, 105 patients were overweight (BMI: 25-30 kg/m$^2$) and 49 obese (BMI >30 kg/m$^2$). GFR was 43±18 ml/min/1.73 m$^2$. During the follow-up (average: 30 months; range: 0.2-76 months), 89 patients had renal events [ESRD in 77 cases and doubling of serum creatinine in 12 cases]. In the placebo group, the renal events rate was similar in overweight and in those with normal BMI but higher in obese [Table 1a: combined renal end point; Table 1b: ESRD].

| Table 1a | Crude incidence rate (and 95% CI) of the combined renal end point *(events/100 person-years)* | | Crude hazard ratio and 95% CI and P value *(Ramipril versus placebo)* |
|---|---|---|---|
| | **Placebo group** | **Ramipril group** | |
| <25 kg/m$^2$ | 14 (9-20) | 8 (5-11) | 0.55(0.31-0.99), P<0.05 |
| 25-30 kg/m$^2$ | 14 (8-21) | 7 (3-13) | 0.52(0.24-1.13), P=0.09 |
| >30 kg/m$^2$ | 25 (11-41) | 5 (1-14) | 0.21(0.06-0.81), P=0.02 |

| Table 1b | Crude incidence rate (and 95% CI) of ESRD occurrence *(events/100 person-years)* | | Crude hazard ratio and 95% CI and P value *(Ramipril versus placebo)* |
|---|---|---|---|
| | **Placebo group** | **Ramipril group** | |
| <25 kg/m$^2$ | 10 (7-16) | 6 (4-10) | 0.58(0.31-1.09),P=0.09 |
| 25-30 kg/m$^2$ | 11 (7-8) | 6 (3-12) | 0.55(0.24-1.23),P=0.14 |
| >30 kg/m$^2$ | 24 (11-45) | 3 (0.4-11) | 0.14(0.03-0.65),P=0.01 |

Ramipril reduced renal events as compared to placebo in all BMI strata (Table 1) but the effect of this drug was much higher in obese (incidence rate reduction: combined end point -79%; ESRD -86%) than in those with overweight (-48% and -45%, respectively) or normal BMI (- 45% and -42%, respectively). The effect modification of BMI on the Ramipril response was confirmed in Cox models adjusting for confounders.

In this secondary analysis of the Rein study, obesity predicted a higher incidence of renal events in the placebo arm but such a risk excess was virtually abolished in Ramipril treated patients and the risk reduction by this drug was actually larger in obese than in non obese patients.

Disclosure of Financial Relationships: nothing to disclose

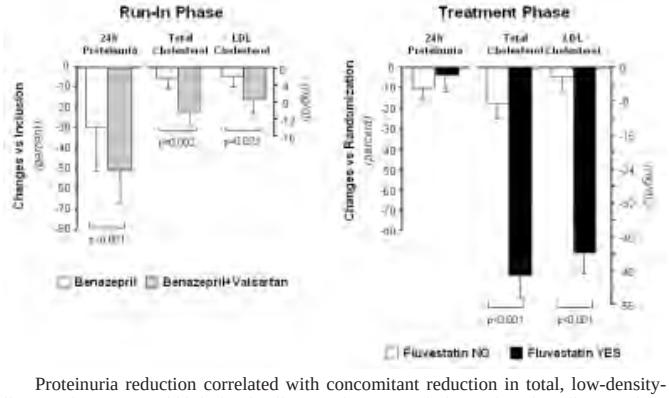
**F-PO1221**

**Effects of Add-On Fluvastatin Therapy in Patients with Chronic Proteinuric Nephropathy on Dual RAS Blockade: Esplanade Trial** Giuseppe Remuzzi. *Mario Negri Institute and Azienda Ospedaliera Ospedali Riuniti di Bergamo, Italy.*

Background: Effects of statins in chronic kidney disease (CKD) patients on optimized antiproteinuric therapy by angiotensin-converting-enzyme (ACE) inhibition and angiotensin receptor blockade (ARB) are not known.

Methods: After 1-month benazepril (10-20 mg/day) therapy followed by 1-month benazepril-valsartan (80-160 mg/day) combined therapy (Run-In), 186 consenting CKD patients with residual proteinuria >0.5 g/24-h were randomized to 6-month benazepril-valsartan therapy alone or combined to fluvastatin (40-80 mg/day). Between-groups changes in proteinuria (centrally measured primary outcome), serum lipids and glomerular filtration rate (GFR, by iohexol plasma clearance) were compared by blinded and intention to treat ANCOVA.

Results: On Run-in, proteinuria decreased more with benazepril-valsartan than benazepril alone.



Proteinuria reduction correlated with concomitant reduction in total, low-density-lipoprotein (LDL) and high-density-lipoprotein (HDL) cholesterol, and apolipoprotein B (p<0.001 for all) and apolipoprotein A (p<0.05) levels. After randomization, proteinuria similarly decreased in the fluvastatin and benazapril-valsartan therapy alone arms. Fluvastatin further reduced total and LDL cholesterol and apolipoprotein B vs benazepril-valsartan alone (p<0.001 for all), but did not affect serum triglycerides and GFR. Treatment was well tolerated.

Conclusions: In CKD patients with residual proteinuria despite ACE inhibitor and ARB therapy, add-on fluvastatin does not affect urinary proteins, but further reduces serum lipids and is safe. Whether combined ACE inhibitor, ARB and statin therapy may help improving cardiovascular outcomes in this high-risk population is worth investigating.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1222**

**Stroke in Patients with Diabetes and CKD Treated with Darbepoetin Alfa. The TREAT Experience** Hicham Skali,[1] Hans-Henrik Parving,[2] Patrick S. Parfrey,[2] Emmanuel A. Burdmann,[2] Eldrin F. Lewis,[1] Peter Ivanovich,[2] Janet B. McGill,[2] Jerome A. Rossert,[2] Ajay K. Singh,[1] Scott D. Solomon,[1] Hajime Uno,[1] Marc Pfeffer.[1] *[1]Brigham & Women's Hospital; [2]On Behalf of TREAT Investigators.*

We sought to investigate baseline and post-randomization (rz) factors that could be associated with the increased incidence of stroke (CVA) observed in the Trial to Reduce cardiovascular Events with Aranesp Therapy (TREAT).

**Methods:** Baseline characteristics were compared between patients with a CVA [n=154/4038 (4%): darbepoetin alfa (darb):101/2012 (5%) and placebo:53/2026 (2.6%)] and those without. A multivariate logistic regression model was used to identify baseline predictors and generate a propensity score for a nested case-control (1:10 matching) analysis that evaluated post-rz blood pressure (BP), hemoglobin level (Hb) and darb dose.

**Results:** Baseline predictors of stroke were: assignment to darb [OR 2.1(95%CI:1.5,2.9)], history (hx) of stroke [2.0(1.4,2.9)], higher proteinuria, hx of CV disease, insulin use and lower Hb or BMI.

Case-control analyses of post-rz factors (1:10 matching), did not show any difference in the most recent value (90 days prior to the stroke) of systolic or diastolic BP, Hb, and darb dose.

| | Darb | | Placebo | |
|---|---|---|---|---|
| **Most recent value-3 months** | **Stroke** | **No Stroke** | **Stroke** | **No Stroke** |
| | **Controls** | **Cases** | **Cases** | **Controls** |
| n | 86 | 923 | 44 | 468 |
| SBP mmHg | 135(120,150) | 134(121,145) | 136(122,148) | 137(124,150) |
| DBP mmHg | 72(64,80) | 71(65,80) | 70(63,80) | 71(64,80) |
| n* | 80 | 866 | 42 | 436 |
| HGB mg/dL | 12.3(11.1,13.1) | 12.5(11.7,13.2) | 10.4(9.4,10.8) | 10.4(9.7,11.3) |
| Darb dose µg/week | 150(100,300) | 150(80,300) | 0(0,0) | 0(0,0) |
| Rescue darb | | | 6(14%) | 82(19%) |

Median(IQR).Stroke vs. no stroke comparisons all NS Wilcoxon test. * lower sample size due to available data

Additional sensitivity analyses using maximal or latest values (or averages) over varying periods of exposure yielded similar results.

**Conclusion:** Rz to darb and prior hx of CVA were strong predictors of a heightened risk of stroke. In the treated group, the increased risk does not appear to be mediated by either higher BP, Hb or darb dose.

**Prolylhydroxylase Inhibitor Modulation of Erythropoietin in a Randomized Placebo Controlled Trial** Richard A. Brigandi,[1] Steven F. Russ,[2] Mahir Al-Banna,[1] Jianping Zhang,[2] Connie L. Erickson-Miller,[1] Bin Peng.[1, 3] *[1]GlaxoSmithKline, King of Prussia, PA; [2]GlaxoSmithKline, Research Triange Park, NC; [3]Current Address, Novartis, East Hanover, NJ.*

GSK1278863A is a novel small molecule that has demonstrated *in vitro* and *in vivo* inhibition of the hypoxia-inducible factor (HIF) prolyl hydroxylases EGLN1/3. GSK1278863A increases erythropoietin (EPO) protein levels and hemoglobin levels after oral administration in rats, mice and dogs. Through prolylhydroxylase inhibition, GSK1278863A has the potential to modulate HIF targets, including those impacting erythropoiesis, angiogenesis, and iron metabolism and utilization. Study PHX111427 was a single-blind, randomized, placebo controlled, dose-rising, single dose, sequential parallel group study to investigate the safety, tolerability, PK and PD of GSK1278863A in healthy adult subjects. Subjects were dosed sequentially in six ascending cohorts ranging from 2 to 300 mg with randomization to receive GSK1278863A or placebo in a ratio of 2:1. Single dose, oral administration of GSK1278863A was generally well tolerated. Pharmacokinetics were linear with dose proportional increases in plasma exposure as the dose increased from 2 to 300 mg, $T_{max}$ ranged between 1.25-2.00 hours post dose, and $t_{1/2}$ ranged from 0.8-4.0 hours. No consistent statistically significant change, across doses, in pro-hepcidin levels were observed, although there were significant increases in vascular endothelial growth factor (VEGF) observed only at GSK1278863A doses of 150 and 300 mg. As expected, there were no observed effects on hemoglobin following single dose, however, significant increases in circulating plasma EPO were observed at 15, 50, 150, and 300 mg dose levels of GSK1278863A compared to placebo at one or more post-dose time points.

Conclusion: These data indicate that GSK1278863A has the potential to induce erythropoiesis in patients with anemia.

**Estimated Net Endogenous Acid Production and Serum Bicarbonate in the AASK Cohort Study** Julia J. Scialla,[1] Lawrence J. Appel,[1] Edgar R. Miller,[1] Brad C. Astor,[1] Rulan S. Parekh,[2] Cheryl A. Anderson.[1] *[1]Johns Hopkins University; [2]University of Toronto.*

Metabolic acidosis may contribute to CKD progression. Dietary protein, the major source of fixed acid, and dietary potassium, which is naturally complexed to alkali precursors, can be used to estimate net endogenous acid production (NEAP). We evaluated the cross-sectional association between NEAP and serum bicarbonate (HCO3) in participants from the AASK Cohort Study. Exclusion criteria were >10% decline in weight over 6 months and use of potassium or alkali supplements. Included were 360 African American adults (ages 31 to 76y) with hypertensive CKD (median GFR 44.3 mL/min/1.73 $m^2$). NEAP was estimated using published equations: NEAP (mEq/d) = -10.2 + 54.5 [protein (g/d) /potassium (mEq/d)]. Dietary protein and potassium intake were estimated from the average 24 hour urinary excretion of urea nitrogen and potassium, respectively, during the first year of the study (98% had 2 measurements). Using linear regression adjusted for confounders (age, sex, randomized group during trial phase, BMI, GFR, albuminuria, years of hypertension, diabetes, ACE inhibitor/ARB use, and diuretic use) higher estimated NEAP was associated with lower serum HCO3 in a graded fashion (p trend <0.001). Estimated protein intake was not associated with serum HCO3 (p=0.28), but higher estimated potassium intake was associated with higher serum HCO3 (p trend=0.001).

| | Difference in serum HCO3 (mmol/L) compared to reference | **p-value** |
|---|---|---|
| **Estimated NEAP (mEq/d)** | | |
| Quartile 1 (27.5-57.2) | Ref | |
| Quartile 2 (57.8-70.9) | -0.42 (-1.11, 0.26) | 0.21 |
| Quartile 3 (70.9-86.1) | -0.72 (-1.80, 0.38) | 0.18 |
| Quartile 4 (86.2-199.7) | -1.66 (-2.37, -0.94) | <0.001 |
| **Estimated Potassium Intake (mEq/d)** | | |
| Quartile 1 (10.6-30.2) | Ref | |
| Quartile 2 (30.2-40.2) | 0.57 (-0.47, 1.60) | 0.27 |
| Quartile 3 (40.2-53.4) | 1.33 (0.24, 2.43) | 0.02 |
| Quartile 4 (53.6-106.5) | 1.65 (0.64, 2.65) | 0.003 |

Reducing NEAP through intake of potassium rich foods may prevent metabolic acidosis in patients with CKD, challenging the current practice of potassium restriction.

**Difference in Age-Related Patterns of Arterial Stiffness among Patients with Kidney Disease** Laurie A. Tomlinson,[1] Helen Eddington,[2] Philip A. Kalra,[2] Chris W. McIntyre,[4] David J. Webb,[5] David C. Wheeler.[3] *[1]University of Cambridge; [2]Salford Hospitals NHS Trust; [3]UCL Medical School; [4]Derby Hospital; [5]University of Edinburgh; [6]University of Birmingham.*

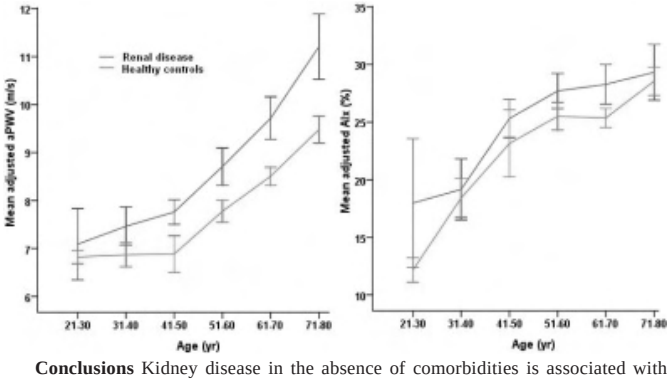
**Background** Patients with CKD may have higher aortic pulse wave velocity (aPWV) and augmentation index (AIx) but studies are limited by size and lack of control population and differences may be due to joint risk factors. The UK Research Alliance Into Kidney Disease And Arterial Stiffness (UREKA) Collaboration examined whether aPWV and AIx are increased in CKD patients with no vascular co-morbidities compared to controls and how change with age varies between populations.

**Methods** Cardiovascular risk factor data, aPWV and AIx were obtained from CKD patients at 8 UK renal centres and participants in ACCT, a community-based study of the general population. Those with diabetes and/or vascular disease were excluded.The relationship of age to aPWV and AIx was compared between patients with CKD (stages 1-5, not on dialysis, non-vascular diagnosis, n=524) and healthy controls (eGFR>60mL/min, n=1535). The control group was stratified by age and gender to ensure comparability.

**Results** Adjusted aPWV and AIx were higher in CKD patients (P<0.001).

| | Kidney disease | Healthy controls |
|---|---|---|
| **Age (y)** | 55±14 | 56±18 |
| | | |
| **eGFR (ml/min)*** | 43±21 | 96±30 |
| **SBP (mmHg)** | 133±20 | 134±19 |
| **DBP (mmHg)** | 80±11 | 80±11 |
| **Adj PWV(m/s)*** | 9.0±2.5 | 7.8±1.8 |
| **Adj AIx (%)*** | 26.0±9.2 | 19.3±8.5 |

There was a significant interaction (P<0.001) between age and the presence of CKD on aPWV, but this was not seen for AIx (P=0.19).



**Conclusions** Kidney disease in the absence of comorbidities is associated with increased arterial stiffness compared to controls. In CKD patients aPWV increases more rapidly with age than controls but there was no difference in the pattern of change of AIx with age between groups.

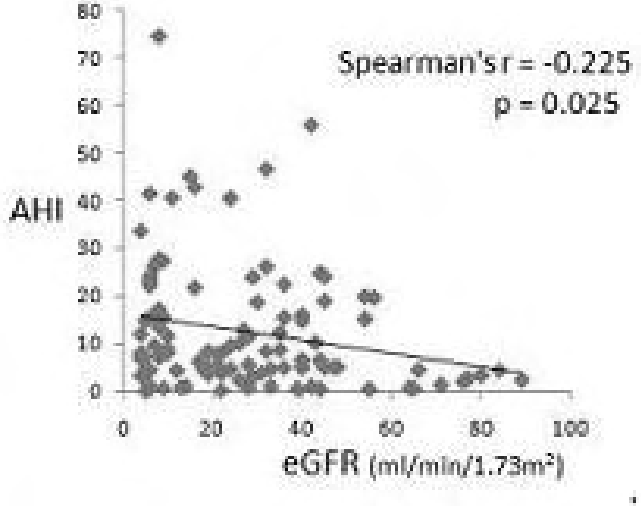
**Obstructive Sleep Apnea in Non-Dialysis Chronic Kidney Disease Patients**
Yusuke Sakaguchi, Akira Suzuki, Tatsuya Shoji, Yoshiharu Tsubakihara. *Kidney Disease and Hypertension, Osaka General Medical Center, Osaka, Japan.*

**Background**
Recently, obstructive sleep apnea (OSA) has been widely recognized as an important risk factor for cardiovascular disease. Although a high prevalence of OSA was reported in ESRD patients, there is little information regarding OSA in non-dialysis CKD patients. The aim of this study was to examine OSA in non-dialysis CKD patients and elucidate the relationship between renal function and the prevalence and severity of OSA.
**Study design**
Cross-sectional study.
**Setting** & Participants
Consecutive patients hospitalized mainly for CKD educational program or renal biopsy from June 2009 to November 2009.
**Predictors**
Age, sex, body mass index (BMI), diabetes mellitus, eGFR, history of cardiovascular disease and history of stroke.
**Outcomes**
The prevalence and severity of OSA.
**Measurements**
Apnea-hypopnea index (AHI) measured by type 3 (cardiorespiratory) monitor devices (Morpheus; Teijin Pharma Ltd.).
**Results**
One hundred patients (men 68%), median (interquartile) age 66.5 (58.0, 74.8) years, BMI 23.1 (20.8, 24.8) kg/m$^2$, eGFR 28.5 (8.0, 40.0) ml/min/1.73m$^2$ and 31% with diabetes mellitus were enrolled. Overall, 65% of the subjects were suffering from OSA (mild (5≤AHI<15): 32%, moderate (15≤AHI<30): 25%, and severe (30≤AHI): 8%). In multiple logistic regression analysis, lower eGFR was significantly associated with increased prevalence of OSA adjusted for age, sex, BMI, diabetes mellitus, history of cardiovascular disease and history of stroke (adjusted odds ratio 0.97, 95% confidence interval 0.97 to 0.99). Moreover, in a generalized linear model, eGFR was inversely correlated with AHI after adjusting for covariates (p=0.007).



**Conclusions**
Our data demonstrated that the prevalence of OSA was also high in non-dialysis CKD patients and suggested the vicious cycle between the decline of GFR and OSA.

**Gender Differences in the Prevalence of Depression and Increased Stress among Older Americans with Chronic Kidney Disease**
Nancy G. Kutner,[1,2,3] John J. Isitt,[2,3] Suzanne E. Judd,[2] Brian D. Bradbury,[2,3] Manjula Kurella Tamura,[2] Virginia G. Wadley,[2] Neil A. Zakai,[2] David G. Warnock,[2] William M. McClellan.[2] *[1]Emory University School of Medicine, Atlanta, GA; [2]For the Renal REGARDS Working Group, UAB, Birmingham, AL; [3]Amgen Inc., Thousand Oaks, CA.*

Introduction. Reduced kidney function may be associated with increased psychological distress, but there has been little investigation of gender differences in the prevalence of depressive symptoms and stress among individuals with impaired kidney function. Methods. Participants in a population-based cohort study aged 45 years with a urine albumin-to-creatinine ratio of >= 30 mg/g or eGFR < 60 ml/min/1.73 m$^2$ were included in the study. Recruitment was conducted between 2003 and 2007. Our main exposure was hemoglobin level. Outcomes included a four-item Center for Epidemiologic Studies Depression Scale (CES-D-4) score4 and a short four-item Cohen's perceived stress scale (PSS-4) score7. Covariates included age, sex, race, education, income, marital status, history of heart disease, hypertension, diabetes, and stroke, cigarette and alcohol use and access to medical care. The association between gender and individual outcomes was assessed by multivariable logistic regression. Results. The 3,817 individuals with CKD, 20.3% of all subjects, had a mean age 68.3 years, 39.8% males and 45.9% African American. Elevated depressive symptoms were reported for 6.9% of men and 10.9% of women, M:F OR (95% CI) adjusted for age and race was 0.63 (0.51, 0.79); 12.4% of men and of 20.0% women reported high stress, age- and race-adjusted M:F OR (95% CI) =0.62 (0.53, 0.73). After adjustment for demographic characteristics, socioeconomic status, behavioral factors and comorbidity, the association between gender and depressive symptoms was attenuated and no longer significant, M:F OR (96%CI), 0.77 (0.56, 1.04). In contrast, age- and race-adjusted associations between gender and stress persisted after adjustment for other covariates, M:F OR (95%CI) = 0.63 (0.50, 0.80). Conclusion. Women with CKD have increased prevalence of high stress compared to men which cannot be fully explained by other participant attributes.

**Does Lower Hemoglobin Explain Gender Differences in the Prevalence of Depressive Symptoms and Increased Stress among Older Americans with Chronic Kidney Disease?**
Nancy G. Kutner, Suzanne E. Judd, Manjula Kurella Tamura, Virginia G. Wadley, Neil A. Zakai, David G. Warnock, William M. McClellan. *Renal REGARDS Working Group, UAB, Birmingham, AL.*

**Introduction.** We assessed gender differences in the prevalence of depressive symptoms (DS) and stress among individuals aged 45 years and older with a urine albumin-to-creatinine ratio of >= 30 mg/g or an eGFR less than 60 ml/min/1.73 m$^2$ in the Reasons for Geographic and Racial Differences in Stroke (REGARDS) study. **Methods.** We defined our exposure as hemoglobin <12 g/dL (HGB); elevated DS as a four-item Center for Epidemiologic Studies Depression Scale (CES-D-4) score ≥ 4; and high stress as a four-item Cohen's perceived stress scale (PSS-4) score ≥ 7. We adjusted for age, race, education, income, marital status, history of heart disease, hypertension, diabetes, and stroke, cigarette and alcohol use and access to medical care. The association between HGB and individual outcomes was assessed by multivariable logistic regression. **Results.** There were 3,817 individuals with CKD, 20.3% of all subjects; mean age 68.3 years, 39.8% men and 45.9% African American. Overall 10.9% of women and 6.9% of men had elevated DS and high stress was reported by 20.0% of women and 12.4% of men (Table). HGB was more prevalent in women (26.3%) then men (9.8%), OR (95% CI) = 2.27 (1.96, 2.64). Men without HGB were substantially less likely to have elevated DS or high stress than women while the prevalence of both increased in men and women with HGB (Table). The fully adjusted M:F OR (95% CI) for elevated DS was 0.67 (0.48, 0.95) for individuals without and 1.74 (0.84, 3.63) for those with HGB. Comparable M:F OR (95%CI) for high stress were 0.53 (0.41, 0.68) and 1.71 (0.96, 3.05). **Conclusion.** Rates of elevated DS and high stress increased substantially more in men than in women with HGB.

| | Elevated DS | | M:F OR (95% CI) | High Stress | | M:F OR (95% CI) |
|---|---|---|---|---|---|---|
| Hgb g/dL | Male | Female | Fully adjusted | Male | Female | Fully adjusted |
| ≥12 | 6.3% | 10.7% | 0.67 (0.48, 0.95) | 11.7% | 20.3% | 0.53 (0.41, 0.68) |
| <12.0 | 12.3% | 11.5% | 1.74 (0.84, 3.63) | 19.6% | 19.2% | 1.71 (0.96, 3.05) |

Disclosure of Financial Relationships: nothing to disclose

**Anemia and Risk of Reduced Health-Related Quality of Life among Older Americans with Chronic Kidney Disease in the Reasons for Geographic and Racial Differences in Stroke (REGARDS) Study**
John J. Isitt,[1,2] Nancy G. Kutner,[1] Suzanne E. Judd,[1] Manjula Kurella Tamura,[1] Virginia G. Wadley,[1] Neil A. Zakai,[1] David G. Warnock,[1] Brian D. Bradbury,[1,2] William M. McClellan.[1] *[1]Renal REGARDS Working Group, UAB, Birmingham, AL; [2]Amgen Inc, Thousand Oaks, CA.*

**Introduction.** This study examines reduced health-related quality of life (HRQoL) among older adults with chronic kidney disease (CKD). **Methods.** Participants 45 years in a population-based cohort study with a urine albumin-to-creatinine ratio of >= 30 mg/g or an estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73 m$^2$ were included. Primary exposure was hemoglobin (HGB). HRQoL was concurrently assessed by reported health status, frequency and intensity of physical activity and the Medical Outcomes Study Short Form-12 mental (MCS) and physical (PCS) composite scores. Associations between HGB and HRQoL were assessed with multivariable regression models controlled for age, sex, race, socioeconomic status, health behaviors and co-morbidity. **Results:** Among 3,817 individuals with CKD the prevalence of poor health, decreased activity and absence of intense activity all increased as HGB level declined from 12 to <10.0g/dL. In fully adjusted models stratified by gender the mean MCS was not associated with HGB while PCS decreased as HGB decreased. The OR for poor health, being less active, not engaging in intense activity increased, compared to the referent level 12 g/dL, among men as HGB levels declined, while among women only poor health increased (Table). **Conclusions.** In these individuals with CKD an inverse association between HGB levels and measures of physical function and poor health was observed in men and women and lower activity was more evident among men.

| | Men | Women |
|---|---|---|
| Hgb g/dL | Poor Health: OR (95%CI) | |
| 10-11.9 | 1.58 (0.72, 3.45) | 1.31 (0.81, 1.36) |
| <10 | 9.2 (2.08, 41.0) | 3.23 (1.27, 8.22) |
| | Less active: OR (95%CI) | |
| 10-11.9 | 1.14 (0.89, 1.15) | 1.37 (1.07, 1.74) |
| <10 | 4.52 (1.28, 16.4) | 1.30 (0.67, 2.53) |
| | No intense activity: OR (95%CI) | |
| 10-11.9 | 1.48 (0.98, 2.23) | 1.17 (0.93, 1.47) |
| <10 | 2.85 (0.83, 9.78) | 0.70(0.37, 1.32) |

**Leg Muscle Cross-Sectional Area Is Associated with Serum 1,25-Dihydroxyvitamin D Level in Chronic Kidney Disease Stage 3 and 4** Patricia L. Gordon,[1,2] Julie W. Doyle,[2] Kirsten L. Johansen.[1,2] *[1]Medicine, SFVAMC, San Francisco, CA; [2]Nephrology Division, UCSF, San Francisco, CA.*

Declines in 1,25-dihydroxyvitamin D ($1,25(OH)_2$ D) follow the course of chronic kidney disease (CKD). The molecular mechanisms of vitamin D in skeletal muscle are well known, but there is little information regarding vitamin D status and muscle loss in patients with CKD. Thus we examined baseline data of an ongoing blinded randomized controlled trial of paricalcitol on muscle size in CKD patients stage 3 and 4. We previously reported that $1,25(OH)_2$ D but not 25-hydroxyvitamin D (25(OH)D) was associated with walking speed and distance, leg strength and balance. We now report the results of magnetic resonance imaging (MRI) of the thigh muscle in the same group of patients (22 M, 2 F, 60 ±13 years), stage 3 (n = 14) and 4 (n = 10) CKD. Clinical measures include eGFR (31±9 ml/min by MDRD), iPTH (132, 74-249 pg/ml), albumin (3.6±0.56 gm/dL), plasma calcium ($Ca^{2+}$) (9.01±0.44 mg/dL), 25(OH)D (20.3, 7.0-39.8 ng/ml) and $1,25(OH)_2$D (19.7, 5-74 pg/ml). Muscle cross-sectional area (MCSA) of the quadriceps was determined by MRI. Overall 67% of the subjects were either 25(OH)D deficient (n = 8), or insufficient (n = 8) but there was no association between 25(OH)D levels and MCSA. MCSA was associated with eGFR (r=0.54, p=0.006), but there was no association of age, sex, albumin or iPTH with MCSA. Using least-squares regression, variance in MCSA was best explained (adj $R^2$ = 0.45, p =0.005) by a model containing $1,25(OH)_2$D (β =0.635, p=0.02), plasma $Ca^{2+}$ (β = -13.98, p=0.02), and daily physical activity (PA) measured by accelerometry (β =0.008, p=0.02). The negative coefficient of plasma $Ca^{2+}$ with MCSA is supported by reports that sedentary behavior is associated with higher plasma $Ca^{2+}$ due to cellular damage associated with changes in $Ca^{2+}$ metabolism and transport leading to loss of $Ca^{2+}$ into plasma. There was no association of $1,25(OH)_2$D with plasma $Ca^{2+}$ or PA, although $Ca^{2+}$ was inversely but not significantly related to PA. These results suggest that $1,25(OH)_2$D, known to be essential to muscle function may be an important determinant of muscle size in patients with stage 3 and 4 CKD.

**Health Related Quality of Life as a Predictor of Adverse Outcomes in African Americans with Chronic Kidney Disease** Anna C. Porter,[1] Deborah Heffley Brooks,[2] Marino A. Bruce,[2] Jennifer J. Gassman,[2] Cynthia A. Kendrick,[2] Keith C. Norris,[2] Michael J. Fischer,[1] Denyse Thornley-Brown,[2] Mark L. Unruh,[2] James P. Lash.[1] *[1]Medicine, U. Illinois, Chicago, IL; [2]For the AASK Study Group.*

Health-related quality of life (HRQOL) has been associated with increased risk for hospitalization and mortality in patients with ESRD, but has not been evaluated as a predictor in CKD. We examined the relationship of baseline measures of HRQOL with CKD progression, cardiovascular (CV) events, and all-cause mortality among 691 participants with hypertensive CKD in the African American Study of Kidney Disease and Hypertension (AASK) Cohort Study. HRQOL was assessed using the Medical Outcomes Study Short Form (SF-36). At baseline, mean participant SF-36 Mental Health Composite (MHC) and Physical Health Composite (PHC) scores were 40.4±10 and 46.3±10.5, respectively. As summarized in the table, Cox proportional hazard models were used to assess associations between HRQOL and risk for CV events, CKD progression, and mortality, adjusting for age, sex, eGFR, proteinuria, and CVD history.

| | No. events | Mean time to event (mos.) | PHC Unadjusted RR per 5-pt. lower score | PHC Adjusted RR per 5-pt. lower score | MHC Unadjusted RR per 5-pt. lower score | MHC Adjusted RR per 5-pt. lower score |
|---|---|---|---|---|---|---|
| CV events | 96 | 47.7 | 1.19 (1.08,1.3) p=0.001 | 1.11 (1,1.23) p=0.04 | 1.09 (0.99,1.2) p=0.07 | 1.03 (0.93,1.13) p=0.6 |
| Doubling of SCr/ESRD | 143 | 48.7 | 1.08 (0.99,1.17) p=0.07 | 0.99 (0.9,1.07) p=0.7 | 1.05 (0.97,1.13) p=0.2 | 0.98 (0.91,1.07) p=0.7 |
| Death | 99 | 54.7 | 1.16 (1.06,1.28) p=0.002 | 1.13 (1.02, 1.26) p=0.02 | 1.00 (0.91,1.1) p=0.9 | 1.00 (0.9,1.12) p=0.9 |

Lower baseline SF-36 PHC but not MHC scores were associated with increased relative risk of CV events and death. Neither PHC nor MHC scores were associated with CKD progression. Future work should focus on mechanisms underlying the association between PHC scores and adverse outcomes.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1232**

**Dyslipidemia and Mortality in CKD: NHANES III** Magdalena B. Sikora,[1] Guo Wei,[1] Alfred K. Cheung,[1,2] Bradley C. Baird,[1] Tom H. Greene,[1,2] Srinivasan Beddhu.[1,2] *[1]Univ Utah; [2]VA, SLC, UT.*

Uremic dyslipidemia is characterized by ↑serum triglyceride (TG) levels and ↓ serum HDL-cholesterol (C) levels. As statins are not effective against these, this might be a potential explanation for the lack of efficacy of statins in dialysis patients. However, it is unclear whether ↑serum TG and ↓ serum HDL-C levels are associated with ↑ mortality in earlier stages of CKD. We examined these associations in National Health And Nutrition Examination Survey (NHANES) III, a complex, multistage survey conducted by the National Center for Health Statistics (NCHS) in 1988 to 1994. Mortality data were obtained by NCHS by linkage with National Death Index records through December 31, 2006. The sub-population with CKD (eGFR < 60 ml/min/1.73 $m^2$) and fasting (8 hrs or more) lipid profile were studied (n=1269).

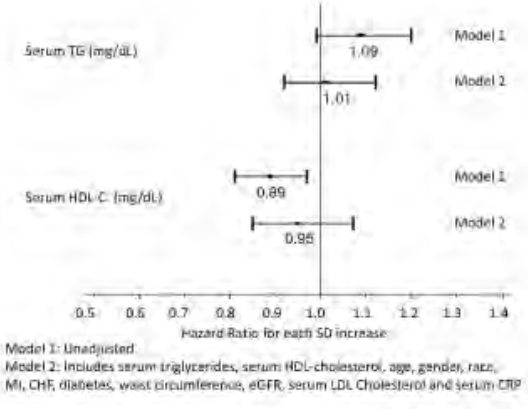
Baseline characteristics by the levels of serum TG are summarized in Table 1.

Baseline Characteristics in CKD Sub-population by Triglyceride Levels

| | TG < 150 mg/dl (42%) | TG ≥ 150 mg/dl (58%) |
|---|---|---|
| TG (mg/dL) | 105±2 | 262±6 |
| Age (years) | 69.7±0.9 | 69.4±0.8 |
| Male (%) | 36 | 37 |
| AA Race (%)** | 10 | 5 |
| MI (%)* | 11 | 20 |
| CHF(%)* | 9 | 15 |
| DM (%)** | 13 | 27 |
| Waist (inch)** | 37±0.4 | 39±0.4 |
| GFR (ml/min/1.73m²) | 49±0.7 | 49±0.4 |
| HDL-C (mg/dL)** | 56±1 | 44±1 |
| LDL-C (mg/dL) | 143±2 | 146 ±3 |

Percentages shown as percent; Continuous measures shown as mean ± standard error; * 0.001< P ≤0.05, ** P ≤0.001.

In unadjusted as well as adjusted analyses, higher serum TG were associated with non-significant ↑ in mortality. Higher serum HDL-C levels were associated with ↓ mortality risk which was attenuated when adjusted for factors that might potentially fall in the causal pathway between HDL-C and mortality (Figure 1).



Lower HDL-C levels might be associated with ↑ mortality in CKD. Interventional trials are warranted to determine the causal effects of increasing HDL-C on mortality in CKD.

**Barriers to Exercise among Dialysis Patients** Cynthia Delgado,[1] Lindsey Storer,[1] Julie W. Doyle,[1] Kirsten L. Johansen.[1,2] *[1]Nephrology, UCSF, San Francisco, CA; [2]Nephrology, SFVAMC, San Francisco, CA.*

Patients with chronic kidney disease (CKD) are inactive compared to sedentary individuals. Physical inactivity is a strong predictor of mortality in CKD patients and associated with poor physical functioning in this population. Recent evaluation of practice patterns demonstrated low exercise counseling behavior among nephrologists. However, patient barriers must also be identified in order to increase physical activity (PA).

Methods: Patients greater than age of 21 were recruited from dialysis centers affiliated with UCSF and Satellite Dialysis, which provide care for more than 250 dialysis patients. The study survey was composed of questions designed to ascertain information in the following areas: self reported level of physical functioning, PA recall, patient PA preference and barriers to PA. Components of the Physical Activity Scale for the Elderly (PASE) and the 7-day Physical Activity Recall, which are validated in original form, were abstracted to create the study instrument. Univariate and multivariable linear regression analyses were performed to study the association between reported barriers to PA and reported levels of PA.

Results: A total of 100 dialysis patients agreed to participate, the majority were male (73%) mean age of 60 ±15 years. 27% identified themselves as white, 30% Black and 21% Hispanic. The majority of participants strongly agreed that sedentary lifestyle was a health risk (98%) and that increasing exercise was a benefit (98%). Only 8% of participants reported no barriers to PA. Commonly reported barriers to PA were fatigue on dialysis days and non-dialysis days (67% and 40%, respectively) and shortness of breath (48%). Older patients reported fewer barriers to exercise (p<0.002). There were no differences in reported barriers by sex or race/ethnicity. In multivariate analysis, a greater number of reported barriers was associated with lower levels of PA (p <0.02) when adjusted for age and sex.

Conclusion: Low levels of PA were associated with higher numbers of reported barriers. Dialysis fatigue was the most commonly reported barrier. Future studies should focus on addressing such barriers in an effort to increase levels of PA.

**Extracellular Volume and Disease Progression in Children with Chronic Kidney Disease** Alison G. Abraham,[1] Alvaro Munoz,[2] Susan L. Furth,[2] Bradley A. Warady,[2] George J. Schwartz.[2] *[1]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health; [2]CKiD Investigator.*

Extracellular volume (ECV) is the fluid contained in all non-cellular compartments of the body and is a tightly controlled quantity. A primary function of the kidneys is maintenance of the fluid-solute balance through volume control and filtration. Thus, there is a strong link between ECV and kidney function. As a physiologic metric, ECV may serve an important role as an indicator of disease progression and cardiovascular disease risk. The direct calculation of ECV is viable only through the direct assessment of plasma disappearance of an injected marker. The Chronic Kidney Disease in Children (CKiD) study uses injected iohexol to obtain direct measures of glomerular filtration rate (GFR) and the descriptors of the fast and slow components of the disappearance curves were used to calculate ECV from 790 iohexol studies with medians for GFR= 43.4 ml/min per 1.73 m², weight= 35 kg and height= 1.4 m. The median ECV was 8.6 L (IQR: 5.9L to 12.2 L) and the median ECV normalized to body weight (ECV/wt) was 0.23 L/kg (IQR: 0.20 to 0.25 L/kg). ECV/wt declined with maturation, which was consistent with previous reports. We found ECV to be a function of height [m] and weight [kg] according to the relationship ECV=√wt×ht ($R^2$=0.92). Using linear regression methods on the log-transformed variables, biomarkers of kidney disease (serum creatinine, BUN and cystatin C) were significantly related to ECV/wt ($P<0.05$) but the strength of association was small compared to relationships with GFR. We found no significant association between ECV/wt and hypertension, defined as systolic blood pressure > 95th percentile for age, sex and height, or edema. However edema was only reported at 3% of study visits. In this pediatric cohort ECV was related to CKD progression but to a lesser degree than to GFR and was not a clear predictor of hypertension or edema, though the small numbers of edematous participants may have hindered the detection of a relationship. Nevertheless, ECV has relevance to fluid and electrolyte management and can be easily estimated from the square root of weight and height.

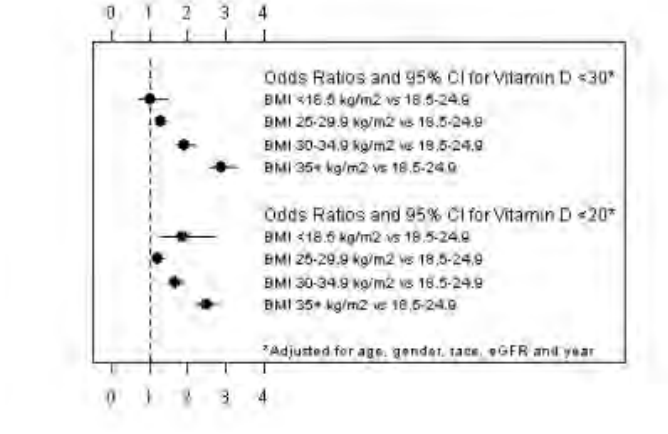
**F-PO1235**

**Obesity Is Associated with Higher Rates of Vitamin D Deficiency among CKD Patients** Sankar D. Navaneethan,[1] Jesse D. Schold,[2] Welf Saupe,[3] Susana Arrigain,[2] James F. Simon,[1] Joseph V. Nally.[1] *[1]Nephrology and Hypertension, Cleveland Clinic; [2]Quantitative Health Sciences, Cleveland Clinic; [3]eResearch, Cleveland Clinic.*

**Purpose:** Prevalence of obesity and chronic kidney disease (CKD) are increasing and vitamin D insufficiency and deficiency is widely prevalent in CKD. Obesity is associated with low vitamin D levels in people without CKD. We examined the association of body mass index (BMI) with vitamin D levels in patients with CKD.

**Methods:** Patients with stage 3 CKD (GFR 30-59 ml/min/1.73m2) who had vitamin D levels measured after their inclusion in our Cleveland Clinic CKD registry (n=11,857) were included in this analysis. We conducted separate analysis for patients with vitamin D levels <30 ng/ml and < 20 ng/ml.

**Results:** Sixty-five % of patients (n=7770) had vitamin D levels <30 ng/ml and 32% had levels <20 ng/ml during follow up. The proportion of patients with vitamin D levels <30 ng/ml increased with BMI (BMI 18.5-24.9: 55% vs. BMI 25-29.9: 63% vs. BMI 30-34.9: 72% vs. BMI >35: 79%). In the multivariable analysis, male gender (OR 1.30, 95% C.I. 1.19-1.41), African American race (OR 1.78, 95% C.I.1.56-2.04), overweight and obesity were associated with vitamin D levels <30 ng/ml.



Increasing age and higher GFR levels were inversely associated with vitamin D levels <30 ng/ml. Analysis restricted to vitamin D levels <20 ng/ml yielded similar results. 7% of patients with vitamin D levels <30 ng/ml died while 5% with vitamin D ≥30 ng/ml died during the follow-up ($p<0.001$).

**Conclusions:** Vitamin D insufficiency and deficiency are widely prevalent in overweight and obese stage 3 CKD patients. We observed a dose-response relationship between BMI and low vitamin D levels and increased mortality among those patients with low vitamin D levels. Future studies should address the impact of these associations and interventions on morbidity and mortality in CKD.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1236**

**Concurrent Complications of Chronic Kidney Disease (CKD) by Level of Albuminuria and Estimated GFR (eGFR)** Lesley A. Stevens,[1] Josef Coresh,[2] Andrew S. Levey,[1] Marcello Tonelli,[3] Paul Muntner.[4] *[1]Tufts Medical Center; [2]Johns Hopkins University; [3]University of Alberta; [4]University of Alabama at Birmingham.*

**Background** Higher levels of albuminuria are associated with increased risk for mortality, cardiovascular disease and kidney outcomes independent of eGFR. It has not been established whether albuminuria is associated with concurrent complications of CKD independent of eGFR.

**Methods** The association of spot albumin-to-creatinine ratio (ACR) level with anemia (hemoglobin < 12 g/dL for women and <13.5 g/dL for men), acidosis (bicarbonate < 22 mmol/L) and hyperphosphatemia (phosphate ≥ 4.5 mg/dL) was assessed using 30,528 participants, ≥ 20 years of age, in the National Health and Nutrition Examination Survey 1988-1994 and 1999-2006. GFR was estimated using the CKD-EPI equation.

**Results** The table shows age adjusted associations of ACR and eGFR with anemia, acidosis and hyperphosphatermia. Results were similar in models adjusted for age, race, sex and eGFR/ACR and stratified by eGFR/ACR.

**Conclusions** After adjustment for eGFR, albuminuria was associated with anemia, but not acidosis or hyperphosphatemia. Algorithms for management of concurrent complications, as well as for risk stratification of concurrent complications and future events, may need to be tailored to specific outcomes.

Table: Age adjusted odds ratios for CKD complications associated with level of albuminuria and eGFR.

| ACR, mg/g | Anemia | Acidosis | Hyperphosphatemia |

**The Relationship between Cognitive and Physical Function in Patients with CKD** Patricia Lynn Painter,[1] Katy Van Schyndle,[1] Deirdre A. Palmer,[1] Marc L. Weber.[1] *[1]School of Nursing, University of Minnesota, Minneapolis, MN; [2]School of Nursing, University of Minnesota, Minneapolis, MN; [3]Division of Renal Diseases, University of Minnesota, Minneapolis, MN; [4]Division of Renal Diseases, University of Minnesota, Minneapolis, MN.*

It is well documented that patients with CKD have low physical functioning (PF) and significant cognitive impairment. It is unclear whether there is an relationship between low PF and cognitive impairment. In this study, we aimed to characterize the relationship between PF and cognitive function (CF) in older patients with CKD and to compare levels in patients treated with hemodialysis (HD) and those with reduced renal function (CKD). Fifty one patients (21 HD and 30 CKD) were tested once using the Montreal Cognitive Assessment tool (MoCA)and the Short Physical Performance Battery (SPPB, which assesses lower extremity function). A shuttle walk test (SWT) (a progressive walking test) was also used to assess PF. Physical activity was assessed using step counters for 7 days. Comparisons were done using independent T-tests and X2 for categorical variables. The HD group (10 males/11females age 63.8± 8.5 y) was on dialysis an average of 45.0±35.8mo. The CKD group (17 males/13 females; 68.7± 9.6 y) had eGFR of 37.4±15.9 ml/min/1.73m2 (range 12 to 71). The CKD group had higher average steps/day (5909±4735 vs. 2713 ± 1996; p=0.009), longer distance on the SWT (297.7±121.1 vs. 121.4 ± 83.8 m' p=0.006), and higher MoCA scores (23.7 ± 4.6 vs 19.9 ± 5.1; p=0.01). More HD had MoCA scores <26 (mild cognitive impairment cutpoint) (95.3%) compared to 56.6% of CKD (p=.002). Only 23.8% of the HD group had SPPB scores in the highest category (10-12) compared to 50% of the CKD group. The MoCA score was significantly correlated with the SPPB total score (r=.39; p=.006), SWT distance (r=.39; p=.007) and peak walk speed on the SWT (r=.438; p=.002). CKD patients, whether treated with HD or not have significant cognitive impairment and low levels of PF. The significant relationship between CF and PF warrants further study to develop interventions to prevent or attenuate deterioration.

**F-PO1238**

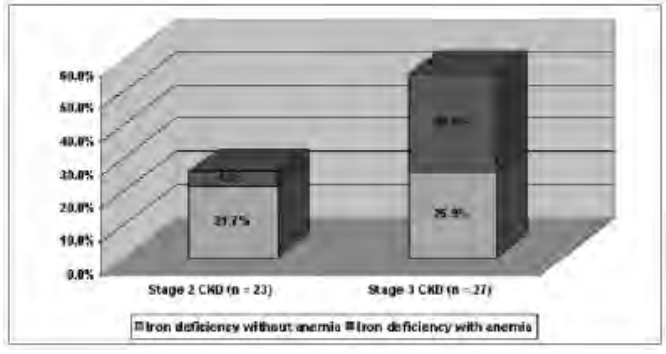
**Anemia and Iron Deficiency in Children with Early Chronic Kidney Disease** Rossana G. Baracco Maggi, Sermin Saadeh, Rudolph P. Valentini, Tej K. Mattoo, Amrish Jain. *Pediatric Nephrology, Children's Hospital of Michigan/Wayne State University, Detroit, MI.*

**Background**: Normocytic, normochromic anemia is a well known complication of advanced chronic kidney disease (CKD). Very little is known about anemia and iron deficiency (ID) in children with early CKD.

**Objectives**: To determine the frequency of ID and iron deficiency anemia (IDA) in early CKD.

**Methods:** Retrospective chart review of 50 patients 0 to 18 years of age with CKD stages 2 and 3. Anemia was defined per KDOQI guidelines, according to the age and sex of the patient. ID was defined as transferin saturation (Tsat) <20% and low ferritin according to patient's age, and/or patient already on iron supplementation. IDA was defined as ID plus low hemoglobin (Hb). GFR was calculated using the Schwartz formula. The lowest hemoglobin while the patient was in CKD stage 2 and 3 was identified and the average of three consecutive levels was used for analysis. The GFR, ferritin level and Tsat done at the time of low Hb were noted.

**Results:** The study included 36 (72%) male and 14 (28%) female patients; 23 (46%) had obstructive uropathy or dysplastic kidneys, 12 (24%) had vesicoureteral reflux, 11 (22%) had focal segmental glomerulosclerosis, the rest had other causes of CKD. The mean GFR was 55.4. 21 (42%) patients had ID and of these, 9 (42.9%) patients had anemia. The frequency of ID without anemia increased from 21.7% to 25.9% from stage 2 to stage 3 and the frequency of ID with anemia increased from 4.3% to 29.6% from stage 2 to stage 3 respectively.



Females had a higher frequency of IDA than males (28.6% vs 13.9% respectively), as well as higher frequency of ID (35.7% vs 19.4% respectively).

**Conclusions:** ID is common in children with CKD 2 and 3, and 42.9% of such patients present with anemia. IDA increases with advancing CKD. Early identification and management of IDA in early CKD is recommended.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1239**

**Supplementary School-Based Education Services for Children with Mild to Moderate Chronic Kidney Disease** Arlene C. Gerson, Susan R. Mendley, Stephen R. Hooper, Matthew Matheson, Shlomo Shinnar, Debbie S. Gipson, Judith Jerry-Fluker, Amira Al-Uzri, Robert W. Butler, Bradley A. Warady, Susan L. Furth. *CKiD Neurocognitive WorkGroup.*

Purpose: Final educational attainment and successful employment lag in adults with childhood onset chronic kidney disease (CKD) compared to their unaffected peers. We sought to determine the proportion of youth with mild to moderate CKD receiving supplementary school services and variables associated with receipt of extra help.

Methods: In a cross-sectional analysis of youth enrolled in the Chronic Kidney Disease in Children (CKiD) study with complete data for all variables of interest, 219 children were available for analysis. Multiple logistic regression was used to identify risk factors for receipt of supplementary school services. We controlled for variables suspected of influencing school performance including age, race, gender, SES, GFR, %life with CKD, low birth weight, proteinuria, height percentile and anemia.

Results: Study population was 15% Black, 40% female, with median age 12.5 (IQR 9.6-15.2), height percentile 23.2 (IQR: 8.0-54.3), GFR 42.4 ml/min/1.73m$^2$ (IQR: 33.3-52.1), percent of life with CKD =90 (IQR: 35-100). The presence of poor academic achievement (WIAT-IIA Total Achievement Score < 85), parent observation of social functioning problems (PedsQL Social Subscale < 62) and/or parent observation of school functioning problems (PedsQL School Subscale <57), were associated with receipt of supplementary school services (OR 7.7, p<.01; OR 2.6, P<.05, OR 3.9, p<.01 respectively). Short stature (p=.04) and marked proteinuria (urine protein/creatinine ratio >2, p=.01)) were also associated with receipt of supplementary school services. 59% of the group could be considered at risk for poor academic performance, poor school functioning and/or poor social functioning problems, yet only 36% received supplementary school services.

Conclusion: A subtantial fraction of youth with CKD and risk factors for poor school performance do not receive supplementary educational services to which they may be entitled. Further prospective studies on the effectiveness of supplementary school interventions are appropriate.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1240**

**Bioimpedance Spectroscopy (BIS) Derived Normalized Extracellular Water (nECW) as an Index Hydration Status: A Tool To Attain Fluid Balance** Mauricio Paredes-Fernandez, Klearly M. Tinoco, Ricardo Correa-Rotter. *Nephrology and MM, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, DF, Mexico.*

Introduction: BIS is a multifrequency bioimpedance technique that assesses hydration. Volume expansion of dialysis pts can be estimated by BIS, yet comparison with reference values from ECW measurements of a demographically and ethnically similar yet healthy population would enhance accuracy to estimate dry weight.

Purpose: To describe reference values for ECW in a Mexican population and to analyze normalized ECW (nECW) correlations with demographic and somatometric variables to generate a mathemathical model to predict ECW.

Methods: We performed BIS (3 measurements) with a Body Composition Monitor (BCM®, Fresenius Medical Care) in healthy adults, 3 hours fasted. ECW was normalized with: a)intracellular water (ECW/ICW), b)Height (ECW/height), c)total body water (ECW/TBW). We also analyzed correlation of these values with age and body surface area (BSA) to obtain linear regression specific formulas for nECW normal values in euvolemic controls.

Results: 200 subjects (male=90), age 40.6±11.6 y (19-63), weight 71.9±13 kg, height 161.8±9 cm, BMI 27.4±4.5 kg/m2 and BSA 1.76±0.18 m2. The coefficient of variation (CV%) of ECW was 0.33%. ECW normalized by ICW, height, and TBW showed a poor correlation with age (r=0.11, r=0.26 and r=0.12, respectively) in contrast to what others have shown. In our population ECW, normalized by height (ECW/H) showed good correlation with BSA (r=0.86, p<0.001). By multiple regression (stepwise) we obtained a ECW/H formula with R2=0.85 (adjusted R2=0.84, p<0.001) employing BSA, BMI and gender [ECW/H =-0.007594+0.03557BSA+0.001229BMI +0.008608gender (0= females, 1=males)].

Discussion: We find a very low CV% for ECW measurements in euvolemic controls. In this population nECW does not correlate with age. In contrast, we found good correlation with BSA. This phenomenom has not been previously reported. Our nECW formula derived from demographic and somatometric parameters could be useful to objectively estimate overhydration (measured nECW in a dialysis patient minus nECW values from euvolemic controls) and is easily applicable to PD or HD.

**CT and MR Imaging Criteria for Diagnosis of Cyst Infection and Intracystic Hemorrhage in Autosomal Dominant Polycystic Kidney Disease** Tatsuya Suwabe, Yoshifumi Ubara, Keiichi Sumida, Rikako Hiramatsu, Junichi Hoshino. *Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Background and objectives: Cyst infection and intracystic hemorrhage are serious complications of autosomal dominant polycystic kidney disease (ADPKD). However, they are often difficult to differentiate from each other. PET was reported to be useful for detecting infected cysts, however it has limited availability and is an expensive imaging method. PET might also be unable to differentiate infection from intracystic hemorrhage. Magnetic resonance imaging (MRI) and computed tomography (CT) are presumed to be easy and useful imaging methods for detecting infected or bleeding cysts in patients with ADPKD, but the diagnostic criteria have not been clarified. Accordingly, we investigated the MRI and CT findings for diagnosis of cyst infection or intracystic hemorrhage in patients with ADPKD.

Design, setting, participants, & measurements: Patients with definite cyst infection or definite intracystic hemorrhage were enrolled, among all patients with ADPKD who were referred to our institution from January 2004 to December 2009. We compared the MRI and CT features of patients with infected cysts and intracystic hemorrhage. First, we identified intracystic fluid-fluid levels and thickening of the cyst walls. Second, we compared the signal intensity (SI) ratio and CT density among infected cysts, normal cysts, and cysts with hemorrhage.

Results: Thirteen patients with definite cyst infection and 6 patients with definite intracystic hemorrhage were enrolled. With MRI, infected cysts showed a lower intensity on T2WI and a significantly higher intensity on T1WI and DWI than normal cysts. Many infected cysts also had a fluid-fluid level and wall thickening. Cysts with hemorrhage showed a significantly higher intensity on T1WI, T2WI, and DWI than infected cysts, and also had a higher density on CT. Moreover, intracystic hemorrhage displayed an irregular high density on CT.

Conclusions: CT and MRI are both useful for diagnosis of cyst infection and intracystic hemorrhage.

**F-PO1242**

**Expression of Intrarenal Renin-Angiotensin System and Its Relationship with Clinical-Pathological Injury in Primary IgA Nephropathy Patients** Xiaoyan Zhang, Xiaoqiang Ding, Wenlv Lv, Jie Teng, Yihong Zhong. *Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

**Introduction**

Little information is available about the RAS expression and regulation in the human kidney and particularly in kidney diseases. These data in humans and in diseased kidneys

would be worthwhile being evaluated because changes in general RAS do not closely reflect local expression and regulation of intrarenal RAS.

**Methods**

Thirty-six biopsy-proved IgA nephropathy patients who were hospitalized between January 2009 and June 2009, had not received ACEI, ARB, glucocorticoids or immunosuppressive agents. We recorded gender, age, height, body weight, blood pressure, urine routine, renal function, serum electrolytes, urinary protein of 24 hours and urinary sodium. We assessed pathological injury by semiquantitative Katafuchi score and assessed intrarenal experssion of all the components of the intrerenal RAS by immunohistochemistry staining. We assessed expression and regulation of all the components of intrarenal RAS and the relationship between intrarenal Ang II activity and clinical-pathological injury index in primary IgA nephropathy patients.

**Results**

Positive IHCS area of intrarenal renin, angiotensinogen and AngII were 26.86±13.66%(7-55%), 38.34±9.71%(12-57%) and 32.73±14.74%(6-70%), respectively. There were positive correlation between positive IHCS area of intrarenal renin and positive IHCS area of intrarenal Ang II ($P<0.01$), positive IHCS area of intrarenal angiotensiongen and positive IHCS area of intrarenal Ang II ($P<0.05$). Average eGFR in 36 IgA nephropathy patients was 55.92±22.87 ml/min/1.73m$^2$(6.62-92.49 ml/min/1.73m$^2$) and there was negative correlation between positive IHCS area of intrarenal Ang II and eGFR($P<0.01$). Average pathological chronicity index in 36 IgA nephropathy patients was 3.06±2.60 (0-10) and there was positive correlation between positive IHCS area of intrarenal AngII and pathological chronicity index ($P<0.05$).

**Conclusion**

Expression of intrarenal Ang II correlates positively with expression of intrarenal renin and angiotensinogen in IgA nephropathy. Intrarenal Ang II activity plays an important role in kidney fibrosis in IgA nephropathy.

## F-PO1243

**Impaired Maximal Aerobic Capacity Is Parallel to GFR Decline in Elderly Population** Ammar Almehmi,[1] Mike Broce.[2] [1]*Division of Nephrology, The Kidney Institute, Kansas City, KS;* [2]*CAMC Research Institute, Charleston, WV.*

**Background:**

It is well known that adult patients with end stage renal disease have impaired maximal aerobic capacity *($VO_2^{max}$)*. However, studies on $VO_2^{max}$ in elderly patients with early stages of chronic kidney disease (CKD) are limited.

**Objective:**

To examine the relationship between $VO_2^{max}$ and glomerular filtration rate (GFR) in elderly subjects and to determine factors associated with decreased $VO_2^{max}$ in elderly patients with different stages of CKD.

**Methods:**

Subjects aged 60 and over were included in this study. GFR was estimated using Cockcroft-Gault formulae. $VO_2^{max}$ was assessed using the standard graded treadmill test. Dual energy x-ray absorptiometry was utilized to assess lean mass. ANOVA, nonparametric tests, and linear regression were used to explore the relationship between $VO_2^{max}$ and GFR.

**Results:**

This study included 112 subjects, 57.1% were women with mean age of 73 ± 6.9 yr (mean ± SD), blood pressure 130 ±14.9 / 71 ± 9.2 mmHg, LDL-cholesterol 110 ± 27.6 mg/dL, blood urea nitrogen 16 ± 4.7 mg/dL, and serum creatinine 0.85 ± 0.20 mg/dL. Maximal aerobic capacity ($VO_2^{max}$) was reduced in subjects with different GFR: 40.87 mL/Lean mass (kg)/min for GFR ≥ 90 ml/min, 35.9 mL/Lean mass (kg)/min for GFR 60-89 ml/min, and 32.95 mL/Lean mass (kg)/min for GFR < 60 ml/min ($p = 0.0001$). In univariate analysis, $VO_2^{max}$ was associated with age ($p = 0.0001$), total cholesterol (($p = 0.011$), LDL- cholesterol ($p = 0.003$), body mass index ($p = 0.0001$), maximum heart rate ($p = 0.013$), and GFR ($p = 0.001$). In multivariate regression analysis, after controlling for age, sex, BMI, and duration of exercise, GFR was an independent predictor of lower $VO_2^{max}$.

**Conclusion:**

$VO_2^{max}$ is reduced in the early stages of CKD in elderly patients. These results suggest that the ability of cardiovascular system to respond to the metabolic challenge is impaired early in the development of CKD. Longitudinal studies are required to determine if improving physical activity would affect the cardiovascular outcomes in this population.

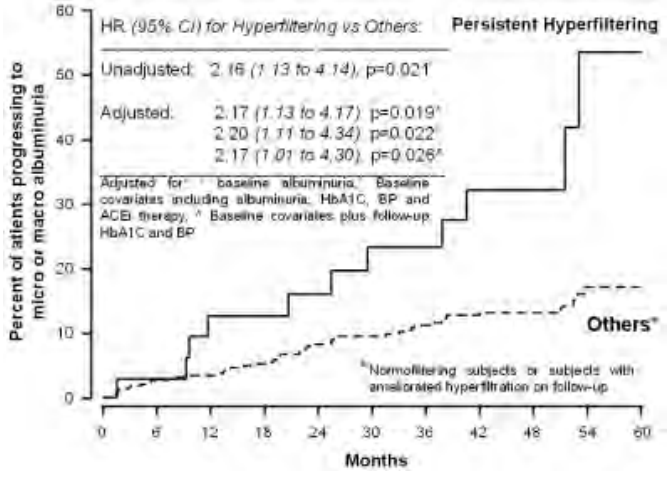
## F-PO1244

**Glomerular Hyperfiltration Accelerates Renal Disease Progression in Type 2 Diabetes** Esteban Porrini, Piero Ruggenenti, Giuseppe Remuzzi. *Mario Negri Institute for Pharmacological Research, Bergamo, Italy.*

Background: The role of glomerular hyperfiltration in onset and progression of human diabetic nephropathy is uncertain.

Methods: To assess the relationships between glomerular hyperfiltration [glomerular filtration rate (GFR) ≥120 ml/min/1.73m$^2$], GFR decline and nephropathy, we centrally measured GFR (iohexol plasma clearance) and albuminuria every 6 months over 4.0 years of intensified metabolic and blood pressure (BP) control in 600 type 2 diabetes subjects with normo- or micro-albuminuria. Glucose disposal rate (GDR) was measured by hyperinsulinemic euglycemic clamps at baseline and 1 year.

Results: GFR declined by a median (interquartile range) of 3.37 (5.26-1.54) ml/min/1.73m$^2$ per year. Independent of metabolic and BP control, concomitant therapy with ACE inhibitors, and level of initial albuminuria, more GFR reduction at 6 months significantly predicted slower GFR decline on subsequent follow-up ($p<0.0001$). The proportion of progressors to micro- or macro- albuminuria (24.4 vs 10.3%) was significantly higher in persistently hyperfiltering subjects than in non-hyperfiltering subjects and subjects who had their hyperfiltration ameliorated on follow-up.



Excess risk in hyperfiltering subjects was independent of initial albuminuria and metabolic and BP control, and was associated with more GDR reduction ($p=0.038$ by ANCOVA) at 1 year. Serum creatinine based prediction formulas failed to detect hyperfiltration at inclusion and to describe short- and long-term GFR changes in all patients.

Conclusions: GFR decline in type 2 diabetes patients with normo- or micro-albuminuria is 3 to 5 folds faster than normal. Hyperfiltration is a determinant of GFR decline and nephropathy, and its amelioration is renoprotective. Prediction formulas should not be used to identify subjects at risk and reliably monitor the effect of treatment in this population.

**Malnutrition-Inflammation Score Is Reliable Tool for Assessment of Malnutrition Status and Mortality in Chinese Peritoneal Dialysis Patients** Huiling Wang, Jinyuan Zhang. *Nephrology Division, Jimin Hospital of Shanghai, Shanghai, China.*

The malnutrition inflammation score (MIS) was reported to be a reliable tool for screening malnutrition and inflammatory status, but has not been validated in Chinese continuous ambulatory peritoneal dialysis(CAPD)patients. We studied 98 adult patients (47 men, 51 women; age 59.1±18.0 years) on CAPD at least 3 months (4~13 months). The MIS and Quantitative Subjective Global Assessment (MQSGA), and the anthropometry, inflammation makers and biochemical assays were measured. The correlation of MIS with the prospective hospitalization, mortality and morbidity of peritonitis were followed by 12months. **Results** The morbidity of malnutrition was 77.9% according to MQSGA, in which the mild 65.3%, moderate 27.5% and severe 7.1% respectively. But according to MIS, the mild 53.1%, moderate 39.8% and severe 7.14% respectively. MIS significantly correlated with the MQSGA score ($r$=0.894, $P$<0.001). The higher MIS score reflects the worse nutritional status and the more severe inflammation status including increased high sensitive-C Reactive Protein and Interleukin-6. A higher MIS score was positively correlation with a bad nutrition (lower Alb, pre-Alb and Serum creatinine) and severe anemia, which also means a higher morbidity of peritonitis(r=0.292; $P$<0.01). Case-mix–adjusted correlation coefficients for the MIS were significant for hospitalization days (r =0.469; $P$<0.001) and frequency of hospitalization (r=0.513; $P$<0.001). MIS was the independent risk factor of peritonitis ($p$=0.013, odds ratio 1.185, 95% confidence interval 1.036~1.335). During the 12-month followed-up, 12 patients died and 8 patients left the cohort. The Cox proportional hazard–calculated relative risk for death for each increased MIS score was 1.242 (95% confidence interval1.102~1.401, $P$<0.001). ***Conclusion:*** The MIS showed a simple and reliable tool for the assessment of malnutrition status in CAPD patients, as well as a predictor of PD outcome and an indicator of MICS. A higher score means a worse nutrition-inflammation status, and a higher hospitalization and mortality.

## F-PO1246

**The CRISIS Study: Clinical Outcomes of the Elderly in a Referred CKD Cohort** Richard Hoefield,[1] Philip A. Kalra,[1] Robert N. Foley,[2] Donal J. O'Donoghue,[1] Rachel Middleton.[1] [1]*Vascular Research Group, University of Manchester, Salford Royal Hospital Foundation Trust, UK;* [2]*Chronic Disease Research Group and University of Minnesota, Minneapolis, MN.*

The clinical outcomes and natural history of evolution of eGFR in elderly patients with CKD is not well described. CRISIS is a prospective epidemiological investigation of a prevalent population receiving standard nephrological care with CKD stages 3-5, not on dialysis.

The aim of this analysis was to describe the outcomes of death, requirement of renal replacement therapy (RRT) and outline the evolution of eGFR in an elderly cohort of patients in our referred CKD population.

The CRISIS cohort was categorised into 3 groups; ≤ 69, 70-79 and ≥ 80 years, based on age at inception into the study. Cox proportional hazards model was used to identify variables associated with the endpoints of RRT and death.

1317 patients were available for analysis. Median follow-up was 33 months. Mean age 65 years, with 54% ≤ 69 years of age, 32.5% between 70-79 and 13.5% ≥ 80 years of age. Those patients ≥ 70 years demonstrated slower median rates of decline in renal function than patients < 69 years of age in our cohort. Annual median rate of change of eGFR for patients ≤69 years was -1.78ml/min/y, 70-79, -1.35ml/min/y and ≥80 -1.33 ml/min/y ($p<0.01$). Significantly higher rates of death were seen in those patients ≥ 70 **(Table1).**

Multivariate associations of RRT included; greater proteinuria, lower eGFR and serum calcium. Older age, smoking, presence of baseline cardiovascular disease and diabetes, lower eGFR, higher serum phosphate and CRP were associated with death.Non- smoking status and use of statin therapy was associated with a reduced hazard ratio for mortality. This study demonstrates higher risk of death and slower rates of decline in eGFR in elderly patients with CKD in a referred cohort; highlighting the importance of strategic targeting of cardiovascular risk reduction in these older patients.

| **Age(years)** | **≤69** | **70-79** | **≥80** |
|---|---|---|---|
| **RRT %** | 26.2 | 18.6 | 10.1 |
| **RRT Rate (per100 patient years)** | **7.5** | **6.0** | **3.5** |
| **Death %** | 13 | 31.7 | 49.4 |
| **Death Rate (per100 patient years)** | **3.7** | **10.2** | **17.5** |

Disclosure of Financial Relationships: nothing to disclose

## F-PO1247

**Epidemiology and Microbiology of Joint Infections in Chronic Kidney Disease** Vanbric R. Casilla,[1,2] Brenda Hemmelgarn,[1,2] Matthew T. James.[1,2] *[1]Medicine, University of Calgary, Canada; [2]Community Health Sciences, University of Calgary, Canada.*

Patients with end-stage renal disease experience increased morbidity and mortality due to acute infections. Hematogenous spread of bacteria secondary to dialysis vascular access likely contributes to this risk, including that of bone and joint infections. Adults with chronic kidney disease (CKD) not receiving renal replacement therapy also experience an increased risk of hospitalization with joint infections. The purpose of this study was to determine the causative pathogens of these infections among patients with CKD. A cohort of adults from the Calgary Health Region with at least one outpatient serum creatinine measurement between July 1, 2003 and June 30, 2004 were identified. Patients with a prior transplant or who were receiving dialysis prior to study entry were excluded. GFR was estimated using the Modification of Diet in Renal Disease (MDRD) Study equation. The results of the first positive culture from joint and periarticular samples were obtained for patients with and without CKD (eGFR <60 and ≥60 mL/min/1.73m$^2$, respectively) during follow-up from the date of the first available serum creatinine measurement through December 31, 2008. During a median follow-up of 5 years, a total of 332 culture-positive joint or periarticular samples were obtained from 252,508 participants. The unadjusted incidence rates (per 1000 person-years) of culture-positive infections were 0.63 (95%CI 0.52-0.76) for those with CKD and 0.22 (95% CI 0.19-0.25) for those without CKD. Among those with positive cultures, there were no differences in the distribution of micro-organisms isolated from patients with and without CKD (p=0.116); 28.4 vs. 23.2% coagulase-negative *Staphylococcus* species, 35.3 vs. 46.4% *S. aureus*, 20.6 vs. 20.3% other Gram-positive organisms, and 15.7 vs. 10.1% other pathogens. The risk of culture-positive joint and periarticular infections is increased almost 3-fold among patients with CKD. Similar to patients without CKD, Gram-positive organisms, in particular *Staphylococcal* species, cause the majority of these infections. The consequences of these infections on patient outcomes remains to be determined.

## F-PO1248

**Diabetes, Podocytes and Lectins: A Glycobiology Study with Diagnostic Potential** Alessandra Ravida,[1] Marjut Kreivi,[1] Luca Musante,[1] Ilkka Miinalainen,[1] Mayank Saraswat,[1] Barry Byrne,[1] Moin Saleem,[2] Harry B. Holthofer.[1] *[1]Centre for Bioanalytical Sciences, Dublin City University, Dublin, Ireland; [2]Academic and Children's Renal Unit, University of Bristol, Bristol, United Kingdom.*

**BACKGROUND:** Glycosylation is one of the most common post-translational modifications of proteins, mirroring variations in metabolism, developmental and functional status of cells and organs.

**AIM:** In this study we aim to study weather the development of the diabetic nephropathy onset associates with changes in the glycosylation of key glycoproteins of podocytes.

**METHODS:** Detection and analysis of differential glycosylation patterns as associated with progression of the disease is carried out by the means of lectin assays on immortalized human podocytes cells treated in diabetes-mimicking conditions (high-glucose, insulin starvation, high-insulin). The results obtained in the *in vitro* studies are validated on the well established *in vivo* rat model of Streptozotocin-induced diabetes.

**RESULTS:** In this study we have probed podocyte glycoproteins with 18 commercially available plant lectins by lectin blots and immunocytochemistry. By lectin blots, we have identified 4 lectins which are able to detect specific alterations in the glycoprotein profile of podocytes treated in diabetes mimicking conditions. Furthermore, by immunocytochemistry studies, we have identified one *O*-glycan-binding lectin which selectively recognises glycoproteins secreted by podocytes in an insulin dependent fashion.

**CONCLUSIONS:** This study represents the first systematic approach towards a novel understanding of the glycobiology of diabetic nephropathy. We demonstrated the feasibility of detecting diabetes-induced changes in podocytes glycosylation patterns by lectin assays. Furthermore, it is expected that these promising lectin candidates will pave the way for a novel approach to the early-stage diagnosis of diabetic nephropathy.

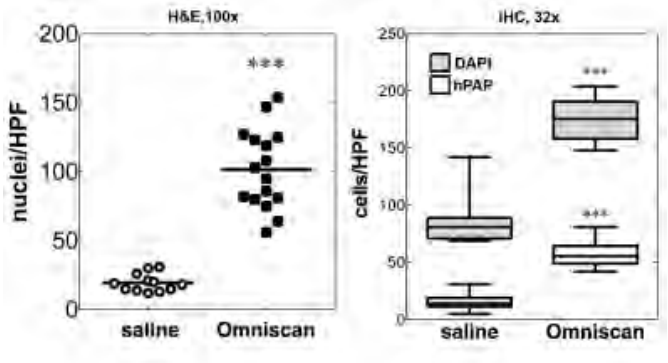
**Nephrogenic Systemic Fibrosis: Both Resident Tissue and Bone Marrow-Derived Cells Are Increased in the Dermis of Gadolinium-Based MRI Contrast-Treated Rodents** Brent Wagner,[1,2] Seema S. Ahuja,[1,2] Jeffrey L. Barnes.[1,2] *[1]South Texas Veterans Health Care System, San Antonio, TX; [2]Department of Medicine, University of Texas Health Science Center at San Antonio, San Antonio, TX.*

**Background:** Nephrogenic systemic fibrosis (NSF) is a disorder associated with gadolinium-based MRI contrast exposure given acute or chronic renal compromise. It has been proposed that circulating fibrocytes mediate the disease, however experimental evidence is lacking. A study was conducted to determine if bone marrow-derived cells are involved in mediating dermal fibrosis in rodents. **Methods:** Fisher 344 rats status post 5/6 nephrectomy were used. A sub-group of rodents underwent lethal irradiation followed by salvage bone marrow transplant (BMT) from human placental alkaline phosphatase-(hPAP-) expressing donors. Animals were treated with the gadolinium-based MRI contrast, Omniscan (2.5 mmol/kg IP), during weekdays or an equivalent volume of saline for 4 weeks. Tissues were fixed in 4% neutral buffered formalin for H&E stain or flash-frozen for immunohistochemistry (IHC) and immunoblot. H&E and trichrome-stained skins were read by a blinded dermatopathologist. Nuclei from H&E-stained tissues and IHC were quantitated. **Results:** Regardless of BMT status, gross dermal signs were mild. Skin from Omniscan-treated animals demonstrated fibrosis and increases in fibronectin and type IV collagen. Dermal cellularity in the Omniscan-treated group was greater than control (*** $P < 0.0001$ by 2-tailed t test). There were significant and proportional increases in dermal hPAP$^+$ and hPAP$^-$ cells.



**Conclusions:** Both resident tissue and bone marrow-derived cells are increased in the skins of MRI contrast-treated rodents. Elucidation of these mechanisms may aid in discovering therapies to this devastating disease.

## F-PO1250

**Isolation of Urinary Nanovesicles and a Method for Protein-Vesicle Interactions** Luca Musante, Alessandra Ravida, Mayank Saraswat, Barry Byrne, Harry B. Holthofer. *Centre for BioAnalytical Sciences, Dublin City University, Dublin, Ireland.*

BACKGROUND: Urine contains a heterogeneous population of nanovesicles which carry proteins, microRNA, RNA and transcriptional factors. However, little is known about urinary nanovesicles and their interactions with soluble proteins.

AIM: We compared two different methods to isolate exosomes from a pool of healthy donors to evaluate nanovesicle-protein interactions.

METHODS: The urine from 4 healthy volunteers was subjected to serial centrifugations at 1,000g, 18,000g and 200,000g, respectively. The final 200,000g supernatant was further processed by ammonium sulphate precipitation and was subjected to the serial centrifugation steps one more time. In the second method, the urine pool was first dialysed and the volume was reduced by lyophilisation. Nanovesicles were subsequently prepared following serial centrifugations. In order to evaluate co-precipitation of high abundant proteins with exosomes, 200,000g pellets were both treated with either dithiotreitol (DTT) or zwitterionic detergent and re-centrifuged respectively at 200,000g. Zymography was performed to detect enzymatic activities.

RESULTS: Our results show that all pellets expressing exosomal markers are a heterogeneous population of nanovesicles of different size. Surprisingly, we could detect WT-1 antigen in urine of healthy people. Furthermore, our results show that the apparent interference soluble protein is a direct and specific interaction with the 200,000g nanovesicle pellet. Moreover, zymography results showed an association of nanovesicles with protease activity which may be both intra- and extra-vesicular.

CONCLUSION: This study establishes preferential methods to yield a more comprehensive understanding of the physiological role of the abundant nanovesicles in urine and demonstrates the feasibility of detecting the nanovesicle-protein interactions.

**F-PO1251**

**Assessment of Hydration State in CKD Patients Not on RRT Using Whole Body and Calf Bioimpedance Techniques** Usama T. Hussein,[1] Fansan Zhu,[2] Li Liu,[2] Peter Kotanko,[2] Nathan W. Levin,[2] Fredric O. Finkelstein.[1] *[1]Nephrology Department, St. Raphael Hospital/Yale, New Haven; [2]Renal Research Institute, NY.*

Chronic kidney disease (CKD) is characterized by loss of volume homeostasis, often leading to overhydration that in turn is associated with hypertension(HTN) and increased risk for cardiovascular morbidity and mortality. The aim of this study was to evaluate the assessment of fluid overload in CKD pts not on renal replacement therapy (RRT) utilizing three bioimpedance approaches: ratio of extracellular fluid volume to body weight (wECV/Wt), wECV/TBW and calf normalized resistivity (nRho).

Methods. 50 clinically stable CKD pts without a history of DVT or lower studied. 45 patients (90%) had HTN. Clinical assessment of volume status was determined by the attending nephrologist. Bioimpedance was studied with whole body (wBIS) and calf bioimpedance (cBIS) measurement using Hydra 4200. 20 of the 50 pts were measured for reproducibility in two different ways. In 10 pts wBIS and cBIS measurements were made twice in one hour intervals. In another 10 pts, measurements were made twice on two consecutive days.. Healthy subjects (n=15) were measured once with wBIS and cBIS. Overhydration was defined by cBIS when nRho was less than 0.18 $Wm^3$/kg in males and 0.2 $Wm^3$/kg in females respectively

Results. Although only 24% of CKD pts were assessed clinically to be overhydrated, 86% CKD pts (n=50) were identified as being overhydrated by nRho. nRho was significantly lower in CKD pts than in HS . 28% and 26% were overhydrated by wECV/Wt and wECV/TBW, respectively; wECV/Wt and wECV/TBW were not significantly different between CKD patients and HS . Relative change in -1.14%, 1.7% and 0.42% in the same day measurements and -1.2%, 0.22% 4.6% in two consecutive days study were observed for nRho, wECV/Wt and wECV/TBW respectively.

Discussion and Conclusion. The main finding in this study was that nRho was significantly lower in CKD pts than in HS, however, no difference in wECV/Wt or in wECV/TBW was observed. Given that 86% of patients were hypertensive, calf resistivity could be a useful marker to identify degree of hydration state in CKD pts not on RRT

**F-PO1252**

**Changes in the Mitochondrial Network and Bioenergetic Capacity of Human Podocytes during Differentiation** Ilkka Miinalainen, Marjut Kreivi, Alessandra Ravida, Barry Byrne, Luca Musante, Louise Sewell, Harry B. Holthofer. *Centre for Bioanalytical Sciences, Dublin City University, Dublin, Ireland.*

Background: Changes in the amount of mitochondria/their functional capacity are associated with several metabolic diseases, including diabetes.

Methods: Mitochondrial functional parameters were determined from transformed human podocytes (AB 8/13) by high-resolution respirometry, fluorescent microscopy and Real-time quantitative PCR.

Results: During differentiation, cellular routine respiration increased from 50 pmols s-1 10-6 cells up to 131 pmols s-1 10-6 cells, and oligomycin-inhibited respiration increased from 7.2 pmols s-1 10-6 to 63.3 pmols s-1 10-6 cells. Uncoupled respiration showed maximal capacity of the respiratory chain was 2.5 times higher in differentiated podocytes. After result normalisation, it was shown that both routine respiration and uncoupled respiration were lower in differentiated podocytes, while leak respiration rates remained significantly higher. In undifferentiated podocytes, mitochondria showed fragmented perinuclear morphologies which changed to filamentous network with long tubules extending to the periphery of the cell during differentiation. Differentiation greatly induced the expression of PGC-1a, while expression of the mitochondrial transcription factor A (TFAM) remained unchanged.

Conclusion: The coactivator PGC-1a plays a central role in podocyte differentiation by promoting the mitochondrial biogenesis, although no large changes are needed for control of transcription and replication of the mitochondrial genome as judged by unchanged levels of TFAM. Respiratory control ratios indicate that approximately 40 % of the electron transport capacity is utilised in the routine respiration in both undifferentiated and differentiated cells, indicating large respiratory excess capacity over routine respiration. In undifferentiated cells, 37 % of the total uncoupled electron transport capacity was activated to ATP production, while in differentiated podocytes this figure was only 19 %. This demonstrates that non-mitochondrial respiration and other oxygen-consuming processes are markedly induced in differentiated podocytes.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1253**

**Role of Glycosylation in the Diabetic Kidney Disease – The Effect of Insulin on Glyco-Gene Expression of Podocytes** Marjut Kreivi,[1] Alessandra Ravida,[1] Ilkka Miinalainen,[1] Suzanne Papp,[2] Lana Schaffer,[2] Luca Musante,[1] Louise Sewell,[1] Barry Byrne,[1] Steve Head,[2] Moin Saleem,[3] Harry B. Holthofer.[1] *[1]Centre for Bioanalytical Sciences, Dublin City University, Dublin, Ireland; [2]DNA Array Core Facility, Scripps Research Institute, CA; [3]Academic and Childrens Renal Unit, University of Bristol, Bristol, United Kingdom.*

**BACKGROUND:** The developmental/functional status of podocytes is reflected by glycodecoration. Podocytes increase glucose uptake when stimulated by insulin via an effect on glucose transporters GLUT1 and GLUT4.

**AIM:** This study aims to map glyco-genes regulated in podocytes under insulin-induced diabetes mimicking stress and those involved in the alteration of the glomerular filtration barrier and podocytes during development of diabetic kidney disease.

**METHODS:** Changes in glyco-gene expression were screened in a human conditionally immortalized podocyte cell line after insulin treatments (normal culture conditions, insulin starvation, and a series of different insulin concentrations). The glyco-gene expression changes were screened using the GlycoV4 oligonucleotide array. A set of genes was further analyzed using real-time RT-PCR, Western blotting and immunocytochemistry.

**RESULTS:** Differential expression compared to the normal control sample was detected both in the insulin-starved and in the insulin-treated samples. Several glyco-genes that are not previously linked to human podocytes under diabetic/insulin stress were also identified. These included glyco-genes from several categories including glycan-transferases, glycan degradation enzymes, growth factors and receptors. In total, 25 glyco-genes were found to be differentially expressed. From these, a set of 6 genes was selected for further analysis.

**CONCLUSIONS:** Diabetes mimicking stress represented by different concentrations of insulin in the culture media resulted in differential glyco-gene expression in cultured human podocytes. Changes in insulin concentration induced differential expression in 25 glyco-genes. The changes in 5 glycan-transferases and a glycan degradation associated protein were confirmed using real-time RT-PCR, Western blotting and immunocytochemistry.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1254**

**High Intake of Insoluble Dietary Fiber (IDF) Is Associated with ↓ Inflammation and All-Cause Mortality (ACM) in CKD: NHANES III** Vidya M. Raj Krishnamurthy,[1,2] Neelakanta A. Dadi,[1,2] Bradley C. Baird,[1] Guo Wei,[1] Tom H. Greene,[1,2] Michel B. Chonchol,[3] Srinivasan Beddhu.[1,2] *[1]Univ Utah; [2]VA, SLC, UT; [3]Univ Colorado, Denver, CO.*

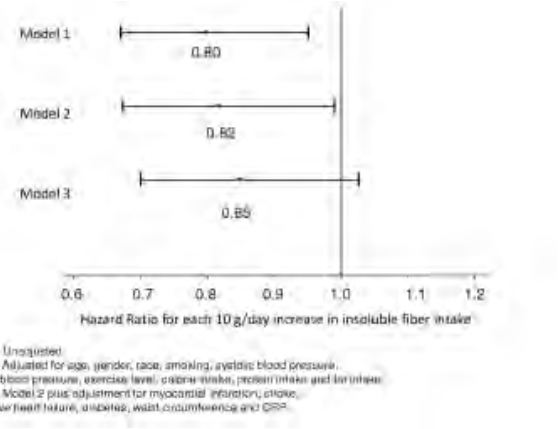
Dietary fiber intake is often low in CKD due to ↓ fruit /vegetable intake. We examined the associations of IDF with elevated serum CRP (>3mg/L) and ACM in CKD sub-population (N=1105) in National Health and Nutrition Examination Survey (NHANES) III, a multistage survey conducted by the National Center of Health Statistics (NCHS) in 1988 -1994. IDF intake was estimated from 24h dietary recalls. Mortality data were obtained by NCHS by linkage with National Death Index records through 12/31/2006.

Characteristics of CKD Population by IDF intake

| | ≤6.4 g/d | 6.5-11 g/d | ≥11.1 g/d |
|---|---|---|---|
| IDF(g/d) | 4.2±0.1 | 8.6±0.1 | 16.7±0.4 |
| Age(yr) | 69±0.9 | 69±1.3 | 70±0.9 |
| Male(%)** | 29 | 31 | 49 |
| AA Race(%)* | 12 | 5 | 4 |
| MI(%) | 16 | 15 | 15 |
| DM(%) | 23 | 20 | 19 |
| Smoking(%)* | 19 | 12 | 9 |
| Inactivity(%)** | 37 | 28 | 20 |
| Waist(inch) | 38.4±0.4 | 38.0±0.4 | 38.3±0.4 |
| Calorie Intake(kcals/d) ** | 1232±42 | 1668±80 | 1953±63 |
| Fat Intake(g/d)** | 48±3 | 63±3 | 72±4 |
| Protein Intake(g/d)** | 50±2 | 63±2 | 78±4 |
| CRP(mg/L) | 8.1±0.8 | 6.1±0.4 | 5.6±0.8 |

* 0.001<P value ≤0.05, ** P value ≤ 0.001

In a multivariable logistic regression model adjusted for age, sex, race, BP, smoking, inactivity, dietary protein, calorie and fat intake, each 10g↑ in IDF was associated with ↓ odds (OR 0.60, 95% CI 0.43 - 0.85) of elevated serum CRP. In a multivariable cox regression model (Model 2 in Figure 1), ↑ IDF intake was associated with ↓ACM which was attenuated when adjusted for factors that are potentially in the causal pathway between IDF intake and ACM (Model 3 in Figure 1).



We conclude high IDF might be associated with ↓ inflammation and ACM in CKD population. Interventional trials are needed to establish the causal relationships of IDF with inflammation and ACM in CKD.

**F-PO1255**

**Positron Emission Tomography in Diagnosis and Follow-Up of the Infected Cysts in ADPKD and in "Cystic" Kidneys. Report of 9 Cases** Giorgina B. Piccoli, Valentina Consiglio, Maria Chiara Deagostini, Stefania Scognamiglio. *SS Nephrology, ASOU san Luigi, University of Torino, Torino, Italy.*

**Background.** Intracystic infection, both in Autosomal Dominant Polycystic Kidney Disease (ADPKD) and in kidneys with multiple cysts, poses important diagnostic and therapeutic challenges, as conventional imaging techniques do not discriminate among "complicated" cysts. Positron Emission Tomography with fluorodeoxyglucose (FDG-PET) was recently suggested as a tool to detect infection in ADPKD (7 cases published so far).

**Aim.** To report on FDG-PET in the diagnosis and management of 9 cases of suspected cystic infections in ADPKD and in multiple kidney cysts.

**Results**. In 2008-2010, 6 patients with ADPKD and 3 with multiple kidney cysts were referred for suspected intracystic infections (liver and kidney). There were 3 males, 6 females, aged 55-83 years; one patient was on dialysis, one had a kidney graft; all CKD stages were represented. The clinical picture and/or conventional imaging techniques (ultrasounds in all, CT in 7/9) did not allow diagnosis in any patient. All patients displayed moderate-severe inflammatory signs, 8/9 constitutional symptoms; fever was present in 7/9. In 5 cases, FDG-PET was positive (4 kidney and 1 liver cyst); it was repeated during follow-up and the results were used to tailor the duration of antibiotic therapy (1-3 months). No relapse was recorded after discontinuation of therapy. The 4 negative cases did not develop clinically active cystic infection; in one case, FDG-PET identified a positive lymph node, to be further assessed by agobiopsy.

**Conclusion**. FDG-PET is a promising tool to diagnosis intracystic infection and to tailor the duration of antibiotic therapy in ADPKD and in multiple kidney cysts.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1256**

**Determinants of the Levels of Undercarboxylated Osteocalcin in Patients with Chronic Kidney Disease** Mieko Miyazaki, Masahito Tamura, Narutoshi Kabashima, Ryota Serino, Tatsuya Shibata, Tetsu Miyamoto, Yumi Furuno, Junichi Nakamata, Yoko Fujimoto, Emi Hasegawa, Yutaka Otsuji. *Kidney Center, University of Occupational and Environmental Health, Kitakyushu, Fukuoka, Japan.*

Background: Undercarboxylated osteocalcin (ucOC) is a marker of vitamin K deficiency and is associated with an increased risk of bone fractures. We have reported that the levels of ucOC increase along with chronic kidney disease (CKD) stages and are independent risk markers for arteriosclerosis in patients with CKD. We investigated the dietary and nondietary factors that affect ucOC levels in patients with CKD.

Methods: We measured the levels of ucOC and osteocalcin (OC) in 207 outpatients (mean age, 61.2 ± 16.1 years) with CKD stages 1-5, excluding those undergoing renal replacement therapy. Plasma ucOC is expressed as the ratio of ucOC to OC (ucOC/OC). Patient characteristics, including daily diet, medicines, complications, history of fracture, and lifestyle, were examined by performing computer-aided personal interviews and by using self-answered questionnaires. Determinants of ucOC/OC were investigated by analysis of variance, Scheffe test, and logistic regression models.

Results: The median ucOC/OC was 0.71. The levels of ucOC/OC were significantly affected by estimated glomerular filtration rate (eGFR), use of warfarin ($p < 0.0005$) or glucocorticoids ($p < 0.0005$), history of cardiac events ($p = 0.0001$), smoking, and sports activity. However, intake of food with high levels of dietary vitamin K, such as vegetables and beans; history of bone fracture; use of vitamin D or Ca carbonate; and alcohol intake did not influence the levels of UcOC/iOC after adjusting for age, sex, body mass index, and eGFR.

Conclusion: These data suggest that an increase in ucOC is involved in the progression of CKD-mineral and bone disorder and that the levels of ucOC are influenced by medications, complications, and lifestyle in patients with CKD.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1257**

**Metabolic Acidosis Is Associated with Rapid Decline of Renal Function in Pre-Dialysis CKD Patients** Wael F. Hussein,[1] Abdulrahman Esam Alfraih,[2] Ahmad Abdulreda Lari,[2] James Lineen,[1] Patrick O'Kelly,[1] Mark D. Denton.[1] *[1]Department of Nephrology, Beaumont Hospital, Dublin, Ireland; [2]Royal College of Surgeons in Ireland, Dublin, Ireland.*

Metabolic acidosis has been suggested as a risk factor for CKD progression.

**Methods**:

Patients with eGFR 25-30 ml/min/1.73m$^2$ under nephrologists follow up in our centre with at least 12 months follow up were reviewed retrospectively until start of dialysis. In-patient blood results were excluded. Patients were censored for pre-emptive transplantation, death and loss to follow up. Rate of MDRD-eGFR decline per year and 'Average Bicarbonate' were estimated using linear regression for eGFR and bicarbonate values respectively versus time. Associations were studied between quartiles of bicarbonate and (1) Rate of eGFR change/yr, and (2) Incidence of dialysis.

**Results:** 179 patients were followed up for 42±24 months (mean±SD). Mean age was 59±17 yrs. Patients were 56% males, 21% had diabetes, 76% hypertension and 64% were on ACEI/ARB therapy. Nephrotic proteinuria was present in 12% of patients and 21% had 1.0 to 2.9 g/24hr proteinuria at time of inclusion.

For each 1 mmol/L reduction in serum bicarbonate there was a 0.37 (95% CI 0.19 to 0.54) ml/min/1.73m$^2$/yr faster decline in eGFR. This remained statistically significant after adjustment [β 0.22 (0.09 to 0.46)].

Using Cox regression analysis, the second highest bicarbonate quartile (25 to 26 mmol/L) had the least event rates and, compared to the lowest bicarbonate quartile (18 to 22), the OR of starting dialysis was 0.32 (95% CI 0.13 to 0.78) (figure 1).

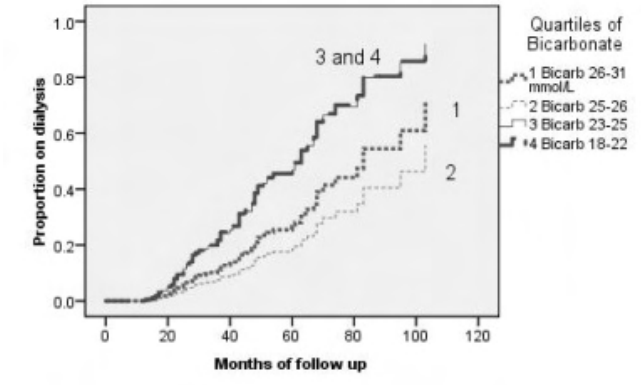

Figure 1. Proportion of patients starting dialysis in each bicarbonate quartile. Model was adjusted for age, gender, hypertension, diabetes, underlying kidney disease, proteinuria and use of ACEI/ARB at time of inclusion.

**Conclusion**: Lower serum bicarbonate level is associated with a more rapid decline in renal function.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1258**

**The Impact of Short Stature on HRQOL in Children with CKD** Amira Al-Uzri,[1] Arlene C. Gerson,[2] Matthew Matheson,[2] Debbie S. Gipson,[3] Ora Yadin,[4] Susan L. Furth,[5] Bradley A. Warady.[6] *[1]Oregon Health & Science Univ; [2]Johns Hopkins; [3]Univ Mich; [4]UCLA; [5]Children's Hosp of Phili; [6]Children's Mercy.*

Short stature (SS) and Health-related quality of life (HRQOL) impairments are common in children with chronic kidney disease (CKD). Our hypothesis is that children with CKD and SS, defined as height z score < 3rd percentile for age and gender, have lower QOL scores compared to those with CKD and normal height (NH).

Methods: This was a cross-sectional review of HRQOL in 483 children with mild-moderate CKD who were enrolled in the NIH multicenter CKiD study. HRQOL was assessed using the Child and Parent Report Pediatric Inventory of Quality of Life Core Scales (PedsQL, V4.0). Uni and multivariate regression analyses were used.

Results: Mean age was 10.4 ± 4.5 in SS and 11.3 ± 4.3 in NH groups. 51% (n =36) in SS and 63% (n =261) in NH group were male ($p>0.05$), with no differences in ethnicity/race. In univariate analysis, only parent-report PedsQL physical domain was different in the SS vs. NH group ($p=.02$) (Table), and GH therapy did not appear to impact QOL scores. Multivariate analysis adjusted for height Z-score, GH use, age, and gender, showed that higher height z-scores were associated with an increase in parent-reported PedsQL physical domain ($p=0.03$) and PedsQL social domain ($p=0.01$). No significant associations were seen with any of the child self-reported PedsQL domains.

Conclusion: Adjusted child and parent reported HRQOL scores in children with SS are not different compared to NH children with mild-moderate CKD, except in parent-reported physical and social domains. Longitudinal analysis on the effect of SS on QOL in CKD is ongoing.

**Upregulation of HDAC2 Expression by Oxidative Stress Is Associated with Interstitial Fibrosis in Experimental Model of Chronic Cyclosporine Nephropathy** Ji-Hyun Song,[1] Yeon Tae Jeon,[2] Jungyeon Ghee,[1] ShangGuo Piao,[1] Sol Kim,[3] Chul Woo Yang.[1] *[1]Transplant Research Center, The Catholic University of Korea, Seoul, Republic of Korea; [2]Integrative Research Support Center, The Catholic University of Korea, Seoul, Republic of Korea; [3]Department of Bioengineering, University of Pennsylvania, Philadelphia.*

**Background**: Cyclosporine A (CsA)-induced chronic nephrotoxicity is associated with oxidative stress. It is well known that the histone deacetylases (HDACs) is activated by oxidative stress, and that activation of HDAC leads to interstitial fibrosis in diabetic nephropathy. We performed this study was performed to evaluate the association between oxidative stress and expression of HDAC2 in an experimental model of chronic CsA nephropathy.

**Methods**: Sprague-Dawley rats were maintained on a low-salt diet (0.05% sodium) and treated daily for 4 weeks with vehicle (olive oil; 1 ml/kg sc) and CsA (15 mg/kg sc). Induction of chronic CsA nephropathy was confirmed with typical histopathological findings. HDAC2 expression was evaluated with immunohistochemistry and immunoblot of HDAC2. Oxidative stress was detected with immunoblotting, 24-h urinary excretion, and tissue expression of 8-hydroxy-2'-deoxyguanosine (8-OHdG).

**Results**: Four-week treatment of CsA developed interstitial inflammatory cells infiltration and typical tubulointerstitial fibrosis(TIF). Immunoblot of HDAC2 revealed that the expression of HDAC2 increased in CsA treatment group of rat kidney, and immunohistochemical analysis showed that HDAC2 expression was localized to renal tubular cells. Oxidatve stress measured with 24-h urinary excretion of 8-OHdG was significantly increased in CsA group (61.2±7.9 ng/day) compared with VH group (39.1±4.7 ng/day), and it was confined to renal tubular cells. There was a close correlation between HDAC2 expression and 8-OHdG ($r$=–0.64, $P$<0.01).

**Conclusions**: Increased HDAC2 expression by oxidative stress may be associated with interstitial fibrosis in chronic CsA nephropathy.

**Metabolic Syndrome, Its Components, and Chronic Kidney Disease: A Systematic Review** George Thomas, Titte Srinivas, Sankar D. Navaneethan. *Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH.*

**Purpose**: Metabolic syndrome (MetS) and its components are widely prevalent in patients with chronic kidney disease (CKD). However, MetS as a risk factor for development of CKD in the general population has not been sufficiently evaluated. We conducted a systematic review to assess the associations between MetS, its components, and the risk for development of CKD and microalbuminuria.

**Methods**: We searched MEDLINE (August 2009) for relevant studies that examined the associations between MetS (using NCEP-ATP III and modified NCEP-ATP III criteria) and kidney disease in adults. Two reviewers independently assessed eligibility and extracted data using a standardized form. Odds ratios (OR) reported in individual studies were pooled using a random effects model.

**Results**: Eighteen studies (132,678 patients) were included in this review. Thirteen studies defined MetS according to the NCEP-ATP III diagnostic criteria, 3 studies using the modified NCEP-ATP III criteria, and 2 studies according to the definition proposed by the Japanese Society for Internal Medicine. MetS was associated with development of CKD (11 studies, OR 1.70, 95% CI 1.52-1.90) and microalbuminuria (7 studies, OR 2.04, 95% CI 1.72-2.42). The associations became stronger as the number of components of MetS increased from 1 to 5.

| Variable | Pooled Odds Ratio | 95% CI | $p$ – value |
|---|---|---|---|
| 1 component of MetS | 1.35 | 1.03 – 1.79 | 0.03 |
| 2 components of MetS | 1.68 | 1.37 – 2.06 | <0.001 |
| 3 components of MetS | 2.36 | 1.83 – 3.05 | <0.001 |
| 4 components of MetS | 2.64 | 1.74 – 4.00 | <0.001 |
| 5 components of MetS | 3.88 | 2.24 – 6.70 | <0.001 |
| Metabolic syndrome | 1.70 | 1.52 – 1.90 | <0.001 |
| Impaired fasting glucose | 1.61 | 1.28 – 2.03 | <0.001 |
| Hypertension | 1.48 | 1.14 – 1.91 | 0.002 |
| Triglycerides | 1.34 | 1.26 – 1.42 | <0.001 |
| HDL | 1.25 | 1.03 – 1.55 | 0.04 |
| Obesity | 1.20 | 1.06 – 1.35 | 0.003 |

Among components of MetS, patients with impaired fasting glucose had a 61% higher risk of developing CKD, followed by hypertension (48%), elevated triglyceride levels (34%), low HDL levels (25%), and obesity (20%).

**Conclusion**: MetS and its components are independently associated with a dose-dependent increased risk for CKD and microalbuminuria. This emphasizes the need for identifying and studying interventions for individual components of MetS, and its effects on CKD.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1261

**Elevated Endogenous Erythropoietin Levels Are Associated with Mortality in Diabetic Chronic Kidney Disease** Martin Wagner,[1] Ahsan Alam,[2] Angelika Koljaja-Batzner,[1] Josef Zimmermann,[1] Christoph Wanner,[1] Lothar Schramm.[1] *[1]Div. of Nephrology, University Hospital Wuerzburg, Germany; [2]Div. of Nephrology, McGill University, Montreal, Canada.*

Anemia and chronic inflammation are prevalent in diabetic chronic kidney disease (CKD) and are both associated with increased mortality. Previously we found elevated endogenous erythropoietin (EPO)-levels that were associated with inflammation in advanced CKD. Resistance of the bone marrow to EPO might explain this phenomenon. In this prospective cohort study we evaluated the impact of EPO on mortality.

Between 2004 and 2005, 214 patients with type 2 diabetes were enrolled. Exclusion criteria included end-stage renal disease and EPO-stimulating agent-therapy. The association of baseline EPO with mortality was investigated using Cox proportional hazards models, while controlling for age, estimated glomerular filtration rate (eGFR) and C-reactive protein (CRP) at baseline.

Patients (median age 67 yrs, 51% male, median duration of diabetes 10 yrs, median eGFR 50 ml/min/1.73 m$^2$, mean hemoglobin 13.1 g/dl) were followed for up to 6.5 yrs (median 3.8 yrs). Forty-one patients died (19.2%). Elevated EPO levels were associated with increased mortality, even after adjustment for age and GFR (table). The effect of CRP as a predictor of mortality became non-significant when including EPO in the model.

| | univariate | multivariate |
|---|---|---|
| | HR (p-value) | HR (p-value) |
| EPO | 2.56 (<0.001) | 2.88 (0.001) |
| age | 1.07 (<0.001) | 1.05 (0.03) |
| eGFR | 0.97 (<0.001) | 0.98 (0.04) |
| CRP | 1.52 (0.002) | 1.18 (0.28) |

In our cohort of diabetic patients with CKD, elevated EPO-levels were independent risk factors for mortality. The impact of EPO was even stronger than that of CRP, indicating that not only inflammatory processes play a role. We propose a role for EPO-resistance of the bone marrow as a symptom of aggravated inflammatory processes as well as of potentially inflammation-independent mechanisms, which confer a detrimental effect on mortality.

### F-PO1262

**Coincidence of HCV and HGV Infections in Hemodialysis Patients** Wladyslaw Sulowicz, Jerzy Kopec, Przemyslaw Miarka, Katarzyna Janda, Barbara Tabor-Ciepiela. *Department of Nephrology, Jagiellonian University, Krakow, Poland.*

HCV and HGV were recognized as highly prevalent in maintenance dialysis population and variable from country to country and unit to unit. The introduction of serologic tests, for detecting antibodies to HCV (anti-HCV) and HGV (anti-HGV) antigens, has facilitated the study of the epidemiology as well as clinical significance of HCV and HGV infections in patients on maintenance dialysis. The implementation of molecular biology techniques (polymerase chain reaction) for detecting HCV and HGV viremia (HCV-RNA, HGV-RNA) facilitate diagnosis and transmission routes of the infection.

The aim of the study was to evaluate the coincidence of HCV and HGV infections in dialysis population. The study was performed in the group of 215 patients aged 26-81 years (mean 53.2) on 3 x week maintenance hemodialysis from 33 to 301 months (mean 101.8 months). Anti-HCV and anti-HGV antibodies were determined based on immunoenzymatic, III$^{rd}$ generation, methods. HCV-RNA and HGV-RNA were estimated using polymerase chain reaction (PCR).

The anti-HCV antibodies were present (+) in 40 (18.6 %) of patients and negative (-) in 175 (81.4%) patients. From the group of patients with anti-HCV (+) antibodies (42.5%) were also HCV-RNA (+) whereas from the patients with anti-HCV (-) antibodies 10.4% were HCV-RNA (+).

Anti-HGV antibodies tested in the group of 32 anti-HCV (+) patients and 61 anti-HCV (-) patients were positive in 20 (62.5 %) and 22 (36.1 %) patients, respectively. In the group of patients with anti-HGV (+) antibodies HGV-RNA (+) were detected in 63.6%.

Anti-HCV (+) and anti-HGV (+) patients were dialysed longer as compared with negative ones: 144.5 vs. 83.5 months, p<0.001 and 119 vs. 96.4 months, p NS, respectively.

**Conclusions**: 1. The prevalence of HCV and HGV infections in the dialysis population is very high. 2. The coincidence of HCV and HGV infections is frequent. 3. Our result showed that even anti-HCV (-) and anti-HGV (-) patients carry the risk of viral infection due to detected HCV-RNA and HGV-RNA in some of them.

**Large Scale Genotype-Phenotype Integration of GFR Susceptibility Loci Identifies CKD Associated Molecular Pathways** Sebastian Martini,[1] Katherine Gurdziel,[1] Carsten A. Böger,[4] Viji Nair,[1] Caroline S. Fox,[3] Clemens D. Cohen,[2] Matthias Kretzler.[1] *[1]University of Michigan; [2]University of Zürich; [3]National Institutes of Health; [4]Regensburg University Medical Center.*

Despite recent progress determining risk alleles for chronic kidney disease (CKD), translating novel insights into underlying pathophysiologic mechanisms remains a challenge. Integrating genome-wide association studies (GWAS) with gene expression data sets might help to define associated molecular pathways. The study's aim was to merge CKDGen GWAS with European Renal cDNA Bank (ERCB) CKD transcript profiles to define CKD associated regulatory networks.

CKDGen recently reported 18 susceptibility loci for glomerular filtration rate (GFR) and CKD in European-ancestry participants. At these loci, 42 genes were located within 60 kb of the lead SNP. Thirty of 42 genes were detected by expression profiles from glomerular compartments patients with 10 different diseases in the ERCB (n=196; eGFR range 6–193 mL/min/1.73m2) and a living kidney donor control group (n=41). Ten of 30 CKDGen-associated transcripts showed significant correlation with GFR in the ERCB CKD cohort (|R|>0.25, FDR<0.01). Monte Carlo simulations confirmed significant enrichment of GFR correlation compared to randomly selected gene sets (p<0.001).

Next, CKDGen associated transcripts that correlated with GFR were interrogated for shared biological functionality. Starting from the hypothesis that genes expressed in the same tissue with concordant disease specific regulation share common transcriptional regulators, co-regulated mRNAs for each CKDGen associated transcript were identified in the ERCB CKD gene expression cohort (|R|>0.6, FDR<0.01,). In the correlated gene sets (106 transcripts/CKDGen candidate gene), 88 KEGG pathways were significantly enriched, e.g. transcripts co-regulated in CKD with VEGFA were enriched in ischemia and IL-8 pathways, PIP5K1B co-regulated transcripts in Rac signaling pathways.

CKDGen associated transcript levels were correlated with GFR in the ERCB CKD cohort. CKDGen transcripts and co-regulated mRNAs identified known and novel pathways of progressive kidney disease for further analysis.

**The Antiproteinuric Efficacy of an ACE-Inhibitor Treatment Depends on the *ACE I/D* Genotype in Children with Chronic Nephropathies** Rainer Buescher, Ilja Finkelberg, Anja K. Büscher, Peter F. Hoyer. *University of Duisburg-Essen, Pediatrics 2, Pediatric Nephrology, Essen, Germany.*

**BACKGROUND:** A successful inhibition of the renin-angiotensin-aldosterone system (RAS) using ACE-inhibitors (ACE-I) has been shown to be renoprotective in adult and pediatric patients. However, it remains unclear whether the ACE-genotype has an impact on the effect of the ACE-I therapy. The aim of our retrospective study was to analyze whether the antiproteinuric efficacy of an ACE-I treatment is influenced by the *ACE I/D* genotype in children with chronic nephropathies. **METHODS:** We included 60 children and adolescents (28 male/32 female, age 5-18 years, mean age 14.4±3.8 years) with different proteinuric nephropathies in our study. A final ACE-I dosage of 5.3±1.6 mg/m$^2$ was administered. In 26 children arterial hypertension could also be confirmed. **RESULTS:** Allelic frequencies of the *ACE I/D* polymorphism were not different from healthy controls. Long-term treatment with ACE-I exceeding 6 months led to a slight decline of the glomerular filtration rate (GFR). However, this GFR-reduction was not different among carriers of the different genotypes. Proteinuria significantly dropped in the overall population within 6-12 months after initiation of ACE-I treatment. Homozygous carriers of the D-allele showed a diminished therapeutic response when compared to homozygous I-allele carriers (Figure 1) and the long-term therapeutic effect was much shorter in carriers of the D-allele (Δ proteinuria II: 61% of baseline after 6 months and 48% of baseline after 12 months vs. DD: 94% of baseline after 6 months and 99% of baseline after 12 months). **CONCLUSIONS:** Children carrying the D-allele of the ACE I/D polymorphism show a reduced antiproteinuric response when treated with an ACE-I. Our retrospective data suggest that adapted therapeutic concepts are necessary in children receiving ACE inhibitors.

**F-PO1265**

**Nonmuscle Myosin Heavy Chain IIA Encoded by *MYH9* Is Localized in the Primary Process of Podocytes and Its Expression Is Significantly Decreased in Human FSGS** Ken-Ichiro Miura,[1] Hidetake Kurihara,[2] Hiroko Chikamoto,[3] Motoshi Hattori,[3] Satoshi Sasaki,[4] Takashi Igarashi,[1] Takashi Sekine.[1,5] *[1]Pediatrics, The University of Tokyo, Tokyo, Japan; [2]Anatomy, Juntendo University School of Medicine, Tokyo, Japan; [3]Pediatric Nephrology, Tokyo Women's Medical University, Tokyo, Japan; [4]Pediatrics, Hokkaido University Graduate School of Medicine, Sapporo, Hokkaido, Japan; [5]Pediatrics, Toho University Ohashi Medical Center, Tokyo, Japan.*

Objective: To investigate the precise localization of nonmuscle myosin heavy chain (NMMHC)-IIA encoded by *MYH9* in podocytes and analyze its expression in experimental and human proteinuric diseases.

Methods: Localization of NMMHC-IIA in podocytes was determined by immunofluorescence and immunogold labeling analyses in normal rat kidneys. Dual immunostaining of NMMHC-IIA and podocyte-associated molecules was performed in normal and puromycin aminonucleoside (PAN) nephrosis rats. Immunohistochemical analysis of NMMHC-IIA was performed in patients with childhood-onset idiopathic nephrotic syndrome (6 patients with FSGS and 2 with minimal change disease (MCD)) and a variety of chronic glomerulonephritis (CGN) with heavy proteinuria.

Results: Immunofluorescence analysis demonstrated the colocalization of NMMHC-IIA and nestin, a protein located in the cell body and the primary processes of the podocyte. This finding was confirmed by immunogold labeling analysis. The glomeruli of the PAN-treated rats (day 11) showed significantly decreased staining of NMMHC-IIA, while the staining of podocalyxin and ZO-1 was preserved. Immunohistochemical analysis in the human proteinuric diseases revealed that the staining of NMMHC-IIA was markedly decreased only in steroid resistant FSGS, while that in MCD and CGN was preserved.

Conclusion: Our results demonstrated that decreased expression of NMMHC-IIA is specific to FSGS in the human, suggesting that NMMHC-IIA is a key molecule participating in the pathophysiology of steroid resistant FSGS.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1266**

**Dependency on Immunosuppressants in Children with Steroid-Resistant Nephrotic Syndrome after Cyclosporine and Steroid Therapy** Yuko Hamasaki, Norishige Yoshikawa, Satoshi Sasaki, Kazumoto Iijima, Koichi Nakanishi, Shuichi Ito, Takeshi Matsuyama, Kenji Ishikura, Tetsuji Kaneko, Masataka Honda. *Pediatric Nephrology, Japanese Study Group of Renal Disease in Children, Fuchu, Tokyo, Japan.*

Background

We previously showed in a prospective, multicenter trial in children with steroid-resistant nephrotic syndrome (SRNS) that high remission rates (>80%) were obtained after 12 months of treatment with cyclosporine and steroid therapy (Hamasaki et al., PN 2009). Recently, remission rates of SRNS have improved with cyclosporine; however, there are few data about the long-term prognosis.

Methods

We analyzed the outcome at 5 years after being enrolled in the previous trial. The statuses were classified as complete remission (CR), partial remission (PR), persistent nephrotic syndrome (NS) and over stage 3 chronic kidney disease (CKD). Steroid-sensitive nephrotic syndrome (SSNS) and frequently relapsing nephrotic syndrome (FRNS) were included in CR.

Results

We obtained follow-up data for 5 years in 32 of the 35 patients. The first renal biopsy showed 20 cases with minimal changes, 5 with diffuse mesangial proliferation and 7 with

focal segmental glomerulosclerosis. The patients' statuses at five years were as follows (the median age, 7.6 years): 28 patients had CR, 1 had PR, 1 had persistent NS and 2 had CKD (including 1 with end stage renal failure). Among the 28 patients with CR, 5 had no relapse and 3 had SSNS without immunosuppressants; however, 20 required immunosuppressants (71.4%). The most commonly used immunosuppressant was cyclosporine. Nine of the 20 patients continued to show FRNS with immunosuppressants. The frequent adverse events were hypertension (n=7), osteoporosis (n=2), cataracts (n=2) and hypertrichosis (n=2). The mean standard deviation score for height at the last follow-up was -0.45.

Conclusion

The present results show that high renal survival and remission rates can be obtained. However, many children require immunosuppressants, which can cause serious problems. The advancement of treatment for SRNS has resulted in a shift of management of SRNS from prevention of end stage renal failure to long-term maintenance of relapse after induction therapy.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1267

**Immunosuppressive-Dependent Glomerular Minimal Change Disease – A Case for Rituximab?** Elion Hoxha, Rolf A. Stahl, Sigrid Harendza. *Department of Internal Medicine III, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Introduction

Glomerular minimal change disease (MCD) is a major cause of nephrotic syndrome. Steroid therapy is effective in achieving remission but relapses, steroid-dependence and steroid-resistance are therapeutic challenges. The use of second-line agents such as cyclophosphamide is associated with toxicity and adverse effects. Therefore we studied the effect of rituximab (RTX) on proteinuria in adult patients with immunosuppressive (IS) -dependent MCD.

Methods

Seven patients with IS-dependent MCD and frequent relapses on IS regimes were included. Patients needed steroids or some other IS agents in order to maintain remission and tapering of IS medication lead to a relapse of proteinuria. Clinical data were gathered and blood tests and urinalysis were performed before RTX therapy, one week, four weeks and then every three months afterwards. Patients were treated with a single dose of RTX (375 mg/m²). An additional dose of RTX was administered-if necessary-depending on B-cell count and proteinuria.

Results

After RTX treatment all patients remained relapse-free, all additional IS agents were tapered and eventually stopped. Three patients needed more than one RTX treatment. All patients had a reduction in peripheral CD20+ B cells, which returned to almost normal level six months after RTX therapy. Return of B cells was not associated with relapses of the disease. Proteinuria ceased completely after RTX treatment in five patients, another patient achieved complete remission at the end of follow-up. Serum albumin increased in all seven patients, reaching normal range at the end of the follow-up period. Blood levels of cholesterol and triglycerides decreased to normal range at the end of the follow-up period. Further medication-besides IS-was reduced from 3.6 drugs/patient to 1.2 drugs/patient during the follow-up period.

Conclusions

Our data show that RTX could be an alternative in the therapy of patients with IS-dependent MCD. These promising results have to be further investigated in larger, randomized patient cohorts. RTX may also allow to better understand the factors and cells that may play a role in the pathogenesis of this disease.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1268

**The Impact of Antiproteinuric Therapy on the Prothrombotic State in Patients with Overt Proteinuria** Bakhtawar Khan Mahmoodi,[1] André Mulder,[2] Femke Waanders,[3] Henri Spronk,[4] René Mulder,[2] Maartje C. J. Slagman,[3] Gerjan Navis,[3] Hugo Ten Cate,[4] Hanneke Kluin-Nelemans,[1] Gozewijn Dirk Laverman.[3] *[1]Dep. Hematology; [2]Dep. Laboratory Medicine; [3]Dep. Nephrology, University Medical Center Groningen, Groningen, Netherlands; [4]Cardiovascular Research Institute Maastricht, Maastricht University, Maastricht, Netherlands.*

**Background:** Overt proteinuria is a strong risk factor for thromboembolism due to changes in levels of various coagulation proteins and urinary antithrombin loss. The described coagulation disturbances in these patients are based on outdated studies conducted primarily in the 1970's and 80's. Whether these coagulation disturbances resolve with anti-proteinuric therapy has yet to be studied.

**Methods:** A total of 32 adult patients with overt proteinuria (median 3.7 g/d; interquartile range 1.5-5.6) were matched for sex and age with 32 healthy volunteers. Patients were participants of an intervention trial designed to assess optimal antiproteinuric therapy with losartan and diuretics. Levels of various coagulation factors and inhibitors, and two thrombin generation assays (i.e., Calibrated Automated Thrombogram [CAT] and prothrombin fragment 1+2) were performed at baseline and 36 weeks after antiproteinuric treatment initiation.

**Results:** Whereas levels of various procoagulant proteins were higher in patients, levels of antithrombin were comparable in patients versus controls. Based on both thrombin generation assays, patients were substantially more prothrombotic than controls (P<0.001). After 36 weeks of antiproteinuric therapy, median proteinuria was reduced to 0.9 g/d (interquartile range 0.6-1.4). Similarly, levels of various liver-synthesized coagulation factors and inhibitors as well as prothrombin fragment 1+2 levels were significantly reduced; however, in CAT parameters only moderate amelioration in activated protein C resistance was observed. Increased levels of endothelial derived factor VIII and von Willebrand factor persisted.

**Conclusions:** Patients with overt proteinuria are in a more prothrombotic state with increased thrombin generation, as compared to non-proteinuric controls. Antiproteinuric therapy reverses the protrombotic state.

### F-PO1269

**Anti-Protease Drugs To Treat Idiopathic Nephrotic Syndrome: A New Working Hypothesis** Roberta Camilla, Maria Gabriella Porcellini, A. Amore, Bruno Gianoglio, Valentina Daprà, Elisa Loiacono, Pier Angelo Tovo, Rosanna Coppo. *Nephrology, Dialysis and Transplant, Regina Margherita Hospital, Turin, Italy.*

**INTRODUCTION**

Podocyte alterations characteristic of nephrotic syndrome (NS), i.e.changes in slit diaphragm and cytoskeleton reorganization, are regulated by enzyme pathways. Interest has been focused on the lysosomal cystine-protease cathepsin L. We have been treating some cases of steroid resistant or steroid-dependent NS (SRNS or SDNS) with protease inhibitors adopted in HIV infection, aiming at depressing the proteasome and the consequent activation of NF-kB. The interest of our pilot study cohort has been increased not only for a higher number of cases with longer follow-up, but also on the light that an unsuspected target of these antiprotease drugs could be the podocytary proteases regulating cathepsin L.

**MATERIALS AND METHODS** We used the protease inhibitor saquinavir (750 mg/m2 bid) in 7 patients, 5 SDNS and 2 SRNS (aged 11 years, range 8-24), with history of NS lasting 7 (1-14) years already treated with prednisone and iv metylprednisolone (7/7), cyclosporine A (CyA) (6/7), tacrolimus (TAC) (6/7), mycophenolate (4/7), plasma-exchange (2/7) and rituximab (4/7).

**RESULTS** In 5 cases the follow-up was longer than 6 months. In 4/5 patients we obtained a complete remission or a partial remission with infrequent relapses easily controlled with minimum increase in steroid therapy; in 1/5 a decrease of proteinuria below nephrotic range was obtained.

Saquinavir was given in association very low doses of calcineurin-inhibitors (CyA 2 mg/Kg/day, TAC 0.007-0.07 mg/Kg/day) and prednisone (0.1-0.5 mg/Kg/day). In these 5 cases the cumulative dose of steroids during the follow-up (6 months-4 years) was reduced of an average of 53% (range 32%-85%) in comparison with the 12 months before saquinavir.

In 2 cases the therapy was started < 6 months ago: one patient achieved a good result with remission of proteinuria, while the other one has failed to show response so far.

**CONCLUSIONS** This pilot study using anti protease drugs for multidrug resistant/dependent NS is providing some interesting results, opening new perspectives for NS unresponsive to traditional treatments.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1270

**Circulating Angiopoietin-2 but Not Angiopoietin-1 Can Be Removed through Plasma Exchange – A Pilot Study in Critically Ill Patients with Thrombotic Microangiopathy and Anti-Glomerular Basement Membrane Disease** Svjetlana Lovric,[1] Alexander Lukasz,[1] Carsten Hafer,[1] Jan T. Kielstein,[1] Marion Haubitz,[1] Hermann G. Haller,[1] Philipp Kümpers.[2] *[1]Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Medicine D, Divison of General Internal Medicine, Nephrology and Rheumatology, University Hospital Münster, Münster, Germany.*

Introduction: In critically ill patients, the massive release of angiopoietin-2 (Ang-2) from Weibel-Palade bodies interferes with protective angiopoietin-1 (Ang-1)/Tie2 signaling in endothelial cells, thus leading to vascular inflammation and subsequent organ-dysfunction. We hypothesized that plasma exchange (PE) is efficient for lowering excess Ang-2 levels in critically ill patients with thrombocytic microangiopathy (TMA) or anti-glomerular basement membrane (anti-GBM) disease.

Methods: Plasma Ang-1 and Ang-2 were measured by immuno-luminometric assays in patients with TMA (n=9) or anti-GBM disease (n=4) before and after up to four PE sessions. Twenty apparently healthy volunteers served as controls.

Results: Median (IQR) plasma levels of Ang-2 were markedly increased in patients with TMA (7.3 (2.4-21.1) ng/mL) and anti-GBM disease (5.8 (3.4-7.0) ng/mL) compared to healthy controls (1.0 (0.9-1.4) ng/mL, P <0.001). Moreover, Ang-1 plasma levels were decreased in both, TMA (1.02 (0.62-1.62) ng/mL) and anti-GBM disease patients (0.74 (0.59-3.62) ng/mL) compared to healthy controls (2.5 (1.93-3.47) ng/mL, P <0.005). During a total of 32 treatments, PE effectively lowered elevated mean (SD) Ang-2 plasma levels by 36.7 ± 19.6 % per treatment (P <0.0001), whereas low Ang-1 plasma levels remained unchanged ( 0.3 ± 58.5 %; P =0.147). Ang-2 levels declined to almost normal values during ≤ 4 PE treatments (Friedman 's test P <0.0001).

Conclusions: PE effectively restored the balance between Ang-1 and Ang-2 by lowering excess systemic Ang-2 levels. It remains to be elucidated if the removal of Ang-2 is crucial to ameliorate endothelial damage in critically ill patients with severely altered endothelial integrity.

**Efficacy and Safety of Low Dose of Oral Sirolimus on Refractory Nephrotic Syndrome** Jian Hui Yang. *Renal Division, The 456th Hospital Kidney Center of P.L.A., Jinan, Shandong, China.*

**Purposes**: To evaluate the efficacy and safety of sirolimus on refractory nephrotic syndrome.

**Methods**: Twenty-five patients with primary nephrotic syndrome were refractory to regular dose of prednisone and other immunosuppressors such as intravenous cyclophosphamide, oral cyclosporine or mycophenolate mofetil. After cessation of immunosuppressors for more than 3 months, they were administrated with 0.3~0.5mg/d.kg$^{-1}$ oral prednison and 2 mg/d sirolimus (NCPC GENETECH BIOTECHNOLOGY CO. LTD) for 6 to 12 months. Sirolimus doses were adjusted so that the serum sirolimus concentration could be maintained between 4 to 10 ng/ml. No angiotensin-converting enzyme inhibitors or angiotensin receptor blockers were taken in these patients. The clinical manifestations, laboratory parameters and adverse reactions were observed.

**Results**: After 3 months of therapy, complete remission was induced in fourteen patients while partial remission was found seven patients. Mesangial proliferative glomerulonephritis (MsPGN) had the higher remission rate and shorter time to relieve compared with IgA nephropathy, membranoproliferative glomerulonephritis and focal segmental glomerulosclerosis. Their serum creatinine level decreased markedly. The most common side effects were dyslipidemia. Thirteen patients' hyperlipidemias were obviously exacerbated during the early stage of therapy. However, their serum triglyceride, cholesterol, low density lipoprotein and ApoB levels declined drastically after the patients got complete or partial remission. On the contrary, those parameters remained elevated in patients who failed to response to sirolimus. Acnes were seen in six patients. Influenza-like symptom happened in four patients. Slightly elevated serum aspartate aminotransferase or creatinine level was only seen in one patient respectively. Bone marrow depression was not found in all these patients. During follow-up, the relapse rate in MsPGN was much lower than that in other types of glomerulonephritis.

**Conclusions**: Low dose of oral sirolimus was effective and safe for refractory nephrotic syndrome. Dyslipidemia in nephrotic syndrome was not the contradictions of oral sirolimus.

**F-PO1272**

**The Combination of Very Low-Dose Prednisolone with Cyclosporine as an Initial Treatment for Minimal Change Nephrotic Syndrome (MCNS) in Adults** Yoshihiko Inoue, Takahiro Nakayama, Kiyoko Inui, Ashio Yoshimura. *Division of Nephrology, Showa University Fujigaoka Hospital, Yokohama, Kanagawa, Japan.*

MCNS is characterized by good response to glucocorticoid (prednisolone, PSL), however frequent relapses may occur and increasing amount of PSL dosage is a critical problem. We tried combination of very low-dose of PSL to 50% of conventional therapy with cyclosporine (CsA) as an initial treatment for adult MCNS patients. Prospectively 14 patients who had all biopsy-proven MCNS were studied for one year. They were randomly assigned to two groups, Group A (PSL 0.8mg/kg/day, n=7) and Group B (PSL 0.4mg/kg/day + CsA 1.5~2 mg/kg/day, n=7). PSL tapering was begun three days after complete remission. The daily PSL dosage was gradually reduced by 5mg/day every two weeks, by 5mg/day every four weeks after 20mg/day, and 5mg/day every six months after 10 mg/day in each group. The daily CsA doseage was sustained by using concentration monitoring with 2 h post-dosing level (C2) (600~1000ng/ml). There were no differences in serum albumin levels, renal function, or protein excretion between both groups before treatment. Initial PSL dosage was 48.6±6.3 mg/day (mean±SE) in Group A and 22.9±3.9 mg/day in Group B. Total PSL dosage in Group A (6455.0±764.6 mg/year) was more than in Group B (3917.5±450.3 mg/year ($p<0.01$). However, there were no differences in duration for complete remission between Group A (14.3±5.5 days) and Group B (15.1±3.3 days). Average hospitalization was significantly longer in Group A (51.6±19.5 days) than in Group B (19.4±4.2 days) ($p<0.01$). Furthermore, There were no relapse and no renal impairment of both groups in one year. Side effects by PSL treatment was observed in two patients in Group A (steroid induced DM and hypercholesterolemia) but none in Group B. C2 level was 628.4±178.1ng/ml after one year. In conclusion, combination of 50% of PSL dosage with CsA as an initial treatment was effective as well as the conventional therapy with PSL alone. The combination treatment may provide a new way to decrease PSL dosage and reduce length of hospital stay for adult MCNS patients.

**Urinary Biomarkers for the Clinical Efficacy in FSGS Patients Treated with GC1008** Nikolay Bukanov, Sarah E. Moreno, Oxana Beskrovnaya, Steven R. Ledbetter. *Department of Cell Biology, Genzyme Corporation, Framingham, MA.*

We used SELDI-TOF technology to identify biomarkers of efficacy as well as response-predicting biomarkers from the phase I clinical trial on steroid-resistant FSGS patients treated with a single dose of GC1008 (anti-TGFb antibody). In this clinical trial, four cohorts of patients (four patients in each cohort) were treated with four different single doses of GC1008 ranging from 0.3 to 4 mg/kg. From each patient, multiple urine samples were collected over a 16 week period (at 0, 0.5, 1, 2, 3, 4, 8, 12, and 16 weeks) after treatment with GC1008 and subjected to proteome profiling with SELDI-TOF technology. A three-step approach was used for analysis. First, we used proteinuria measurements to identify responders to treatment. Analysis of protein/creatinine ratio in patients from the GC1008 study suggested that there are two responders in cohort A and two responders in cohort C (treated with 1 and 4 mg/kg, respectively) that showed a significant reduction in proteinuria by weeks 12-16 after treatment. Cohorts B and D (treated with 2 and 0.3 mg/kg, respectively) showed no obvious responders. All non-responder patients had sustained urine protein levels through out the 16 week study within the range observed prior to treatment. Second, we performed comparative responder/non-responder proteome analysis in the strongest responders from cohort A and identified a set of 44 anonymous urinary biomarkers: 7 biomarkers of efficacy and 37 predicative biomarkers of a response to treatment. Finally, we conducted comparative analysis of these markers with less prominent responders from cohort C and identified a subset of 7 biomarkers that showed similar trends in all four responders from both cohorts A and C.

**Safety & Efficacy of Eculizumab in aHUS Patients on Chronic Plasma Therapy: Interim Analysis of a Phase II Trial** Petra Muus,[1] Christophe M. Legendre,[2] Kenneth Douglas,[3] Maryvonne Hourmant,[4] Yahsou Delmas,[5] Birgitta Maria Herthelius,[6] Antonella Trivelli,[7] Chantal Loirat,[8] Timothy H. Goodship,[9] Christoph Licht.[10] *[1]Radboud Univ Med Ctr, Netherlands; [2]Hôpital Necker, France; [3]Beatson, West Scotland Cancer Ctr, United Kingdom; [4]CHU Nantes-Hôtel Dieu, France; [5]CHU Bordeaux - Pellegrin, France; [6]Huddinge Hospital, Sweden; [7]Istituto G. Gaslini, Italy; [8]Hopital Robert Debré, France; [9]Newcastle Univ, United Kingdom; [10]Hospital for Sick Children, CA.*

Atypical hemolytic uremic syndrome (aHUS) is a rare, chronic, life-threatening disease due to constitutive complement dysregulation resulting in ongoing, diffuse thrombotic microangiopathy (TMA).TMA causes organ ischemia, renal failure, and hemolytic anemia, leading to 1 year 60% ESRD/death. TMA continues despite chronic plasma therapy (PT), a debilitating procedure that subjects patients (pts) to blood-induced injuries, toxicity and poor quality of life. The safety/efficacy of terminal complement inhibitor eculizumab (Ecu) to prevent TMA, maintain renal function, and eliminate PT in 20 adult/adolescent aHUS pts treated with chronic PT is evaluated in a 26-week (wk) open-label single-arm clinical trial. Ecu dosing:900mg/wk x4; 1200mg Q2 wks starting week 5. Neisseria vaccine ≥14 days before Ecu. Primary endpoint(endpt): TMA-Event Free Status (stable platelets, no PT, no new dialysis). Interim analysis (12 wk; n=15) was positive: 87% (13/15; 95% CI 60-98) TMA-Event Free. Median time to first TMA-Event not reached. Secondary endpt: With Ecu, TMA Intervention (TMAI; PT or dialysis) not observed, median time to first TMAI not reached. Exploratory endpt: eGFR stabilized/increased with Ecu vs chronic PT(30.5 vs 27 mL/min/1.73*m∧2 respectively). Similar results in pts with/without mutations. Ecu was well tolerated. Most frequent AEs: diarrhea, nausea, headache and hypertension(all mild-moderate). All pts remain alive. These interim results show that Ecu led to discontinuation of chronic PT, sustained suppression of TMA, maintained renal function, and was well tolerated.

| Cohort | Value |
|---|---|
| Age: median yrs (range) | 28 (13 -63) |
| Complement Mutation/Auto-antibody | 14 (70%) |
| Prior Kidney Transplant | 8 (40%) |

**Phase 1, Single-Dose Study of Fresolimumab in Patients with Treatment-Resistant (TR) Primary Focal Segmental Glomerulosclerosis (pFSGS)** Howard Trachtman,[1] Fernando C. Fervenza,[2] Debbie S. Gipson,[3] Peter J. Heering,[4] David R. W. Jayne,[5] Harm Peters,[7] Giuseppe Remuzzi,[6] Lars C. Rump,[8] Lorenz Sellin,[8] Flavio G. Vincenti,[9] Stefano Rota.[10] *[1]Cohen Children's Medical Center, New Hyde Park, NY; [2]Mayo Clinic, Rochester, MN; [3]University of Michigan, Ann Arbor, MI; [4]Städtisches Klinikum, Solingen, Germany; [5]Addenbrooke's Hospital, Cambridge, United Kingdom; [6]Mario Negri Institute for Pharmacological Research, Bergamo, Italy; [7]Charité Universitätsmedizin, Berlin, Germany; [8]Universitätsklinikum, Düsseldorf, Germany; [9]University of California, San Fransisco, CA; [10]Ospedali Riuniti, Bergamo, Italy.*

This open-label, dose-escalating study was performed to test safety, tolerability and PK of fresolimumab, an IgG4 antibody that neutralizes all 3 isoforms of TGF-β, in patients with TR pFSGS.

Patients with biopsy-confirmed pFSGS, resistance to steroid/immunosuppressive therapy, GFR ≥25 mL/min/1.73m$^2$ and persistent proteinuria (urine protein:creatine ratio [UPC] >200 mg/mmol creatinine) were eligible. Patients were infused fresolimumab (0.3, 1, 2, or 4 mg/kg) over 30 min, then followed for 112 days or until complete antibody clearance.

All 16 patients enrolled completed the study, 4 per dose level. Mean age was 37 yr, disease duration 3 yr, half were male, 13 White and 3 Black. Antibody infusion was well-tolerated and there were no SAEs; only 1 AE occurred in >1 patient (Grade 1 pustular rash, n=2). 1 patient was reported to have a new primitive neuroectodermal tumor 2 yr after dosing. Overall, GFR declined; median change from Baseline to Day 112 was -5.85 mL/min/1.73m$^2$. Proteinuria fluctuated during the study; median UPC change from Baseline to Day 112 was -133.31 mg/mmol creatinine. Proteinuria declined substantially in the 3 Black patients. Half-life of fresolimumab was 14 days, mean dose-normalized $C_{max}$ and

AUC values were 0.27-0.37 µg/mL/mg and 48.3-88.1 ng*hr/mL/mg, respectively, and appeared independent of dose.

Fresolimumab, up to 4 mg/kg, was safe and well-tolerated in patients with TR pFSGS. Results suggest inhibition of TGF-β with fresolimumab should be evaluated in a larger dose-ranging study.

**F-PO1276**

**Long-Term Morbidity in Children with Frequently Relapsing Nephrotic Syndrome after a Randomized Controlled Trial with Cyclosporine** Kenji Ishikura, Norishige Yoshikawa, Satoshi Sasaki, Kazumoto Iijima, Koichi Nakanishi, Shuichi Ito, Takeshi Matsuyama, Nahoko Yata, Takashi Ando, Masataka Honda. *The Japanese Study Group of Renal Disease in Children, Japan.*

We previously conducted a randomized controlled trial (RCT) with cyclosporine (Sandimmune®) in children with frequently relapsing nephrotic syndrome (FRNS)(Ishikura et al., KI 2008). Although safety and effectiveness of 2-year treatment with cyclosporine have been established, concern for cyclosporine dependency has emerged and the long-term prognosis is unknown.

After 2 years of treatment, management was at the discretion of the physicians in charge. In October 2009, a follow-up study was completed. The primary end point was the nephrotic syndrome relapse at the last observation. Multiple logistic regression analysis estimated the relationships between age, previous protocol treatment (high dose or low dose of cyclosporine), and previous administration of cyclophosphamide before RCT to relapse.

Valid information from 46 out of 56 patients was gathered. The median follow-up period from the administration of cyclosporine was 10.3 years (2.9-13.5). At the last follow-up (median age, 17.6 years), 10 patients (21.7%) showed disease-free remission (no relapse for at least 2 years), whereas 23 (50.0%) continued to relapse frequently or were on immunosuppressants including cyclosporine, cyclophosphamide, and high dose mizoribine, 5 (10.9%) were on low dose mizoribine, and 8 (17.4%) had infrequent relapses. Younger age (less than 8 years) was a significant risk factor contributing to relapse (odds ratio; 4.95, P=0.02). The adverse effects of steroids and immunosuppressants were: short stature in 6 patients, osteoporosis in 6, obesity in 4, cataracts in 3, and hypertension in 2. None developed decreased renal function.

In summary, after a 2-year treatment of cyclosporine, the majority of children with FRNS continued to experience relapses for approximately 10 years; particularly, younger patients were at risk. A well-planned strategy for treatment consisting of steroids and immunosuppressants is necessary for long-term management to avoid complications of disease as well as adverse effects of treatment.

**F-PO1277**

**Effect of Rituximab on T-Cell Subsets in Nephrotic Children with Focal Segmental Glomerulosclerosis (FSGS)** Wee Song Yeo,[1] Chang Yien Chan,[1] Tarun K. Maheshwari,[1] Henry Yang,[2] Kong Peng Lam,[3] Hui Kim Yap.[1] *[1]Pediatrics, National University of Singapore, Singapore; [2]SIgN, A-Star, Singapore; [3]Bioprocessing Technology Institute, A*STAR, Singapore.*

FSGS is an important cause of steroid-resistant nephrotic syndrome (SRsNS) in children. Recently, rituximab (anti-CD20 monclonal antibody) has been used successfully to treat therapy resistant cases, suggesting a possible role for B-cells in the pathogenesis of FSGS, either directly or indirectly through B-T interactions. This study aimed to delineate the effect of B-cell depletion through rituximab therapy on T-cell subsets, in an attempt to gain a further understanding of the B-T interactions that may be important in the pathogenesis of FSGS. Six patients (median age 14 years) with SRsNS or cyclosporine-dependent FSGS were given 2-weekly doses of rituximab (375 mg/m$^2$) for 4 doses. Blood was obtained on D-1, D+14 and 6 months post-rituximab infusion or when the patient goes into remission (end of study) for quantification of B- and T-cell subsets using multi-color flow cytometry. Fifty percent of the patients achieved complete remission defined as urine protein:creatinine (PCR) ratio of <0.02 g/mmol, whereas the rest only had partial remission with urine PCR 0.02-0.2 g/mmol. The percent CD19+ cells decreased significantly from 15.29±7.63% (D-1) to 0.61±0.50% (D+14) and 0.43±0.28% (end of study) (p=0.004). In all patients, analysis of T-cell subsets showed a mean percentage decrease of 42.2% in CD3+CD4+CD25+CD45RA+ and 8.3% in CD3+CD4+CD25+CD45RO+, whereas the T-regulatory cell population (CD3+CD4+CD25+FoxP3+) showed a mean percentage increase of 38.5% during the study period. The CD3+CD8+CD25+CD45RA+ subset showed a similar decrease post-rituximab of 51.4%, whereas there was minimal change in CD3+CD8+CD25+CD45RO+ subset. None of these reached statistical significance. In conclusion, rituximab therapy in patients with FSGS did not appear to affect the activation profile of either naive or memory CD4+ and CD8+ cell subsets, but its effect on T-regulatory cells remains to be determined and awaits studies involving a larger pool of patients.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1278**

**Tacrolimus as a Rescue Therapy in Steroid-Resistant Minimal Change Nephrotic Syndrome with Reversible Acute Renal Failure** Xiayu Li, Heng Li, Jianghua Chen. *The Kidney Disease Center The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

A proportion of patients with steroid-resistant minimal change nephrotic syndrome (SR-MCNS) developed reversible acute renal failure. Tacrolimus may be a rescue agent for such patients. Ten patients with steroid-resistant nephrotic syndrome biopsy proven minimal changes who developed reversible acute renal failure were studied from January 2005 to October 2008. Eight patients were also refractory to treatment with cyclophosphamide (n=5) and MMF(n=3)before this observational study. Oral tacrolimus was administered (target trough levels of 3-6 ng/ml) before serum creatinine (SCr) decreasing to ≤ 133µmol/L, and then increased doses were given (target trough level of 5-10 ng/ml) when SCr decreased to ≤133µmol/L. Outcome variables included recovery of acute renal function, complete remission (CR), partial remission (PR), change in renal function, relapse rate, and tacrolimus dosing and serum levels. One patient discontinued treatment for deterioration of renal failure. All patients who completed at least 12 weeks of tacrolimus therapy had recovery of renal function. Recovery of renal function paralleled with the increasing of urine output or reduction of proteinuria. The mean time required for achieving recovery of renal function is 14.7 ± 4.5 (7-21) days. Complete remission was achieved in 7 patients (70%) and partial remission was achieved in 1 (10%). The mean time for achieving CR or PR is 6.1 ± 2.0 (4-10) weeks and 2.9 ± 0.8 (2-4) weeks. Among patients who achieved complete remission or partial remission, 3 (37.5%) patients experienced relapses during follow-up. One patient had a doubling of SCr level because of primary resistance to tacrolimus therapy during follow-up. Tacrolimus may be an effective rescue therapy for SR-MCNS with reversible acute renal failure.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1279**

**Efficiency of Plasmatherapy in Factor H-Associated Hemolytic Uremic Syndrome** Chantal Loirat,[1] Marie-Alice Macher,[1] Patrick Niaudet,[1] Albert Bensman,[1] Michel Tsimaratos,[2] Georges Deschenes,[1] Veronique Fremeaux-Bacchi.[1] *[1]AP-HP, Paris, France; [2]AP-HM, Marseille, France.*

During the last decade, a clear link has been demonstrated between mutations in complement genes and atypical hemolytic uremic syndrome (aHUS). Factor H (FH)-associated HUS has been shown to have a poor prognosis and recent guidelines recommend early intensive plasmatherapy (PT). We report the first evaluation of the efficacy of PT in a group of 22 children with aHUS and mutations in FH gene.

We retrospectively analyzed the outcome of 22 children, of whom 11 (Group 1, 1984-2002) received conservative treatment and 11 (Group 2, 2003-2010) received intensive and prolonged plasmatherapy (daily plasma exchange (PE) or infusion (PI) for ≥ 10days, tapered to intervals of 1/week to 1/month on an individual basis and maintained as long as efficient). Patients carried homozygous FH mutation (n=6), compound heterozygous FH mutation (n=1) or heterozygous FH mutation located in SCR19-20 (n=9) or SCR1-18 (n=6).

Mean age at onset was 11.5m (3d-3.4y) and 10.9m (12d- 4.2y) in group 1 and 2 respectively. All patients presented hemolytic anemia, thrombocytopenia and acute renal failure, of similar severity in both groups. At 1 year follow up, 10 of the 11 untreated patients (91%) had died (n=2) or reached ESRD (7 at first episode), whereas 10 of the 11 patients receiving plasmatherapy (91%) were in remission with normal GFR. One severe recurrence leading to ESRD occurred at 4.5y during the total follow-up of 30.6 patient-years on plasmatherapy. The overall renal survival was significantly better in group 2 than in group 1 (p = 0.001).This study highlights for the first time the efficiency of intensive plasmatherapy to rescue the most severe forms of aHUS. In addition, it gives evidence that long term plasmatherapy prevents recurrence. This treatment has modified early and mid-term prognosis. However it requires trained centers and central vascular access for PE, and affects quality of life.

Disclosure of Financial Relationships: Honoraria: from Alexion Pharmaceuticals, as coordinator for France of the "Eculizumab in atypical HUS" trials C08-002A, C08-002B, C08-003A, C08-003B.

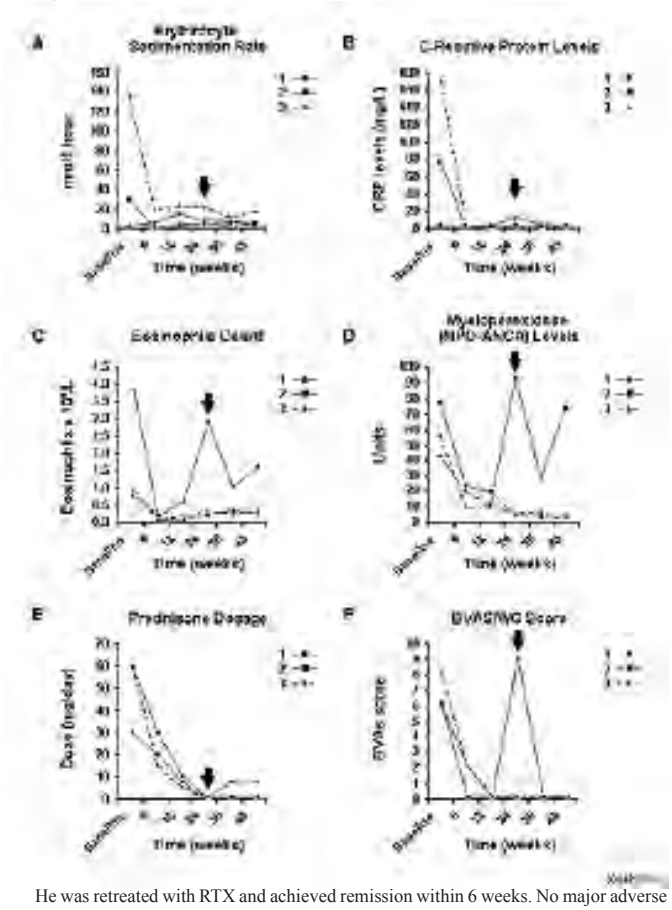
**F-PO1280**

**Rituximab for Churg-Strauss Syndrome with Renal Involvement** Rodrigo Cartin-Ceba,[1] Ulrich Specks,[1] Karina A. Keogh,[1] Fernando C. Fervenza.[2] *[1]Division Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN; [2]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

**Introduction and aim:** Churg-Strauss Syndrome (CSS) is a small vessel vasculitis that causes glomerulonephritis in about 25% of patients. Rituximab (RTX) is an anti-CD20 monoclonal antibody which depletes B-cells and has been effective in ANCA-associated vasculitis. We aim to evaluate the safety and efficacy of RTX in inducing remission of renal disease activity (RDA) in patients with CSS.

**Methods:** Single center, open label pilot study using RTX (375 mg/m2 per week x 4) for induction of remission in CSS patients with RDA (>25% dysmorphic red cells, RBC casts, or pauci-immune GN on biopsy). Patients were eligible if untreated, had failed glucocorticoid therapy, or had failed glucocorticoid dose reductions because of disease relapses. Primary outcome was remission of RDA defined as stability or improvement of creatinine clearance, absence of active urinary sediment and reduction of the glucocorticoid dose to <50% of the average dose received over 3 months before enrollment or <10 mg/day at 6 months. Patients were followed for 1 year.

**Results:** Three patients (ages 54, 55, 65) were enrolled. All patients had MPO-ANCA and active urinary sediments. Two patients had biopsy-proven pauci-immune GN. All achieved the primary end-point within the first three months and remained in renal remission during the year following RTX treatment. Patient 1 experienced a non-renal relapse (eye and joint involvement) at 6 months coinciding with the reconstitution of CD 19 cells and eosinophilia as seen in the figure(black arrow).



He was retreated with RTX and achieved remission within 6 weeks. No major adverse effects were recorded.

**Conclusions:** In this pilot study, RTX was safe and successful in controlling RDA in patients with CSS. This agent deserves further study in CSS.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1281

**Cardiac Troponin T (Tnnt2) Expression Is Induced by TGFβ Signaling in Podocytes** Christina M. Bracken, John N. Vassiliadis, Susan Schiavi, Stefan Wawersik. *Endocrine and Renal Sciences, Genzyme Corp., Framingham, MA.*

TGFβ signaling has long been recognized as a regulator of podocyte apoptosis and survival. More recently, however, evidence has emerged suggesting that TGFβ may also regulate podocyte phenotype by inducing changes in cytoskeleton and cell adhesion. To further explore podocyte phenotypic changes induced by TGFβ, we performed microarray analysis on RNA from cultured immortalized podocytes treated with 5 ng/ml TGFβ for 24 hours. Consistent with other reports, we find that TGFβ upregulates mesenchymal markers (MMP9, α-smooth muscle actin, Fibronectin 1, Col1a1), markers associated with Notch signaling (Jagged 1, Hes1), and elements of the integrin signaling pathway (ILK, Integrin-β3). In addition, we note substantial upregulation of a number of cytoskeletal constituents, including keratin 8, myosin light chain 9, myosin 7a, palladin, and the most highly upregulated gene in this study (>77 fold), Tnnt2. Tnnt2 encodes cardiac troponin T, a thin filament protein known to be involved in muscle contraction, but whose expression has not been reported in the podocyte. Tnnt2 is also affected by glomerular injury in vivo, as we find altered Tnnt2 expression in kidney samples from several in vivo models of proteinuria. We are currently examining functional roles of Tnnt2 in the podocyte to determine whether Tnnt2 expression alters podocyte behavior during injury.

## F-PO1282

**Complement Dysregulation in Hemolytic Uremic Syndrome (HUS)** Arvind Bagga, Aditi Sinha, Ashima Gulati, Pankaj Hari. *Pedaitric Nephrology, All India Institute of Medical Sciences, New Delhi, India.*

**Background:** Mutations in genes encoding complement regulatory proteins are an important cause of HUS

**Objectives:** To prospectively screen for abnormalities in complement regulatory proteins & antibodies in consecutive patients with HUS

**Methods:** Levels of C3, C4, CD46, factors H (CFH), I & B, & anti-CFH antibodies were estimated in 25 patients (19 boys) with HUS during Jan 2007-Dec 2009. Those with antibodies were tested for deletion of CFH-related genes *CFHR1/CFHR3* by multiplex ligation probe amplification. These patients received plasmapheresis, IVIG (2 g/kg), IV cyclophosphamide (500 mg/m$^2$ monthly x 6) & prednisone (1 mg/kg/d for 4 wk, taper). Levels of creatinine, C3 & CFH antibodies were monitored; outcome was assessed by eGFR & dialysis dependence.

**Results:** The mean age was 102±52 (7-190) months; a diarrheal (D+) prodrome was seen in 7. Low levels of C3 & C4 were seen in 7 and 1 patient respectively. Low levels of CFH were seen in 4, factor B in 7 & factor I in 2. *CFH* gene had a homozygous deletion (c.3693-3696delATAG) in an infant with D+ HUS; the parents were heterozygous for this deletion. Sixteen patients (64%) had anti-CFH antibodies (180-60000 U/ml), with high titer in those with dialysis dependence. All these patients showed a homozygous *CFHR1/CFHR3* gene deletion. Immunosuppressive therapy resulted in decline of antibody titers. Six patients had CKD 1-3 at follow up of 1-yr; 4 had ≥1 relapses. The patient with homozygous deletion of CFH progressed to ESRD; one with factor I deficiency died in the acute stage. Of 8 patients without demonstrable complement abnormalities, 4 survived with CKD 1-3 at 1-yr follow up.

**Conclusions:** Our observations highlight that majority of patients with D+/D- HUS in India have anti-CFH antibodies or mutations in the genes encoding complement regulatory proteins. In the former, therapy with plasmapheresis, IVIG & immunosuppressive agents translate into better clinical outcomes. The reasons for the high prevalence of anti-CFH antibodies and their isotype & epitope specificity need to be studied.

## F-PO1283

**Uridine Adenosine Tetraphosphate Acts as an Autocrine Hormone Affecting Glomerular Filtration Rate** Vera Jankowski,[1] Raymond C. Vanholder,[2] Walter Zidek,[1] Joachim Jankowski.[1] *[1]Charite, Germany; [2]University of Ghent, Belgium.*

**Objectives:** Recently, uridine adenosine tetraphosphate (Up4A) was described as a strong vasoconstrictor released from endothelial cells after stimulation with mechanical stress. In this study, we isolated and identified Up4A from kidney tissue, and we characterized the essential varying effects of Up4A on the afferent and efferent arterioles.

Methods: [/bold]Porcine and human kidney tissue was fractionated by size-exclusion-chromatography affinity-chromatography, anion-exchange-chromatography, and reverse phase-chromatography In fractions purified to homogeneity, Up4A was identified by matrix assisted laser desorption/ionisation mass-spectrometry (MALDI-TOF-MS), MALDI-LIFT-fragment-massspectrometry (MALDI-TOF-TOF-MS), retention-time comparison, and enzymatic cleavage analysis. We analysed the release of Up4A from cultivated renal proximal tubule cells after stimulation of protein kinase C with OAG. Up4A was identified in renal tissue, and the effect of Up4A on the vascular tone of isolated perfused afferent and efferent arterioles was tested. **Results:** Stimulation of tubule cells with OAG increased the release-rate of Up4A from tubule cells about ten fold. Up4A acts as a strong vasoconstrictive mediator on afferent arterioles, but has no significant effect on the tone of efferent arterioles, suggesting a functional role of Up4A a an autocrine hormone for glomerular perfusion. Because of the predominant effect of the Up4A on afferent arterioles, we assume that Up4A may decrease glomerular perfusion, intraglomerula pressure, and hence glomerular filtration rate. The release of Up4A from renal tubular cells may be an additional mechanism whereby tubular cells could affect renal perfusion. Up4A release may further contribute to renal vascular autoregulation mechanisms. **Conclusion:** As Up4A occurs in renal tissue and has marked effects on afferent but not efferen arterioles, Up4A may play a role in renal hemodynamics and blood pressure regulation.

**Podocytes Have a Primary Cilium and Calcium Mediated Response to Fluid Flow Shear Stress** Robert J. Kolb,[1] Martin R. Pollak,[3] P. Darwin Bell,[4] Jing Zhou.[3] *[1]Pediatrics, Medical University of South Carolina, Charleston, SC; [2]Pharmacology, The University of Toledo, Toledo, OH; [3]Renal Division, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [4]Division of Nephrology, Department of Medicine, Medical University of South Carolina, Charleston, SC.*

Primary cilia are sensory organelles found at the cell surface of most cell types in the human body. However, it is not known if cilia develop in podocytes, the unique cell type that wraps around the glomerular tuft to help form the filtration barrier. Here we report that podocytes develop a cilium in vitro and in vivo. Cultured podocytes can be stimulated by a fluid shear stress triggering a transient increase in cytosolic calcium. This result is consistent with our hypothesis that the podocyte cilium monitors fluid movement within

Bowman's space. Previously, we have shown that this podocyte flow response is dependent upon an intact cytoskeleton and that the actin binding protein, α-actinin-4, is a prerequisite to the flow response. Recently, we have identified podocytes as having multiple cilia in both cultured Actn4-/- cells over-expressing a human disease mutant variant and in tissue sections from patients with FSGS. The functional significance of multiciliated podocytes and a potential diagnostic role is the focus of our future studies. We propose that the podocyte cilium is a sensory organelle that functions to monitor fluid flow in Bowman's space where it acts to modulate the quality of glomerular filtration through foot process contraction or relaxation. A loss in podocyte cilia function may be contributing factor to human glomerular diseases such as FSGS.

**Platelet Uptake and Release of Complement Factor H** Viola F. van Eimeren,[2] Fred G. Pluthero,[2] Walter H. Kahr,[2] Christoph Licht.[1] *[1]Nephrology, The Hospital for Sick Children, Toronto, ON, Canada; [2]Hematology/Oncology, The Hospital for Sick Children, Toronto, ON, Canada.*

Complement Factor H (CFH) inhibits alternative complement pathway activation on the surface of vascular endothelial and blood cells, including platelets. In a recent study of the role of platelet-complement interactions, we observed uptake of CFH by platelets *in vivo* and *in vitro*. Platelets take up proteins that are stored in and released from secretory granules. Surface glycoprotein IIb/IIIa (GPIIb/IIIa) is involved in the endocytotic uptake of fibrinogen from plasma and has been implicated in platelet uptake of CFH, which we have shown is not stored in secretory granules.

The possible role of GPIIb/IIIa in CFH uptake of resting platelets was examined by comparing the results of incubating cells with fluorescently-labeled CFH under 3 conditions: 1) platelets from patients with Glanzmann thrombasthenia lacking functional GPIIb/IIIa; 2) normal platelets; 3) normal platelets treated with the GPIIb/IIIa blocker abciximab. In each case similar uptake of CFH was observed, indicating that loss or blockage of GPIIb/IIIa receptor does not prevent platelet CFH uptake. When normal cells were activated in the presence or absence of abciximab similar surface uptake of CFH was observed, indicating that GPIIb/IIIa does not play a prominent role in binding of CFH to the surface of activated platelets.

The surface mobilization and release of CFH from normal platelets was investigated by stimulating quiescent cells *in vitro* and monitoring the protein content of releasates and lysates via immunoblotting, and assessing surface CFH by flow cytometry. We observed that platelets can release CFH in conditions that do not trigger α-granule secretion or the release of other cytoplasmic proteins. Full activation of platelets results in release of CFH and granule contents, but not in significant changes in cell surface CFH, indicating that CFH is released from within platelets rather than from the surface.

We conclude that the uptake and release of CFH in platelets is not dependent on interactions with GPIIb/IIIa, and likely involves mechanisms distinct from those involved in the uptake and release of granule-borne proteins.

**A New Disease Mechanism for MPGN II/DDD: Increased CFHR1 Expression Results in Competitive Loss of CFH Cofactor Activity** Christoph Licht,[1] Paul S. Thorner,[2] Christine Skerka,[3] Peter F. Zipfel.[3] *[1]Nephrology, The Hospital for Sick Children, Toronto, ON, Canada; [2]Laboratory Medicine and Pathobiology, The Hospital for Sick Children, Toronto, ON, Canada; [3]Leibniz Institute for Natural Product Research and Infection Biology, Jena, Germany.*

Membranoproliferative glomerulonephritis II (MPGN II) / dense deposit disease (DDD) is characterized by electron dense deposits within the glomerular basement membrane (GBM). The pathogenesis has been recently linked to impaired alternative complement pathway (AP) control caused by Factor H (CFH) deficiency, and by antibodies to the alternative C3 convertase – C3 nephritic factor – or complement Factor B (CFB). In addition, we recently identified CFB mutations and deletions in CFH related proteins (CFHR) 1 and 3 in MPGN patients. Despite these advances, the pathogenesis is still only poorly understood.

We present an 11 y/o boy with biopsy-proven MPGN II. Despite treatment with prednisone and mycophenolate mofitil, he progressed to ESKD within months and was started on PD. After 4 years he received a deceased donor transplant but developed disease recurrence within 1 week (graft biopsy on day 6). He was treated with plasmapheresis followed by plasma infusions. Following transient success for 9 months, renal function deteriorated and graft nephrectomy became necessary due to hypertension. Complement work-up revealed AP activation and a positive C3NeF. Genetic analysis identified 3 copies of CFHR1 along with increased plasma levels (150%). By immunofluorescence, a graft biopsy at 6 months and the graft removed at 17 months showed glomerular CFHR1 staining while control tissue was negative. *In vitro*, CFHR1 competed with CFH for binding to endothelial cells and C3b. In addition, CFHR1 affected CFH cofactor activity with increasing CFHR1 levels causing decreasing CFH cofactor activity.

In conclusion, we identified a new pathomechanism for MPGN II. A patient with 3 allelic copies of CFHR1 showed increased CFHR1 levels causing local loss of CFH cofactor activity. Plasma therapy after early posttransplant recurrence was transiently successful, implying more efficient treatment strategies like targeted complement blockade (e.g. Eculizumab) are required.

**Impaired Ability of GCs To Induce IL-10 and/or Inhibit TNF-alfa Secretion by LPS-Stimulated PMBC Might Underlie Modifications in Steroid Sensitivity of Patients with INS** Martina Cizmarikova,[1] Katarina Szilagyi,[1] Ludmila Podracka,[2] Jan Mojzis,[1] Ladislav Mirossay.[1] *[1]Department of Pharmacology, Faculty of Medicine, University of Pavol Jozef Safarik, Kosice, Slovakia (Slovak Republic); [2]Department of Paediatrics, Faculty of Medicine, University of Pavol Jozef Safarik, Kosice, Slovakia (Slovak Republic).*

**Aim:** The influence of IL-10 and TNF-alfa on sensitivity to glucocorticoids (GCs) was investigated in children with idiopathic nephrotic syndrome (INS).

**Methods:** 43 patients with INS (13 girls, 30 boys, mean age 9.8 years) and 13 healthy children (mean age 14.5 years) were enrolled into the study. Patients were classified according to GCs sensitivity as responders (RE, n=16), partial responders (PR, n=19) and non-responders (NR, n=8). Patients were also subdivided based on the onset/relapse and remission of NS. No immunosuppressants were administered at the time of blood collection. Secretion of IL-10 and TNF-alfa was measured and IL-10/TNF-alfa ratio was determined after LPS stimulation and/or concomitant dexamethasone (DM) therapy to asses dynamicity of cytokine production by the PMBC. Percentage of IL-10/TNF-alfa increase by DM was calculated and correlated to LPS stimulation.

**Results:** Significantly higher increase in IL-10/TNF-alfa after GCs was observed in relapsing RE than in PR and/or NR. In particular, DM concentration of $10^{-8}$M significantly increased IL-10/TNF-alfa ratio in relapsing RE in comparison to relapsing NR ($p=0.049$). Moreover, higher DM concentration of $10^{-7}$ M significantly increased this ratio in relapsing RE in comparison to both PR and NR ($p<0.05$). Surprisingly, these changes were not observed in the remission of the disease. Stimulated PMBC of PR or NR in relapse failed to increase IL-10/TNF-alfa after DM in contrast to the RE group and that might contribute in some patients to lower response to GCs.

**Conclusion:** We hypothesized that impaired ability of GCs to induce IL-10 and/or inhibit TNF-alfa secretion by LPS-stimulated PMBC might underlie modifications in steroid sensitivity of patients with INS. Further data are needed to confirm our hypothesis. Supported by Norway grant through the EEA and the Norwegian Financial Mechanisms.

**Screening Characteristic Protein Profiles of Primary Glomerular Diseases Using Proteomics** Nan Chen, Fang Zhong, Weiming Wang, Xie Yinyin. *Nephrology, Ruijin Hospital, Shanghai Jiao Tong Univeristy, Shanghai, China.*

Objective: Primary glomerulonephritis was the main cause of end-stage renal disease in China. Diagnosis of these diseases needs to renal biopsy, which is invasive inspection. Early diagnosis of the pathological types by the biological markers of blood or urine has a high practical value.

Methods: Forty-five patients with primary glomerulonephritis: IgA nephropathy (IgAN, n=15) , focal segmental glomerulosclerosis (FSGS, n=15) and membranous nephropathy (MN, n=15) were enrolled. All these patients had proteinuria (> 0.5g / day), GFR> 15ml/min/1.73m$^2$. Those patients who took immunosuppressant before renal biopsy were not enrolled. These patients were excluded with hepatitis, cancer and immune and other secondary diseases. And 15 healthy subjects were used as a control group. 20ul sera were collected for every subjects and patients. The samples were removal of high abundance proteins using the Multiple Affinity Removal LC Column, desalinated, quantified and marked. Then we applied mass spectrometry HPLC-MS/MS and statistics.

Results: 15 IgA patients(M/F: 7/8, average age 29.6 ± 10 yrs)had 24-hr urine protein output (1491 ± 752 mg/d ), serum creatinine (Scr) (112 ± 56 μmol/L ). 15 FSGS patients(M/F: 7/8, average age 39.8 ± 13.4 yrs)had 24-hr urine protein output (877 ± 640 mg/d), Scr(121 ± 50 μmol/L). 15 MN patients(M/F: 7/8, average age 53.2 ± 12.6 yrs)had 24-hr urine protein output (3988 ± 2332 mg/d),Scr(91 ± 55 μmol/L ).1956 proteins were identified with mass spectra (MS) in these patients . Compared with normal healthy controls, serum of patients with primary glomerulonephritis exist 447 differentially expressed protein peaks. Compared with the control , 48 proteins in IgA nephropathy patients, 68 proteins in FSGS patients and 120 proteins in MN patients were significantly different. In the expression profile, there are some differences in the expression of specific proteins.

Conclusions: There are differences in serum protein expression profiles in primary glomerulonephritis compared with normal healthy people and difference protein expression profiles in different pathological types of primary glomerulonephritis.

**Electrical Forces Determine Glomerular Permeability** Marcus J. Moeller,[1] Christoph Kuppe,[1] Wilhelm Kriz,[2] Sylvia Menzel,[1] Jurgen Floege.[1] *[1]Department of Nephrology and Clinical Immunology, University Hospital of RWTH Aachen University, Aachen, Germany; [2]CBTM, Anatomy and Developmental Biology, Medical Faculty Mannheim, University Heidelberg, Mannheim, Germany; [3]Department of Cellular and Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN.*

The functioning of the glomerular filter is an intriguing and still only partially resolved question in the field of Nephrology. Per day, about 180 l of plasma are filtered across the glomerular filtration barrier. During this process, more than 99% of the plasma proteins are retained, yet the filter never clogs.

We tested the hypothesis that extracellular electrical potential differences are generated by the flow of the filtrate across the charged glomerular filter. For this purpose, glomerular capillaries were for the first time successfully micropunctured in Necturus maculosus (common mudpuppy), a model organism with an unusually large capillary diameter. With this setup, a potential difference was directly measured across the glomerular filtration barrier, which depended directly on glomerular filtration pressures. The potential difference was generated without temporal delay. It was negative in Bowman's space and it was completely reversible when decreasing the perfusion pressures to baseline levels.

To compare the relative contributions of diffusion, convection and electrophoretic effects on the total flux of albumin across the filter, an independent mathematical model was created using published experimental data. The model predicted that potential differences within a similar range as in our experiments induce an electrophoretic flux that significantly influences the glomerular sieving coefficient of albumin.

In summary, the new model provides a mechanistic theory on the filtration characteristics of the glomerular filtration barrier and is based on experimental data. It provides a novel (patho-) physiological explanation for the microanatomy of the glomerulus, renal autoregulation, why the filter does not clog and the pathogenesis of proteinuria.

**F-PO1290**

**Blood Pressure Abnormalities in Children with Sickle Cell Anemia** Amy M. Becker,[1] Jordan H. Goldberg,[1] Michael Henson,[2] Liyue Tong,[3] Michel G. Baum,[1] George R. Buchanan.[1] *[1]Pediatrics, UT Southwestern Medical Center, Dallas, TX; [2]Pediatrics, Children's Medical Center Dallas, Dallas, TX; [3]Clinical Sciences, UT Southwestern Medical Center, Dallas, TX.*

Kidney disease is a major cause of morbidity and mortality in adults with sickle cell anemia (SCA). Many patients will develop proteinuria and progress to end stage renal disease requiring dialysis and/or transplantation. The factors that modify progression of renal disease are unknown. Alterations in blood pressure (BP), including hypertension and lack of the normal nocturnal dip in blood pressure, are important factors in the progression of kidney disease. Mild increases in BP, termed relative hypertension, are associated with increase risk of stroke, end stage renal disease, and death in adults with SCA. This prospective study of children with SCA characterizes ambulatory BP profiles and presence of microalbuminuria (MA). 46 adolescents (25 females) with SCA mean age of 14.7 years (range 12-18 yrs) underwent 24 hour ambulatory BP monitoring and collected a first morning urine sample to measure MA. 17% of subjects have relative hypertension, and 59% lack the normal nocturnal dip in BP. 33% have previously unrecognized hypertension. 15% have MA with 86% lacking the normal nocturnal dip and 43% with hypertension. Univariate analysis shows that MA is not significantly associated with age, gender, and number of previous blood transfusion, hospitalized pain episodes, or splenic sequestration episodes. Fewer acute chest syndrome events was seen in the MA group (p=0.04). The percent of systolic dip in BP is significantly lower (5.2±3.8%) in the subjects with MA compared to those without MA (9.1±3.6%), p=0.01. Stepwise logistic regression analysis identifies a 26% less chance of having MA with every 1% increment increase in systolic dip. Comparison of clinic BP to mean day ambulatory BP reveals no significant difference. In conclusion, MA is associated with a lack of normal nocturnal variation in blood pressure. Blood pressure abnormalities are common in adolescents with SCA and may be an important modifiable risk factor in the progression of sickle cell nephropathy.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1291**

**Urinary Hepcidin: A Marker of Renal Tubular Dysfunction** Hilde P. Peters,[1] Coby M. M. Laarakkers,[2] Rosalinde Masereeuw,[3] Dorine W. Swinkels,[2] Jack F. Wetzels.[1] *[1]Nephrology, Radboud University Nijmegen Medical Center; [2]Laboratory of Genetic, Endocrine and Metabolic Diseases, Radboud University Nijmegen Medical Center; [3]Toxicology and Pharmacology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.*

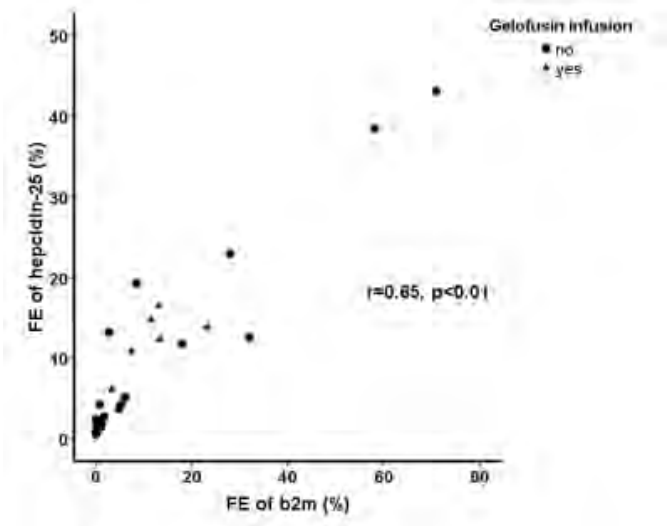
Urinary (U) hepcidin is elevated in various renal diseases and may serve as a biomarker. It is unknown which processes – filtration, reabsorption, local production, and/or degradation - contribute to elevated Uhepcidin levels. We aimed to assess whether tubular dysfunction affects Uhepcidin levels, through comparison with $\beta_2$-microglobulin ($\beta_2$m) excretion. $\beta_2$m is filtered by the glomerulus and reabsorbed by the proximal tubules.

**Method**

Serum and urine levels of hepcidin-25 were determined by a MALDI-TOF Mass Spectrometry based assay in controls and patients with varying degrees of tubular dysfunction due to glomerular disease. U$\beta_2$m was measured by ELISA. Gelofusine, an inhibitor of tubular protein reabsorption, was administered to 2 healthy volunteers. Uhepcidin was measured in megalin deficient mice and wt controls.

**Results**

We studied 21 patients with glomerulopathies, median serum creatinine was 116 (range 70-301) µmol/L, proteinuria 7.1 (1.7-19.1) g/d, and fractional excretion (FE) of $\beta_2$m 1.3 (0.1-71)%. FE of hepcidin was 2.8 (0.6-43) vs 1.9 (range 0.2-5.8)% in 24 controls (p=0.04). FE of hepcidin correlated strongly with FE of $\beta_2$m (r=0.85, p<0.01).



During Gelofusine infusion a rapid increase in FE of $\beta_2$m and hepcidin was observed; ~150 (0.1⇒16.5%), and ~7 fold (3.0⇒15.4%), respectively. Uhepcidin in megalin deficient mice was increased 7-fold compared to controls (n=5, p<0.01).

**Conclusion**

Hepcidin-25 is reabsorbed by the tubules, a process mediated by megalin. Increased levels of Uhepcidin may largely reflect tubular dysfunction. This should be considered when evaluating Uhepcidin as a biomarker in patients with kidney disease.

**Altered Activity of Drug Metabolism and Transport Pathways in Glomerulonephritis** Melanie S. Joy,[1] Kim L. R. Brouwer,[2] Joyce A. Goldstein,[3] Mary Anne Dooley,[4] Ronald J. Falk,[4] Reginald F. Frye.[5] *[1]Schools of Medicine and Pharmacy, University of North Carolina, Chapel Hill, NC; [2]School of Pharmacy, University of North Carolina, Chapel Hill, NC; [3]NIH, NIEHS, Research Triangle Park, NC; [4]School of Medicine, Kidney Center, University of North Carolina, Chapel Hill, NC; [5]College of Pharmacy, University of Florida, Gainesville, NC.*

Cytochrome P450 (CYP) pathways metabolize numerous drugs and the P-glycoprotein drug transporter is linked to chemotherapy resistance. The objectives of the research were to characterize the activities of drug metabolizing enzymes and P-glycoprotein in glomerulonephritis.

Glomerulonephritis patients (n=12) with lupus(n=5) and small vessel vasculitis(n=7) received a drug cocktail containing selective probe drugs; fexofenadine 60mg (P-glycoprotein), flurbiprofen 50mg (CYP2C9), bupropion 150mg (CYP2B6), and intravenous $^{14}$C N-methylerythromycin 3µcuries (CYP3A4). Serial blood and urine was collected and analyzed by LC/MS and liquid scintillation counting. Pharmacokinetics were assessed with WinNonlin®.

Patient were 9F/3M, 42% Caucasian, serum creatinine 1.3±0.7mg/dL, UP:Cr 1.6±1.5, creatinine clearance 102±43mL/min, and serum albumin 2.0±0.2g/dL. The pharmacokinetics for glomerulonephritis versus ESRD and healthy controls are provided in Table (a-clearance, b-metabolic ratio).

| | Glomerulonephritis | ESRD | Healthy Controls |
|---|---|---|---|
| CYP3A4 (erythromycin) | 2.0±0.8% dose/h | 1.9±0.7% dose/h | 2.7±1.0% dose/h |
| CYP2C9 (flurbiprofen)[a] | 1.9±0.5 L/h | 1.3 L/h | 1.1±0.4 L/h |
| CYP2B6 (bupropion) [b] | 8.9±5.0 | NR | 35.8 |
| P-glycoprotein (fexofenadine)[a] | 58.8±34.5 L/h | 37.9±19.5 L/h | 103±38 L/h |

The activity of each pathway was reduced in glomerulonephritis, with the exception of increased CYP2C9. CYP3A4 activity in glomerulonephritis was consistent with reported activity in ESRD, despite minimal kidney function declines.

Glomerulonephritis patients with minimal kidney function declines can have significant alterations in activity of drug metabolizing enzymes and transporters. These findings could have repercussions in terms of treatment-related toxicities and responses in patients.

**Increased Cardiac Troponin T Levels Are Correlated with Inflammatory Markers and Various Indices of Renal Function in Chronic Renal Disease Patients** Siren Sezer, Sebnem Karakan, Nurhan Ozdemir. *Nephrology, Baskent University Hospital, Ankara, Turkey.*

**Background/Objectives:** Serum cardiac troponin T (cTnT) concentrations are commonly increased in end-stage renal disease in the absence of an acute coronary syndrome. Cardiovascular disease begins early in the course of chronic kidney disease

(CKD), and the glomerular filtration rate (GFR) is an independent risk factor for it. Evidence suggests that raised troponin concentrations in uraemic patients do indeed reflect myocardial injury. There is little information on cardiac troponin concentrations in patients with chronic kidney disease (CKD) who have not commenced dialysis. However, factors associated with this deleterous process are not completely understood. We aimed to determine associated laboratory abnormalities of increased cTnT in patients with CKD.

**Methods:** Between 2008-2009 104 patients were recruited to the study. Sixty-three (60%) and 79 (75%) of patients had diabetes mellitus and hypertension, respectively. Exclusion criteria included patients <18 years of age or other vulnerable groups; patients with acute renal failure, a functioning renal transplant, or receiving dialysis; and patients having had a recent (<1 month) cardiac event. Glomerular filtrasyon rate (GFR) was estimated (44,62±14,38 mL/min/1,73 m²) based using the Modification of Diet in Renal Disease (MDRD) study formula.

**Results:** cTnT is correlated with blood urea ($r=0.262$, $p<0.05$), uric acid ($r=0.399$, $p<0.001$), blood phosphourus ($r=0.550$, $p<0.001$), trigliceride ($r=0.329$, $p=0.011$), ferritin ($r=0.325$, $p=0.021$), C-reactive protein ($r=0.768$, $p<0.001$), vitamin $B_{12}$ ($r=0.672$, $p<0.001$), GFR ($r=-0.755$, $p=0.011$), renal resistive index ($r=-0.412$, $p=0.017$). Linear regression analysis revealed that CRP ($\beta=+0,72$, $p<0.001$), serum phosphorus ($\beta=+0,22$, $p<0.05$) were statistically significant risk factors for increased cTnT.

**Conclusion**: Increased cTnT shows not only ongoing inflammation but is a sensitive marker of functioning renal mass. It is strongly correlated with factors influencing the decline in renal function, thus can be used as a renal risk parameter.

## F-PO1294

**CT Scan Guided Method More Effective Than Non-Real Time Ultrasound for Kidney Biopsy** Amit J. Joshi, George Dunea, Peter D. Hart. *Division of Nephrology, Stroger Hospital of Cook County, Chicago, IL.*

Objective: To examine the diagnostic yield and complications of percutaneous kidney biopsy using either ultrasound or CT scan guidance.

Methods: We retrospectively reviewed 201 native percutaneous kidney biopsies done over a period of 3 years at an urban teaching hospital, using ultrasound in 100 patients and CT scan guidance in 101 patients. In the ultrasound group we used a 14 -gauge needle manually without real time imaging; in the CT scan group we used an 18- gauge needle with an automated gun and confirmed the position of the needle by CT scanning. Biopsy was considered optimal when adequate tissue was obtained without complications.

Results: The mean number of glomeruli and of complications from the procedure was similar in both groups. There were more cases with adequate glomeruli for histological diagnosis in the CT scan group. More patients in the CT scan group required blood transfusions while non-renal tissue was obtained in more cases in the ultrasound group.

Outcomes

| | CT scan n=101 | Ultrasound n=100 | p-value* |
|---|---|---|---|
| **Effectiveness** | | | |
| ≥6 glomeruli n (%) | 98 (98%) | 85 (85%) | 0.003 |
| ≥10 glomeruli n (%) | 90 (90%) | 82 (82%) | 0.15 |
| Glomeruli mean±SD | 21.5±1.04 | 21.7±1.39 | 0.94 |
| **Safety** | | | |
| Complications n(%) | 9 (9%) | 9 (9%) | 0.98 |
| Non-renal organ biopsy n(%) | 1 (1%) | 4 (4%) | 0.17 |
| Blood transfusion n(%) | 8 (8%) | 5 (5%) | 0.4 |
| Sepsis, surgery, death | 0 | 0 | |
| **Optimal biopsy** | 90 (89%) | 81 (81%) | 0.117 |

* Adjusted for all baseline characteristics: age, sex, ethnicity, hemoglobin, platelet count, creatinine, BUN, INR, PTT, bleeding time, blood pressure

Conclusion: Compared to ultrasound without real time imaging, the CT-scan method, even though using a smaller needle, resulted in better localization of the kidney, consistently yielding adequate tissue samples for diagnosis, decreasing the risk of injuring non-renal tissue, and indicating that accurate localization is more important than needle size in renal biopsy.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1295

**Elevated Uremic Toxins in Anephric Sheep** Garry J. Handelman,[1] Isso Bayala,[1] Mary Carter,[2] D. Buffington,[4] L. Charles,[5] K. Johnston,[4] L. Lou,[4] J. Jung,[3] David Humes,[3] Nathan W. Levin,[2] Peter Kotanko.[2] *[1]University of Massachusetts, Lowell, MA; [2]Renal Research Institute, New York, NY; [3]University of Michigan, Ann Arbor, MI; [4]Innovative Biotherapies, Ann Arbor, MI.*

Uremic toxins are of great interest because of the challenge of removing these molecules with standard dialysis procedures, and because of their potential for long-term harmful effects. Sheep were made anephic and established on peritoneal dialysis, and maintained in this conditions for 9 days. BUN increased from 19(±3) to 73(±13) mg/dL ($p<0.001$), and creatinine from 0.72(±.04) to 9.6(±1.4) md/dL ($p<0.001$). Using HPLC, we characterized the profile of low-MW molecules in the sheep; para-cresol sulfate (PCS), indoxyl sulfate (IS), hippuric acid (HA), and tryptophan (Try). PCS and IS reached high levels, compared to baseline.

Changes in molecules, mg/dL (mean ± SD)

| Time point | Para-cresol sulfate | Indoxyl sulfate | Hippuric acid | Tryptophan |
|---|---|---|---|---|
| BL | 1.8±0.4 | 0.03±0.02 | 0.02±0.01 | 0.81±0.11 |
| 2 days | 34±11# | 1.21±0.22# | 0.93±0.15# | 0.23±0.03# |
| 7 days | 57±6# | 1.71±0.17# | 0.61±0.48(NS) | 0.28±0.05# |
| 9 days | 51±9# | 1.99±0.11# | 0.38±0.34(NS) | 0.26±0.09# |

#, $p<0.001$ vs BL, paired t-test, NS, not significant

The decrease in tryptophan is may result from the loss of tryptophan in the dialysate, with no renal mechanism to conserve this amino acid. A similar change needs to be examined in human subjects on dialysis. The transient increase in hippuric acid, with a trend back to lower levels, corresponds to the effectiveness of dialysis treatment to clear this highly-soluble non-protein bound compound.

A similar HPLC pattern was observed in measurement of these compounds in a sample from a human ESRD patient. Several other new molecules were also observed in the analysis of the uremic sheep. The sheep model of uremia, with provision of dialysis therapy, provides an ideal strategy for understanding the accumulation and depletion of several low-MW substances during development and management of renal failure.

**Discovery and Validation of Biomarkers for Diagnosis of Early and Late Diabetic Nephropathy** Mary Y. Yeh,[1] Wei-Ya Lin,[1] Hung-Yi Li,[1] Tsai-Wei Shu,[1] Ping-Fu Cheng,[1] Chih-Jen Wu,[2] Chi-Hung Cheng,[3] Kuo-Hsiung Shu,[3] Chwei-Shiun Yang,[4] Han-Hsiang Chen,[2] Yen-Peng Li,[1] Yuh-Feng Lin,[5] Jin-Shuen Chen,[5] Tzu-Ling Tseng.[1] *[1]Biomedical Engineering Research laboratories, Industrial Technology Research Institute, Hsinchu, Taiwan; [2]Nephrology, Mackay Memorial Hospital, Taipei, Taiwan; [3]Nephrology, Taichung Veterans General Hospital, Taichung, Taiwan; [4]Nephrology, Cathay General Hospital, Taipei, Taiwan; [5]Nephrology, Tri-Service General Hospital, Taipei, Taiwan.*

**Introduction:** Non-invasive diagnosis biomarkers for diabetic nephropathy (DN) can be used regularly to determine the opportune time to initiate therapy and to evaluate therapeutic response. A panel of biomarkers was discovered in serum and urine. Further testing in expanded patient samples and immunohistochemistry staining (IHC) of renal biopsies were performed to confirm diagnostic value and organ/disease-specificity of these biomarkers. **Methods:** Serum and urine samples were collected from healthy individuals and diabetic patients at various DN stages in participating medical centers of the Taiwan Renal Biomarker Consortium. A panel of five biomarkers was discovered based upon novel proteomic platforms. Verification of panel performance was made in a group of 300 patients. Renal biopsies from DN and minimal change disease (MCD) patients were IHC stained against these markers. **Results:** While none of the individual biomarker performed sufficiently in the group of 300 patients, the biomarkers in combination was highly specific and sensitive for DN diagnosis at various stages, with auROC up to 0.98 and inversely correlated with patient's glomerular filtration rate. These markers stained strongly in DN tissue and were minimally present in MCD demonstrating disease specificity that was independent from proteinuria. Biomarkers were detected primarily in the tubules rather than in glomeruli supporting their complex and relevant roles in the pathogenesis of DN. **Conclusion:** A novel biomarker panel for diagnosing DN was validated and performed well for early and late DN stages and thus holds great promise in facilitating non-invasive DN diagnosis and long-term DN monitoring for effective disease management.

**Low and High Transferrin Saturation Levels Are Associated with Mortality among Persons with Normal and Reduced Kidney Function in the General Population** Austin G. Stack,[1] Hoang Thanh Nguyen,[3] Catherine A. Wall.[2] *[1]Regional Kidney Centre, Letterkenny General Hospital, Letterkenny, Donegal, Ireland; [2]Department of Renal Medicine, Adelaide & Meath, National Childrens Hospital, Tallaght, Dublin, Ireland; [3]MD Anderson Cancer Center.*

**Background:** Serum transferrin saturation (Tsat%) is a commonly used indicator of iron deficiency and iron overload in clinical practice. We determined the relationship between Tsat% and death in the U.S. population and among those with reduced kidney function.

**Methods:** A cohort of 15,823 subjects age ≥ 20, and representative of the U.S. population, was identified from the Third National Health and Nutrition Examination Survey (1988-1994). Vital status was obtained through linkage with the National Death Index. Serum Tsat% (serum iron/total iron binding capacity %) measured at baseline was modeled with all-cause mortality according to estimated glomerular filtration rate (eGFR) (< 60, 60-90 and > 90 ml/min) using Cox regression.

**Results:** Adjusting for demographic characteristics, the Tsat%-mortality relationship followed a u-shaped correlation. Compared to the referent group [Tsat% between 23.7-26.4%: Relative Mortality Risks (RR)=1.00], individuals with Tsat% values within the five lowest deciles of 0-12.5 %, 12.5-16.1 %, 16.1-18.8 %, 18.1-21.3 %, and 21.3-23.7 % experienced significantly higher risks of 2.32 (1.78-3.03), 1.57 (1.17-2.10), 1.44 (1.11-1.88) 1.44 (1.11-1.88), 1.41 (1.03-1.91) respectively while those with values in the highest decile, greater than 39.7 %, also experienced significantly higher mortality risks [RR=1.39 (1.04-1.86)]. Adjusting for comorbid conditions, inflammation markers, haemoglobin & ferritin, the Tsat%-mortality relationship remained unaltered. However, among persons with reduced kidney function, (eGFR< 60 ml/min), the mortality risks associated with low Tsat% values were greatly magnified compared to those with GFR > 60 ml/min. (P-value interaction <0.01).

**Conclusions:** Both low and high Tsat% levels contribute independently to increased mortality in the U.S. especially among those with reduced GFR. Optimal targets for Tsat% appear to be in the range of 24-40 %. These relationships should be considered when interpreting results from clinical trials of anaemia correction.

**Glomerular and Tubular Damage Markers Are Elevated in Patients with Diabetes Mellitus** Ferdinand L. Nauta,[1] Wendy E. Boertien,[1] Stephan J. L. Bakker,[1] Henk Bilo,[3] Harry Van Goor,[2] Paul E. de Jong,[1] Ron T. Gansevoort.[1] *[1]Nephrology, Groningen, Netherlands; [2]Pathology and Medical Biology, Groningen, Netherlands; [3]Diabetes Center, Isala Clinics, Zwolle, Netherlands.*

Albuminuria is an established risk marker for renal function decline in diabetes mellitus (DM). Although albuminuria is regarded as the consequence of glomerular damage, the renal tubulo-interstitium is plays an important role in the genesis of DM nephropathy.

We aimed to investigate in a cross-sectional study the levels of serum and urinary biomarkers in patients with DM (n=94) and non-diabetic controls (n=45) to study the association between glomerular (IgG and IgG-4), proximal tubular (KIM-1, NAG, NGAL, β-2-microglobulin, cystatin C) and distal tubular damage (H-FABP) markers and kidney disease severity (albuminuria and eGFR (MDRD)). Biomarkers were measured in triplo in fresh morning urine samples and in plasma.

Of the DM patients 40 were normo-, 40 micro- and 14 macro-albuminuric. Compared to non-diabetic controls urinary IgG-4 (13 fold), NAG (8.5 fold), NGAL (4.6 fold) and H-FABP (16 fold) were already significantly elevated in normo-albuminuric diabetic patients. Urinary concentrations of glomerular and tubular biomarkers increased per albuminuria stratum, except KIM-1 and β-2-microglobulin. All these urinary biomarkers concentrations were significantly associated with albuminuria, also in multivariate analyses. (Std β 0.34-0.78; all $p<0.003$). All urinary biomarkers except KIM-1 and β-2-microglobulin were significantly associated with eGFR in univariate models (Std β-0.38- -0.21; all $p<0.04$). However, after correction for age, sex, albuminuria and plasma concentration of the corresponding biomarker, only H-FABP was significantly associated with eGFR (Std β-0.26, $p=0.037$).

In conclusion, glomerular and tubular markers are associated with albuminuria, independently of eGFR, suggesting that albuminuria reflects both glomerular and tubulo-interstitial damage. Only urinary H-FABP is associated with eGFR independently of albuminuria and may thus be a promising urinary biomarker for diabetic kidney disease.

**A New Index To Characterize Iron Status in CKD Patients. Nephrotest Cohort** Lucile Mercadal,[1] Marie Metzger,[1] Martin Flamant,[2] Jean-Philippe Haymann,[3] Benedicte Stengel,[1] Marc C. Froissart.[1,4] *[1]Inserm U1018; [2]Bichat Hospital; [3]Tenon Hospital; [4]G Pompidou European Hospital, Paris, France.*

Taken separately, the markers of iron status do not adequately characterize the mechanisms of anemia in CKD. We investigated the value of an index (table) combining ferritin, transferrin saturation (TSAT) and total iron binding capacity (TBIC) to characterize iron status in 1011 nondialysis CKD patients free from IV iron or ESA. Glomerular filtration rate was measured (mGFR) in all patients by $^{51}$Cr-EDTA renal clearance. Functional ID without inflammation and transferrin deficiency were the 2 most common pathologic profiles. They both steadily increased from 10% and 13% to 28% and 31% with decreasing mGFR from > 60 to < 15ml/min/1.73m², respectively. The relation of Hb with iron index classes differed by mGFR in 2 categories (≥40 and <40 mL/min/1.73m², interaction $p=0.02$). Hb was lower in all ID classes as compared with the reference one before and after adjusting for gender, age, ethnicity, diabetes, BMI, albumin, alpha 1 acid glycoprotein, oral iron therapy, RAS inhibitor use, and mGFR. But except for real ID, relations between Hb and ID classes were stronger in the lower mGFR category. This iron status index made it possible to define 2 main abnormal iron profiles associated with CKD anemia. While noninflammatory functional deficiency may be linked to hepcidin increase with renal function decline, transferrin deficiency may reflect the impact of malnutrition.

| | TSAT (%) | TBIC µmol/L | Ferritin ng/ml | N (%) | Crude Hb mean (g/dL) (sd) | Change in Hb (g/dL), adjusted estimates (sd) | |
|---|---|---|---|---|---|---|---|
| | | | | | | mGFR≥40 | mGFR<40 |
| Normal | ≥20 | ≥50 | ≥ 40 | 546 (53) | 13.0 (1.5)* | reference | |
| Real iron deficiency (ID) | <20 | ≥50 | <40 | 62 (6) | 11.6 (1.7)* | -1.1 (0.3)** | -0.7 (0.2)** |
| Functional ID without inflammation | <20 | ≥50 | ≥ 40 | 188 (18) | 12.3 (1.6)* | -0.3 (0.2) | -0.5 (0.1)** |
| Functional ID with inflammation | <20 | <50 | ≥ 40 | 21 (2) | 12.0 (1.4)* | -0.3 (0.5) | -0.8 (0.3)* |

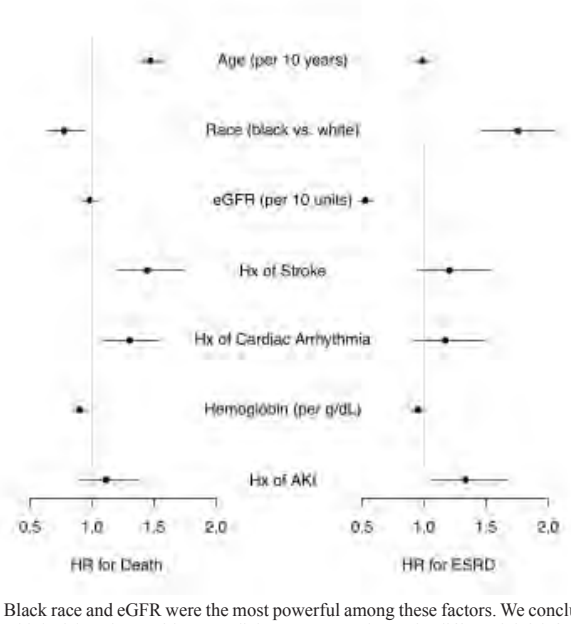
**Differential Risk Factor Profiles for End-Stage Renal Disease (ESRD) and Death in Patients with Type 2 Diabetes, Chronic Kidney Disease (CKD) and Anemia** Robert D. Toto,[1] Andrew S. Levey,[2] Marc Pfeffer,[3] Hajime Uno,[3] Emmanuel A. Burdmann,[4] Chao-Yin Chen,[5] Peter Ivanovich,[6] Eldrin F. Lewis,[3] Julie Lin,[3] Patrick S. Parfrey,[7] Jerome A. Rossert,[5] Kai-Uwe Eckardt.[8] *[1]UT Southwestern, Dallas; [2]NEMC, Boston; [3]Brigham and Women's, Boston; [4]Faculdade de Medicina de Sao Jose do Rio, Sao Paulo, Brazil; [5]Amgen, Thousand Oaks; [6]Northwestern Univ., Chicago; [7]Memorial Univ., Newfoundland, Canada; [8]Univ. of Erlangen-Nuremberg, Erlangen, Germany.*

Preventing ESRD and death in patients with type 2 diabetes and CKD is a major public health priority. We hypothesized that differential risk factor profiles exist for the competing outcomes of: 1) ESRD and 2) Death among 4010 subjects with type 2 diabetes, CKD and anemia in the Trial to Reduce cardiovascular Events with Aranesp Therapy (TREAT). Cox proportional hazards models were used with a stepwise variable selection procedure including the following baseline factors thought to be involved in causal pathways for ESRD and Death: age, sex, race, need for insulin use, body mass index, BUN, eGFR, log urine protein/creatinine ratio, history of acute kidney injury (AKI), stroke, peripheral arterial disease, heart failure, arrhythmia, hemoglobin, serum albumin, CRP, and log serum ferritin. There were 666 (7.4/100 pt-yr) ESRD and 798 (8.1/100 pt-yr) Death events. Hazard ratios with 95% confidence intervals for factors demonstrated to have differential effects on ESRD and Death, based on these preliminary results, are shown.



Age, Black race and eGFR were the most powerful among these factors. We conclude that among high-risk patients with type 2 diabetes, CKD and anemia, differential risk factor profiles exist for ESRD and Death. These can be used to improve bedside risk stratification and design of future clinical trials.

**Plasma Follistatin Level Is Associated with Protein-Energy Wasting, Bone Mineral Density and Inflammation in Patients with Stage 5 Chronic Kidney Disease** Tetsu Miyamoto, Juan J. Carrero, Abdul Rashid Tony Qureshi, Björn Anderstam, Olof Heimburger, Peter F. Barany, Bengt Lindholm, Peter Stenvinkel. *Division of Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

**Background**: Follistatin, a neutralizer of biological activities of TGF-β superfamily members including myostatin and activin, is known to be involved in the regulation of muscle growth and bone mineralization. As recent animal studies shows that follistatin inhibit myostatin action, this suggests a potential therapeutic use for this molecule. However, possible alterations in this pathway have not been characterized in CKD.

**Methods**: Circulating follistatin levels were analyzed in relation to protein-energy wasting (PEW), bone-mineral density (DEXA) and inflammation in 280 incident dialysis patients, 40 CKD 3-4 patients and 40 healthy controls. Mortality in the dialysis patients was evaluated after a median follow up of 58 months.

**Results**: No difference in follistatin levels was observed between the CKD 5 (1.57 [range 0.9-2.8] ng/mL), CKD 3-4 patients (1.62 [0.91-2.85] ng/mL), and controls (1.45 [1.02-2.14] ng/mL). In CKD 5 patients, plasma follistatin positively correlated with age ($r=0.18$; $p<0.01$), hsCRP ($r=0.35$; $p<0.0001$), IL-6 ($r=0.27$; $p<0.0001$) and negatively

with handgrip strength (HGS, r=-0.28; p<0.0001), s-creatinine (r=-0.13; p<0.05) and bone-mineral density (BMD, r=-0.30; p<0.0001). Patients with PEW (SGA≥2) had higher follistatin levels (1.97 vs 1.65 ng/mL, p<0.01). In multivariate regression analysis, follistatin independently contributed to HGS (β=-4.1, SE=1.5, P<0.01) and BMD (β=-0.03, SE=0.008, P<0.01). Patients with increased follistatin (the middle and highest tertile together) had a worse survival compared to patients within the lowest tertile in crude Cox analysis (HR 1.59, 95%CI 1.1-2.4, p=0.02). However, after adjustment for age, sex and co-morbidities the predictive power disappeared.

**Conclusions**: Elevated follistatin concentration is associated with inflammation, low HGS, low BMD and weakly predicted mortality in incident dialysis patients. Our findings may imply an involvement of the myostatin- and activin- interplay in the renal wasting process.

**The Appearance of Anemia in Stage 3 CKD Patients Represents a Poor Prognosis Factor. NADIR-3 Prospective 3-Year Study** J. M. Portolés,[1] Jose L. Gorriz,[2] Alberto M. Martinez-Castelao,[3] Fernando Dealvaro-Moreno,[4] Florencio García,[5] Vicente Álvarez,[6] Isabel Martínez,[7] Jesus Arteaga.[8] *[1]H.U.F.Alcorcón, Spain; [2]H.U.Dr.Peset, Spain; [3]H.U.Bellvitge, Spain; [4]GEENDIAB-SEN, Spain; [5]H.12 Octubre, Spain; [6]H.La Princesa, Spain; [7]H.Galdakao, Spain; [8]H.Navarra, Spain.*

Purpose: There are no longitudinal studies about anemia development in CKD-3. Our objective was to estimate time and rate of appearance of anemia and its associated factors.

Methods: Epidemiological, prospective, multicentre, 3-yr study. Inclusion: age 18-78 yrs, CKD-3 (MDRD-4), without anemia or ESA treatment. Data every 6 months (m) until start of renal replacement therapy or death. A specific diagnostic study is conducted if anemia appears (EBPG criteria).

Results: 431 patients: 63.4 yrs, 69.9% male. Nephropathy: vascular 28.4%;DM: 17%;GN 12.3%;CTIN 10.4%;APKD 7.2. Comorbidity: 32.8% with DM; 68.6% dyslipidemia, 92.8% HT and Charlson score: 3.2(1.6). Baseline parameters: Cr 1.8mg/dl, MDRD 39.1ml/min, proteinuria 0.69g/day (20.4%>1g/day), Hb 14.3g/dl, ferritin 131.8ng/ml, TSI 30.2%, PCR 2.1mg/dl and Alb 4.3g/dl. At 3 yrs, 25% had required hospitalization, 9.9% had presented at least one major CV Event, 26 patients had died, 13 had started kidney replacement and 173 reached CKD 4-5. 29.6% of patients were diagnosed with anemia, 85% of them from a renal cause. The likelihood of developing anemia was: 0.12 after 1 year, 0.20 after 2 and 0.25 after 3. Mean time to anemia was 34.9 m 95%CI[33.7-36.1] (Kaplan-Meyer). Those who developed anemia vs those who did not had: greater median age (68.0 vs 65.5yrs), greater % of men (71.6 vs 68.8), lower baseline MDRD (35.9 vs 40.0ml/min), greater baseline proteinuria (0.94 vs 0.62g/day); lower albumin (4.1 vs 4.3g/dl); greater MDRD reduction (6.8 vs 1.6ml/min at 3 yrs; p<0.001), earlier progression to CKD-4 (18.0 vs 28.1 m; p<0.001); greater rate of major CV events (16.1 vs 6.9%, p<0.05), hospitalization (33.7 vs 19.4%, p<0.001) and mortality (10.3 vs 6.6%, p<0.005).

Conclusions: We have the first estimation of the rate of appearance of renal anemia in stage 3 CKD. Those who develop anemia present worse clinical evolution.

**F-PO1303**

**Successful Weight Loss in Obese Patients with Chronic Kidney Disease Is Associated with Compliance and Maintenance of Kidney Function** Helen L. MacLaughlin,[1] Sharlene A. Greenwood,[1] Katrina L. Campbell,[2] Iain C. Macdougall.[1] *[1]Department of Renal Medicine, King's College Hospital, London, United Kingdom; [2]Department of Nutrition and Dietetics, Princess Alexandra Hospital, Brisbane, Australia.*

Obesity is a risk factor for developing CKD & progression to kidney failure. This study examined factors associated with successful weight loss in obese patients with CKD.

Consenting patients with CKD & BMI >30 kg/m$^2$ were referred to a structured weight loss program of 9 sessions over 12 mths plus a low-fat, 1500 kcal renal diet, physical activity & orlistat. Weight loss, attendance & eGFR (4 variable MDRD Study eq) were measured at 0, 6 &12 mths. Mean % weight loss was determined with an intention to treat analysis. Predictors of weight loss & change in eGFR were assessed using linear regression analysis and ANOVA.

102 patients (57% male), aged 52.2 ±13.2 (±SD) years, weight 101.8 ±21.2 kg, & BMI 35.8 ±5.4 kg/m$^2$ commenced the weight loss program in 2005-2007. 82/102 were in CKD stages 1-4 (17 post transplant) with mean eGFR 36.9 ±32.2 ml/min & 20/102 were on dialysis & otherwise fit for transplantation. 49% of patients were compliant, 21% part-compliant and 30% non-compliant, attending 7-9, 4-6, or 1-3 sessions, respectively. Complete data was obtained for 90 patients, & the last observation carried forward for 12 patients for the primary analysis.

Mean weight loss for all patients commencing the program was 4.1 ±9.0% at 6 mths (p=0.01) & 4.1 ±9.1% at 12 mths (p=0.01). Weight loss was predicted by compliance (adj R2=0.36; p<0.001), adjusted for baseline BMI, weight, CKD stage & age. After 12 mths, compliant patients lost more weight (8.2 ±4.9%) than part-compliant (4.2 ±4.9%) or non-compliant patients (1.7 ±3.8%) (p=0.006), & in stages 1-4 CKD patients, eGFR increased by 1.5 ±2.0 ml/min with >10% weight loss & decreased by 3.3 ±1.2 ml/min, with <10% weight loss (p=0.02).

Significant weight loss was achieved overall, demonstrating the effectiveness of the weight loss program. Compliance predicted weight loss & >10% weight loss was associated with stabilisation of kidney function. Weight loss treatments that can reduce body weight by >10% may slow the progression of CKD in obese patients.

Disclosure of Financial Relationships: nothing to disclose

**Plasma Tenascin-C, Inflammation, Extracellular Matrix Remodeling and Outcomes in Chronic Kidney Disease Patients – A Pilot Study** Sophie Liabeuf,[1] Daniela Veit Barreto,[1] Axel Kretschmer,[2] Fellype Barreto,[1] Michel Andrejak,[1] Gabriel Choukroun,[3] Ziad Massy.[1,3] *[1]Department of Pharmacology, Amiens University Hospital and INSERM ERI12, Amiens, France; [2]GDD-TD-Biomarker Research, Bayer Schering Pharma AG, Wuppertal, Germany; [3]Department of Nephrology, Amiens University Hospital, Amiens.*

**Background and objectives:** Tenascin-C (TN-C) is an adhesion-modulating extracellular matrix glycoprotein which is overexpressed in various organs under disease conditions (infection, inflammation). Chronic kidney disease (CKD) is associated with a state of chronic inflammation and high cardiovascular morbidity and mortality.

**Design, setting, participants & measurement:** To examine the impact of plasma TN-C levels on cardiovascular outcomes, we studied a cohort of 94 prevalent CKD patients (mean ± SD age: 68 ± 13; 31% at CKD stages 2-3, 31% at stages 4-5, 38% at stage 5D).

**Results:** Plasma TN-C levels were elevated in this population and tended to rise as CKD progressed, with the increase becoming statistically significant at CKD stage 5D. Multivariate linear regression analysis indicated that CKD stage (p=0.04), IL-6 (p=0.02) and albumin (p=0.02) were independently associated with plasma TN-C levels. During follow-up (mean: 969 ± 405 days), 32 patients died (19 from cardiovascular events, 7 from infectious diseases and 6 from other causes). In crude analysis, higher plasma TN-C levels predicted overall and CV mortality (p=0.007 and p=0.003 respectively) and were associated with higher occurrence of CV events. Cox analyses confirmed that elevated plasma TN-C levels were independently associated with cardiovascular events, cardiovascular and overall mortality.

**Conclusions:** Our findings suggest that plasma TN-C levels are independently associated with cardiovascular outcomes in CKD patients. Further studies are needed to confirm our observations and better understand TN-C's role in inflammation and extra cellular matrix remodeling in CKD.

**F-PO1305**

**Quantification of Inflammatory and Immune Mediators in Serum, Whole Blood and Urine: Correlation with CKD Stage** Alan Perlman,[1] James M. Chevalier,[1] Thomas Parker,[1] Daniel Levine,[1] Patrick F. Wilkinson,[2] Hao Liu,[2] Francis X. Farrell.[2] *[1]The Rogosin Institute and Weill Medical College, Cornell University, NY, NY; [2]Centocor Research and Development, Inc, Radnor, PA.*

Diabetic nephropathy (DN) is caused by uncontrolled hyperglycemia and is the leading cause of ESRD. Traditional risk factors for progression of DN include hyperglycemia, hypertension and genetic predisposition. Recent evidence suggests that inflammatory and immune processes may be pathogenic in the progression of DN. Identification of specific inflammatory and immune mediators and their prevalence during CKD progression is the central objective of this study. We examined the relationship between CKD stage in patients with DN to serum, whole blood and urine concentrations of a variety of inflammatory and immune cytokines. Protein and/or RNA levels of inflammatory and immune mediators were quantified by ELISA, Luminex® and QuantiGene® System. We identified a positive correlation between CKD stage and EGF, EOTAXIN, FGF2, GMCSF, GRO, IL1RA, IL1a, MCP1 and VEGF. Serum IL5, MCP3 and IL8 were inversely correlated with CKD stage. Notably, several cytokine levels increased through stage 4 CKD, then declined in stage 5 suggesting that cytokine elevation was not simply due to a reduction of GFR. Other cytokines increased as early as stage 1 and 2 when GFR was preserved suggesting a possible pathogenic role for these mediators. Inclusion criteria were patients with evidence of diabetic nephropathy. Patients with an active infectious or inflammatory state, exposure to immunosuppressants, renal transplant or dialysis were excluded. 20 patients were targeted from CKD stages 1 or 2 and 20 patients per stages 3,4 and 5. As a comparative group, 5 polycystic kidney disease (PKD) patients without diabetes were also targeted for inclusion from stages 1 or 2 and stages 3, 4 and 5. 90 diabetic and 22 PKD subjects met the inclusion and exclusion criteria. 25 healthy matched subjects were utilized as controls. Patients GFR were estimated from serum creatinine using the MDRD formula. Our results are consistent with other reports that inflammatory and/or immune processes may contribute to the initiation and progression of DN.

**Digital Deconstruction of Heterogeneous Renal Cell Preparations with High-Content Imaging and Cell Specific Biomarkers** Peter A. Antinozzi, Brandi C. Barnes, Daniel Deegan, Lijun Ma, Barry I. Freedman, Mariana Murea. *Wake Forest Health Sciences, Winston Salem, NC.*

Traditionally, detailed analyses of isolated cellular functions are carried out in enriched populations of a single cell type. For many biochemical measurements, isolation of cell sub-types is a necessity to eliminate what may be counter observations from contaminating cell types. In general, efforts to increase purity of specific cell types are often accompanied

by a decrease in quantity, which is further exacerbated by low abundance of the desired cell types. Thus, a major shortcoming of many physical enrichment procedures is they provide biological material of limited quantities, varying quality, and at high labor and reagent costs.

As an alternative to such enrichment procedures, we have developed a strategy to analyze heterogeneous primary cell populations. Typically, mixed cell populations would be regarded as a technical disadvantage; however our imaging-based strategy exploits heterogeneity with the ability to identify cell subtypes with specific fluorescent biomarkers and to measure multiplexed functional readouts. Thus, in a single specimen, multiple cell types can be evaluated simultaneously. The method uses a minimal quantity of biospecimen, where the analyzed area is 3mm x 3mm in a 384 multi-well plate.

The kidney has over 27 cell types, which include multiple types of tubular epithelial cells, glomerular cells, interstitial cells, and those of the vasculature. This heterogeneity and often scarce supply of tissue is well suited for our high-content imaging strategy. Here, we demonstrate two methods to identify individual cell types from primary renal cell preparations: 1) using multiplexed morphology fluoroprobes and 2) using a cell surface marker screen with over 200 probes. Bioinformatic design of cell subtype identifiers enables live cell functional assays to be performed on heterogeneous cultures, where the effects on individual cell types can be evaluated by a cell-by-cell analysis.

**Relationship between the Accuracy of Glycemic Markers and the Stage of CKD in the Patients with Type 2 Diabetes Mellitus** Koji Harada,[1] Yasuhiro Akai,[2] Mikiko Yoshikawa,[1] Hiroki Takahashi,[1] Yukinari Yamaguchi,[2] Masayuki Iwano,[2] Yoshihiko Saito.[2] *[1]Department of Nephrology, Rakuwakai-Otowa Hospital, Kyoto, Japan; [2]First Department of Internal Medicine, Nara Medical University, Kashihara, Nara, Japan.*

**Background:** Adequate glycemic control improves the survival of diabetics by reducing the macrovascular and microvascular complications of diabetes. Although glycated hemoglobin (A1C) is widely used as a reliable marker of glycemic control, A1C could underestimate the hyperglycemia in anemic and dialysis patients. Recently, it is reported that glycated albumin (GA) provide better index to estimate glycemic status in dialysis patients than A1C. This might be true in advanced CKD patients without dialysis because they have similar pathophysiological features to dialysis patients, however, adequate glycemic markers in advanced non-dialysis CKD patients have not been established. We conducted this study to evaluate the accuracy of glycemic markers in advanced CKD patients without dialysis. **Materials and Method:** 139 non-dialysis CKD patients with diabetes were enrolled. The patients were divided into 3 groups; diabetic patients with estimated GFR (eGFR) ≥60 ml/mintute/1.73 m$^2$ were referred to as group 1 (G1), 30≤eGFR< 60 were group 2 (G2), and eGFR <30 were group 3 (G3). **Result:** 28 diabetic patients were in G1, 69 in G2, and 42 in G3. GA was positively correlated with random plasma glucose (PG) in all group, and Spearman rank-correlation coefficient (Rs) decreased with deterioration of eGFR [G1: Rs=0.670, p=0.0005, G2: Rs=0.556, p<0.0001, G3: Rs=0.361, p<0.02]. A1C was positively correlated with random PG in G1 and G2, however, no significant correlation was noted in G3. To clarify the significance of A1C and GA, we examined the relations between A1C, GA and various clinical parameters. Although GA was only correlated with serum albumin, A1C was significantly correlated with hemoglobin, dose of recombinant human erythropoietin, and eGFR. **Conclusion:** Because A1C was affected by various clinical factors, it is necessary to choose the adequate glycemic markers according to the stage of CKD. GA was shown to be superior glycemic index in the patients with CKD.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1308

**ADMA and Endotoxaemia a Newly Recognised Potential Link in the Inflammatory Pathways of Chronic Kidney Disease and Dialysis** Mohamed Tarek Eldehni,[1] Mhairi K. Sigrist,[1] Jan T. Kielstein,[2] Cheuk-Chun Szeto,[3] Philip K. T. Li,[3] Chris W. McIntyre.[4] *[1]Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]Department of Nephrology and Hypertension, Medical School Hannover, Germany; [3]Medicine & Therapeutics, Chinese University of Hong Kong, China; [4]School of Graduate Entry Medicine and Health, University of Nottingham, United Kingdom.*

Asymmetric dimethylarginine (ADMA) is an endogenous inhibitor of nitric oxide (NO) that correlates with markers of cardiovascular disease (CVD) burden. ADMA levels are elevated in chronic kidney disease (CKD) and are implicated in reduced vasodilatory reserve and endothelial dysfunction. Recently endotoxaemia, resulting from probable gut translocation, has been reported across the spectrum of CKD, as a possible factor in systemic inflammation and CVD. We aimed to explore the link between ADMA and endotoxin (ET).

Serum ET and ADMA levels were measured in 134 patients (46 CKD 4, 28 PD and 60 HD). Arg, ADMA, and SDMA were measured by liquid chromatography-mass spectrophotometry and endotoxin quantified by commercially available Limulus Amoebocyte assay.

HD patients had the highest ADMA levels (0.7, IQR= 0.64-0.80) and in this group ADMA significantly correlated with ET levels (r = 0.27, P = 0.05). Overall ADMA maintained its correlation with ET (r = 0.29, P = 0.002) and its levels were highest at the highest ET tertile (Figure). It is recognised that lower serum albumin can result in reduced ADMA protein binding, leading to higher ADMA levels. This was not demonstrated in the HD group (r = - 0.16, P = 0.25).

Although high ADMA is associated with increased systemic vascular resistance; in conditions when NO generation increases (e.g. septic shock), elevated ADMA is a compensatory response to down regulate NO and maintain SVR. Extrapolating from this scenario allows us to postulate that HD patients may exhibit the same compensatory mechanism to the repeated inflammatory stress produced by repetitive and sustained systemic exposure resulting from haemodialysis induced translocation from the gut. This unrecognised link between ADMA and ET may contribute to enhance understanding the pathophysiology of Inflammation and CVD in CKD patients.

**Urinary Proteomics for Early Diagnosis in Diabetic Nephropathy** Petra Zürbig,[1] Sianna Panagaiotopoulos,[2] Stine Nielsen,[3] Richard J. Macisaac,[2] Harald Mischak,[1,4] Hans-Henrik Parving,[5,6] George Jerums,[2] Peter Rossing.[3] *[1]Mosaiques Diagnostics GmbH, Hannover, Germany; [2]Austin Health and University of Melbourne, Heidelberg, Australia; [3]Steno Diabetes Centre, Gentofte, Denmark; [4]University of Glasgow, Glasgow, United Kingdom; [5]University Hospital of Copenhagen, Rigshospitalet, Denmark; [6]Aarhus University, Aarhus, Denmark.*

Diabetic nephropathy may be detectable even at early stages in the urinary proteome. In this study we present recent data indicating that urinary proteome analysis is a valuable tool for early and sensitive detection of diabetes-associated patho-physiological changes, assessment of disease progression and monitoring of therapy success.

High-resolution capillary-electrophoresis coupled to time-of-flight mass-spectrometry (CE-MS) was used to profile the low-molecular-weight proteome in urine of diabetic patients collected in longitudinal trials for up to 15 years at two different clinical centers in Denmark and Australia.

When applying previously defined biomarker patterns for chronic kidney disease onto the data obtained from urine samples of normoalbuminuric subjects, we could demonstrate that these biomarkers enabled prediction of development of macroalbuminuria with an AUC>0.92 (p<0.001) for a period of 3-4 years. One of the hallmarks of diabetes and associated complications appears to be the increase in extracellular matrix (ECM) and the release of its components, most notably collagen. This process appears to be in part due to reduced proteolysis and is reflected at a very early stage by the decrease in urinary collagen fragments. Assessment of these seems to result in a much higher accuracy of predicting DN than clinical parameters like urinary albumin.

Urinary proteome analysis enables the non-invasive prediction of diabetic kidney disease at an early stage in normoalbuminuric patients, via determination of specific collagen fragments. This opens an avenue towards targeted therapeutic intervention towards DN potentially before irreversible damage has occurred.

**Human Urinary Peptides for Use in Diagnosis of CKD** Petra Zürbig,[1] Angel Argiles,[2] Christian Delles,[3] Jochen H. H. Ehrich,[4] Frank Eitner,[5] Danilo Fliser,[6] Mark Girolami,[3] Wilfried Gwinner,[4] Marion Haubitz,[4] Holger Jahn,[7] Bruce A. Julian,[8] Walter Kolch,[9] Andrzej S. Krolewski,[10] Mario Luppi,[11] Ziad Massy,[12] Michael Melter,[13] Jan Novak,[8] Karlheinz Peter,[14] Peter Rossing,[15] Joost Schanstra,[12] Jesns-Uwe Stolzenburg,[16] Dan Theodorescu,[17] Visith Thongboonkerd,[18] Raymond C. Vanholder,[19] Harald Mischak.[1,3] *[1]Mosaiques Diagnostics GmbH; [2]RD Néphrologie; [3]University of Glasgow; [4]Hannover Medical School; [5]RWTH University Hospital; [6]Saarland University Hospital; [7]University Hospital Hamburg-Eppendorf; [8]University of Alabama at Birmingham; [9]University College Dublin; [10]Joslin Diabetes Center; [11]University of Modena and Reggio Emilia; [12]Inserm; [13]University of Regensburg; [14]Baker Heart Research Institute; [15]Steno Diabetes Centre; [16]University of Leipzig; [17]University of Virginia; [18]Mahidol University; [19]University Hospital Ghent.*

Owing to its availability, ease of collection and correlation with physiology and pathology, urine is an attractive source for clinical proteomics. However, the lack of comparable data sets from large cohorts has greatly hindered the development of clinical proteomics. Here, we report the establishment of a reproducible, high-resolution method for peptidome analysis of naturally occurring human urinary peptides and proteins using samples from 3,600 individuals analyzed by capillary electrophoresis coupled to mass spectrometry (CE-MS). All processed data were deposited in a SQL database. This database currently contains <5,000 relevant urinary peptides that serve as a pool of potential classifiers for diagnosis and monitoring of various diseases. As an example, by using this source of information, we were able to define urinary peptide biomarkers for CKD allowing diagnosis of these diseases with high accuracy. Application of the CKD-specific biomarker set to an independent test cohort in the subsequent replication phase resulted in 85.5% sensitivity and 100% specificity. These results indicate the potential usefulness of CE-MS for clinical applications in the analysis of naturally occurring urinary peptides.

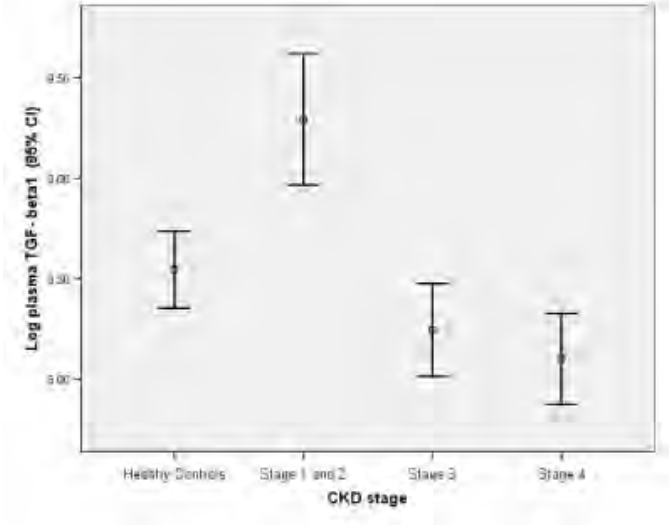
**Circulating TGF-β1 Levels Predict Progression of Chronic Kidney Disease** Priyanka Jain, Vaidyanathapura S. Balakrishnan, Madhumathi Rao. *Nephrology, Tufts Medical Center, Boston, MA.*

TGF-β1 is a multifunctional cytokine that mediates glomerulosclerosis, interstitial fibrosis and epithelial cell atrophy, processes associated with progression of chronic kidney disease (CKD). The relationship between plasma levels of TGF-β1 and CKD progression has not been explored. In a prospective cohort study we enrolled 161 adult patients with CKD (eGFR >15 ml/min); exclusions were active inflammation, re-transplant, immunosuppression or severe illness. Healthy individuals (N=54) provided baseline control comparisons. Plasma TGF-β1 was measured in patients and controls using the Quantikine Human TGF-β1 Immunoassay (R&D Systems, Inc., Minneapolis, MN). As its distribution was non-normal, TGF-β1 data was log transformed for analyses. The mean±SD age of the CKD cohort was 61±15 years, 61% were male, 81% Caucasian and 30% diabetic; 19% of subjects were CKD KDOQI stages 1 and 2, 51% stage 3 and 30% stage 4. Plasma TGF-β1 levels correlated positively with eGFR (r=0.36, p <0.001), with the highest levels seen in CKD stages 1 and 2 (median levels 9945pg/ml vs. 2836pg/ml for stage 3 and 2627pg/ml for stage 4) (figure). Patients with CKD stages 1 and 2 also showed TGF-β1 levels that were significantly higher than in healthy controls, at comparable levels of GFR (median levels 9945pg/ml vs 4535pg/ml, p<0.001). TGF-β1 levels did not differ by age, race, sex or diabetic kidney disease. TGF-β1 levels predicted CKD progression when adjusted for black race and stage of CKD (doubling of TGF-β1 levels was associated with an HR of 1.8, 95% CI: 1.1-3.0 for the composite outcome of doubling of serum creatinine or need for renal replacement therapy). Our results suggest that TGF-β1 levels predict CKD progression at all stages. However, significant elevations of TGF-β1 levels in the earlier stages of CKD highlights the important of targeted intervention in early kidney disease.



Disclosure of Financial Relationships: nothing to disclose

**F-PO1312**

**Markers of Nutrition and Inflammation Predict Mortality Independent of Each Other in CKD: NHANES III** Nirupama Ramkumar, Bradley C. Baird, Srinivasan Beddhu. *Univ Utah.*

Inflammation and malnutrition are thought to be closely interlinked but there is a paucity of data on whether markers of inflammation and nutrition predict mortality independent of each other in CKD. Therefore, we examined the associations of serum C-reactive protein (CRP), serum albumin and mid-arm muscle circumference (MAMC) with mortality in CKD in National Health And Nutrition Examination Survey (NHANES) III, a complex, multistage survey conducted by the National Center for Health Statistics (NCHS) in 1988 to 1994. The sub-population (N = 1066)with CKD (eGFR < 60 ml/min/1.73 m²) and non-missing data were included in this analysis. Mortality data were obtained by NCHS by linkage with National Death Index records through December 31, 2006.

Baseline characteristics by serum CRP levels are summarized in Table 1.

Baseline characteristics by inflammation in NHANES III CKD subpopulation

| | CRP ≤ 3 mg/L | CRP > 3 mg/L |
|---|---|---|
| Age(years) | 69±1 | 69±1 |
| Male(%) | 38 | 38 |
| Caucasian(%) | 92 | 90 |
| Diabetes(%) | 17 | 22 |
| Htn(%)* | 70 | 77 |
| MI(%)* | 12 | 20 |
| CHF(%)* | 8 | 16 |
| Stroke(%) | 9 | 9 |
| Cancer(%) | 11 | 9 |
| Smoker(%)* | 9 | 18 |
| GFR* | 51±1 | 48±1 |
| BMI(kg/m²)* | 27±2 | 29±1 |
| MAMC(cm) | 26±1 | 26±1 |
| Serum albumin(mg/dl)* | 4.1±0.1 | 3.9±0.1 |

* p ≤ 0.05

There were 715 deaths over average of 76.3 months of follow-up. Because proportionality assumptions were violated by CRP, Cox proportional hazards models were constructed for early (< 36 months of follow-up) and late (≥ 36 months of follow-up) periods. After adjusting for age, gender, race, diabetes, hypertension, stroke, CHF, MI, cancer, smoking, and eGFR, in the early period, serum CRP (for each doubling HR 1.29, 95% CI 1.13-1.47), serum albumin (for each g/dl increase HR 0.48, 95% CI 0.30-0.75) and MAMC (for each cm increase HR 0.87, 95% CI 0.82-0.93) were associated with mortality. In the late period, the corresponding HR (95% CI) for serum CRP, serum albumin and MAMC were 1.02 (0.93-1.12), 0.58 (0.39-0.85) and 0.93 (0.89-0.98), respectively.

We conclude that muscle mass and inflammation are independent predictors of death in CKD. Therefore, interventions that target muscle mass might improve survival in CKD even in those with inflammation.

**The Association of Parathyroid Hormone Levels and the Metabolic Syndrome in Chronic Kidney Disease** Georges Saab,[1] Adam Whaley-Connell,[2] Suying Li,[3, 4] Keith C. Norris,[5] George L. Bakris,[6] Peter A. McCullough.[7] *[1]Washington University School of Medicine, St. Louis, MO; [2]University of Missouri-Columbia School of Medicine, Columbia, MO; [3]KEEP Data Coordinating Center, Minneapolis, MN; [4]Minneapolis Medical Research Group, Minneapolis, MN; [5]David Geffen School of Medicine, Univ of California, Los Angeles, CA; [6]University of Chicago School of Medicine, Chicago, IL; [7]William Beaumont Hospital, Royal Oak, MI.*

OBJECTIVE: To examine the relationship of parathyroid hormone (PTH) and the Metabolic Syndrome (MetS) among non-diabetic persons with chronic kidney disease (CKD).

METHODS: This was a cross-sectional analysis of 3215 non-diabetic participants in the National Kidney Foundation-Kidney Early Evaluation Program (KEEP) found to have CKD (eGFR <60 ml/min/1.73m²) examining the relationship of PTH levels and the MetS.

RESULTS: In unadjusted analysis, the prevalence of the MetS increased along increasing PTH quartiles (31.7%, 33.8%, 37.3%, and 48.7% respectively, p for trend <.0001). After multivariate adjustment, as compared to the first PTH quartile, odds of the MetS were 16% (p=.18), 35% (p=.006), and 89% (p <.0001) higher for the second, third, and fourth quartiles respectively. When taken as a continuous predictor, each standard deviation increase of natural log transformed PTH was associated with a 26% (p<.0001) higher odds of the MetS. The association of PTH with the MetS was not modified by age or gender (p for interaction = NS for both modifiers).

CONCLUSIONS: Among an outpatient non-diabetic population with CKD, higher PTH levels were associated with an increasing prevalence of the MetS.

**Biomarkers of Endothelial Dysfunction in the Continuum of CKD: Relationship to Medication Use** Darius Mason, Magdalene M. Assimon, Katie E. Cardone, Darren W. Grabe, Amy B. Pai. *ANephRx, Albany College of Pharmacy & Health Sciences, Albany, NY.*

Endothelial dysfunction contributes to the pathogenesis of cardiovascular disease (CVD) in chronic kidney disease (CKD). Soluble adhesion molecules (e.g. sICAM) are easily measured biomarkers that correlate with diagnostic measures of endothelial dysfunction. The aims of this study were to characterize concentrations of adhesion molecules in the continuum of worsening kidney function and to explore possible relationships with commonly used medications.

CKD patients ≥18 years old with an etiology of diabetes and/or hypertension were enrolled in the Albany Pharmacy Bio-surveillance Cohort Study, designed to evaluate the relationship of medications with relevant CVD biomarkers. This study represents a cross-sectional baseline analysis. Medical histories, laboratory values and medication lists were obtained. Plasma markers of endothelial dysfunction including sICAM-1, P-selectin and E-selectin were measured by multiplex bead array assay. Student's t-test was used to compare between CKD groups and within group comparisons were made using Wilcoxon Rank Sum test.

Thirty-two CKD (age 64.8±14.5 years, 40.6% male, GFR 33.8±15.6 ml/min/1.73m2) and forty hemodialysis (HD) (age 64.3±15.6 years, 52.5% male, HD vintage 3.4±2.8 years) were included in this analysis. sICAM concentrations were higher in pre-dialysis patients compared to HD patients (223.41 ng/ml [175.2-403.5] vs. 194.4 ng/ml [105.4-383.7], p=0.009). Conversely, P-selectin and E-selectin concentrations were lower in CKD vs. HD patients: P-selectin (72.3±29.1 ng/ml vs. 102.9±58.2 ng/ml, p=0.0053) and E-selectin (56.2±25.6 ng/ml vs. 88.2±50.5 ng/ml, p=0.0009). Among HD patients, statin use (n=18) was associated with lower P-selectin concentrations (p=0.05) and ergocalciferol use (n=20) was associated with lower sICAM and P-selectin concentrations (p=0.004 and p=0.017, respectively).

These data suggest biomarker profiles of endothelial dysfunction may change as kidney disease progresses. The association of statin and ergocalciferol use with lower adhesion molecules suggests possible non-classical effects of these agents and warrants further investigation.

**The Association of Parathyroid Hormone, Calcium, and Phosphorus Levels and Short Term Mortality in Persons with Chronic Kidney Disease Not on Dialysis** Georges Saab,[1] Adam Whaley-Connell,[2] Suying Li,[3,4] Shu-Cheng Chen,[3] Keith C. Norris,[5] George L. Bakris,[6] Peter A. McCullough.[7] *[1]Washington University School of Medicine, St. Louis, MO; [2]University of Missouri-Columbia School of Medicine, Columbia, MO; [3]KEEP Data Coordinating Center, Minneapolis, MN; [4]Minneapolis Medical Research Group, Minneapolis, MN; [5]David Geffen School of Medicine, Univ of California, Los Angeles, CA; [6]University of Chicago School of Medicine, Chicago, IL; [7]William Beaumont Hospital, Royal Oak, MI.*

To examine the association of Ca, Phos, and PTH levels among persons with CKD (eGFR < 60 ml/min/1.73m²) and short term mortality

This was a cross-sectional analysis of 5780 participants in the National Kidney Foundation-Kidney Early Evaluation Program (KEEP) found to have CKD (eGFR <60 ml/min/1.73m²) and not on dialysis examining the relationship of Ca, Phos, and PTH levels with short term mortality.

Of 5780 KEEP participants with CKD, a total of 152 deaths occurred over a median follow-up of 2.0 years. After adjustment for age, race, gender, smoking, alcohol use, eGFR, education level, recent doctor visits, insurance coverage, prior CVD, each standard deviation increase in natural log transformed PTH was associated with a 20% higher risk of death (HR: 1.20 (95% CI: 1.01-1.44,p=.04). Conversely, each 1 mg/dL increase in serum calcium and phosphorus was not associated with increased mortality (HR: 0.81 (95% CI: 0.58-1.12,p=.20) and 0.86 (95% CI: 0.66-1.13,p=.27 respectively). Since PTH levels are associated with an increased prevalence of the MetS, we additionally adjusted for individual components of the MetS (hypertension, dysglycemia, dyslipidemia, obesity, and microalbuminuria). After additional adjustment, the association PTH and mortality was mildly attenuated (HR 1.18 (95% CI: 0.98-1.41,p=.08) and while there was a strong trend, it was no longer statistically significant.

Higher PTH levels are associated with increased risk of death, possibly due to a higher prevalence of the MetS and possibly through other pathways. Higher calcium and phosphorus levels are not associated with short term mortality.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1316**

**A Low 25D3 Level Is Associated with Increased Prevalence of Comorbidities in the General Population across a Wide Range of eGFR** Francis Dumler. *Division of Nephrology, William Beaumont Hospital, Royal Oak, MI.*

Several epidemiological and clinical observations suggest that a deficient vitamin D status may increase the risk of cardiovascular events, decrease insulin secretion and sensitivity, and enhance inflammation. We evaluated the relationship between vitamin D, and the prevalence of comorbid conditions in 10,617 NHANES participants (age: 47 ± 20 years; 24% black, 76% white, and 47% female. Comorbidities evaluated: congestive heart failure (CHF), stroke (CVA), hypertension (HTN), diabetes mellitus (DM), hypercholesterolemia (CHOL), myocardial infarction (MI), and peripheral vascular disease (PVD). Participants were allocated to one of three vitamin D levels (Group I: < 20; Group II: 29 – 39.9; Group III: 40 – 100) mg/dL.

Biochemical, nutritional and inflammatory parameters are shown below:

Group I: BMI 26 ± 4 kg/m2, serum calcium 9.3 ± 0.4 mg/dL, serum phosphorus 3.5 ± 0.5 mg/dL, CRP 0.44 ± 0.70 mg/dL; Phase Angle 7.47 ± 1.22 º; eGFR 74 ± 17 mL/min/1.73m2.

Group II: BMI 26 ± 4 kg/m2, serum calcium 9.3 ± 0.4 mg/dL, serum phosphorus 3.4 ± 0.5 mg/dL, CRP 0.41 ± 0.80 mg/dL; Phase Angle 7.55 ± 1.13 º; eGFR 68 ± 14 mL/min/1.73m2.

Group III: BMI 24 ± 4 kg/m2, serum calcium 9.3 ± 0.4 mg/dL, serum phosphorus 3.4 ± 0.5 mg/dL, CRP 0.40 ± 0.69 mg/dL; Phase Angle 7.57 ± 1.13º; eGFR 67 ± 14 mL/min/1.73m2.

Differences between groups were statistically significant (P<0.001).

The prevalence for positive comorbid conditions is shown below:

Group I: CHF 3%, CVA 2%, HTN 25%, DM 8%, CHOL 33%, MI 4%, PVD 23%

Group II: CHF 3%, CVA 2%, HTN 24%, DM 6%, CHOL 33%, MI 4%, PVD 21%

Group III: CHF 2%, CVA 2%, HTN 19%*, DM 3%*, CHOL 34%, MI 4%, PVD 18%*

*P<0.0005

Differences between vitamin D groups and biochemical and anthropometric parameters were statistically significance but with no clinical value. However, the decreasing prevalence of the comorbid conditions with incremental vitamin D level indeed suggests a protective effect on HTN, Dm and PVD. These salutary effects remained significant across a wide range of eGR.

These observations add credence to the efforts in raising prevailing serum of vitamin D levels in the general population.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1317**

**Use of Phase Angle Parameter for Identification of Malnutrition and Micro Inflammation in the General Non Dialysis Dependent Chronic Kidney Disease Population** Francis Dumler. *Division of Nephrology, Willaim Beaumont Hospital, Royal Oak, MI.*

Malnutrition, whether alone or in combination with a micro inflammatory is clearly associated with increased morbidity and mortality in dialysis patients. A low bioimpedance phase angle (an index of tissue hydration, cell membrane integrity, and cell mass) may be a consequence of both processes. Our objective was to determine if a low phase angle is associated with the presence of malnutrition and inflammatory markers in 10,242 NHANES III participants (age: 47 ± 20 years; 24% black, 47% female; eGFR 71 ± 16 (range 20-120) mL/min/1.73m2. Study parameters were evaluated by phase angle tertile groupings (< 7.0o, 7.0-8.9 o, and 9.0-12.0 o). Results were as follow:

Low tertile: haemoglobin 13 ± 1 g/dL, lymphocyte/white blood cell ratio 0.316 ± 0.09, serum iron 83 ± 34 µg/dL, CRP 0.52 ± 0.89 mg/dL, serum albumin 40 ± 3 g/L, µalbuminuria 59 ± 440 mg/dL, body cell mass 23 ± 6 kg, fat free mass 49 ± 12 kg.

Middle tertile: haemoglobin 14 ± 1 g/dL, lymphocyte/white blood cell ratio 0.331 ± 0.08, serum iron 90 ± 38 µg/dL, CRP 0.39 ± 0.67 mg/dL, serum albumin 42 ± 3 g/L, µalbuminuria 32 ± 256 mg/dL, body cell mass 26 ± 6 kg, fat free mass 51 ± 12 kg.

Upper tertile: haemoglobin 15 ± 1 g/dL, lymphocyte/white blood cell ratio 0.342 ± 0.09, serum iron 98 ± 39 µg/dL, CRP 0.35 ± 0.54 mg/dL, serum albumin 43 ± 3 g/L, µalbuminuria 23 ± 123 mg/dL, body cell mass 30 ± 6 kg, fat free mass 57 ± 12 kg.

The differences between groups across the phase angle tertiles were statistically significant (P<0.001), and were maintained at a wide range of both eGFR and age during post hoc testing. All potential inflammatory markers outlined above were significantly correlated with body cell mass and fat free mass (P<0.001) by simple regression analysis. In addition, they were found to be independent determinants of a decreased nutritional status by multivariate and logistic regression analysis at a wide range of eGFR and age ranges.

In conclusion, a low phase angle is associated with the presence of a micro inflammatory processes and a lower nutritional status in the general population as sampled by the NHANES III study.

**F-PO1318**

**Central Fat Distribution Is More Closely Related with Key Risk Factors Than Elevated BMI in Patients with CKD Stage 3** Philip D. Evans,[1] Natasha J. Mcintyre,[1] Richard J. Fluck,[1] Chris W. McIntyre,[1,2] Maarten W. Taal.[1] *[1]Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]School of Graduate Entry Medicine, University of Nottingham, Derby, United Kingdom.*

**Purpose:** Body Mass Index (BMI) as a marker of obesity is an established risk factor for chronic kidney disease (CKD) and cardiovascular disease (CVD). However, BMI can overestimate obesity. Waist-to-hip ratio (WHR), a marker of central obesity, is emerging as a more important risk factor. We studied BMI and WHR in a cohort of patients with CKD stage 3 and compared the results with other known risk factors for CKD progression and CVD.

**Methods:** We recruited 1741 patients with CKD stage 3 from primary care for the Renal Risk in Derby study. Each participant underwent clinical assessment, including measurement of BMI, WHR, pulse wave velocity (PWV) and urine and serum biochemistry tests.

**Results:** The mean age (±SD) of the cohort was 72.9±9yrs with 60% female. Mean BMI was 29.1±5 kg/m² and mean WHR was 0.91±0.09. 37% of the cohort was classified as obese (BMI ≥30 kg/m²) and 88% classified as centrally obese (waist to hip ratio >0.8 for females and >0.9 for males).

Central obesity was associated with a higher mean uric acid, PWV, albumin:creatinine ratio (ACR) and a lower mean eGFR(p=<0.01). BMI ≥30kg/m² was associated with a higher mean uric acid and a lower mean PWV(p=<0.01).

Univariate analysis revealed significant correlations between BMI and age(r=-0.13; p=<0.001), uric acid(r=0.19; p=<0.001) and PWV(r=-0.13; p=<0.001). Significant correlations were also revealed between WHR and age (r=0.11; p=<0.001), uric acid(r=0.31; p=<0.001), PWV(r=0.12; p=<0.001), ACR(r=0.1; p=<0.001) and eGFR (r=-0.17; p=<0.001).

Multivariable linear regression analysis identified WHR as an independent determinant of ACR, uric acid and PWV, when modelled with other known risk factors(p=<0.001). BMI was identified as an independent determinant of PWV (inversely), uric acid and eGFR(p=<0.05).

**Conclusions:** WHR is closely related to more key risk factors in CKD stage 3 patients than BMI. Central obesity as represented by WHR may be of greater importance as a risk factor in CKD than BMI and reliance on BMI alone may therefore underestimate the associated risk.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1319**

**Plasma and Urinary Levels of Vasohibin-1 in Patients with Chronic Kidney Disease** Daisuke Saito,[1] Yohei Maeshima,[1] Tatsuyo Nasu,[1] Hiroko Yamasaki,[1] Norikazu Hinamoto,[1] Masaru Kinomura,[1] Shinji Kitamura,[1] Hitoshi Sugiyama,[2] Hirofumi Makino.[1] *[1]Medicine and Clinical science, Okayama university, Okayama, Japan; [2]Center for Chronic Kidney Disease and Peritoneal Dialysis, Okayama university, Okayama, Japan.*

CKD is associated with cardiovascular complications and tubulointerstitial ischemia is involved in the progression of CKD. Vasohibin-1 (MW: 43 kD) is an unique endogeneous angiogenesis inhibitor, initially identified in endothelial cells induced by proangiogenic factors such as VEGF-A, serving as a negative feedback regulator of angiogenesis. The aim of the present study is to examine the plasma and urinary levels of Vasohibin-1 in patients with chronic kidney disease (CKD) and to evaluate its clinical usefulness. We measured plasma and urinary levels of Vasohibin-1 by ELISA in 69 patients with CKD and assessed the relationship between the levels of Vasohibin-1 and clinical parameters or histological findings of renal biopsy specimens. The levels of plasma Vasohibin-1 were significantly lower in hypertensive patients as compared to non-hypertensive patients and inversely correlated with systolic blood pressure (r=0.551, P<0.0001), but were not correlated with renal function or proteinuria. Urinary Vasohibin-1 levels were significantly lower in patients with CKD stages 3-5 (eGFR <60), and there was a significant positive correlation between urinary Vasohibin-1 levels and eGFR (r=0.369, P=0.0065). Urinary Vasohibin-1 levels tended to be lower in patients with moderate to severe interstitial fibrosis and tubular atrophy compared with those with no or mild involvement. Taken together, these results suggest that plasma levels of Vasohibin-1 may reflect systemic vascular endothelial dysfunction in association with hypertension and that reduction of urinary Vasohibin-1 may reflect tubulointerstitial injuries and ischemia in patients with CKD, potentially counterbalancing excessive anti-angiogenic milieu.

**F-PO1320**

**Intact PTH as a Predictor of Renal Recovery in Acute Kidney Injury** Hilana H. Hatoum,[1] Ali K. Owda,[1] Fadi S. Rzouq.[2] *[1]IM/Renal Division, MRMC, Flint, MI; [2]IM, University of Washington, Seattle, WA.*

Background:AKI is the abrupt loss of kidney function that results electrolyte dysregulation as well as the accumulation of nitrogenous waste products. Renal recovery (RR) post AKI is an important concept that is understudied. We sought to evaluate the prognostic power of elevated intact-PTH during AKI on RR in the next 6-12 months (T1) after hospital discharge (RR defined as having glomerular filtration rate (GFR) at T1 >75% of baseline (T0) GFR which is measured within the last year before admission for AKI). Method:Patients who were discharged from a tertiary medical center with the diagnosis of AKI were involved in the study. Patients' charts were reviewed and those who had a T0 GFR, PTH level and T1 GFR were involved. Patients were then divided into 2 groups: Group A with incomplete RR (T1 GFR <75% of T0 GFR) and Group B with complete RR (T1 GFR >75% of T0 GFR). Characteristics of patients in both groups were recorded and multiple regression analysis was applied to evaluate if any variable could predict achieving complete Vs incomplete RR.Results:1200 charts of patients with AKI were reviewed, of whom 42 met the criteria and were the final study group. 18 patients had incomplete RR (group A) Vs 24 patients had complete RR (Group B). Patients in both groups were similar in baseline characteristics including age (64.3 Vs 63, expressed as group A Vs B, P of 0.8), gender, race, T0 GFR ( 92.9 Vs 90.8 ml/min, P 0.7), presence of HTN (P 0.7) and DM (P 0.8). None of these variables was able to predict the status of RR. Nevertheless, PTH level was significantly higher among group A patients (109+_68) compared to group B (74.1 +_30), (P 0.03). Logistic regression analysis was applied with a PTH value >100 as the independent variable and achieving complete RR as the dependent variable. Patients with elevated PTH >100 were more likely to have incomplete RR but that didn't reach statistical significance (OR 4.0, 95% CI 0.96-16.5). Conclusion: Intact PTH level during AKI seems like a promising predictor of RR in the future. This may help risk stratify patients discharged after an episode of AKI and may dictate a closer follow up for them in the future.

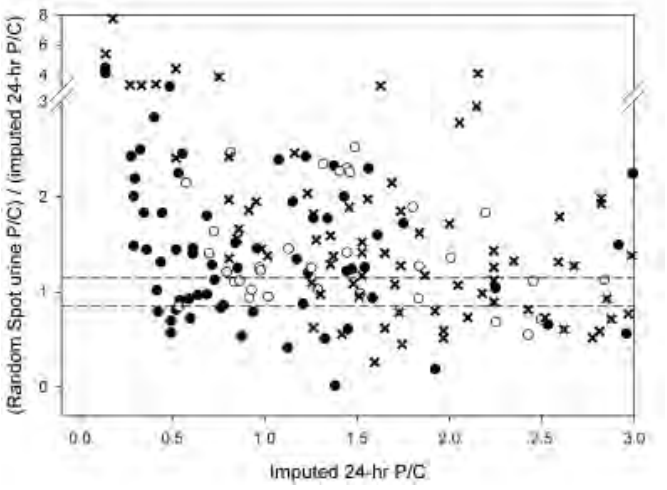
**Random Spot Urine Protein/Creatinine (P/C) Ratio Is an Unreliable Estimate of 24-hr Proteinuria in Individual Chronic Kidney Disease (CKD) Patients** Ganesh B. Shidham,[1] Daniel J. Birmingham,[1] Haikady Nagaraja,[2] Brad H. Rovin,[1] Lee A. Hebert.[1] *[1]Internal Medicine/Nephrology, Ohio State University Medical Center, Columbus, OH; [2]Statistics, Ohio State University, Columbus, OH.*

K-DOQI recommends monitoring random spot P/C ratio to monitor proteinuria because of the numerous studies showing high correlation coefficients (CC) between random spot P/C ratio and 24-hr proteinuria. However, the high CC are mainly the result of comparing these variables over a large range (AJKD 47(1):8-14, 2006). In SLE GN patients, 2 independent studies show that, although spot P/C and 24-hr proteinuria are correlated, concordance is poor. Thus, use of P/C ratio would commonly result in diagnostic errors regarding proteinuric flare (Kidney Int 72:865-870, 2007; Neph Clin Pract 113:c177-c182, 2009). The present work uses the approach of the SLE GN study (ibid. Neph Clin Pract) but applies it to CKD patients. A systematic literature review identified 3 CKD studies with suitable measures of spot P/C ratio and data to estimate imputed 24-hr urine P/C ratio (ibid. Neph Clin Pract). Our analysis shows the calibration plot in relationship to the expected limits of agreement (dashed lines) if random spot P/C ratio was as accurate as the 24-hr urine P/C ratio in estimating 24-hr proteinuria (ibid. Kidney Int).



Each study's results are represented by a different symbol. The calibration plot is for those with sub-nephrotic proteinuria. Similar inaccuracy is seen in those with nephrotic proteinuria. Conclusion: Random spot urine P/C ratio is highly inaccurate for estimating 24-hr proteinuria in individuals with CKD. To monitor proteinuria, we recommend the P/C ratio of intended 24-hr collections that are at least 50% complete (ibid. Kidney Int, Neph Clin Pract). These collections can also be used to estimate salt and protein intake, which is important in CKD management.

**Correlates of Resistin in Children with CKD** Edward Nehus,[1] Susan L. Furth,[2] Bradley A. Warady,[2] Mark Mitsnefes.[1,2] *[1]Cincinnati Children's Hospital Medical Center; [2]CKiD Study.*

Resistin, a 12.5 kDa protein secreted by mouse adipocytes, has been implicated in the development of insulin resistance in murine models. However, its contribution to insulin resistance in humans is uncertain. The aims of this study were: 1) to determine resistin concentrations in children with CKD and their association with demographic and clinical parameters and 2) to evaluate its potential association with insulin resistance.

We cross-sectionally analyzed data from 222 children and adolescents from the CKiD cohort who had serum resistin levels measured. Cohort characteristics were as follows: median age 13 years, median GFR 43ml/min/1.73m2, 58% male, 48% pre-pubertal. GFR was estimated using iohexol disappearance. Univariate analyses were performed to assess associations between resistin and the following data: iGFR, insulin resistance markers, lipid profiles, urine protein/creatinine ratios, and demographic characteristics of interest. Significant associations were then included in a multivariate analysis.

Statistically significant correlations with resistin levels in univariate analyses included average weight (r = 0.15; p<0.05), iGFR (r = -0.029; p<.0001), triglyceride level (r = 0.13; p<.05), HDL (r = -0.17, p<.05), and log urine protein/creatinine ratio (r = 0.24, p<.001). HOMA-IR was not significantly associated with resistin in univariate analysis. In multivariate analysis, higher iGFR and pubertal stage were independently associated with resistin levels.

Multivariate Analysis of predictors of resistin

| Variable | Coefficient | 95% C.I. | p value |
|---|---|---|---|
| Pre-pubertal | -0.25 | -0.39, -0.11 | <.001 |
| iGFR | -0.01 | -0.02, -0.01 | <.0001 |

Our study showed that levels of resistin become increasingly elevated with GFR decline in children with CKD. Furthermore, it demonstrated that elevated resistin levels were not associated with insulin resistance in the CKiD participants.

**Predictors of Longitudinal Change in Neurocognitive Functioning in Pediatric CKD** Stephen R. Hooper,[1] Arlene C. Gerson,[8] Robert W. Butler,[9] Debbie S. Gipson,[2] Marc Lande,[3] Susan R. Mendley,[4] Shlomo Shinnar,[10] Matthew Matheson,[8] Christopher Cox,[8] Bruce Z. Morgenstern,[5] Susan L. Furth,[6] Bradley A. Warady.[7] *[1]U. North Carolina; [2]U. Michigan; [3]U. Rochester; [4]U. Maryland; [5]Phoenix Children's Hospital; [6]Children's Hospital of Philadelphia; [7]U. Missouri; [8]Johns Hopkins; [9]Oregon Health Sciences Center; [10]Albert Einstein College of Medicine.*

**Purpose:** To determine how changes in kidney function over time relate to changes in neurocognitive abilities.

**Methods:** The sample comprised 224 children and adolescents, average age of 10.9 yrs, with a median baseline iGFR = 44.4 ml/min/1.73m$^2$. About 24% had CKD from a glomerular diagnosis. Measures of IQ and executive functions were obtained at baseline and at 2 year intervals, with 224 participants having at least two assessments. Baseline

cognitive scores were within the average range. Longitudinal mixed models were used to examine the predictive value of CKD-related variables (i.e., glomerular diagnosis, age at CKD diagnosis, CKD duration, iohexol GFR [iGFR] at baseline, iGFR change, degree of proteinuria, hypertension, anemia) on the neurocognitive outcomes.

**Results:** Increasing proteinuria was associated with a decline in Full Scale IQ ($p<.03$) such that having elevated proteinuria (protein/creatinine ratio >2) was associated with Full Scale IQ being 3 points lower. Lower baseline iGFR was associated with a decline in Performance IQ ($p<.03$), although having a baseline iGFR 10 units lower was associated with only a 0.9 point decrease. A greater decline in iGFR predicted lower ratings of Behavior Regulation over time ($p<.05$), such that a 1-unit decline in iGFR was associated with a 0.2 unit worsening of behavioral regulation.

**Conclusions:** The CKD variables of lower baseline iGFR, declining iGFR, and increased proteinuria were significant predictors of declines in neurocognitive functions over time. Glomerular diagnosis, age of diagnosis, CKD duration, anemia, and change in hypertension did not predict neurocognitive changes. Findings suggest that baseline levels of iGFR or changes in selected CKD variables place children at-risk for at least mild neurocognitive deterioration.

Disclosure of Financial Relationships: nothing to disclose

**Higher Level of Proteinuria during RAS Inhibitors Treatment Is a Strong Predictor for Renal Outcome in Non-Diabetic Kidney Disease** Di Xie, Fan Fan Hou, Xun Zhang, Min Liang, Biling Fu. *Nephrology, Nanfang Hospital, Guangzhou, Guangzhou, Guangdong, China.*

This study is to investigate whether proteinuria could not only serve as a marker of renal outcome, but also function as a monitor of the renoprotection of renin-angiotensin-system (RAS) inhibitors treatment, in patients with non-diabetic chronic kidney disease (CKD). The data from the Renoprotection of Optimal Antiproteinuric Doses (ROAD) trial were used to examine the contribution to the antiproteinuric effect of benazepril and losartan on the renal outcome (the primary composite end point of doubling of serum creatinine and end stage renal disease or death) in 339 Chinese non-diabetic CKD patients with overt proteinuria and renal insufficiency. The degree of proteinuria at month 6 of treatment (residual proteinuria) and during follow-up (time average proteinuria, TA-proteinuria) showed a close relationship with renal endpoint. Lowering of proteinuria reduced risk of renal progression in patients with high, as well as low proteinuria at baseline. After adjusting for baseline risk markers, therapy-induced change in these variables at month 6 and during follow-up, high residual proteinuria and TA-proteinuria (≥1.0 g/d) remained the independent predictors for renal endpoint. Therefore, minimization of proteinuria at least to the level <1.0 g/d should be a therapeutic goal in the management of non-diabetic patients with heavy proteinuria and renal insufficiency.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1325

**Elevated Serum Intact Parathyroid Hormone May Predict Increased Cardiovascular Events in Moderate Chronic Kidney Disease** Smrita Dorairajan, Anton Lishmanov, Kunal Chaudhary, Anand Chockalingam, Youngju Pak. *Divisions of Cardiology & Nephrology, Harry S Truman Memorial Veterans Hospital, Columbia, MO.*

**Introduction:** Over 8% of adults in the United States are estimated to have moderate (stage III and IV) chronic kidney disease (CKD) which is increasingly recognized as one of the strongest independent predictors for cardiovascular (CV) disease and related mortality. Secondary hyperparathyroidism with elevated serum intact parathyroid hormone (iPTH) is associated with increased all-cause and CV mortality in end stage renal disease, but limited data in CKD.

**Hypothesis -** iPTH elevation is associated with increased CV events in patients with moderate CKD.

**Methods -** Medical records of 196 CKD stage III and IV (glomerular filtration rate, GFR 16-59ml/min/1.73 $m^2$) patients at Harry S. Truman Memorial Veterans Hospital who had iPTH levels determined from 4/2006 to 9/2007 were reviewed. CV event was defined as occurrence of any of the following during follow-up: Myocardial infarction, stroke, coronary/carotid/peripheral artery revascularization and death due to CV reasons. The Wilcoxon rank sum test was used to compare the distribution of iPTH level between the two CV event groups. Multivariate analysis was performed using the multivariate logistic model.

**Results -** During median follow up of 27.2 months, 48 patients had CV events while 148 did not. Both groups were well matched with no significant clinical and CV risk profile differences at baseline. iPTH was elevated (156.43±107.49) for patients who had CV events compared to those without (109.12 ±86.54, p=0.003). Among the covariates studied in the multivariate analysis including history of vascular disease, 25-OH Vit D, corrected calcium, phosphorus, calcium phosphorus product and GFR, iPTH level was found to have a positive association with CV events (odds ratio=1.58 as 10 unit changes in iPTH, p=0.03). Vascular disease history was the only other significant variable with estimated odds ratio of 5.9 (p=0.002).

**Conclusion-** iPTH level in stage III and IV CKD patients is associated with increase in cardiovascular events. This effect was independent of phosphorus level and calcium phosphorus product.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1326

**Proteins Induced by Vitamin K Absence or Antagonism (PIVKA-II); a Comparison of Biomarkers of Subclinical Vitamin K Deficiency in Dialysis Patients** Meghan J. Elliott,[1] Wilma M. Hopman,[2] Jocelyn S. Garland,[3] Alexander R. Morton,[3] Rachel M. Holden.[3] *[1]Medicine, University of Calgary, Calgary, AB, Canada; [2]Clinical Research Center, Kingston General Hospital, Kingston, ON, Canada; [3]Medicine, Queen's University, Kingston, ON, Canada.*

**Introduction**

Vitamin K dependent proteins (VKDPs) play an important role in the inhibition of vascular calcification. We determined the prevalence of subclinical vitamin K deficiency in our hemodialysis population. In this cross-sectional study, vitamin K status was determined as circulating concentrations of phylloquinone, PIVKA-II, percentage undercarboxylated osteocalcin (%ucOC), apolipoprotein E (apoE) genotype and vitamin K Epoxide Reductase (VKOR) polymorphism. 44 patients with a mean age of 64.2 years (SD 14.5) and median dialysis duration of 34.5 months (range 3-183) were enrolled. Criteria for subclinical vitamin K deficiency were met in 13.6% (phylloquinone <0.4 nM/L), 50% (%ucOC > 20%) and 90.9% (PIVKA-II > 2.0 nM/L) of subjects. In bivariate analysis, phylloquinone was positively associated with total cholesterol (r=0.43, p=0.004), triglyceride levels (r=0.45, p=0.002) and non-smoking status (p=0.043). Higher %ucOC was associated with increased serum calcium-phosphate product (r=0.40, p=0.009). Increased PIVKA-II levels were observed with advancing age (r=0.37, p=0.015), reduced dialysis adequacy (r=-0.33, p=0.027), lower HDL (r=-0.31, p=0.046), a history of coronary artery disease (CAD) (p=0.009). In our regression analysis model, serum triglycerides (TG) were the only significant predictor of phylloquinone (p=0.004). Increasing phosphate (p=0.006) and decreasing PTH (p=0.041) were independent predictors of %ucOC. PIVKA-II levels increase by 0.54 nM/L for every 10-year increase in age (p=0.033). In summary, 50% (%ucOC) and 90% (PIVKA-II) of subjects met criteria for sub-clinical vitamin K deficiency. Phosphate concentrations, CAD, VKOR homozygosity (%ucOC); and age (PIVKA-II) were significant predictors of sub-clinical vitamin K deficiency in our models. Future research should examine the impact of sub-clinical vitamin K deficiency on clinical outcomes such as vascular calcification and bone health.

**Complications of Chronic Kidney Disease (CKD) by Level of Albuminuria and Measured Glomerular Filtration Rate (GFR) in the MDRD Study** Gautham Viswanathan,[1] Hocine Tighiouart,[1] Paul Muntner,[2] Mark J. Sarnak,[1] Lesley A. Stevens.[1] *[1]Tufts Medical Center; [2]University of Alabama at Birmingham.*

Based on the improved prediction of cardiovascular and renal outcomes, it has been proposed to revise the classification of CKD using levels of both albuminuria and GFR. However, it is not known whether albuminuria is associated with concurrent complications of CKD.

**Methods** Cross-sectional analysis of 1713 participants screened for the Modification of Diet in Renal Disease (MDRD) Study evaluated the association of albumin-creatinine ratio (ACR) and GFR with anemia (hemoglobin < 12 g/dL for women, <13.5 g/dL for men), acidosis (bicarbonate < 22 mmol/L) and hyperphosphatemia (phosphate > 4.6 mg/dL) using logistic regression.

**Results** The mean GFR was 39 ml/min/1.73$m^2$ (SD 21) and the median ACR was 152 mg/g (IQR 631). The table shows the associations of ACR categories with anemia, acidosis and hyperphosphatemia. In multivariable models adjusted for age, sex, race and ACR, GFR levels lower than 30 ml/min/1.73$m^2$ were associated with higher odds (95% CI) of anemia 13.76 (9.23-20.50), acidosis 7.31 (4.71-11.33) and hyperphosphatemia 31.98 (11.63-87.95) when compared to GFR levels greater than 60ml/min/1.73$m^2$.

**Conclusions** Albuminuria had a significant relationship with hyperphosphatemia and showed a trend with acidosis in non-diabetic kidney disease. The implications of these findings in the management of CKD should be taken into account when considering including albuminuria level in the classification of CKD.

Table: Adjusted OR for CKD complications associated with level of ACR

| | | ACR, mg/g | | | |
|---|---|---|---|---|---|
| | Adjustment | <29 (n=323) | 30-299 (n=721) | > 300 (n=669) | p-trend |
| Anemia | Age | 1 (ref) | 1.71 (1.28-2.28) | 2.81 (2.10-3.76) | <0.001 |

**25-Hydroxyvitamin D Deficiency Is Associated with an Increased Risk of Metabolic Syndrome in Patients with Severe Chronic Kidney Disease**
Jessica B. Kendrick,[1] Alfred K. Cheung,[2,4] James S. Kaufman,[3] Tom H. Greene,[4] William L. Roberts,[4] Gerard John Smits,[1] Michel B. Chonchol.[1] *[1]University of Colorado Denver Health Sciences Center, Denver, CO; [2]VASLCHCS, Salt Lake City, UT; [3]VA Boston Healthcare System, Boston, MA; [4]University of Utah, Salt Lake City, UT.*

Purpose: 25-hydroxyvitamin D (25(OH)D) deficiency has been associated with insulin resistance and the metabolic syndrome (MetS) in the general population. Patients with CKD have a high prevalence of 25(OH)D deficiency but the relationship between 25(OH) D levels and MetS is unknown.

Methods: This study was conducted among 1,099 subjects with severe kidney disease, not yet on dialysis, who participated in the Homocysteine in Kidney and End Stage Renal Disease study. 25(OH)D levels were measured in stored plasma samples. Participants met criteria for MetS if all three of the following were present: (1) Triglycerides ≥150 mg/dl or drug treatment; (2) high density lipoprotein-cholesterol <50 mg/dl for women or <40 mg/dl for men or drug treatment; and (3) blood pressure ≥130/85 mmHg or drug treatment. Multivariate regression models were used to evaluate the cross-sectional association between 25(OH)D levels and MetS.

Results: The mean (SD) age, eGFR and 25(OH)D was 69±11 years, 18.1± 6.5 mL/min/1.73m2 and 20 ±11 ng/mL. After adjustment for baseline demographics, body mass index, albumin, calcium, phosphorus, eGFR, intact parathyroid hormone (iPTH), calcitriol, and fibroblast growth factor-23 (FGF-23) there was a strong inverse association of 25(OH) D level with MetS. For each log10 increase in 25(OH)D levels, there was a 60% reduction in the risk of MetS (adjusted OR 0.40, 95% CI 0.20 to 0.81, p=0.01). Similarly, when evaluated as a categorical predictor, 25(OH)D < 15 ng/mL vs. higher (adjusted OR 1.63 95% CI 1.16 – 2.28, p= 0.005) and < 20 ng/mL vs. higher (adjusted OR 1.73 95% CI 1.27-2.36, p=0.0005) was also strongly associated with the MetS. Calcitriol, iPTH and FGF-23 levels were not related to the MetS.

Conclusion: 25(OH)D deficiency is strongly associated with an increased risk of MetS in patients with severe CKD. Further studies are needed to confirm our results.

**Complications of Chronic Kidney Disease (CKD) by Level of Albuminuria and Estimated Glomerular Filtration Rate (eGFR) in the IDNT Trial**
Gautham Viswanathan,[1] Hocine Tighiouart,[1] Paul Muntner,[2] Julia Lewis,[3] Mark J. Sarnak,[1] Lesley A. Stevens.[1] *[1]Tufts Medical Center; [2]University of Alabama at Birmingham; [3]Vanderbilt University Medical Center.*

Based on the improved prediction of cardiovascular and renal outcomes, it has been proposed to revise the classification of CKD using levels of both albuminuria and GFR. However, it is not known whether albuminuria is associated with concurrent complications of CKD.

**Methods** Cross-sectional analysis of 1683 participants screened for the Irbesartan in diabetic Nephropathy (IDNT) trial evaluated the association of albumin-creatinine ratio (ACR) and eGFR with anemia (hemoglobin < 12 g/dL for women, <13.5 g/dL for men) and hyperphosphatemia (phosphate > 4.6 mg/dL) using logistic regression. GFR was estimated using the CKD-EPI equation.

**Results** The mean eGFR was 47 ml/min/1.73m$^2$ (SD 18) and the median ACR was 1467 mg/g (IQR 1932). The table shows the associations of ACR categories with anemia and hyperphosphatemia. In multivariable models adjusted for age, sex, race and ACR, eGFR levels lower than 30 ml/min/1.73m$^2$ were associated with higher odds (95% CI) of anemia 5.59 (3.99-7.83) and hyperphosphatemia 2.33 (1.43-3.8) when compared to eGFR levels greater than 60 ml/min/1.73m$^2$.

**Conclusions** Albuminuria had a significant relationship with anemia and hyperphosphatemia in diabetic nephropathy. The implications of these findings in the management of CKD should be taken into account when considering including albuminuria level in the classification of CKD.

Table: Adjusted OR for CKD complications associated with level of ACR

| | | ACR, mg/g | | | | |

**Haptoglobin Phenotype Is Associated with Elevated Levels of High Sensitivity CRP and Interleukin-6 in Patients with Stage 3-5 Chronic Kidney Disease**
Charlotte Strandhave,[1] My Svensson,[2] Jeppe Hagstrup Christensen.[1] *[1]Nephrology, Aalborg Hospital, Aalborg, Denmark; [2]Nephrology, Skejby Hospital, Aarhus, Denmark.*

*Introduction:* Three major phenotypes for the haptoglobin (Hp) gene have been identified: Hp 1-1, Hp 2-2 and the heterozygous Hp 2-1. Due to lower phenotype-dependent antioxidant capacity, Hp 2-2 acts as a weaker innate antioxidant and is associated with a poor outcome in several clinical conditions such as ischemic heart disease and diabetic nephropathy. High sensitivity CRP (hsCRP) and Interleukin-6 (IL-6) are markers of low-grade inflammation and have been implicated as independent predictors of cardiovascular events and mortality among chronic kidney disease (CKD) patients.

*Aim:* To examine whether Hp phenotyping in patients with CKD could identify patients with a pro-inflammatory profile with high levels of hsCRP and IL-6.

*Methods:* We included patients (n = 64) with stage 3-5 CKD and without ongoing infection from our outpatient clinic. The Hp phenotype was determined using a high-performance liquid chromatography. HsCRP was measured using an ADVIA 1650 analyzer and an immunoturbidimetric assay while Il-6 was measured using Luminex multiplex liquid array.

*Results:* The CKD patients were divided in two groups according to haptoglobin phenotypes: Hp 1-1 and 2-1 (n=45) and Hp 2-2 (n=19). They were comparable regarding clinical relevant parameters although a trend was observed towards lower age, lower plasma PTH, and fewer women in the Hp 2-2 group. The median hsCRP was 5.9 mg/L CI 95% (3.4;10.2) among Hp 2-2 patients compared to 2.6 mg/L CI 95% (1.9;3.5) in Hp1-1 and Hp 1-2 patients (p<0.01). The median IL-6 was 5.8 pg/mL CI 95% (4.2;8.1) in the Hp 2-2 patients compared to 4.2 pg/mL CI 95% (3.5;5.2) in the group with Hp1-1 and 2-1, showing a non-significant trend (p=0.08).

*Conclusion:* Haptoglobin phenotyping in patients with CKD revealed that Hp 2-2 patients had significantly higher levels of hsCRP compared to Hp 1-1 and Hp 2-1 patients. Also, a trend towards higher levels of IL-6 was seen. Thus, this phenotype may identify a group of CKD patients with a pro-inflammatory profile potentially predicting a higher risk of cardiovascular disease and mortality.

**Serum 25-Hydroxyvitamin D and Change in Estimated Glomerular Filtration Rate**
Ronit Katz,[1] Ian H. de Boer,[1] Michel B. Chonchol,[5] Joachim H. Ix,[2] Mark J. Sarnak,[4] Michael Shlipak,[3] David Siscovick,[1] Bryan R. Kestenbaum.[1] *[1]University of Washington; [2]University of California, San Diego; [3]University of California, San Francisco; [4]Tufts Medical Center; [5]University of Colorado Denver.*

**Background:** The prevalence of chronic kidney disease (CKD) is growing most rapidly among older adults, but the determinants of impaired kidney function in this population are not well understood. Vitamin D deficiency may be a novel, modifiable risk factor for the progression of CKD.

**Methods:** We examined associations of 25-hydroxyvitamin D concentration (25OHD) with change in kidney function over four years among 1,705 participants in the community based Cardiovascular Health Study (aged≥65) who were free of cardiovascular disease at baseline. 25OHD was measured by high performance liquid chromatography-tandem mass spectrometry. Change in estimated glomerular filtration rate (eGFR) was calculated using longitudinal measurements of serum cystatin C, measured at baseline and four years later. Rapid loss of GFR was defined as 12mL/min/1.73m$^2$ or more over 4 years. In addition we also looked at a combined endpoint which further included incident ESRD or death prior to follow-up cystatin C measures.

**Results:** The mean age of the cohort was 74 years, 70% were female, 14% had a baseline eGFR<60mL/min/1.73m$^2$ and the mean 25OHD concentration was 26ng/ml. Each 10ng/mL lower 25OHD was associated with a 19% greater risk of rapid GFR loss (p=0.01) in a model adjusted for age, gender, race, site, season, education, income, diabetes, smoking, physical activity, antihypertensive medications, body mass index, blood pressure, and C-reactive protein. Compared with 25OHD≥30 ng/mL, 25OHD<15 ng/mL was associated with a 52% greater risk of rapid GFR loss. Each 10ng/mL lower 25OHD was associated with a 19% greater risk of a combined endpoint of rapid GFR loss, incident ESRD, or death (p=0.002), and 25OHD<15ng/mL was associated with a 76% greater risk of the combined endpoint compared with 25OHD≥30 ng/mL.

**Conclusions:** Lower 25OHD concentrations were associated with increased risk of eGFR loss among community-dwelling older adults.

**Kidney in Chronic Lymphocytic Leukemia and Related B Cell Lymphoma**
Arvind Ponnusamy, Krish S. Raman, Houssam Atwa, Alladin Shurrab. *Renal Department, Salford Royal NHS Trust Foundation, United Kingdom.*

Introduction: Glomerulonephritis (GN) in chronic lymphocytic leukemia (CLL) and related B cell lymphomas may include membranous GN, membranoproliferative GN, immnunotactoid GN, fibrillary GN, type 1 cryoglobunemia GN, AL amyloidosis.

Method: A retrospective analysis of patients with CLL presenting with proteinuria, haematuria and renal impairment was undertaken. 4 electronic case notes were reviewed. The clinical, demographic, immunological and laboratory data at the time of renal biopsy

were recorded. Creatinine and proteinuria was recorded at the last follow up. All analyses were performed using excel. Results: Presentation of these patients included acute kidney injury (AKI), nephrotic syndrome and heamaturia. Mean proteinuria was [mean+ SD] 2gm+ 2.4 at presentation with mean follow up proteinuria 2.6gms + 2.4. The median age was 70 (range 68 to 72).

| Age | Proteinuria (presentation) | Creatinine (presentation) (mg/dl) | Creatinine (follow up) | Immunology | Light Microscopy | Electron Microscopy |
|---|---|---|---|---|---|---|
| 68 | 5.74gm/24hr | 5.2 | 2.9 | Monoclonal IgG kappa | MCGN type I | Subendothelial deposits |
| 73 | 0.4gm/24hr | 1.5 | 1.4 | Monoclonal of IgG kappa | MCGN type I, infiltrates of monotonous lymphoid cells consistent with infiltrance by CLL | Immunotactoid |
| 70 | 2.2gm/24hr | 1.5 | 1.1 | Low C4, no cryo | Atypical MCGN | Fibillary |
| 72 | 0.54gm/24hr | 3.8 | 1.9 | Raised serum and urine free lambda light chain | lymphomatous infiltration | n/a |

Clinical, Laboratory, Immunological and Renal biopsy features

All patients received some form of chemotherapy. The patient who presented with fibillary GN was diagnosed with CLL 2 years later.

Conclusion: Renal manifestations of CLL appear to be a paraneoplastic phenomenon and may be an under diagnosed entity. It should be considered in any patient with CLL who presents with AKI and proteinuria or those with no obvious cause for slowly deteriorating renal function. Renal histology is an important tool to confirm diagnosis. Treatment is indicated and may lead to remission of renal impairment and is associated with a good outcome. Our data suggest presentations are heterogeneous and kidney involvement may precede the diagnosis of CLL.

**Recurrent Proliferative Glomerulonephritis with Monoclonal IgG Deposits** Samih H. Nasr,[1] Sanjeev Sethi,[1] Lynn D. Cornell,[1] Mary E. Fidler,[1] Mark R. Boelkins,[2] Fernando C. Fervenza,[1] Fernando G. Cosio,[1] Vivette D. D'Agati.[3] *[1]Pathology and Nephrology, Mayo Clinic, Rochester, MN; [2]Pathology, Columbia University, New York, NY; [3]St. Mary's Health Care, Grand Rapids, MI.*

**Introduction:** We have recently described a proliferative glomerulonephritis associated with monoclonal IgG deposition (PGNMID) (JASN 2009, 20, 2055-64).

**Methods:** We reviewed the clinical and kidney biopsy (Bx) data in a cohort of 4 white pts (3F; 1M), mean age at Tx of 58.5 yrs, with PGNMID who underwent kidney transplant (KTX) and developed recurrent disease.

**Results:** Recurrent disease was documented histologically in 14 KTX Bxs in these 4 pts. At the time of first Bx showing recurrence (3-5 mo. post TX), all pts had worsening S. creatinine (SCr; mean 3.1 mg/dl); 3 had proteinuria (mean 4.7 g/d), 2 had nephrotic syndrome, and 3 had hematuria. Serum and urine immunofixation were negative for a monoclonal protein. In each pt, the glomerular deposits in the KTX Bxs were monoclonal (IgG3 κ in 3 pts, IgG3 λ in 1 pt) and had the same heavy and light chain isotypes as the deposits in the native kidney. Ultrastructurally, all native and KTX Bxs had granular glomerular electron dense deposits. In 2 pts, light microscopy (LM) showed endocapillary proliferative glomerulonephritis (EPGN) in both the native and KTX Bxs. In the other 2 pts, native Bxs showed an MPGN pattern while the KTX Bxs showed EPGN in 1 and mesangial proliferative GN in 1. Recurrent disease was treated with high dose prednisone and rituximab in 3 pts and with high dose prednisone and cyclophosphamide in 1 pt. After a mean follow-up of 43 mo. (range 11-83 mo.), proteinuria decreased to a mean of 0.3 g/day in all pts and SCr decreased to a mean of 1.6 mg/dl in 3 pts. Repeat Bxs after therapy showed less disease activity.

**Conclusions:** PGNMID recurs following KTX, and is usually manifested by proteinuria, hematuria, and graft dysfunction. The monoclonal protein deposited in glomeruli of the allograft is identical to that in the native kidney, although the glomerular pattern on LM is not always the same. The recurrent disease appears to respond to immunosuppressive therapy with clinical and histologic improvement.

### F-PO1334

**Laser Microdissection and Mass Spectrometry in the Diagnosis of Renal Heavy Chain and Light and Heavy Chain Amyloidosis** Sanjeev Sethi,[1] Ahmet Dogan,[1] Lynn D. Cornell,[1] Mary E. Fidler,[1] Nelson Leung,[2] Samih H. Nasr.[1] *[1]Pathology, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic, Rochester, MN.*

The vast majority of cases of primary amyloidosis involving the kidney are composed of immunoglobulin (Ig) light chains only (AL-amyloid). Very rarely, the amyloid deposits are composed of Ig heavy chains alone (AH-amyloid) or Ig light and heavy chains (AL+AH amyloid). The diagnosis of AH amyloid or AL+AH amyloid can be very challenging, particularly in cases in which no tissue is available for immunofluorescence (IF) or when the IF findings and Congo red stain are inconclusive. Herein, we report 4 cases of renal AH amyloid or AL+AH amyloid that were diagnosed by laser microdissection (LMD) and mass spectrometry (MS) based proteomic analysis. All patients were adult males with a mean age of 52 years (range 36-64 years). 3 patients had plasma cell dyscrasia and 1 had MGUS. All patients presented with proteinuria (range 2.5-12.7 g/day) and 2 had renal insufficiency (creatinine range 1.0-1.9 mg/dl). Hematuria was present in all patients and hypoalbuminemia was present in 3 patients. On biopsy, the Congo-red positive amyloid deposits involved glomeruli and vessels in all cases, and the interstitium in 2 cases. Electron microscopy, performed on 3 cases, showed randomly-oriented fibrillar deposits. On IF, performed on 3 cases, the deposits stained only for IgG and lambda in 1, only for IgA and kappa in 1, and equally for IgA, IgG, IgM, kappa, and lambda in 1. By LMD/MS proteomic analysis of the glomerular amyloid deposits, 1 case showed Ig gamma 1 chain constant region and lambda light chains variable and constant regions; 1 case showed Ig alpha chain constant region and kappa light chains variable and constant regions; and 2 cases showed Ig gamma 3 chain constant region and heavy chains variable region I and/or III without light chains. We conclude that LMD/MS is a valuable diagnostic technique for the diagnosis of AH and AL+AH amyloid and is superior to immunofluorescence in some cases.

### F-PO1335

**The Anion Gap in IgG, IgA, and Light Chain Monoclonal Gammopathies with Focus on the Impact of Serum Free Light Chains** Karen van Hoeven,[1] Laura McBride,[2] Danielle Schillen,[2] Ann McNeill,[2] Linda Schmidt,[2] Elizabeth Bilotti,[2] David Siegel.[2] *[1]The Binding Site Inc, San Diego, CA; [2]Hackensack University Medical Center, Hackensack, NJ.*

**Purpose:** IgG monoclonal gammopathies (MG) are associated with a decreased anion gap (AG), and IgA MG are associated with an increased AG. We explored the AG in IgG, IgA, and light chain MG with a focus on the impact of serum free light chains (sFLC).

**Methods:** $Na^+$- ($Cl^-$ + $HCO3^-$) was calculated in patients (pts) with MG (mostly myeloma) at presentation or at relapse, and in pts with no evidence of MG by serum protein electrophoresis (sPEP), serum immunofixation and sFLC. After raw data analysis, pts were excluded if serum albumin was <2.5 g/dL, serum $Ca^{++}$ was >11.0 mg/dL, or serum creatinine was >2 mg/dL.

**Results:** The AG in 40 pts without MG ranged from 9 to 15 (in 37 of 40 pts, the AG range was 9 to 14). The AG was decreased (<9) in 35% of 102 IgG and increased (>14) in 36% of 50 IgA MG. In 60 LC MG, the AG was increased in 25% and decreased in 3% of pts. Applying exclusion criteria, the AG was decreased in 34% of 89 IgG and increased in 31% of 42 IgA MG. In 40 LC MG, 17% had increased and 3% had decreased AG. Correlation coefficients were poor (strongest *r* was 0.58) between the AG and the paraprotein spike on sPEP, and also poor between the AG and the mean concentration of the involved Ig (IgG 4.64 g/dL±0.18 (SEM), IgA 3.27 g/dL±0.26, free kappa 0.5 g/dL±0.08 [or 4956 mg/L±769; n=20], free lambda 0.36 g/dL±0.08 [or 3607 mg/L±809; n=20]). Only 23 of 40 (58%) LC MG had measurable paraprotein spikes on sPEP, but of 20 kappa LC MG, free kappa ranged from 478 to 14,400 mg/L (normal 3.3 to 19.4 mg/L), and of 20 lambda LC MG, free lambda ranged from 440 to 17,300 mg/L (normal 5.7 to 26.3 mg/L). Mean clonal sFLC in IgG MG with low AG was 620 mg/L±198 vs 967 mg/L±508 in other IgG MG (*P*=NS). Mean clonal sFLC in IgA MG with high AG was 821 mg/L±420 vs 431 mg/L±177 in other IgA MG (*P*=NS).

**Conclusions:** The AG has been used as a tool for detecting IgG and IgA MG, but it has lower sensitivity in LC MG. sFLC had no significant effect on the AG in IgG and IgA MG, likely due in part to relatively low serum concentrations of clonal FLC versus IgG or IgA.

### F-PO1336

**Evaluation of Microscopic Hematuria Using the Urinary Albumin to Total Protein Ratio** Yu Min Lee, Jeong-Min Cha, Seon-Ho Ahn, Ju-Hung Song. *Division of Nephrology, Department of Internal Medicine, Wonkwang University School of Medicine, Iksan City, Jeonbuk, Republic of Korea.*

Background. Hematuria is a clinically significant finding associated with a number of conditions involving the genitourinary tract, including the kidney, ureter, prostate gland, bladder, and urethra. Depending on the source of bleeding, hematuria can be classified as either glomerular or nonglomerular bleeding. The presence of significant number of dysmorphic RBCs, RBC casts and protein excretion > 500mg/d suggest a renal source of the hematuria. In this study, we report on the use of the urinary albumin-to-total protein ratio to accurately differentiate glomerular and nonglomerular bleeding. Methods. This study included 39 microscopic hematuria patients who confirmed by histopathology (30 IgA nephropathy; group 1, 9 non-specific finding; group 2). The following indices were compared with respect to group 1 and group 2: (1) urinary total protein-to-creatinine ratios(UPCR); (2) urinary albumin-to-creatinine ratios(UACR); (3) urinary albumin-to-total protein ratios(UAPR). Received operating characteristic (ROC) curve of UPCR and UAPR obtained from sensitivity and specificity. Results. The mean UPCR, UACR and UAPR for group 1 and group 2 were 1.34±1.76 vs 0.14±0.14 (p=0.05), 1.1±1.58 vs 0.07±0.1 (p=0.05) and 0.71±0.19 vs 0.29±0.23 (p<0.01), respectively. At a cut off 0.12, the UPCR demonstrated a sensitivity 96.7% in detecting IgA nephropathy. And at a cut off 0.38, the UAPR demonstrated a sensitivity 100% in detecting IgA nephropathy. Conclusions. First, our results suggest that the UAPR is potentially a useful index for the differentiation of

glomerular and nonglomerular disease in the presence of microscopic hematuria. Second, the UPCR detected IgA nephropathy at a cut off 0.12. It means that microscopic hematuria with minimal proteinuria (not exceed 500 mg/d) suggest a glomerular origin of the hematuria and should be confirmed by renal biopsy.

**F-PO1337**

**The Optimal Cutoff Value of Urine Albumin Concentration for Albuminuria in Japanese Population: The Takahata Study** Tsuneo Konta, Kazuko Suzuki, Ami Ikeda, Yusuke Mashima, Kazunobu Ichikawa, Satoshi Takasaki, Isao Kubota. *Department of Cardiology, Pulmonology, and Nephrology, Yamagata University School of Medicine, Yamagata, Japan.*

**Background:** To screen albuminuria in spot urine, urine albumin concentration corrected by urine creatinine concentration (urine albumin-creatinine ratio, UACR) is measured. However, the value of UACR is greatly affected by various factors that modulate urine creatinine excretion. Therefore, the optimal cutoff value in urine albumin concentration (UAC) for albuminuria (UACR ≥30 mg/gCr) might be different depending on the characters of examined subjects. To clarify this point we performed the cross-sectional analysis in the general Japanese population.

**Methods:** The participants of this community-based study were 3,114 subjects (average 63 years old, male 44.3%, hypertension 55.1% and diabetes 7.7%). Single spot urine was collected in the morning and the sensitivity/specificity and receiver operation curve (ROC) analyses were performed.

**Results:** In total subjects the sensitivity for albuminuria in the cutoff value in UAC of 5, 10, 15, 20, 25 and 30 mg/L were 100%, 98.2%, 93.2%, 84.7%, 75.7% and 68.3%, respectively. The specificity in these UAC cutoff values were 19.5%, 65.6%, 84.5%, 91.8%, 95.8% and 97.9%, respectively. The median values in urine creatinine concentration (g/L) were significantly different between subgroups (total subjects 1.05, age <65 1.13, age ≥65 0.98, male 1.23, female 0.94, hypertensive 1.02, non-hypertensive 1.09, diabetic 1.11 and non-diabetic 1.04, respectively). The ROC analysis showed the optimal UAC (mg/L) for albuminuria were 16.0 (total subjects), 15.3 (age <65), 20.8 (age ≥65), 16.6 (male), 16.0 (female), 16.0 (hypertensive), 14.4 (non-hypertensive), 22.3 (diabetic) and 15.9 (non-diabetic), respectively.

**Conclusions:** This study revealed that the optimal UAC cutoff level for albuminuria in Japanese population might be lower than the current definition (<20 mg/L). To screen albuminuria using UAC, the characters of subjects (age, ethnicity and comorbidities) should be considered.

**F-PO1338**

**Diagnosis of Acute Allograft Rejection in Kidney Transplanted Patients by Urinary Proteome Analysis** Christos D. Chatzikyrkou,[1] Jochen Metzger,[2] Verena Broecker,[3] Irina Scheffner,[1] Eric Schiffer,[2] Michael Mengel,[4] Hermann G. Haller,[1] Harald Mischak,[2] Wilfried Gwinner.[1] *[1]Nephrology, Medical School Hannover, Hannover, Germany; [2]Mosaiques Diagnostics, Hannover, Germany; [3]Pathology, Medical School Hannover, Hannover, Germany; [4]Division of Nephrology/Immunology, University of Alberta, Edmonton, Canada.*

Diagnosis of acute renal allograft rejection by non-invasive methods may be advantageous compared to biopsy. In this study, we examine capillary electrophoresis mass spectrometry (CE-MS) of urines for the rejection diagnosis.

In a training set including 16 samples with acute T-cell mediated tubulointerstitial rejection and 23 samples without rejection the low-molecular weight proteome was analyzed. A multi-marker classification model for rejection was defined by multivariate statistical comparison of the CE-MS spectra. This model was extensively evaluated on an independent validation set (n=68) and a blinded set (n=17) of samples.

Application of the rejection model to the validation set resulted in correct classification of 13/14 subclinical and 11/11 clinical rejections (BANFF grades Ia/Ib), and of 31/43 samples without rejection. Comparison of the sub-scores of the BANFF classification with the numerical classifier of the marker set revealed a tight correlation to the i-score and t-score (r=0.62 and 0.63; p<0.0001). Acute tubular injury in the biopsies with and without rejection did not interfere with the CE-MS-based diagnosis. Classification of the blinded test set resulted in an AUC-value of 0.83 (95% CI: 0.57-0.96, p=0.0028) in the corresponding ROC analysis. Sequence information of identified altered collagen alpha(I) and alpha(III) chain fragments in the samples with rejection suggested an involvement of MMP-8. Staining of the biopsies revealed MMP-8 exclusively in polymorphnuclear cells located within peritubular capillaries and sparsely, in the tubulointerstitium of the biopsies with rejection.

CE-MS offers a promising non-invasive method for the diagnosis of acute rejection in the post-transplant surveillance. The established marker set apparently contains peptides which are specifically related to the tubulointerstitial infiltration seen in acute rejection.

**Impact of Nephrotic Leg Edema on OSA: Gathering a Unifying Concept for the Pathogenetic Role of Nocturnal Rostral Fluid Shift** Sydney C. W. Tang, Bing Lam, Jamie Chung Lam, Desmond Y. H. Yap, Mary S. M. Ip, Kar Neng Lai. *Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong.*

***Rationale:*** Nocturnal rostral fluid shift has been suggested to be a risk factor for obstructive sleep apnea (OSA) in healthy subjects after lower body positive pressurization and in heart failure subjects. Here, we tested whether this may apply to nephrotic lower limb edema and whether remission of the nephrotic syndrome may reverse OSA.

***Methods:*** In subjects with primary steroid-responsive nephrotic syndrome presenting with bilateral lower limb edema, we examined the prevalence and severity of sleep apnea and related parameters before and after the induction of disease remission.

***Measurements and Main Results:*** Among 16 nephrotic subjects, 7 (43.7%) had sleep apnea (apnea-hypopnea index [AHI]≥5) upon presentation. Overall AHI was 14.8±5.0 and was predominantly obstructive in nature. After steroid-based treatment, there was remission of proteinuria associated with complete disappearance of lower limb edema, significant reduction of body mass index, waist, hip and calf circumferences, and total body water mainly in the extracellular compartment. Polysomnographic analyses, performed 8.3±2.8 months after initial presentation, showed improvement in sleep efficiency (P=0.036), mean nocturnal oxygen saturation (P=0.005), shorter duration with oxygen saturation <95% (P=0.044) and <90% (P=0.02), and reduced desaturation index (P=0.011). AHI reduction was close to statistical significance, particularly when confined to subjects with baseline AHI≥ 5 (P=0.075). There was subjective improvement in self-reported daytime sleepiness (P=0.03).

***Conclusions:*** Nephrotic lower limb edema is a risk factor for nocturnal hypoxemia and possibly also for OSA. This gathers a unifying concept for the pathogenetic role of nocturnal rostral fluid shift in OSA.

**F-PO1340**

**Hydration Status Influences Kidney Volume in Healthy Adults** Anja M. Jensen,[2] Kristian Karstoft,[2] Bettina Jorgensen,[2] Bente Jespersen,[1] Michael Pedersen.[2] *[1]Nephrology, Aarhus University Hospital, Skejby, Denmark; [2]Institute of Clinical Medicine, Aarhus University Hospital, Skejby, Denmark.*

Kidney volume is positively influenced by BMI, height and male gender whereas older age is associated with reduced kidney volume. Previous studies suggested that the volume of a healthy kidney correlates with the GFR, since a low amount of nephrons (corresponding to a low GFR) occupies a lower volume than a relative large nephron mass. Second, several imaging-based methods allowing estimates of renal function are based on the assumption that GFR is calculated as the average filtration per $cm^3$ in the renal parenchyma multiplied with the cortical volume (CV). Therefore, accurate and reproducible kidney volume measurement is important.

This study aimed to investigate the influence of water intake prior to kidney volume measurements. A total of 8 women and 9 men (all healthy) underwent 2 separate MRI sessions. Before the first MRI, they had no access to water or food for 3 h, whereas the second MRI was commenced after a water intake of 15 ml/kg body weight over a period of 3 h. MRI was performed using a standard clinical system, and high-resolution multislice images were acquired to delineate fine structures of the renal anatomy. Using home-made software, the cortical area was semi-automatically calculated in each slice, and left and right CVs were derived as the sum-of-slice principle.

Male gender was associated with a significantly larger kidney CV adjusted to BMI than female gender. Interestingly, kidney CV was significantly increased in both females (RK: 4.3±0.3 vs. 4.0±0.3 $cm^3$/BMI, $p<0.01$; LK: 4.2±0.3 vs. 3.7±0.3 $cm^3$/BMI, $p<0.01$) and males (RK: 5.2±0.2 vs. 5.0±0.2 $cm^3$/BMI, $p<0.01$; LK: 5.3±0.2 vs. 5.1±0.2 $cm^3$/BMI, $p<0.01$) in response to standardized water intake compared to kidney CV following 3 h dehydration period. Moreover, the hydration-induced increase in kidney CV in percentage was significantly larger in females than males (RK: 8.3±2.1% vs. 3.3±0.7%, $p<0.05$; LK: 12.3±2.7% vs. 3.7±0.9%, $p<0.01$).

In conclusion, standardized protocols for kidney volume measurements including water intake are essential. Interestingly, the response to hydration status was most evident in females.

**F-PO1341**

**Canakinumab (Fully Human Anti-IL-1β Monoclonal Antibody) vs Triamcinolone Acetonide (TA) for Treatment of Acute Flares in Difficult-to-Treat Gouty Arthritis Patients with Renal Impairment** Naomi Schlesinger,[1] M. De Meulemeester,[2] A. Pikhlak,[3] A. E. Yücel,[4] U. Arulmani,[5] D. Richard,[5] V. Murphy,[5] P. Sallstig,[5] A. So.[6] *[1]UMDNJ-RWJMS, NJ; [2]Gozée, Belgium; [3]MSUMD, Moscow, Russian Federation; [4]Baskent Univ., Ankara, Turkey; [5]Novartis, Basel, Switzerland; [6]CHU Vaudois, Lausanne, Switzerland.*

**Purpose**: Many gouty arthritis patients have renal impairment limiting use of standard treatment like NSAIDs or colchicine. Herein, we report results of an 8-week, multicenter, blinded study of canakinumab vs TA for treatment of acute flares in subgroup of renal impaired gouty arthritis patients.

**Methods**: Patients (≥18–≤80 y) with acute gouty arthritis flare, refractory or contraindicated to NSAIDs and/or colchicine were randomized to 1 subcutaneous dose of

canakinumab (10, 25, 50, 90 or 150 mg) or 1 intramuscular dose of TA 40 mg. Efficacy variables were pain intensity at 72 h post-dose on VAS (0–100 mm), time to 50% pain reduction, recurrence of flares and physician's global assessment.

**Results**: 132/200 patients had renal impairment (canakinumab n=95; TA n=37) (eGFR <90 ml/min/1.73 m$^2$) (mild [eGFR 60–89 mL/min/1.73 m$^2$] n=107; moderate [eGFR 30–59 mL/min/1.73 m$^2$] n=25) at baseline. Canakinumab 150 mg showed superior pain relief compared to TA at 72 h: estimated mean difference in pain intensity was –17.3 ($p<0.05$). Median time to 50% pain reduction was reached at 0.5 day with canakinumab 150 mg vs 2 days for TA ($p=0.003$). At Week 8, recurrent flares occurred in none of the patients on canakinumab 150 mg vs 17 (47.1%) patients on TA. At Week 8, patients on canakinumab 150 mg were 3.2 (95% CI 1.03–9.77) times more likely to have a better physician's global assessment than TA ($p=0.045$). Most frequent AEs were infections; incidence was lower in canakinumab (10.5%) vs TA (16.2%). SAEs (canakinumab n=3, TA n=1) were not considered treatment related by investigators. No discontinuations occurred due to AEs.

**Conclusions**: Canakinumab 150 mg provided rapid and superior pain relief vs TA 40 mg in renal impaired acute gouty arthritis patients. Canakinumab prevented recurrent flares and was well-tolerated. Pain reduction and safety profile was comparable to total population.

### F-PO1342

**Platelet Activation during Renal Artery Stenting** Steven T. Haller,[1] Satjit Adlakha,[1] Pamela Brewster,[1] David Kennedy,[2] Haifeng Yu,[1] Dong Zhang,[1] Joseph I. Shapiro,[1] Christopher J. Cooper.[1] *[1]Medicine, University of Toledo, Toledo, OH; [2]Cell Biology, Cleveland Clinic, Cleveland, OH.*

Soluble CD40 ligand (sCD40L) is a prominent marker of platelet activation. Platelet activation leading to thrombus formation is common in coronary revascularization. Whether it occurs in the setting of renal artery stenting is unknown. Additionally, the effect of embolic protection devices (EPD) and glycoprotein inhibitors (GP2b3a) on platelet activation during renal artery stenting is unknown. One hundred patients enrolled at 7 centers undergoing renal artery stenting were randomized to an EPD, Angioguard®, or use of abciximab, in a 2x2 design. Platelet activation was assessed by measuring plasma levels of sCD40L. Blood samples were collected at baseline, immediately post, and 24hr post-procedure. Statistical analysis was performed on patients with data available for all time points (n=84). Additional samples were collected from 30 healthy controls, and 30 patients with atherosclerosis, but without renal artery stenosis (RAS). A natural log transformation was performed to normalize the data. Soluble CD40L levels were higher in RAS patients than normal controls ($5.6 \pm 0.7$ vs $4.2 \pm 0.1$ pg/ml, $P<0.01$), but were similar to patients with atherosclerosis but without RAS. In patients that received an EPD, sCD40L levels rose slightly (p=NS) immediately after stenting, and returned to baseline levels at 24hrs. Platelet rich emboli were captured in 26% (9/35) of EPD patients and in these patients sCD40L was elevated prior to the procedure and rose further afterwards. Soluble CD40L declined with abciximab immediately post-procedure ($5.6 \pm 0.6$ vs $4.9 \pm 0.8$ pg/ml, $p<0.001$), which persisted at 24hrs. Patients randomized to both an EPD and abciximab showed a significant decrease in sCD40L immediately after the procedure. Patients with RAS have elevated levels of sCD40L at presentation but this appears to be related to atherosclerosis, not RAS specifically. In patients undergoing stenting embolization of platelet thrombi is common, is associated with systemic evidence of platelet activation that precedes the procedure, and is inhibited with abciximab administration.

### F-PO1343

**Mycophenolate as Induction Treatment of Lupus Nephritis. Is Its Efficacy Dependent of Initial Renal Function?** Francisco Rivera.[1] *[1]Nephrology, Hospital General de Ciudad Real, Ciudad Real, Spain; [2]Nephrology, Hospital Vall d'Hebron, Barcelona, Spain; [3]Spanish Group for the Study of Glomerulonephritis (GLOSEN).*

Introduction. There is not enough information about efficacy of mycophenolate (M) as induction treatment of lupus nephritis (LN) in patients with initial impairment of renal function.

Aims. To analyse the efficacy of M in LN according its initial renal function.

Patients and Methods. We studied data from 14 Renal Units in Spain. Inclusion criteria: i) biopsy-proven LN, ii) follow-up >3 months, iii) M as induction treatment. Patients were classified according initial Scr in Group 1 (≤1.2 mg/dl) and Group 2 (>1.2 mg/dl). Primary objective: % of patients who reach response (R) defined as proteinuria <3.5 g/24h or stabilization or improvement in whom initial proteinuria ≥3.5 g/24h or when proteinuria decreased ≥ 50% when initial proteinuria was <3.5 g/24h. Secondary objective: % of patients with complete remission (CRem): Scr ≤1.2 mg/dl and proteinuria ≤0.5 g/24h.

Results. We studied 75 patients (Group 1: 57 and Group 2: 18), aged 31±12 year-old, the majority with LN class 4 (80%). The medians of proteinuria and follow-up were 3 g/24h and 36 months, respectively. Scr was 0.8±0.1 mg/dl and 1.5±0.3 mg/dl in Groups 1 y 2, respectively. R: The percentages of patients who reached R was 77% and 78% at 6 and 12 months, respectively; these percentages were maintained for, at least, 60 months since the beginning of treatment. There were any differences in the percentages of cases that reached R in both Groups during the whole follow-up (Kaplan-Meier). Indeed, there was not any relation between initial serum creatinine and R at the end of follow-up (Cox analysis). CRem: The percentages of patients who were in CRem was 28% and 47% at 6 and 12 months, respectively; the percentage of cases who reached CRem was higher in Group 1 compared with Group 2.

Conclusions. M as induction treatment in LN is associated with high percentages of responses that are not related with initial renal function. Complete remissions are more common if initial renal function is well preserved.

### F-PO1344

**Pantoprazole Reduces the Immunosuppressive Potency of Mycophenolate Mofetil** Matthias Schaier, Vedat Schwenger, Martin G. Zeier, Claudia Sommerer. *Department of Nephrology, University of Heidelberg, Heidelberg, Germany.*

Mycophenolate mofetil (MMF) is cleaved in the acidic milieu of the gastric compartment. However, its absorption might be impeded by proton pump inhibitors (PPIs), which suppress acid production and thus increase stomach pH. Since PPIs are widely used, it is useful to clarify whether the total drug amount of MMF is available in patients undergoing PPI treatment.

We analysed 36 patients with autoimmune diseases (20 with ANCA-associated vasculitis, 16 with systemic lupus erythematosus) under stable MMF maintenance therapy. Twenty-three patients received co-medication with PPIs; 13 patients received no treatment with PPIs or antacids. To assess the immunosuppressive potency, we measured MPA levels and inosin monophosphate dehydrogenase (IMPDH) activity with a validated high-performance liquid chromatography method in plasma samples collected at predose and at 0.5, 1, 1.5, 2, 3, 4, 5, 6, 8, 10 and 12h after oral administration.

The mean MMF dosage of the non-PPI patients was 770±249 mg/12h and 771±291 mg/12h in PPI-treated patients (ns). The total AUC of MMF showed a 37% reduction in PPI patients versus those treated with no PPIs ($p<0.01$), and the maximum peak concentration of MMF was 60% lower in the PPI patients ($p<0.001$). The MMF exposure correlated to the inhibition of IMPDH activity. The area of enzyme activity curve (AEC) was 42% higher in the PPI patients ($p<0.01$). Minimal IMPDH enzyme activity was lower in the non-PPI patients than in the PPI patients.

The co-medication of PPIs with MMF significantly influences the drug exposure and immunosuppressive potency of MMF in patients with autoimmune diseases. This finding might at least partly explain the different outcomes in studies using MMF for maintenance therapy.

### F-PO1345

**Renal Lesions in Rheumatoid Arthritis (RA) Patients on Anti-Tumor Necrosis Factor-alpha (Anti-TNF-α) Therapy** Steven P. Salvatore, Surya V. Seshan. *Weill Cornell Medical College, New York City.*

Purpose: Anti-TNF-α agents are anti-inflammatory medications used to mitigate severe RA symptoms. These drugs are associated with formation of auto-antibodies against anti-nuclear antigen (ANA), anti-neutrophilic cytoplasmic antibody (ANCA), and others. This study describes the varied renal disease associated with anti-TNF-α therapy in patients with RA.

Methods: A retrospective clinicopathologic review of renal biopsies was performed on eight patients in the past nine years with RA who have received anti-TNF-α therapy.

Results: All patients were female, between 37 and 65 years old, and had severe RA from 3 to 35 years. Four patients were given Etanercept (a soluble TNFα receptor inhibitor), three Infliximab (a chimeric monoclonal IgG1 anti-TNF-α antibody), and one Adalimumab (a fully humanized anti-TNF-α monoclonal antibody) for an average of 10 months. Three patients presented with hypertension, nephritic syndrome and had pauci-immune crescentic glomerulonephritis (GN). Two patients had acute renal failure and had thrombotic microangiopathy (TMA). One patient developed Methicillin-resistant Staphylococcus Aureus (MRSA) septic arthritis. The final two patients had a long RA history and reactive amyloidosis.

| Case | Urinalysis | Proteinuria (g/day) | Creatinine (mg/dL) | Hypertension | Serology | Pathology |
|---|---|---|---|---|---|---|
| 1 | hematuria/RBC casts | 2 | 1.49 | yes | pANCA+/cANCA+ | Crescentic GN |
| 2 | hematuria/RBC casts | ND | 3.2 | no | pANCA+ | Crescentic GN |
| 3 | hematuria/RBC casts | 16 | 0.8 | no | ANCA negative | Crescentic GN |
| 4 | hematuria | 0.6 | 1.5 | yes | ANA+/dsDNA+ | Chronic TMA |
| 5 | proteinuria | ND | 3.2 | mild | Phospholipid Ab | TMA |
| 6 | proteinuria | 8 | 4.1 | severe | MRSA sepsis | Post-Infectious GN |
| 7 | proteinuria | 2 | 0.6 | yes | negative | Amyloidosis |
| 8 | proteinuria | 2.7 | 2.3 | mild | not done | Amyloidosis |

Conclusions: Patients with RA taking anti-TNFα therapy have a spectrum of renal complications from development of auto-antibodies to autoimmune diseases with renal involvement, increased susceptibility to infections and post-infectious GN, or unrelated renal disease such as reactive amyloidosis. A thorough serologic work-up, clinical history and kidney biopsy is warranted in these patients for definitive diagnosis and appropriate management.

**The Role of EM in Repeat Biopsies in the Management of Persistent Proteinuria in Class V Lupus Nephritis Treated with Rituximab, MMF and No Oral Steroids** Marwa A. Al-Riyami, Marie B. Condon, Liz Lightstone, Jeremy B. Levy, Megan Griffith, Tom Cairns, Candice A. Roufosse, H. Terence Cook. *Imperial College Kidney and Transplant Institute, Imperial College Healthcare NHS Trust, London, United Kingdom.*

**Purpose:** To study the role of EM in repeat renal biopsies in the management of patients treated with a Rituximab-based protocol for class V lupus nephritis (LN).

**Methods:** 22 patients with class V LN were treated with Rituximab & MMF but no oral steroids. 12 patients had repeat biopsies either for partial remission (PR, persistent urine PCR >100mg/mmol, n=8), non-response (n=1) or clinical relapse (n=3). All had membranous LN on light microscopy. EM images were available in 21 out of 24 biopsies from this group. The number & stage of subepithelial deposits were evaluated. Absence of stage I/II deposits defined histological remission. Glomerular and tubulointerstitial scarring were evaluated.

**Results:** Eight of 12 patients had PR and were re-biopsied 14 to 42 months after starting treatment. Four had complete histological remission with either no or only stage III/IV subepithelial deposits. They received no further treatment. The other 4 patients showed a decrease in the proportion of stage I/II compared to stage III/IV deposits. Three patients had relapse of proteinuria & were rebiopsied between 16 and 42 months. EM showed persistence of stage I/II deposits. One non-responder was re-biopsied at 16 months. EM showed an increase in percent of stage I/II deposits. All patients with persistent stage I/II deposits were re-treated with Rituximab. Overall, in the re-biopsies, there was a small increase in global glomerulosclerosis (median = 6.5%, range -15-34), glomerular segmental sclerosis (median = 3.5%, range -38-33) but no increase in tubulointerstitial scarring (median = 0%, range -5-30).

**Conclusion:** EM is an important tool in the evaluation of repeat biopsies in patients with class V LN. The lack of new subepithelial deposits on EM in some cases suggests proteinuria persists due to haemodynamic factors or glomerular basement membrane remodelling rather than disease activity, and avoids the need for increased immunosuppression.

**F-PO1347**

**Rituximab as a Therapeutic Option in Severe Systemic Lupus Erythematosus** Dario Roccatello. *CMID, Ospedale S. Giovanni Bosco, Turin, Italy.*

Systemic Lupus Erythematosus (SLE) is a multisystem autoimmune disease characterized by the production of numerous autoantibodies against a variety of self antigens. B cells play a central role in SLE. Targeting the B cell compartment is therefore an attractive alternative to current available therapies. Rituximab is a human/mouse chimeric monoclonal antibody that specifically reacts with the CD20 antigen, which is restricted to B-cell lineage.

Eight patients, mean age 41.4 years (range 27-65 years), with severe multiorgan involvement including kidney (5 cases, comprising 3 patient with class IV(G) and 2 with class V ISN/RPS glomerulonephritis), skin (6 cases, with necrotizing ulcers in 3), central nervous system (2 cases) having severe polyarthrities (8 cases) and polysierositis (3 cases) were given Rituximab for intolerance or resistance to conventional therapy (6 patients) or as a front line treatment (2 cases).

Rituximab was administered intravenously at a dose of 375 mg/m$^2$ on days 1, 8, 15 and 22. Two more doses were administered 1 and 2 months later. This treatment was combined with two pulses of 750 mg cyclophosphamide and three pulses of 15 mg/kg metylprednisolone followed by oral prednisone, 50 mg quickly tapered until 5 mg in ten weeks. Response was evaluated by assessing the changes in clinical signs and symptoms (SLEDAI score) and laboratory parameters for at least 12 months.

Levels of erythrocyte sedimentation rate, C reactive protein and anti-dsDNA antibodies significantly decreased already at three months, whereas C4 values significantly increased at six ($p<0.05$). Proteinuria improved in all 5 cases presenting with renal involvement decreasing from 4.8 g/die (range 1.5-10.2) to 1.5 (range 0.1-3.7) in 3 months ($p<0.01$). Constitutional symptoms, skin ulcers, arthralgia, weakness, paraesthesia and fever disappeared or improved. SLEDAI score changed from 17.1 (12-28) to 2.8 (1-4) in 12 months ($p<0.01$). No acute or delayed side effects of clinical relevance were shown.

While Rituximab is not recommended for SLE with moderate activity, this therapy maintains a definite role in severe patients found to be refractory or intollerant to conventional treatment.

Disclosure of Financial Relationships: nothing to disclose

**Implications of Protocol Biopsies in Lupus Nephritis** Abdulkareem Alsuwaida, Jamal S. Alwakeel, Mohammed A. Al-Ghonaim, Sufia Husain, Anhar Ullah, Hala M. Kfoury. *King Saud University, Riyadh, Saudi Arabia.*

**Introduction:** The standard clinical and laboratory parameters have limited predictive values especially in discriminating between an active and chronic disease. The main objective of this study is to examine the utility of protocol biopsy in SLE nephritis.

**Methods:**Patients with Lupus Nephritis were advised to undergo a second kidney biopsy at the end of maintenance therapy. Complete remission was defined as serum creatinine <1.4 mg/dl and proteinuria < 0.33 g/d, while partial remission is defined as < 25% increase in baseline creatinine and >50% reduction in baseline proteinuria at the end of maintenance phase of therapy.

**Results:** Seventy three patients were included in the study. Complete and partial remission was achieved in 43.8% and 21.9%, respectively. The majority of the patients with partial or no remission had no histological evidence of active disease, 75% and 52% respectively.

Laboratory and Histological Characteristics of Patients at the time of Second Biopsy.

| | Complete Remission (n=32) | Partial Remission (n=15) | No Remission (n=25) | P |
|---|---|---|---|---|
| **Activity Index** | 1.8 ± 2.6 | 3.1 ± 4.1 | 5.1 ± 4.7 | *P* 0.001 [b] |
| **Chronicity Index** | 4.4 ± 3.0 | 4.9 ± 3.3 | 5.8 ± 2.5 | NS |
| **dsDNA** | 330 ± 493 | 559 ± 703 | 518 ± 608 | NS |
| **Urinalysis Red cells (per HPF)** | 37 ± 116 | 44 ± 70 | 82 ± 142 | NS |
| **Urinalysis White cells (per HPF)** | 25 ± 72 | 10 ± 16 | 32 ± 47 | NS |
| **Serum C3 (g/L)** | 1.3 ± 0.34 | 1.13 ± 0.58 | 0.79 ± 0.41 | 0.0001[b] |
| **Serum C4 (g/L)** | 0.29 ± 0.17 | 0.28 ± 0.18 | 0.24 ± 0.16 | NS |

Data are means ± SD. [a]dsDNA, doudle-stranded DNA; NS, not significant. [b]$P < 0.001$, Complete Remission versus No Remission; $P < 0.01$, Complete Remission versus Partial Remission.

At the most recent follow-up visit, the doubling of the serum creatinine was 25% in patients with partial remission, and 56% of the patients without remission.

**Conclusion:** Protocol biopsy strategy in patients with partial or no remission of lupus nephritis may allow us to avoid the adverse effects of overtreatment with immunosuppressive medications as a significant proportion of these patients do not show histological evidence of active disease.

**F-PO1349**

**Regulatory T Cells in Lupus Nephritis** Andrea Kattah, Vivette D. D'Agati, Vidhyalakshmy Vivek, Sumit Mohan, Jai Radhakrishnan. *Departments of Medicine and Pathology, Columbia University College of Physicians and Surgeons, New York, NY.*

Purpose: To quantitate FoxP3 and CD3 expression in renal biopsies of patients with lupus nephritis and evaluate possible prognostic value

Intro: T regulatory lymphocytes (Tregs) have been implicated in downregulating autoimmunity and decreases may have a role in the pathogenesis of SLE. Our goal was to look at FoxP3, the transcription factor for Tregs, in renal biopsies of patients with lupus nephritis and see if the presence of these cells was renal protective.

Methods: FoxP3 and CD3 immunohistochemistry were performed on 17 patients with lupus nephritis (Class III-V). Slides were examined under 40x and the number of cells/hpf was recorded, as were activity and chronicity indices. Disease progression was defined as a doubling of serum creatinine, transplant, initiation of renal replacement therapy (RRT) or death. Data analysis was performed using Stata 10.1.

Results: Patients were 27.6±12 years with a mean follow up of 4±2.1 yrs and serum creatinine of 1.1±0.5 mg/dL. The mean activity index was 8.6±4.8 with a mean chronicity index of 3.2±2.5 while the mean FoxP3 expression was 3.1±4.3 cells/hpf with mean CD3+ cell count of 33.4±18.9 cells/hpf. Among our cohort, 3 (17.6%) patients reached endpoint (all 3 pts had progressive renal disease requiring renal transplantation). These patients were similar to the rest of the cohort except for a significantly higher activity index (7.2±4.1 vs. 14±2.7, $p=0.02$) at the time of biopsy. No patients initiated RRT and there were no deaths. Kaplan Meier Curves for patients with CD3+ cells counts ≤ and > 40cells/hpf were significantly different (log rank $c^2=6.0$, $p=0.014$). Neither FoxP3+ cells nor FoxP3+/CD3+ ratios were significantly correlated with activity and chronicity index at time of biopsy or disease progression.

Conclusions: We found no relationship between FoxP3 positivity and disease activity or progression. The number of CD3+ cells did show an adverse prognostic value in determining who would progress to end-stage renal disease. This study was limited by sample size and the fact that patients were in different stages of disease and treatment at the time of biopsy.

Disclosure of Financial Relationships: nothing to disclose

**Neph1 Is Reduced in Primary Focal Segmental Glomerulosclerosis (FSGS) and Minimal Change Nephrotic Syndrome (MCNS)** Jenny Hulkko,[1] Jaakko Patrakka,[2] Karl Tryggvason,[3] Kjell R. Hultenby,[1] Annika Wernerson.[1] *[1]Pathology, Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden; [2]Renal Medicine, Clinical Science, Intervention and Technology, Stockholm, Sweden; [3]Matrix Biology, Medical Biochemistry and Biophysics, Stockholm, Sweden.*

**Background**

The transmembrane proteins Neph1 and Nephrin form a complex in the slit diaphragm (SD) of the podocytes. As recent studies indicate the complexes involvement in polymerization of the actin cytoskeleton and proteinuria we wanted to study the subcellular localization of Neph1 in normal human kidney and the expression in the human glomerular diseases Focal Segmental Glomerulosclerosis (FSGS) and Minimal Change Nephrotic Syndrome (MCNS). Both characterized by substantial foot process effacement (FPE) and proteinuria.

**Material and Methods**

Kidney biopsies from patients with primary FSGS (perihilar type) (n=5) and MCNS (n=5) were compared to normal renal tissue (n=5). All patients had proteinuria ranging from 1 to 27 g / 24h at the time of biopsy. Polyclonal antibodies against Neph1 and Nephrin were used for immunoelectron microscopy (iEM). Antibodies were detected by gold-conjugated protein A and semiquantification was performed. The total number of gold makers was calculated in the foot processes and expressed as gold particles /μm$^2$.

**Results**

We localised Neph1 mainly to, and in close proximity, to the SD. Double staining of Neph-1 and Nephrin showed the proteins colocalized in the slit diaphragm. This is, to our knowledge, the first published EM image showing the expression of Neph1 in human kidney.

The total amount of Neph1 in the podocytes was significantly reduced in FSGS 0,3 (0,1) and in MCNS 0,5 (0,1) compared to controls 1,5 (0,2)**.**

Interestingly, the reduction of Neph1 is also seen in areas without FPE in both diseases. Even more intriguing is the fact that the expression of ¨Nephrin is unchanged in these FSGS patients compared to controls. The complex may therefore be interrupted in this disease, in contrast to MCNS, where Nephrin is reduced in a similar pattern.

**Conclusion**

Our results show that Neph1 is expressed in close proximity to the SD and co-localize with Nephrin. The protein may have a role in the pathogenesis of FSGS and MCNS.

## F-PO1351

**Improvements in Glomerular Hyperfiltration Are Associated with Weight Loss after Roux-en-Y Bypass for Obesity** John C. Lieske, Maria L. Collazo-Clavell, Ellen Olson, Xujian Li, Eric J. Bergstralh, Zachary C. Ryan, Rajiv Kumar. *Mayo Clinic, Rochester, MN.*

Obesity is associated with hyperfiltration, proteinuria and development of chronic kidney disease. It is has been hypothesized that weight loss could reverse harmful effects of obesity on the kidney.

*Results:* Iothalamate clearance (Io-Cl), creatinine clearance (Cr-Cl) and 24-h urine albumin, α1-microglobulin (α1-MG) and retinol binding protein (RBP) excretion were assessed in a cohort of 11 morbidly obese women (BMI 46±4, mean±SD) before and 12 months (m) after Roux-en-Y bypass (RYGB) surgery. Weight loss was 46 kg at 12 m. Io-Cl fell from 121 ml/min at baseline to 89 ml/min at 12 m after surgery (p=0.03). Cr-Cl tended to decrease, but the change was not statistically significant. Excretion of α1-MG declined, but albumin and RBP excretion was unchanged. The decrease in Io-Cl correlated with change in weight (r=-0.49) and 24-hr creatinine excretion (r=-0.51). The change in α1-MG excretion did not correlate with change in weight.

Urine values prior to and following RYGB surgery

| Serum or urine test | Baseline, 0 m, mean±SD | 6 m, mean±SD | 12 m, mean±SD | P-value, paired t-test, 0-6 m | P-value, paired t-test, 0-12 m |
|---|---|---|---|---|---|
| Serum creatinine, mg/dL | 0.8±0.19 | 0.8±0.14 | 0.7±0.10 | 0.58 | 0.22 |
| Urine creatinine, mg/24h | 1341.7±434.4 | 1019.1±213.1 | 1035.1±255.0 | 0.01 | 0.006 |
| Creatinine Clearance, ml/min | 120±64 | 95±30 | 98±27 | 0.06 | 0.07 |
| Creatinine Clearance, ml/min/1.73M² | 89±45 | 84±21 | 91±24 | 0.25 | 0.52 |
| Iothalamate Clearance, ml/min | 121.1±31.9 | 93.0±33.9 | 82±23.7 | 0.2 | 0.03 |
| Iothalamate Clearance, ml/min/1.73M² | 94.9±27.7 | 83.0±23.6 | 84.6±20.9 | 0.6 | 0.38 |
| Urine α1-MG excretion mg/24h | 12.4±5.1 | 11.2±5.59 | 8.5±3.3 | 0.58 | 0.04 |

*Conclusions:* Weight loss after RYGB was associated with a fall in GFR measured by Io-Cl, a reduction in urinary creatinine excretion and tubular proteinuria. Further investigations are needed to determine the mechanism(s) by which GFR changes following weight loss and whether resolution in glomerular hyperfiltration after RYGB leads to beneficial long-term outcomes.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1352

**Corticosteroids Augment Cyclosporine Nephrotoxicity in Childhood Nephrotic Syndrome: Potential Role of Alternatively Activated Macrophages** Hiroya Hasegawa,[1] Yohei Ikezumi,[1] Toshiaki Suzuki,[1] Tamaki Karasawa,[1] Hiroshi Kawachi,[2] David J. Nikolic-Paterson,[3] Makoto Uchiyama.[1] *[1]Department of Pediatrics, Niigata University Medical and Dental Hospital; [2]Depatment of Cell Biology, Institute of Nephrology, Niigata University Graduate School of Medical and Dental Sciences, Niigata-City, Japan; [3]Monash University Department of Medicine, Monash Medical Centre, Clayton, Victoria, Australia.*

Aim: Cyclosporine A (CsA) is an effective steroid-sparing agent for patients with steroid-dependent nephrotic syndrome (SDNS) that may, however, cause chronic interstitial damage. We have previously reported that infiltration of macrophages with an alternatively activated phenotype (M2) is closely associated with the pathogenesis of interstitial fibrosis in IgA nephropathy, and that this is augmented by corticosteroid therapy. This study examined the possible involvement of M2-type macrophages in cyclosporine nephrotoxicity in SDNS.

Material and Methods: A total of 12 children diagnosed with SDNS who were treated with CsA for more than 2 years were investigated. Six biopsy specimens from age-matched SDNS children who had not recieved CsA treatment were used as the control. Biopsy sections were stained for α-smooth muscle actin (α-SMA), type I collagen, CD68 (total macrophages), CD163 (M2 marker) and CD86 (B7-2; M1 marker).

Results: The CsA-treated group showed a significant increase in interstitial fibrosis with accumulation of interstitial CD68+ macrophages compared with SDNS control patients (both p<0.01). Dual immunofluorescence staining showed that about 95% of CD68 macrophages expressed CD163, but were negative for CD86, indicating an M2 phenotype. There was a significant correlation between the degree of interstitial fibrosis and the number of interstitial CD163+ cells (p<0.01), and between interstitial fibrosis and the dose of steroid used during CsA treatment (p<0.05), while no correlation was found between the dose of steroid used before CsA treatment and histological changes.

Conclusion: Our findings suggest that M2-type macrophages may participate in the development of interstitial fibrosis induced by CsA. Steroid treatment during CsA treatment might augment CsA nephrotoxicity.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1353

**Focal Segmental Glomerulosclerosis Plays a Major Role in the Progression of IgA Nephropathy** Gary S. Hill,[1] Khalil El Karoui,[1] Alexandre Karras,[2] Christian H. Jacquot,[2] Patrick Bruneval,[1] Dominique Nochy.[1] *[1]Pathology Department, Hôpital Europeen Georges Pompidou; [2]Nephrology Department, Hôpital Europeen Georges Pompidou.*

IgA nephropathy (IgAN) often shows lesions morphologically identical with those of focal segmental glomerulosclerosis (FSGS).

A cohort of 128 patients with IgAN was evaluated (i) according to the Oxford classification of IgAN and (ii) to determine the extent to which IgAN could be interpreted in terms of a FSGS.

We were able to categorize 101 patients (78.9%) as having some form of FSGS, notably FSGS with hyalinosis (46 patients) and collapsing glomerulopathy (11 patients). Eighteen patients (14%) had no glomerular lesions, and 11 (8.6%) had mild lesions not definably FSGS. Patients with FSGS had much worse renal survivals than those without (32.6% vs 95.1% at 80 months, p = .00027). Comparison of pure forms of FSGS (excluding collapsing glomerulopathy) with cases of FSGS with superimposed other glomerular lesions (mesangial hyperplasia, endocapillary hypercellularity, glomerular necroses, extracapillary proliferation), revealed that FSGS with superimposed glomerular lesions did worse than cases of pure FSGS (22.8% versus 49.2% renal survival at 80 months, p = .042). However, the pure cases had relatively poor survival even without superimposed other glomerular lesions. Glomerular capsular adhesions, were studied in our IgAN biopsies, lupus nephritis (100 biopsies), and primary FSGS (26 biopsies). Capsular adhesions with no lesions in the underlying tuft, consistent with podocyte abnormality, were found regularly in FSGS (69%) and IgAN (41%), but infrequently in lupus (8%). Fifteen IgAN biopsies were also studied immunohistochemically. There was early focal loss of podocyte markers (synaptopodin, GLEPP-1, nephrin, VEGF) in glomeruli still histologically normal. Proliferating cells staining as PECs (PAX2+, cytokeratins+), grew inward along the adhesion onto the tuft, forming a monolayer positive for PAX2, WT-1, PCNA, and cytokeratins. All cases showed changes basically similar to those described in FSGS in other studies, and strongly suggest that a podocytopathy similar to that in primary FSGS occurs frequently in IgAN.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1354

**Subclassification of Focal Segmental Glomerulosclerosis in IgA Nephropathy: Is It of Clinical Value? Evidence from the Oxford Classification Cohort** Ian Roberts,[1] Shubha S. Bellur,[1] H. Terence Cook.[2] *[1]John Radcliffe Hospital, Oxford; [2]Imperial College, London, United Kingdom.*

Focal segmental glomerulosclerosis (FSGS) is frequent in IgA nephropathy (IgAN). It may result from fibrosis of proliferative lesions or reflect podocyte injury analogous to primary FSGS. It has been proposed that subclassification of segmental sclerosis in IgAN is of prognostic value. Here we subclassify FSGS in the Oxford Classification patient cohort and correlate histology with clinical variables.

There was segmental sclerosis of at least one glomerulus in 76% biopsies from 265 patients in the cohort; 147 with FSGS had slides available for second review. The slides were reviewed by a single pathologist and segmental sclerosing lesions subclassified.

Sixty-two of 147 biopsies (42%) showed endocapillary hypercellularity, 16 (11%) hyalinosis, 9 (6%) tip lesions, 54 (37%) podocyte hypertrophy and 13 (9%) resorption droplets within podocytes. None of the biopsies showed collapsing FSGS. There was no significant correlation between percentage of glomeruli with endocapillary hypercellularity and extent of segmental sclerosis.

Tip lesions and podocyte hypertrophy were associated with greater initial proteinuria (see table). There was no correlation between any of the above features and initial GFR or rate of loss of renal function at follow-up.

| | Absent (-) Present (+) | Initial urine protein (g/24hrs) mean±SD | Follow-up urine protein (g/24hrs) mean±SD | Initial GFR (ml/min) mean±SD | Rate of loss of renal function (ml/min/1.73m2 per year) |
|---|---|---|---|---|---|
| Endocapillary proliferation | - | 2.5±2.3 | 1.9±1.8 | 71±35 | -3.7±5.9 |
| | + | 2.6±1.9 ns | 1.6±1.2 ns | 84±38 ns | -5.4±10.8 ns |
| Tip lesion | - | 2.4±1.9 | 1.7±1.4 | 77±37 | -4.6±8.4 |
| | + | 4.9±3.3 p=<0.02 | 2.9±3.2 ns | 68±21 ns | -2.4±9.5 ns |
| Podocyte hypertrophy | - | 2.2±1.8 | 1.7±1.5 | 79±37 | -4.2±6.5 |
| | + | 3.1±2.4 p=<0.02 | 2.0±1.7 ns | 73±36 ns | -4.8±10.9 ns |
| Hyalinosis | - | 2.6±2.1 | 1.8±1.6 | 78±37 | -4.6±8.8 |
| | + | 2.2±2.2 ns | 1.9±1.8 ns | 60±28 ns | -3.2±4.3 ns |

We conclude that podocyte hypertrophy and tip lesions in IgAN-associated FSGS are markers of podocyte injury and associated with higher levels of proteinuria. Subclassification of segmental sclerosis is not of prognostic value in this cohort.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1355**

**Use of the Oxford Classification of IgA Nephropathy To Predict Renal Outcome: A Retrospective Analysis** Timothy T. Yau,[1] Stephen M. Korbet,[1] Melvin M. Schwartz,[2] David J. Cimbaluk.[2] *[1]Department of Nephrology, Rush University Medical Center, Chicago, IL; [2]Department of Pathology, Rush University Medical Center, Chicago, IL.*

The Oxford classification of IgA nephropathy (IGAN) assesses 4 histologic features (Mesangial hypercellularity (M)- </>50%, Endocapillary proliferation (E)- N/Y, Segmental scars (S)- N/Y, Tubulointerstitial fibrosis(T)- 0=<25%, 1=26-50%, 2=>50%) and has been reported as having prognostic value. We tested the clinical significance of the classification in a retrospective study of 72 of our adult pts with IGAN. The pts were 42±15 yrs old, with 56% male and 54% white, 21% Asian, 19% Hispanic and 6% black. The baseline SCr was 2.0±1.9 mg/dl, MDRD eGFR 57±29 ml/min (>60 ml/min in 49% and <15 in 11%,6 pts with ESRD) and the UPro was 2.1±1.7 g/d. All pts had microscopic hematuria and in 26% it was macroscopic. Of the 4 histologic features evaluated, only the degree of tubulointerstitial fibrosis (T0, T1, T2) demonstrated a significant correlation to worsening baseline SCr (1.4±1.4, 1.5±0.5, & 3.8±2.4: p<0.0001), eGFR (71±26, 56±19 & 26±17, p <0.0001) and UPro (1.8±1.5, 2.4±2.5 & 2.7±1.4: p<0.05). Follow-up (FU) on 54 pts was 69±56 mo with FU >1 yr in 85% and >5 yrs in 48% of pts. Pts were treated with ACEi/ARBs-78%, fish oil-70% and steroids-32%. At last follow-up, 17% of pts reached the endpoints of doubling SCr (4%) or ESRD (13%). Only the degree of tubulointerstitial fibrosis (T0, T1, T2) was predictive of progressive renal disease with a follow-up SCr of 1.2±0.4, 3.1±2.6 & 4.4±3.0 (p<0.0001) and MDRD eGFR (69±21, 37±25 & 24±17, P<0.0001). This was associated with 3%, 29% and 50% of pts (p<0.001) reaching the composite endpoint and the renal survival at 5 and 10 yrs for T0, T1 & T2 was 100%, 100%, & 34% and 100%, 50%, & 17% (overall, p<0.001). There was no significant difference in follow-up SCr, MDRD eGFR or proportion of pts reaching the composite endpoint based on the M, E or S scores. In conclusion, we find that of the histologic features assessed by the Oxford classification, only the degree of tubulointerstitial fibrosis correlates with renal function and proteinuria at baseline and is predictive of outcome in our IGAN pts.

**Oxford Classification of IgA Nephropathy: Outcomes Predictors** Lilian P. F. Carmo, Igor Marques, Liliany P. Repizo, Lectícia Jorge, Elerson Costalonga, Denise Mac Malheiros, Rui Toledo Barros, Viktoria Woronik. *Nephrology, University of São Paulo, São Paulo, Brazil.*

IgA nephropathy (IgAN) is the most common glomerular disease worldwide. There is continuing debate whether pathological parameters contribute additional prognostic information beyond that provided by clinical features. The Oxford Classification proposed some pathological features that predict risk of progression of renal disease in IgAN. We reviewed biopsies according to this new classification and performed a retrospective study using clinical data to access the factors that determine adverse outcomes.We analyzed 165 patients with biopsy-proven IgAN at our center from 1999 to 2009, 62 patients meet inclusion criteria of age > 18 years, biopsies containing at least 8 glomeruli and follow up longer than 2 years.The primary endpoint was reduction of at least 50% of the initial eGFR (MDRD) and/or ESRD.The multivariate analysis was designed to address which of the select pathology variables (mesangial hypercellularity, segmental glomeruloesclerosis, endocapillary hypercellularity, crescents, tubular atrophy/interstitial fibrosis and artery lesions) were independent predictors of outcome.

Baseline features

| | |
|---|---|
| Age (years) | 37±13,6 |
| Female | 53% |
| Hypertension | 56% |
| eGFR (ml/min/1,73m²) | 57.8 ±34,8 |
| Proteinuria (g/d) | 2.9±2.6 |
| Duration of follow-up (years) | 4.7 ± 2,2 |
| Glomerulus numbers | 12.6 ± 4,3 |
| Mesangial hypercellularity | 79% |
| Endocapillary hypercellularity | 25% |
| Artery lesions | 54.8% |
| Crescents | 35.5% |

In the multivariate linear regression model, we observed that the rate of renal function decline correlated with segmental glomerulosclerosis (p=0,042) and vascular lesions (p=0,006) after adjustments for hypertension, initial eGFR and proteinuria. At multivariate logistic regression analysis, the presence of fibrosis > 50% was an independent factor for the primary endpoint after adjusting for initial eGFR (p=0.028; OR=7.2; CI 1.7-41.7). Histopathologic features of segmental glomeruloesclerosis, fibrosis > 50% and artery lesions correlated with patients who are at high risk for progressive loss of kidney function. These pathological features were independent of clinical parameters in predicting the outcome in IgAN.

**The Oxford Scoring System for IgAN Has Excellent Interobserver Consistency in a Population of Canadian Children** Maury N. Pinsk,[1] Chantal Bernard,[4] Janusz Feber,[6] Ian W. Gibson,[2] Aviva M. Goldberg,[2] Christoph Licht,[7] Aicha Merouani,[5] Andrew W. Wade,[3] Tom D. Blydt-Hansen.[2] *[1]University of Alberta, Edmonton, AB, Canada; [2]University of Manitoba, Winnipeg, MB, Canada; [3]University of Calgary, Calgary, AB, Canada; [4]McGill University, Montreal, QC, Canada; [5]Universite de Montreal, Montreal, QC, Canada; [6]University of Ottawa, Ottawa, ON, Canada; [7]University of Toronto, Toronto, ON, Canada.*

The Oxford classification of IgAN is s scoring system with proven reliability and validity in a mixed international population of adult and pediatric patients. A subanalysis of the pediatric cohort used in the initial study suggested the validity of the scoring system in children. However, in Canada, unique populations such as First Nations/ Aboriginals are known to develop IgAN, but were not represented in the original Oxford classification. Purpose: Using a national Renal Disease Database for the Canadian Pediatric Population (REDDCAPP), we sought to confirm the interobserver consistency of the Oxford scoring system in an independent population Canadian children with biopsy proven IgAN/HSPN. Method: 12 children enrolled in the registry had tissue pathology examined by two independent renal pathologists in a blinded fashion. Scores from each pathologist were analyzed using Intraclass correlation coefficients to determine interobserver consistency. Results: Overall consistency between rating pathologist was excellent. Scores for mesangial proliferation, fibrinoid tuft necrosis, extracapillary proliferation, glomerulosclerosis, tubular inflammation, fibrosis and atrophy were all very good to excellent (ICC>0.7). Similar to the Oxford Classification data, assessment of adhesions to Bowman's capsule and endocapillary proliferation was only poor to good. (ICC < 0.3). Conclusions: When applied to a unique cohort of Canadian children with IgA nephropathy, the Oxford Scoring System has overall excellent interobserver consistency.

**Regulatory T Cells (Treg) and Interleukin 17 Producing T Cells (TH17) in IgA Nephropathy** Roberta Camilla,[1] Valentina Daprà,[1] Elisa Loiacono,[1] Licia Peruzzi,[1] Cristiana Rollino,[2] Giulietta Beltrame,[2] Michela Ferro,[2] A. Amore,[1] Rosanna Coppo.[1] *[1]Nephrology, Dialysis and Transplant, Regina Margherita Hospital, Turin, Italy; [2]Nephrology and Dialysis, G.Bosco Hospital, Turin, Italy.*

**INTRODUCTION AND AIMS:** IgA nephropathy (IgAN) presents with a dysregulation of the immune system leading to abnormal immune response to mucosal antigens. In these patients, we recently reported an increased expression of Toll-like receptor-4 (TLR4) in peripheral blood mononuclear cells (PBMC). Interest has been recently focused on the balance between interleukin (IL)-17 producing T cells (TH17) and regulatory T (Treg) cells in immune-mediated diseases. We aimed at investigating Treg/TH-17 producing cells in patients with IgAN, looking at correlations with TLRs expression, innate immunity marker.

**METHODS:** PBMC were isolated from 28 patients with IgAN (median age 39.6, IQ range 19-65 years), e-GFR 92.6 ± 46.5 ml/min, proteinuria 0.2 g/day (IQ range 0.10-0.40), and from healthy controls (HC).

The research protocol included the measurement in Taqman of mRNA expression of Treg regulation-associated genes (Foxp3), TH17-related factors (IL-17 and retinoid orphan nuclear receptor RORc), and TFG-beta1 which modulates the differentiation of TH17. Similarly, mRNAs encoding for TLR 2, 4 and 4 were measured.

**RESULTS:** The transcriptional level of Foxp3 was significantly lower in patients with IgAN versus HC (0.82 ± 0.30 vs 1.05 ± 0.37, p= 0.041), while those of IL-17 and of its regulatory factor RORc were slightly, but not significantly increased (IL-17 1.17 ± 1.07 vs 1.05 ± 0.41 in HC, RORc 1.25 ± 0.85 vs 1.14 ± 0.71 in HC). A significant correlation was found between IL-17 and RORc mRNAs values (p<0.0001). Transcriptional levels of TGF beta1 were similar to controls and were directly correlated with RORc (p=0.0015) and IL-17 (p=0.031) mRNAs in patients with IgAN. ROR-C level were inversely correlated with e-GFR values (p=0.06). Foxp3 and TLR4 expression were inversely correlated (p= 0.022).

**CONCLUSIONS:** In patients with IgAN there is a functional defect in Tregs correlated with signs of hyperactive innate immunity. TGF beta 1 correlates with the expansion of TH17 cells.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1359**

**Role of Innate Immunity (Toll-Like Receptors) in the Pathogenesis of Henoch-Schoenlein Purpura** Roberta Camilla, Valentina Daprà, Elisa Loiacono, Licia Peruzzi, A. Amore, Rosanna Coppo. *Nephrology, Dialysis and Transplant, Regina Margherita Hospital, Turin, Italy.*

**INTRODUCTION** Toll Like Receptors (TLRs) trigger innate and adaptive immune response. We previously demonstrated (*Clin Exp Immunol* 2009, **159:** 73–81) an up-regulation of TLR4 in peripheral lymphomonocytes (PBMC) of patients with primary IgA nephropathy (IgAN). Since Henoch-Schoenlein purpura (HSP) is a vasculitis which can present with renal involvement and IgAN, we aimed at investigating TLRs in PBMC of patients with HSP.

**METHODS** We studied 15 children (8 males, age 7.4 ±1.8 y) with purpuric rash flare due to HSP before treatment was started; 7 had renal involvement (hematuria, in 4 cases also >0.5 urinary proteine/creatinine excretion).

TLR 3, 4 and 9 was quantified in PBMC both as mRNA (using real-time PCR Taqman, normalizing results on Abelson gene) and as receptor expression with cytofluorimetric method (mean fluorescence intensity, MFI). We then analyzed the switch from proteasome to immuneproteasome (which was activated in IgAN patients and correlated with TRLs expression), studying the ratio between LMP2/β1, MECL1/β2, LMP7/β5 subunits in real-time PCR. Results were compared with a previously studied cohort of 47 patients with primary IgAN.

**RESULTS** We observed a significant up-regulation of TLR4 in HSP patients with respect to healthy controls (HC) (mRNA 3.84 ± 2.88 U vs1.46 ± 1.43 U, p=0.0001, MFI: 2.39 ± 0.75 U vs 1.60 ± 0.44 U, p<0.0001); TLR 9 were also upregulated, but the difference was less statistically significant (mRNA 3.07 ± 2.02 U vs 1.41 ± 1.59 U, p= 0.0125; MFI 1.4 ± 0.2 U vs 1.57 ± 0.26 U, p=ns). The expression of TLR3 did not differ in HSP patients and HC. Results were similar to those observed in primary IgAN.

We failed to show, as opposed to what we observed in primary IgAN, a switch from proteasome to immune-proteasome (LMP2/β1 0.8 ± 0.3 in HSP vs 0.9 ± 0.4 in HC, MECL1/β2 0.7 ± 0.2 vs 1.0 ± 0.3 , LMP7/ β5 1.0 ± 0.2 vs 1.1 ± 0.3).

**CONCLUSIONS** In HSP purpura, as in primary IgAN, we found an activation of innate immunity, with an upregulation of TLRs, especially TLR4, in peripheral lymphomonocytes which, in acute purpuric flare, was independent from the renal involvement.

### F-PO1360

**Thrombotic Microangiopathy in IgA Nephropathy** Khalil El Karoui,[1] Gary S. Hill,[1] Alexandre Karras,[2] Patrick Bruneval,[1] Christian H. Jacquot,[2] Dominique Nochy.[1] *[1]Pathology, Hopital Georges Pompidou, Paris; [2]Nephrology, Hopital Georges Pompidou, Paris.*

The clinical and histologic features of IgA nephropathy (IgAN)are quite varied. Thrombotic microangiopathy (TMA) is a histologic lesion characterized initially by platelet aggregates and fibrin thrombi, with subsequent organization and luminal narrowing. Cases of TMA associated with IgAN have been described, usually in association with severe hypertension. The purpose of this study was to define the frequency and clinical and histologic features of IgAN-associated TMA.

This series is comprised of 132 adults patients (92% Caucasian, 73.5% male, mean age 38.66 ±13.5 ), with a mean follow-up of 41.6±25 months.

In our series, 53% of patients presented lesions of TMA, acute or organized, in arteries and/or arterioles. There were no age or sex differences between those with and without TMA. Hypertension was present in 90.3% of patients, with 23.4% of them showing malignant hypertension. However, 9.7% of patients with TMA were normotensive. Those with TMA had greater proteinuria and worse renal function than those without TMA. Histologically, the group with TMA had greater glomerulosclerosis (53 ± 27% vs 15 ± 17%, p <0.0001) and worse tubulointerstitial fibrosis (47 ± 25% vs 14 ± 15%, p = 0.0001) than the group without TMA. However, 11.6% of patients showed near-normal histology. TMA was associated with a poor prognosis with doubling of SCr or need for dialysis in 50.7% versus 14% in the group without TMA (p=0.0001). On multivariate analysis it sorted as an independent risk factor for poor prognosis.

Lesions of TMA are frequent in IgAN, sometimes quite early. They may appear in normotensive patients with near-normal renal histology. Their prognosis appears to be independent of that due to other histologic lesions and the Oxford criteria. The pathophysiologic mechanisms involved remain undetermined, but the present study rules out severe hypertension as a sole cause.

The frequency and severity of TMA in IgAN suggests that TMA should be sought systematically in IgAN in order that this aspect can be treated appropriately.

**Renal Thrombotic Microangiopathy Associated with Graft Versus Host Disease after Hematopoietic Stem Cell Transplantation** Akiko Mii, Megumi Fukui, Emiko Fujita, Akira Shimizu. *Nippon Medical School.*

Thrombotic microangiopathy (TMA) is one of the main complications after hematopoietic stem cell transplantation (HSCT). The pathogenesis of HSCT-associated TMA is controversial but considered to involve various factors such as total body irradiation, use of calcineurin inhibitors for prophylaxis against graft versus host disease (GVHD), viral infection, and GVHD.

In the present study, we examined the clinical and pathologic features of two renal biopsy and five autopsy cases with pathological TMA after HSCT, in order to clarify the association between GVHD and HSCT-associated TMA.

In our cases, the median interval of renal biopsy or autopsy after HSCT was 14.3 months (range 1-42 months). Acute GVHD was seen in all of seven patients. Chronic GVHD occurred in one biopsy and three autopsy cases. The clinical evidence of TMA was detected in two autopsy cases. All cases showed renal impairment.

The predominant histological findings were diffuse glomerular endothelial cell injury such as diffuse glomerular capillary collapse with pericapsular fibrosis, double contour of the glomerular basement membrane (GBM) with enlarged subendothelial space, and post-mesangiolytic sclerosis with reticular mesangial matrix. Marked hyalynosis was notable in small arteries. In addition, all our cases showed glomerulitis, renal tubulitis, and peritubular capillalitis (PTCitis) with CD3+ cells infiltration. These findings indicate that GVHD is involved in the development of TMA. Furthermore, C4d deposition on diffuse glomerular capillaries and patchy PTCs was evident in two biopsy and one autopsy cases, indicating that some cases of TMA may be mediated by the antibody deposition and complement activation in chronic GVHD.

In conclusion, renal GVHD occurred in our cases of the development of TMA after HSCT. Some cases of TMA were probably associated with the antibody-mediated renal endothelial cell injury in chronic GVHD. Kidney is one of the target organs of acute and chronic GVHD that may be associated with the development of TMA after HSCT.

### F-PO1362

**Contaminated Cocaine and Drug-Induced Vasculitis** Martina M. McGrath,[1] Tamara Isakova,[1] Ann M. Mottola,[2] Karen Laliberte,[1] John Niles.[1,2] *[1]Department of Medicine, Renal Unit, Massachusetts General Hospital, Boston, MA; [2]Department of Pathology, ANCA Laboratory, Massachusetts General Hospital, Boston, MA.*

**Purpose:** We have noted a possible association between cocaine use and ANCA positive vasculitis of the drug-induced pattern.

**Methods**: To address this uncommon presentation we restrospectively reviewed the medical records and laboratory results of individuals seropositive with MPO, PR3 or both. From November 2009 through May 2010 at the Massachusetts General Hospital ANCA laboratory we identified 11 such patients, all of whom had a history of cocaine use. Charts were reviewed for clinical presentation, laboratory and other diagnostic evaluation, including skin biopsies when available. Cocaine exposure was identified from the patient history in all cases.

**Results:** Five patients in this series tested positive for both MPO and PR3, a pattern virtually never found except in rare patients with drug induced vasculitis. Based on the currently available data, 8 out of 11 patients presented with a vasculitic rash, of whom 3 had a biopsy proven diagnosis of leukocytoclastic vasculitis. Three patients had renal involvement (1 with biopsy proven necrotizing and crescentic glomerulonephritis). Additional clinical features included arthritis and fever.

**Conclusion:** Recent reports have indicated that illicit cocaine may be cut with levamisole. Levamisole was formerly used as an antihelminthic and chemotherapy agent, but is no longer sold for use in humans due to its side effect and efficacy profile. Levamisole has previously been linked to neutropenia and cutaneous vasculitis. Given the recent increase in levamisole usage as a cutting agent, and the long exposure time present in most cases of drug induced ANCA vasculitis, it is possible that a rapid increase in cases of cocaine / levamisole induced vasculitis may be developing. Additional testing and review is needed to confirm and extend our findings based on these and future patients.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1363

**Pauci-Immune Crescentic Glomerulonephritis in Rheumatoid Arthritis with Serologic Heterogeniety: A Clinico-Pathological Study** Ryuji Ohashi, Steven P. Salvatore, Surya V. Seshan. *Pathology, Weill Cornell Medical College, New York, NY.*

Purpose: A spectrum of renal diseases (immune-mediated with or without immune complexes, secondary to disease modifying agents-drugs, amyloidosis) are encountered in rheumatoid arthritis (RA), though not as common as in systemic lupus erythematosus. This study presents a cohort of 18 patients with pauci-immune crescentic glomerulonephritis (CrGN).

Methods: A retrospective review of the renal pathology database in our center was conducted for a 25 year period where 120 cases of RA with kidney biopsies were identified, 18 of which showed acute/chronic CrGN. The clinico-pathological findings and serology are described.

Results: The age of the patients ranged from 33-80 yrs, M:F is 4:14 presenting with Cr 1.2-10 mg/dl in 14 pts and <1.5 mg/dl in 4 pts. Six pts had nephrotic range proteinuria, and all others had 1-2 gm/24hrs, and hematuria was noted in 8 pts. Evidence of small vessel vasculitis was observed as skin rash showing leukocytoclastic vasculitis in 5 pts, pulmonary hemorrhage in 2 pts and renal vasculitis in one pt. Other associated autoimmune diseases include ulcerative colitis in 2 pts, Crohn's disease in one pt, amyloidosis in one pt, chronic pulmonary disease in one pt, and psoriasis in one pt. Serology: P-ANCA+ in 3 pts, anti-MPO+ in 3 pts, C-ANCA+ in 1 pt, P&C ANCA+ in 1 pt, negative ANCA in 6 pts, and not known in 4 pts. Positive ANA ranged from 1:40-1:640 in 3 pts, and anti-dsDNA was negative and complement levels were normal in all except one pt. Anti-TNFα therapy was given to 3 pts (2 ANCA+, 1 ANCA-). Renal biopsy findings are as follows: acute CrGN in 6 pts, acute & chronic CrGN in 8 pts and chronic GN in 4 pts. One pt also showed acute interstitial nephritis in the latter group.

Conclusion: CrGN contributes to significant renal insufficiency in RA pts, often associated with renal and extrarenal small vessel vasculitides. CrGN in the setting of RA may be ANCA negative or secondary to coincidental predominantly P-ANCA or anti-MPO ANCA. CrGN in RA pts with anti-TNFα therapy may be associated with positive or negative ANCA serology.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1364**

**Assessment of Lamp2 Autoantibodies in Patients with ANCA Disease** Aleeza J. Roth, Michael C. Brown, Anshul K. Badhwar, Hyun Chul Chung, Donna O. Bunch, JulieAnne G. McGregor, Susan L. Hogan, Yichun Hu, J. Charles Jennette, Gloria A. Preston, Ronald J. Falk. *UNC-Kidney Center, Chapel Hill, NC.*

Kain et al. have reported (Nat Med,2008) that 93% of patients with pauci-immune glomerulonephritis have autoantibodies directed against LAMP-2, a heavily glycosylated type 1 membrane protein expressed by many cell types. Most of these patients also have anti-neutrophil cytoplasmic autoantibodies (ANCA) specific for MPO or PR3. To test the validity of this report, sera from patients with MPO- or PR3-ANCA disease were tested for the presence of anti-LAMP-2 compared to controls. LAMP-2 antigens used for screening included recombinant protein produced in a human cell line (HEK293), protein expressed in a glycosylation-deficient hamster cell line (CHO LDL-D), and a synthetic peptide containing the suggested LAMP-2/FimH-like epitope. The pathogenicity of LAMP-2 antibodies raised to the peptide epitope was also tested in rats.

By ELISA, 17% of ANCA-positive sera (n=104) reacted with LAMP-2 protein purified from the human cell line, and 3% reacted with peptide (2 SD above mean of normal controls). Only two patient sera reacted with both the recombinant protein and the peptide. Similar to ANCA patients, 12% of sera from the general population with FimH positive E. coli urinary tract infections (n=105) reacted to recombinant protein and 4% to peptide. By indirect immunofluorescence assay, no patient sera produced positive staining of cells regardless of cell type or glycosylation state (N- plus O- glycans, N-glycans only, or no glycosylation). Samples deemed positive by ELISA were screened by western blot and thus far 0/3 were confirmed as positive. To explore the pathogenic role of anti-LAMP-2 antibodies, high-titer anti-LAMP-2 rabbit IgG or normal rabbit IgG was injected i.v. into WKY rats. None of the rats developed lesions, including no glomerular crescents or necrosis. These data do not support a high frequency of LAMP-2 autoantibodies in patients with MPO-ANCA or PR3-ANCA disease, and do not confirm the pathogenicity of anti-LAMP-2 in rats. The basis for the discrepancy between our data and the studies by Kain et al. is unknown.

**F-PO1365**

**The Role of In Situ-Immune Complex (MPO-Anti MPO Antibody) in the Pathogenesis of MPO-ANCA Associated Glomerulonephritis** Soko Kawashima,[1] Katuko Sano,[1] Kazuhito Fukuoka,[1] Yoshinori Komagata,[1] Shinya Kaname,[1] Yoshihiro Arimura,[1] Akira Yamada,[1] Akihiko Kudo,[2] Hayato Kawakami.[2] *[1]First Department of Internal Medicine, Kyorin University School of Medicine, Mitaka, Tokyo, Japan; [2]Department of Anatomy, Kyorin University School of Medicine, Mitaka, Tokyo, Japan.*

Myeloperoxidase anti-neutrophil cytoplasmic antibody (MPO-ANCA)-associated glomerulonephritis (GN) is characterized by pauci-immune necrotizing crescentic glomerulonephritis (NCGN). Although MPO-ANCA has been thought to be involved in the activation of neutrophils in the pathogenesis of NCGN, recent studies suggest a different role of immunoglobulins and complements in the formation of glomerular capillary injury in a rat model for NCGN. Here we investigated the possible roles of MPO and IgG in the patients with MPO-ANCA-associated GN. Nineteen patients were analyzed for glomerular infiltration of MPO-positive cells, deposition of extracellular MPO and endothelial cell injury especially in an early stage of the diseases. Immunohistochemistry using enzyme-labeled antibody or immunofluorescence of MPO, IgG and CD34 were performed for the samples of renal biopsies. Sixteen out of 19 patients showed a weak but significantly positive staining for IgG (pauci-immune GN), which was accompanied by MPO deposits in the glomerular capillary walls. Interestingly, the CD34 staining clearly decreased around the area where MPO and IgG were detected, suggesting that the endothelial injury occurs resultantly. These findings suggest that MPO, IgG and the immune complexes composed of MPO-anti MPO antibody may play some direct roles in the pathogenesis of glomerular capillary injury in human MPO-ANCA associated GN.

**F-PO1366**

**Glomerular Endothelial Injuries Contributing to the Formation of Segmental Glomerular Sclerosis in Idiopathic Membranous Nephropathy** Megumi Fukui,[1] Akiko Mii,[1] Akira Shimizu,[2] Emiko Fujita.[2] *[1]Internal Medicine (Division of Neurology, Nephrology, and Reumatology), Nippon Medical School, Tokyo, Japan; [2]Analytic Human Pathology, Nippon Medical School, Tokyo, Japan.*

Membranous nephropathy (MN) with focal segmental sclerosis is associated with a poorer prognosis than MN without these lesions. The mechanism of the development of segmental sclerosis is still uncertain. Vascular endothelial growth factor (VEGF), produced mainly by glomerular podocytes has a crucial role to promote endothelial cell survival and differentiation. We selected renal biopsy cases of idiopathic MN cases with segmental sclerosis (n=27/ total 250), and examined the pathological characterizations. We assessed the formation of segmental sclerosis, focusing on the glomerular endothelial cell injuries, thickening of GBM, and VEGF expression in podocytes. The average age of these cases is 62.6±1.87 years. About 68% (n=19) of these cases developed nephrotic syndrome. eGFR (mean 55.86±3.93 mg/dl) was significantly lower compared to MN without segmental sclerosis. In histopathology, all segmental sclerotic lesions in MN showed the obliteration and loss of glomerular capillaries with disappearance of CD34+ endothelial cells. Interestingly, in all cases with segmental sclerosis, narrowing of glomerular capillaries with ultrastructually endothelial cell injuries was evident even in non-sclerotic areas. No difference of VEGF expression on podocytes was detected between MN cases with and without segmental sclerosis (1.3/0-4 semiquantitative score in MN with sclerosis vs. 1.2/0-4 scores in MN without sclerosis, p=0.82). However, significant difference of the thickness of GBM was evident between MN cases with and without segmental sclerosis (1390nm in MN with sclerosis vs. 955nm in MN without sclerosis, P<0.05). There were no significant differences of the percentage of global sclerotic glomeruli, the degree of interstitial fibrosis and arteriosclerosis were noted between MN cases with and without segmental sclerosis. In conclusion, the glomerular capillary and endothelial cell injuries may be induced by GBM organization and thickening that contributed to the formation of segmental sclerosis in MN.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1367**

**The Value of IgG Subclass Staining in Renal Biopsies with Membranous Glomerulonephritis (MGN)** Cheng C. Huang,[1] Sergey V. Brodsky,[1] Alia S. Albawardi,[1] Anjali A. Satoskar,[1] Gyongyi Nadasdy,[1] Lee A. Hebert,[2] Brad H. Rovin,[2] Tibor Nadasdy.[1] *[1]Pathology, The Ohio State University, Columbus, OH; [2]Medicine, The Ohio State University, Columbus, OH.*

A recent study suggested that the antigen responsible for idiopathic MGN is M-type phospholipase A2. However, differentiating idiopathic from secondary MGN in a kidney biopsy is difficult with the currently available methodologies. Previous studies indicate that the glomerular capillary deposits in idiopathic MGN contain primarily IgG4. The goal of our study was to examine the usefulness of IgG subclass staining in MGN.

We perform immunofluorescence staining for the IgG subclasses in every renal biopsy with IgG pre or codominant immune complex glomerulonephritis, including MGN. Between January 2007 and February 2010, 159 consecutive MGN cases were stained for IgG subclasses. Determining the underlying etiology in MGN can be difficult at the time of the biopsy because associated conditions may not be obvious at that time. Follow-up studies to explore additional underlying conditions in these patients are ongoing. At this stage, we have documented an underlying etiology in 30 of the 159 biopsies: systemic lupus erythematosus (n=14), Hepatitis C virus infection (n=5) hepatitis B virus infection (n=4) and malignancy (n=7). Of the 129 remaining (idiopathic?) MGN cases 84 (65%) were either IgG4 predominant (n=57) or codominant (n=27). In contrast, of the 30 secondary forms of MGN, only 13 (43%) were IgG4 predominant (n=8) or codominant (n=5).

Our findings indicate that based on IgG subclass staining, idiopathic and secondary forms of MGN cannot be differentiated reliably. However, in the absence of IgG4 predominance or codominance, an underlying secondary etiology should be suspected. The finding that in several "idiopathic" MGN cases an IgG subclass other than IgG4 is predominant indicates a heterogenous IgG response to different pathogenic antignens in this disease. Correlating IgG subclass staining with phospholipase A2 receptor and other potential antigens in MGN may be helpful in developing a new, more accurate etiologic classification of MGN

Disclosure of Financial Relationships: nothing to disclose

**F-PO1368**

**IgG1 Is the Predominant Immunoglobulin Subclass in Deposits in Hepatitis C Virus Infection Associated Membranous Glomerulonephritis (MGN)** Alia S. Albawardi,[1] Sergey V. Brodsky,[1] Anjali A. Satoskar,[1] Cheng C. Huang,[1] Gyongyi Nadasdy,[1] Lee A. Hebert,[2] Brad H. Rovin,[2] Tibor Nadasdy.[1] *[1]Pathology, The Ohio State University, Columbus, OH; [2]Medicine, The Ohio State University, Columbus, OH.*

The most common glomerular disease associated with Hepatitis C virus infection is a type of membranoproliferative glomerulonephritis with or without cryoglobulin deposits. Rarely, hepatitis C infection may also be associated with fibrillary glomerulonephritis and MGN but reports on Hepatitis C virus associated MGN are scant. The goal of our study was to see if hepatitis C virus associated MGN can be differentiated from idiopathic MGN based on renal biopsy findings.

We reviewed our renal biopsy files between January 2003 and June 2010 and identified 10 cases of MGN in Hepatitis C virus infected patients. All patients had variable degree of proteinuria and microscopic hematuria. Seven patients had increased serum creatinine levels. Most patients had normal serum complement levels and negative cryoglobulin tests. By routine light microscopy, immunofluorescence and electron microscopy, hepatitis C virus associated MGN could not be distinguished from idiopathic MGN. We performed immunofluorescence with antibodies to the IgG subclasses in all 10 biopsies. In 8 of the 10 biopsies, IgG1 was the predominant (in 5) or codominant (in 3) subclass in the glomerular capillary deposits. IgG4 was predominant in only one case and codominant with IgG1 in two cases. One biopsy was IgG3 dominant, and an additional one was IgG3 and IgG1 codominant. Interestingly, in one biopsy, fibrillary GN and MGN coexisted.

In our and others' experience, in idiopathic MGN, the glomerular capillary deposits are usually IgG4 predominant. The finding that in Hepatitis C infection related MGN the deposits are IgG1 predominant indicates that the pathogenetic antigen (probably a protein related to the virus) induces a different type of immune response than the antigen (e.g., phospholipase A2 receptor) in idiopathic MGN, despite the very similar morphology. Therefore, IgG subclass staining is helpful in differentiating idiopathic MGN from secondary forms, including Hepatitis C infection related MGN.

**Class V Lupus Nephritis – At the Interface between Membranous Glomerulonephritis and Lupus Nephritis – Can IgG Subclass Staining Help?** Anjali A. Satoskar,[1] Cheng C. Huang,[1] Lee A. Hebert,[2] Brad H. Rovin,[2] Tibor Nadasdy.[1] *[1]Pathology, Ohio State University, Columbus, OH; [2]Nephrology, Ohio State University, Columbus, OH.*

From a histologic perspective, Class V (membranous) lupus nephritis overlaps with two major disease categories – idiopathic and other secondary forms of membranous glomerulonephritis (MGN); and proliferative lupus nephritis. It can be the presenting manifestation in systemic lupus erythematosus (SLE) in the absence of proliferative glomerular lesions. Therefore correctly recognizing it as a class of lupus nephritis and differentiating it from idiopathic and other causes of secondary MGN becomes important. The goals of our study are two fold: 1. look for differences in pre/co-dominant IgG subclass staining between lupus MGN and other forms of MGN; 2. see whether IgG subclass pre/co-dominance is similar in membranous lupus nephritis and proliferative lupus nephritides.

We examined 87 cases of lupus nephritis (including Class II, III, IV, V and combined) and 145 cases of MGN, (idiopathic n=129; other secondary forms n=16). We considered the predominant or co-dominant IgG subclass staining in each case for this study. The percentage of cases with pre/co-dominant staining for each IgG subclass in the examined disease categories are shown below.

Table 1. Percentage of cases with respective IgG subclass predominance

| Diagnosis | IgG1 | IgG2 | IgG3 | IgG4 |
|---|---|---|---|---|
| Lupus V | 75 | 20 | 30 | 40 |
| Lupus III/IV and V | 82 | 34 | 39 | 8.6 |
| Lupus III or IV | 84 | 22 | 52 | 4.5 |
| Secondary MGN | 56 | 0 | 12 | 50 |
| Idiopathic MGN | 47 | 2.3 | 19.3 | 65 |

IgG4 pre/co-dominance is highest in idiopathic MGN; it is also common in lupus MGN and other secondary forms of MGN but not in proliferative lupus nephritis, suggesting some association between IgG4 subclass response and subepithelial (membranous pattern) immune complex formation. IgG2 predominance is overall uncommon, but if present, favors lupus nephritis. IgG1 and IgG3 predominance makes idiopathic MGN less likely but cannot differentiate lupus from other secondary forms of MGN. IgG subclass staining in MGN and lupus nephritis is helpful but it should only be interpreted in the context of clinical, serological and morphologic findings.

**Prognosis and Risk Factors of Idiopathic Membranous Nephropathy in China** Ke Zuo, Yongchun Ge, Yan Wu, Sha-Lin Zou, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, Jiangsu, China.*

Idiopathic membranous nephropathy (IMN) is a representative form of refractory nephrotic syndrome in China. Although IMN is thought to run a more benign course in Asia than in the Caucasian population, there was no convincing study to show the long-term prognosis and risk factors of IMN in Chinese population. We enrolled all patients admitted to Nanjing Institution of Nephrology from January 1990 to December 2005 with biopsy proven IMN and at least 24 months follow-up in this retrospective chart review. The clinical and histopathologic parameters were recorded. At last a total of 217 patients were included in the study, age from 19 to 83, with male ratio 58.5%. The overall renal survival rate was 96.8%, 93.0% and 85.5% at 5, 10 and 15 years after renal biopsy, respectively. When clinical and histopathologic features of biopsy were evaluated, patients with hypertension (p=0.012) and elevated serum creatinine (Scr, $p<0.001$) had worse prognosis. Cox univariate analysis showed hypertension (HR=4.85, $p=0.022$), age section (one decade as a section, HR=1.65, $p=0.037$) and elevated Scr (HR=13.627, $p<0.001$) were clinical risk factors, and tubulointestinal chronic change stage (defined as fibrosis area percentage of cortical tubulointestinal tissue, every 25 percent as a stage, HR=3.627, $p<0.001$) was the pathological risk factor for end stage renal function (ESRF). Cox multivariate analysis showed elevated Scr (HR=11.0, $p=0.001$) and tubulointestinal chronic change stages (HR= 6.93, $p=0.002$) were independent risk factors for ESRF. During follow-up, proteinuria remission (including complete remission and partial remission) occurred in 174 patients (80.2%), and those patients have got a better prognosis than Non-remission (NR) patients ($p<0.001$). In conclusion, IMN is a disease with a comparatively good prognosis in Chinese population and elevated Scr, tubulointestinal chronic change and NR of proteinuria are independent risk factors of ESRF.

**Thin Basement Membrane Nephropathy Associated with Idiopathic Membranous Nephropathy: A Clinico-Pathological Study of Seven Cases** Su-Xia Wang, You-Kang Zhang, Lin-Chang Liu, Gang Liu, Zhi-Yong Cai. *Renal Division, Peking University First Hospital, Beijing, China.*

Thin basement membrane nephropathy (TBMN), the leading cause of microscopic hematuria in children and adults, is characterized by a diffusely thinned glomerular basement membrane (GBM). Previous studies indicated that TBMN might present with other glomerulopathies. However coexistence of TBMN with membranous nephropathy (MN) was rarely reported. In this study we investigated the prevalence and clinico-pathological features of subjects with TBMN and MN. Four hundred and seventy one subjects (Jan 2003-Dec 2009) diagnosed as stage IMN by renal biopsy were included in this study. All the specimens were re-evaluated by electron microscope. Seven (1.49%) of the 471 patients were diagnosed as stageIMN accompanied by diffuse thinning GBM (TBMN-MN). Thickness of the GBM was measured as 205.96±45.94nm. Thirteen patients with stageIMN and normal GBM thickness and 14 patients with only TBMN were taken as controls. The mean age and gender ratio were matched in three groups (Table 1). Patients with TBMN-MN had more prominent hematuria (p=0.015) and less proteinuria (p=0.019) compared with patients with stageIMN, and had more prominant proteinuria than TBMN group ($P=0.001$). After a follow-up by 22.3±16.4 months, the rate of remission (proteinuria <0.15g/24h) in TBMN-MN group was higher than in stage I MN group ($P=0.017$). So we conclude that TBMN could coexist with stage IMN. Patients with TBMN-MN presented less proteinuria and might have a better prognosis than patients with only stageIMN.

The clinical features of patients with TBMN-MN, stageIMN and TBMN

| | TBMN-MN (n=7) | Stage IMN(n=13) | TBMN(n=14) |
|---|---|---|---|
| Sex(male:female) | 1:6 | 6:7 | 3:11 |
| Mean age(years) | 43.0±12.2 | 48.5±13.8 | 41.4±9.8 |
| Duration (months) | 2.7±2.1 | 2.3±2.6 | 52.7±108.4 |
| Hematuria (>3 RBC/HP) | 7(100% )* | 5(38.46%) | 14(100%) |
| Proteinuria (g/24h) | 2.09±0.78*# | 7.19±5.14 | 0.30±0.25 |
| Serum albumin (g/L) | 37.17±3.64* | 30.51±6.74 | 40.05±3.73 |
| Creatinine(μmol/L) | 65.30±14.09 | 72.90±13.68 | 68.28±12.79 |

*p<0.05, TBMN-MN vs stage IMN; # P<0.05, TBMN-MN vs TBMN.

**Effect of Fenofibrate on Symmetric Dimethylarginine and Asymmetric Dimethylarginine in Dyslipidemic Patients with Type 2 Diabetes** Jean-Claude Ansquer,[1] Paul E. Valensi,[2] R. Neil Dalton,[3] Isabelle M. Gottlieb,[1] Sylvie M. Le Mouhaer,[1] Michel C. Conte.[1] *[1]Clinical Research and Development, Cardiometabolic Unit, Laboratoires Fournier SA, Solvay Pharmaceuticals Now Part of Abbott, Daix, France; [2]Hôpital Jean Verdier, Bondy, France; [3]King's College London, St Thomas' Hospital, London, United Kingdom.*

Background and purpose of study: Symmetric and asymmetric dimethylarginine (SDMA and ADMA) are proposed as endogenous markers of glomerular filtration and endothelial dysfunction, respectively. It is known that fenofibrate may induce an increase in creatinine as well as homocysteine levels. The relationships between SDMA and creatinine, ADMA and homocysteine were thus explored. Methods: We studied the effect of a 24-week fenofibrate treatment on SDMA and ADMA in a random sample of 118 patients from a double-blind, randomized, 2-arm study in patients with type 2 diabetes previously treated with metformin (HbA1c ≤8.5%) with dyslipidemia not appropriately controlled with a statin (triglycerides ≥1.69 mmol/L and LDL-C ≤3.35 mmol/L). The study compared fenofibrate 160mg and a stable dose of metformin (FM) daily versus placebo and metformin (M), in addition to statin therapy. Results: Creatinine increased by 7.0 μmol/L at end of treatment in the FM group and decreased by 0.6 μmol/L in the M group, from an overall mean baseline value of 75.9 μmol/L. Homocysteine increased by 4.7 μmol/L in the FM group and by 0.8 μmol/L in the M group, from an overall mean baseline value of 11.9 μmol/L. For both parameters the between group difference for absolute changes was significant (p<0.001). Mean values at baseline were 0.46 μmol/L for SDMA and 0.48 μmol/L for ADMA; these parameters were unchanged at end of treatment with FM or M (0.00 to 0.01 μmol/L). In both groups a minimal linear correlation between creatinine and SDMA and no linear correlation between homocysteine and ADMA were observed for changes from baseline. Conclusion: while not definitive, these results, using SDMA and ADMA as surrogate biomarkers, support the hypothesis that moderate increases in creatinine and homocysteine with fenofibrate treatment are independent of glomerular filtration and endothelial dysfunction, respectively.

Disclosure of Financial Relationships: Employer: Laboratoires Fournier S.A., Solvay Pharmaceuticals in now Abbott.

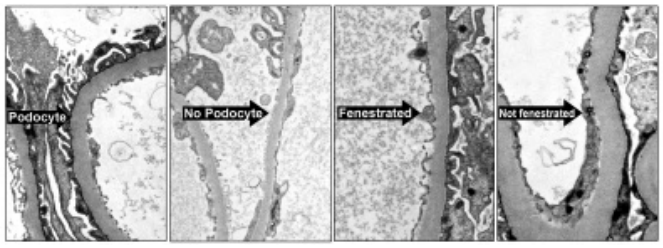
**Podocyte Detachment and Reduced Endothelial Cell Fenestration in Type 2 Diabetic Nephropathy** E. Jennifer Weil,[1] Clinton C. Mason,[1] Berne Yee,[2] Bryan D. Myers,[3] Kevin V. Lemley,[4] Robert G. Nelson.[1] *[1]NIDDK, AZ; [2]Southwest Kidney Institute, AZ; [3]Stanford University, CA; [4]USC, CA.*

The quantitative relationships of podocyte detachment and reduced endothelial cell fenestration with the classic functional and structural changes of diabetic nephropathy and their appearance on microscopy are described in type 1 but not in type 2 diabetes (T2DM). Percent glomerular basement membrane (GBM) denuded of podocytes, percent of endothelium without normal fenestration, and the classic structural changes of diabetic glomerular injury were assessed morphometrically in 37 Pima Indians with T2DM; 11 with normoalbuminuria (albumin/creatinine ratio (ACR) <30 mg/g), 16 with microalbuminuria (ACR=30-299 mg/g), and 10 with macroalbuminuria (ACR≥300 mg/g). Glomerular filtration rate (GFR) was measured by iothalamate clearance. The mean proportion of GBM denuded of podocytes was higher in macroalbuminuric subjects than in those with normo- or microalbuminuria (1.4% vs. 0.3%; p=0.008) and correlated positively with ACR (r=0.36, p=0.030) and negatively with podocyte number per glomerulus (r=-0.40, p=0.015) and GFR (r=-0.33, p=0.047). The mean proportion of non-fenestrated endothelium was also higher in the macroalbuminuric group (81% vs. 73%; p=0.001) and correlated positively with GBM thickness (r=0.39, p=0.017), ACR (r=0.46, p=0.003), and fractional mesangial area (r=0.57, p<0.001) and negatively with GFR (r=-0.47, p=0.004). Percent GBM denuded of podocytes and percent of filtration surface not covered by fenestrated endothelial cells were not correlated (r=0.26, p=0.125).



Podocyte detachment and diminished endothelial cell fenestration are related to classic lesions of diabetic nephropathy and to kidney function in T2DM. The contribution of these factors to impairment of glomerular permselectivity and GFR remains to be determined.

**Altered Expression Profile of Cadherins in Human Diabetic Nephropathy**
Nileshkumar Shah,[1] Jan Willem Leeuwis,[2] Dionne Van der Giezen,[2] Amelie Dendooven,[2] Tri Q. Nguyen,[2] Roel Goldschmeding,[2] Sarah Yates,[1] Mark Edward Dockrell.[1] *[1]SW Thames Institute for Renal Research, London, United Kingdom; [2]Pathology, University Medical Center Urtecht, Utrecht, Netherlands.*

Cadherins (CDH) are transmembrane proteins that maintain epithelial integrity and cell phenotype. CDH1 (E-cadherin) loss in proximal tubule epithelial cells (PTECs) has been studied extensively in the context of renal fibrosis. In this study we investigated CDH6 (K-cadherin) and CDH2 (N-cadherin) along with CDH1 in human diabetic nephropathy to assess their contribution in tubulointerstitial fibrosis.

We stained archived human kidney tissue (normal n=5 and diabetic nephropathy of various stages n=5 (tubular score 0-2, RPS DN Working Group, JASN 2010;21:556-63)) using antibodies to the extracellular domain of CDH1, CDH2 and CDH6 together with megalin (marker of proximal tubule (PT)) or calbindin D28K (marker of distal tubule (DT)). Localization was studied by confocal and epifluorescence microscopy. In a separate cohort we investigated the appearance of CDH6 in urine from 8 patients with diabetic nephropathy (stage 3&4) compared to healthy controls.

In normal human kidney CDH2 and CDH6 co-localized with megalin (PT), while CDH1 co-localized with calbindin D28K (DT). CDH6 and CDH2 staining showed a basolateral distribution in normal renal proximal tubule.

In early diabetic nephropathy lesions, however, expression of CDH6 and CDH2 on the basal side was hazy and discontinuous. In advanced lesions with marked tubulo-intersitial fibrosis, CDH6 and CDH2 expression was lost. 6/8 patients with CKD had detectable urinary full length CDH6; no full length CDH6 was detectable in control urine.

Our data confirm that CDH 2 & 6, but not CDH1 are present in human proximal tubules. In addition, CDH2 & 6 are depleted early in diabetic nephropathy. CDH6 is detectable in urine from diabetic patients with CKD. This loss of CDH6 in renal fibrosis correlates with our *in vitro* work on human proximal tubule cell models (submitted to this meeting in a separate abstract). This reduction may result in reduced cell cell contact, possible epithelial-to-mesenchymal transition or cell shedding.

### F-PO1375

**Better Steroid Response in IgG4-Positive Tubulointerstitial Nephritis (TIN)**
Tae Young Kim,[1] Jung-Sik Park,[1] Kyoung Min Kim,[1] Soon Bae Kim,[1] Young Mee Cho,[2] Sung Hee Kang.[2] *[1]Nephrology, Asan Medical Center, Seoul, Korea; [2]Pathology, Asan Medical Center, Seoul, Korea.*

**Purpose**This study was performed to evaluate clinical manifestations of IgG4-positive TIN.**Methods** Out of 5,174 renal biopsies performed during January1996 to February2010,were 82 patients had TIN.TIN was defined as tubulointerstitial infiltration of inflammatory cells and fibrosis with atrophy and dilatation.Thirty six patients were excluded because of combined kideny disease.Biopsy tissues were lost in 2 patients.Immunperoxidase staining with IgG4 were performed in remaining 44 patients."Improve"was defined as"increase of eGFR more than25%".**Results**The median numbers of IgG4-positive plasma cells were 8(range 1-90)/HPF.The number of IgG4-positive plasma cell was significantly associated with the degree of proteinuria($r$=0.471, $p$=0.018) and age($r$=0.529, $p$=0.007)in 25 patients.Eighteen patients out of 25 IgG4 positive patients received steroid treatment and all of them improved,however thirteen patients out of 19 IgG4 negative patients received steroid treatment and only 7 of them improved($p$=0.002).When we analyzed among 3group(No IgG4 cell, 1≤IgG4cells<10, IgG4 cell≥10 ,no parameter was significantly different.

Characteristics

| characteristics | | IgG4 positive cell | |
|---|---|---|---|
| | positive(n=25) | negative(n=19) | p-Value |
| Age(yr) | 47±14 | 51±15 | 0.477 |
| Female gender [n(%)] | 14 (56) | 9(47) | 0.763 |
| Hypertension [n(%)] | 18(72) | 11(58) | 0.34 |
| Kidney size [n(%)] | | | 0.261 |
| normal or increased | 22(88) | 14(74) | |
| decrease | 3(12) | 5(26) | |
| Hepatobiliary disease [n(%)] | 8(32) | 4(21) | 0.431 |
| Sjogren' disease[n(%)] | 1(4) | 2(11) | 0.407 |
| Drug history [n(%)] | 5(20) | 7(37) | 0.223 |
| eGFR(ml/min/1.73m2) | 17.6±16.11 | 27.3±23.0 | 0.197 |
| Proteinuria (mg/day) | 1614±1017 | 1633±1108 | 0.972 |
| ALP(IU/L) | 144+93 | 149±167 | 0.554 |
| Outcome | | | 0.045 |
| improve | 18(72) | 8(42) | |
| aggravate or maintain | 7(28) | 11(58) | |

**Conclusion** IgG4 positive TIN showed better response to steroid treatment than IgG4 negative TIN.IgG4 staining should be routinely performed for TIN without other specific kidney disease.

### F-PO1376

**Kidney Injury Molecule-1 Identifies High Proximal Tubular Injury as a Prominent Component of Monoclonal Nephropathy**
Ping L. Zhang,[1] Manish Nepal,[2] Michael F. Schultz,[2] Francis Dumler,[1] Joseph V. Bonventre.[3] *[1]Departments of Anatomic Pathology and Nephrology, William Beaumont Hospital, Royal Oak, MI; [2]Department of Nephrology, Geisinger Medical Center, Danville, PA; [3]Renal Division, Brigham and Women's Hospital, Boston, MA.*

The contribution of proximal tubular injury to renal failure has not been well studied in monoclonal nephropathy. The purpose of this study was to characterize proximal tubular injury in variants of monoclonal nephropathy, using kidney injury molecule-1 (KIM-1), a specific and sensitive injury marker for proximal tubules. A group of 20 control nephrectomy sections without injury (removed for renal tumors) and 23 cases of monoclonal nephropathy (including 3 with light chain deposition disease, 13 with cast nephropathy, 6 with AL/AH amyloidosis, and 1 with proximal tubulopathy) were stained for KIM-1 using immunohistochemical techniques (AKG monoclonal antibody). Staining scores in proximal tubules were graded from 0 (no stain) to 1+ - 3 + (mild to strong staining). Control sections stained negatively for KIM-1 (0.15 ± 0.05 arbitrary units). The corresponding serum creatinine (sCr) levels were within the normal range (1.01 ± 0.07 mg/dl). In the monoclonal nephropathy group, values were significantly higher (KIM-1: 2.33 ± 0.21 arbitrary units [p = 0.0001] and sCr: 5.54 ± 0.77 mg/dl [p = 0.0001], using unpaired student t test, respectively). A total of 82.6 % (19/23) of monoclonal nephropathy cases stained moderately or were strongly positive for KIM-1 in the proximal tubules. The KIM-1 staining scores were significantly correlated with sCr levels (r = 0.703; p = 0.0001). Electron microscopy confirmed deposition of monoclonal particles in several variants of monoclonal nephropathy. In summary, toxic monoclonal materials (mainly light chains) affect the proximal tubules in most cases of monoclonal nephropathy, regardless of whether the dominant findings are in glomeruli (light chain deposition disease), distal nephron tubules (cast nephropathy), or monoclonal amyloidosis. We conclude that KIM-1 staining has identified proximal tubular injury as an important component of acute kidney injury in this disease entity.

### F-PO1377

**CD4+ T Cells Play a Major Role in the Development of Histological Phenotype of Kidney Injury**
Hitoshi Nakashima, Katsuhisa Miyake, Maho Watanabe, Takao Saito. *Div of Nephrolo & Rheumatolo, Dpt of Int Med, Fukuoka University, Fukuoka, Japan.*

In glomerulonephritis (GN), the variable Th1-Th2 predominance of response influences the histologic patterns and severity of GN. In most cases of rapidly progressive GN there is evidence for an important role for cellular immune effectors; Th1 cells, macrophages, and neutrophils. On the other hand the predominant deposition of IgG4 in idiopathic membranous nephropathy (MN) indicates that its presence characterizes the humoral immune response (Th2) of the disease. In tubulointerstitial nephritis (TIN), Mickliz's disease associated TIN, which is one of IgG4-related TIN, shows characteristic serum IgG4 elevation and increased IgG4-positive plasma cells in the renal interstitium. IgG4 is the rarest IgG subclass and is a Th2-dependent isotype. Therefore IgG4-related TIN may be developed in Th2 response. While TINs associated with Sjogren syndrome and with sarcoidosis is supposed to be developed in Th1 responses. CD4+ T cells are supposed to be key components of these kidney injuries.

In this study we evaluated the expressions of various cytokines in the biopsied kidney specimens by real time PCR, and compared of cytokine production pattern between ANCA related GN and idiopathic MN, and between Sjögren's syndrome associated TIN and Mickliz's disease associated TIN, respectively. The expression levels of IL-2, IFN-γ, IL-17 and IL-6 in ANCA related GN were significantly higher than those in MN. On the other hand the expression levels of IL-4, IL-10 and TGFβ in MN were significantly higher than those in ANCA related GN. Additionally the expression of Foxp3, a transcription factor specific for Treg cell, was also increased in MN. Similar contrastive results were obtained in the examination between Sjögren's syndrome associated TIN and Mickliz's disease associated TIN.

These findings suggested that Th1 and Th17 cell responses play a central role in pathogenesis in ANCA related GN and Sjögren's syndrome associated TIN. On the contrary in MN and Mickliz's disease associated TIN, Th2 and Treg cell responses play a major role.

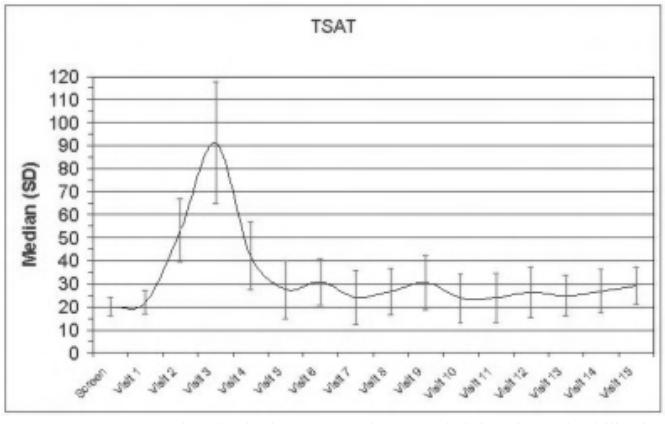
Disclosure of Financial Relationships: nothing to disclose

**F-PO1378**

**Iron Indices and Intravenous (IV) Ferumoxytol: Time to Steady State – A Pilot Study** Myra D. Carreon,[1] Toros Kapoian,[1] Gertrude S. Lefavour,[1] Richard A. Sherman,[1] John A. Walker,[1] Neeta O'Mara,[2] Amelia Gajary.[2] *[1]Med/Neph, UMDNJ-RWJ Med School, New Brunswick, NJ; [2]Dialysis Clinic, Inc., North Brunswick, NJ.*

**BACKGROUND:** Feraheme™ (ferumoxytol), the newest IV iron, is administered as two 510mg doses separated by 3-8 days; however, it is not known when iron saturation (TSAT) and ferritin can be accurately checked after a loading dose. This single center study investigated the time to stabilization of TSAT and ferritin in hemodialysis (HD) patients. **METHODS:** Two 510mg doses of Feraheme™ were administered 3 days apart (on visits 1 and 2) to 15 stable patients on thrice weekly HD (11M, 4F; age 60 ± 14yr; dry weight 80 ± 30kg). Patient selection was as follows: anemia due to iron deficiency, TSAT ≤ 25% or serum ferritin ≤ 200ng/dL; and ferritin <1200ng/dL; hemoglobin 10-13.5g/dL; no IV iron or blood transfusions within 30 days of visit 1. Blood was analyzed on dosing days and preceeding 13 subsequent consecutive treatments. Trends in serum ferritin, TSAT, and high sensitivity CRP were evaluated. **RESULTS:** After loading, TSAT and serum ferritin stabilized 3 and 5 treatments later, respectively. Peak values for TSAT and ferritin occurred 1 and 2 treatments after loading, respectively. No trend in CRP was noted. Three of 15 patients had end-of-study (EOS) visit 15 ferritin > 800ng/mL (2 of 3 had baseline ferritin > 800ng/mL). There were 7 adverse events that occurred during drug dosing visits including headache (3), hypotension (2), nausea (1) and hypertension (1). No events required hospitalization or discontinuation of the study.

| | Baseline | Peak | Stabilization | EOS |
|---|---|---|---|---|
| Ferritin (ng/mL) | 628 | 984 | 713 | 669 |
| TSAT (%) | 20 | 91 | 28 | 29 |
| CRP (mg/dL) | n/a | 5.4 | 5.2 | 5.7 |



**CONCLUSION:** There is a lag between Feraheme™ administration and stabilization of TSAT and ferritin. Iron studies should be drawn no sooner than 2 weeks after completion of a 2-dose load.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1379**

**Weekly (qW) Subcutaneously (SC) Administered Epoetin Alfa (Epo) Reduces Erythropoiesis-Stimulating Agents (ESA) Exposure While Maintaining Hemoglobin (Hb) Concentration** Toros Kapoian,[1] Neeta O'Mara,[2] Amelia Gajary,[2] Kathy Bivens.[2] *[1]Med/Neph, UMDNJ - RWJ Med School, New Brunswick, NJ; [2]Dialysis Clinic, Inc (DCI), North Brunswick, NJ.*

**Background:** In 2007, the FDA issued a warning about complications related to ESA exposure. Following that advisement, we altered our target Hb from 11-13 g/dL to 10-12 g/dL. To further minimize ESA exposure, in late 2008, we developed a SC Epo protocol that was put into effect in Apr/May 2009. We initially transitioned patients from thrice weekly (TIW) intravenous (IV) Epo to TIW SC Epo and then aimed to reduce the frequency to qW as quickly as possible. **Methods:** All DCI New Jersey HD patients who remained in the same facility during the study period from Jan 1, 2009 to Apr 30, 2010 were included. The initial TIW doses of SC Epo were 66-125% of the last IV Epo dose, depending on the baseline Hb. We analyzed the last 3 months (mos) of IV Epo utilization and compared this with SC Epo use during mos 1-3 and 7-9. Data on Epo dose (total Epo given per mo and units/kg/mo), Epo dosing frequency, number of administered (adm) doses and Hb were collected. **Results:** 160 patients (50% male, 56% white, 33% black, 46% diabetes, 24% hypertension) with mean age 66 years (range 26-94 years) and mean dialysis vintage of 5.5 years (range 1-32 years) were evaluated. Overall total monthly Epo utilization was reduced by 15.7%. Two-thirds of patients maintained Hb within the target range.

| | IV Epo | 3-Mo SC | 9-Mo SC | % Change |
|---|---|---|---|---|
| Epo Dose (total/mo) | 32,487,150 | 27,737,550 | 27,390,900 | ↓ 15.7 |
| Epo Dose (units/kg/mo) | 443,392 | 344,812 | 372,577 | ↓ 16.0 |
| Doses Adm | 5152 | 4629 | 2393 | ↓ 53.6 |
| Dosing qW | 14 | 92 | 121 | ↑ 764.3 |
| Dosing BIW | 2 | 8 | 23 | ↑ 1050 |
| Dosing TIW | 144 | 60 | 16 | ↓ 88.9 |
| % Hb < 10 | 5.0 | 13.7 | 15.0 | ↑ 200 |
| % Hb 10-12 | 63.7 | 61.3 | 66.3 | ↑ 4.0 |
| % Hb > 12 | 31.3 | 25.0 | 18.7 | ↓ 40 |

**Conclusions:** Conversion to SC Epo reduces Epo exposure by about 15% and reduces most patients to a weekly Epo dosing schedule while maintaining Hb in the target range.

**Race Does Not Appear To Influence ESA Use or Time to Hemoglobin Threshold among Elderly Patients Initiating Hemodialysis** Areef Ishani,[1,2,3] Haifeng Guo,[1] Suying Li,[1] Lih-Wen Mau,[1] Tom Arneson,[1] Stephan C. Dunning,[1] David T. Gilbertson,[1] Allan J. Collins.[1,3] *[1]Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN; [2]Minneapolis Veterans Affairs Medical Center, Minneapolis, MN; [3]Department of Medicine, University of Minnesota, Minneapolis, MN.*

The Centers for Medicare & Medicaid Services has proposed to change reimbursement for outpatient dialysis to a fixed-payment bundle that will include both outpatient dialysis therapy and injectable medications. The proposal does not include any adjustment for race. We have previously demonstrated that African-Americans (AA) use more ESAs during the first two months after dialysis initiation. For this study we aimed to determine if race influenced the time to a hemoglobin threshold of 11g/dL and total ESA use over the first six months of dialysis.

A cohort was constructed of 12,184 ESA-naïve patients who initiated hemodialysis between 1/2006, and 6/2007, were > 67 years at initiation, had Medicare as the primary payer for 2 years pre-initiation, and received erythropoietin (EPO) therapy (determined from Medicare claims) continuously during the first 6 post-initiation calendar months. Cox regression was conducted to determine the association between race and time to hemoglobin > 11g/dL. Linear regression was performed to determine the association between race and the cumulative EPO dose over six months.

Over the first 6 months of dialysis, AA lagged whites in their time to achieve the threshold hemoglobin value (HR 0.86; 95% CI 0.83-0.90). However, by 6 months the cumulative percent of individuals achieving the threshold hemoglobin value was identical by race (98%). Also, by six months there was no difference in the cumulative EPO dose used between AA and white patients (beta=0.003; p=0.87). These updated results suggest that early after dialysis initiation, AA lag whites in achieving a hemoglobin of 11g/dL, but this difference disappears by 6 months. These similar hemoglobin concentrations are achieved with similar EPO doses. These results suggest that the new Medicare bundle may not disadvantage AA with regard to ESA use within the first six months of dialysis.

**NT-proBNP Levels Are Associated with Severity of Anemia in CAPD Patients without Chronic Heart Failure** Yang Wook Kim,[1] Kyu-Bok Jin,[1] Tae Hee Kim,[2] Hyun Seung Lee.[2] *[1]Nephrology, Internal Medicine, Haeundae Paik Hospital, Inje University, Pusan, Korea; [2]Nephrology, Internal Medicine, Busan Paik Hospital, Inje University, Pusan, Korea.*

**Objective:** Natriuretic peptides are important in the maintenance of body volume homeostasis and elevated in patients with elevated myocardial wall stress. NT-proBNP is as a prognostic marker for risk of cardiovascular events. However, NT-proBNP is almost increased in patients with renal dysfunction. So, It may be limited to clinical application to chronic renal failure and dialysis patients, without symptoms of heart failure,especially.

The aim of this study was to investigate the factors associated with increased NT-proBNP level in asymptomatic patients within 1 month on continous ambulatory peritoneal dialysis(CAPD) without heart failure.

**Methods :** We enrolled 30 patients(14males, 16 females),aged 26-81years, who started to treat with CAPD within 1 month. We measured serum NT-proBNP, Hb, TnI(cardiac troponin I), iPTH, CK-MB and CRP in patients without heart failure through echocardiography during the same period.

**Results:** The mean LV ejection fraction was 62.86%(S.D.: 9.76%) and the mean LVMI was 133.30mg/m2 (S.D.: 30.57 mg/m2). The serum NT-proBNP in all patients was increased by the manufacturer-recommended age-specific cut-off(mean: 8,018 ± 12,119 pg/ml) and all TnI levels were within normal range. The mean hemoglobin was 9.53mg/dl (S.D.: 1.58 mg/dl). In the correlation analysis, the serum NT-proBNP levels showed reverse correlation with hemoglobin(r:-0.48; p <0.05). However, it did not correlate with TnI, CRP, IPTH, and CK-MB.

**Conclusions:** We suggest that elevated levels of NT-proBNP are associated with severity of anemia in CAPD patients without heart failure. The aggressive anemia treatment should be considered for the prevention of cardiovascular events in CAPD patients with elevated NT-proBNT level, not associated with chronic heart failure.

**IV Iron Replacement Therapy in Patients with ESRD Undergoing Home Dialysis: Experience with Ferumoxytol** Andrea Neitzer, Sheila Doss, Sumi Sun, Brigitte Schiller. *Satellite Healthcare, Mountain View, CA.*

IV iron administration in patients undergoing home dialysis is often challenging due to frequent visit requirements in order to administer sufficient iron. Feraheme (ferumoxytol), a novel iron product, allows for a rapid IV push administration of 510 mg. Ferumoxytol was introduced in an iron maintenance protocol for home dialysis patients in January 2010 following routine monthly blood work in 18 home dialysis clinics. The protocol prescribes 510 mg ferumoxytol to be given if TSAT <30% OR ferritin <500 ng/mL. Contraindications are iron hypersensitivity, ferritin ≥ 800 ng/mL, TSAT ≥50% or Hb > 12.5 g/dL.

A total of 431 incident and prevalent patients treated with peritoneal dialysis or home HD received 598 doses of ferumoxytol until the end of May 2010. 1.6% (7/431) of patients experienced adverse events including allergy, hypotension, and gastrointestinal symptoms resulting in an AE rate of 1.2% (7/598 doses). An SAE occurred in one patient due to an anaphylactoid reaction which resolved completely without sequelae.

A subset of 341 patients treated exclusively with ferumoxytol on this iron maintenance protocol with follow-up data during the 5 months required an average of 1.4 doses (range 1-4). 68% of patients were dosed only once, 26% twice, and 6% required three or more doses. Laboratory results are shown as mean ± SD 5 months prior and during ferumoxytol therapy.

| | Pre-ferumoxytol | Ferumoxytol |
|---|---|---|
| Hb (g/dL) | 11.5 ± 1.0 | 11.2 ± 0.9 |
| TSAT (%) | 32.9 ± 12.5 | 31.9 ± 10.5 |
| Ferritin (ng/mL) | 458 ± 245 | 508 ± 259 |

Clinical performance targets in patients treated solely with ferumoxytol have been reached by 74% of patients for Hb (10-12 g/dL), 85% for TSAT (20-50%), and 75% for ferritin (200-800 ng/mL).

These data indicate that ferumoxytol administered as one time 510 mg IV push in home dialysis patients is well tolerated and achieves excellent iron maintenance results. Its favorable utilization with rapid IV push and less frequent administration and a good safety profile confirming published data make ferumoxytol a valuable alternative for treating iron deficiency in home dialysis patients.

**Angiotensin Receptor Blocker Treatment Might Affect ESA Response through Disturbing Iron Homeostasis in Hemodialysis Patients** Kanemitsu Yamaya,[1] Yasushi Shimonaka,[2] Hisao Saitoh,[1] Tomihisa Funyu,[1] Hideaki Yamabe,[3] Chikaraa Ohyama.[3] *[1]Oyokyo Kidney Research Institute, Hirosaki, Aomori, Japan; [2]Chugai-pharmaceutical Co., Ltd., Kamakura, Kanagawa, Japan; [3]Hirosaki University, Hirosaki, Aomori, Japan.*

Purpose

Anemia and hypertension are the major complications in hemodialysis (HD) patients. It has been reported that the antihypertensive treatment such as angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin receptor blockers (ARBs) are related to erythropoiesis stimulating agents (ESA) hyporesponsiveness in hemodialysis (HD) patients. In the present study, we analyzed the relationship between ARB treatment, ESA hyporesponsiveness and iron homeostasis in HD patients.

Methods

We enrolled 456 HD patients, provided written informed consent in Oyokyo Kidney Research Institute. Patients with infection, severe inflammatory disorders or hematologic disorders were excluded. Anemia and other complications were treated according to national and K/DOQI guidelines. ESA dose was altered biweekly to maintain a target hemoglobin (Hb) level of 10-11g/dL. Clinical parameters and serum levels of hepcidin were measured at 0, 3 and 6 months after started observation.

Results

At the start of the study, 170 patients were without antihypertensive agents. On the other hand, 29 patients were received ACEIs and 242 patients were received ARBs. Fifteen patients were received Ca blockers or other agents. ESA dose and serum levels of hepcidin were significantly higher in patients received antihypertensive agents than in patients without antihypertensive agents. ARB received patients exhibited significantly higher ESA dose and serum levels of hepcidin than patients without antihypertensive agents, although Hb and ferritin were comparable. These results were consistent throughout observation period. Moreover, in 30 patients newly received ARB during observation period, serum levels of hepcidin was significantly elevated.

Conclusions

Present results indicate that antihypertensive treatment using ARB might affect ESA responsiveness through interfering with iron homeostasis.

**High Level of Non Transferrin Bound Iron (NTBI) in the Patients with Maintenance Hemodialysis (MHD) Is Linked to Erythropoietin Hyporesponsiveness** Takahiro Kuragano, Takeshi Nakanishi. *Hyogo College of Medicine, Department of Internal Medicine, Division of Kidney and Dialysis, Nishinomiya, Hyogo, Japan.*

Background/Aim; Serum free iron known as 'non transferrin bound iron' (NTBI) is potentially toxic, possibility leading to free radical generation. To clarify how much free iron in serum in maintenance hemodialysis (MHD) patients without intravenous (IV) iron administration and relationship between free iron and anemia therapy, we evaluated serum levels of NTBI, anemia and iron parameters. Method; 126 MHD patients, who were treated with erythropoietin not receiving IV iron in recent 6 months were recruited in this study. We measured blood level of hemoglobin (Hb), total cholesterol, triglyceride, iron, hepcidin, ferritin, total iron binding capacity (TIBC), transferrin saturation (TSAT), non transferrin bound iron (NTBI), IL-6, TNF-α, and high sensitive (h) CRP. Result; Serum levels of NTBI were significantly (P=0.04, R=0.18) correlated ferritin. There was no significant correlation between serum NTBI level and iron, TIBC, TSAT, transferrin, hepcidin, hCRP, IL-6 and TNF-α. Multivariate analysis was performed to investigate the predictors of NTBI in MHD patients using several variables (ferritin, TSAT, total cholesterol), which had a tendency for significant ($p<0.1$). Only ferritin was selected as a significant determinant of NTBI in MHD patient ($\beta=0.69$, $F=92$, $p<0.0001$). To investigate the relationship between NTBI and iron utilization in MHD patients, we divided into 4 groups according to Hb and ferritin level. Group I (n=37): low Hb (<10g/dL) and low ferritin (<100 ng/dL). Group II (n=20): low Hb and high ferritin (≥100g/dL). Group III (n=45): normal Hb (10≥g/dL) and low ferritin. Group IV (n=26): normal Hb and high ferritin. Serum level of NTBI of group II (0.72± 0.5μM)) was significantly ($p<0.05$) higher than group I (0.57±0.35μM), and III (0.58±0.28μM). Conclusion; In MHD patients, serum NIBI could be associated iron storage. In the patients with low Hb and high ferritin, serum level of NTBI was significantly higher than other groups, which might be relevant to the erythropoietin hyporesponsiveness.

**F-PO1385**

**Hepcidin, a Novel Diagnostic Marker of Iron Deficiency in CKD** Joshua Zaritsky,[1] Carlos Eduardo Azucena,[1] Brian Y. Young,[2] Barbara Gales,[1] Mark E. Westerman,[3] Tomas Ganz,[2] Isidro B. Salusky,[1] R. C. Pereira.[1] *[1]Pediatrics, UCLA, Los Angeles, CA; [2]Medicine, UCLA, Los Angeles, CA; [3]Intrinsic Life Sciences, La Jolla, CA.*

Hepcidin is a key regulator of iron homeostasis but its diagnostic utility remains untested in the setting of chronic kidney disease (CKD). Thus, we sought to compare serum hepcidin levels to the gold standard of iron status; bone marrow (BM) stained for iron-laden macrophages and erythroid precursors. Serum hepcidin was measured by competitive ELISA along with other iron markers in 64 pediatric patients with CKD stages 2-5D (Table) who underwent iliac crest bone biopsy. BM was Perl stained and iron was quantified blindly by two methods; 1) semi-quantitative: graded from 0 to 4+ (absent to diffuse) staining and 2) quantitative; positive stained area divided by total tissue area. With the reference standard (grade 0 staining), iron deficiency was present in 50% of patients. Using a cutoff of 200 ng/ml, hepcidin was 93% specific, 64% sensitive and had a positive predictive value (ppv) of 90% for the diagnosis of iron deficiency. This was similar to that of ferritin (cutoff of 150 ng/ml, 93% specific, 66% sensitive, 90% ppv) and superior to transferrin saturation (TSAT) (cutoff of 30%, 72% specific, 80% sensitive, 70% ppv) ($p<0.01$)(Figure). Hepcidin levels showed a high degree of correlation with quantitative staining ($r=0.7$, $p<0.001$) similar to that of ferritin ($r=0.7$, $p<0.001$) and TSAT ($r=0.5$, $p<0.002$). These findings suggest that hepcidin levels are as sensitive and specific for the diagnosis of iron deficiency as current day iron markers. Thus hepcidin may be novel and useful biomarker of iron status across the spectrum of pediatric CKD.

| Biochemical Variables | CKD 2-4 (Mean±SD) | PD (Mean±SD) | HD (Mean±SD) |
|---|---|---|---|
| N (M/F) | 16 (11/5) | 28 (16/12) | 26(15/5) |
| Age (yrs) | 15±3.2 | 16±3.1 | 19±5.5 |
| Hepcidin (ng/ml) | 182±109 | 510±365 | 527±364 |
| Ferritin (ng/ml) | 133±87 | 376±341 | 481±484 |
| TSAT (%) | 22±15 | 45±25 | 31±9 |
| HGB (g/dL) | 12.1±1.7 | 12±2 | 12.0±2.2 |
| iPTH (pg/ml) | 164±245 | 593±472 | 478±527 |
| Weekly sPO (u/kg) | 35±72 | 224±180 | 301±333 |

**Effect of Intravenous and Oral Ascorbic Acid in Hemodialysis Patients with Anemia and Hyperferritinemia** Ji-Min Jeon,[1] Yong-Ki Park,[1] Ji-Hwan Kim.[2] *[1]Division of Nephrology/Internal Medicine, DongRae BongSeng Hospital, Busan, Korea; [2]Division of Nephrology/Internal Medicine, Good Gang-An Hospital, Busan, Korea.*

Hemodialysis patients with anemia and hyperferritinemia often develop resistance to recombinant human erythropoietin(EPO). Ascorbic acid is believed to improve anemia in hemodialysis patients. We evaluated the efficacy of intravenous and oral ascorbic acid on Epo-hyporesponsive anemia in hemodialysis patients with hyperferritinemia. Forty-seven of 156 hemodialysis patients with Hb < 11g/dL and ferritin levels greater than 300ng/ml were prospectively followed up. Patients were randomly divided into three groups. 16 patients had received standard care(group 1), 17 patients had received standard care and daily oral ascorbic acid at a dose of 500mg/day(group 2) and 14 patients had received standard care and 300mg of intravenous vitamin C with each dialysis session(group 3). Each groups were similar in clinical characteristics. Blood samples for measurement of Hemoglobin, hematocrit, serum iron, ferritin, transferrin saturation and EPO dose were obtained at baseline and after three months of treatment. After 3 months, Hemoglobin and hematocrit and transferrin saturation levels significantly increased in group 2,3($p<0.05$) but not changed in group 1. EPO dosage and ferritin levels decreased in group 2,3($p<0.05$).

table 1. Baseline and 3 month Data summary

| | Group 1 | | Group 2 | | Group 3 | |
|---|---|---|---|---|---|---|
| | baseline | after 3 month | baseline | after 3 month | baseline | after 3 month |
| Hb(g/dL) | 8.9 ± 1.4 | 8.8 ± 1.3 | 8.8 ± 1.3 | 9.5 ± 1.1* | 9.0 ± 1.2 | 9.6 ± 1.2* |
| Fe(μ/L) | 55.84 ± 23 | 58.6 ± 19 | 58.57 ± 25 | 63.7 ± 22* | 61.12 ± 21 | 67.29 ± 19* |
| EPO dose(unit/week) | 14729 | 14538 | 15584 | 12369* | 14986 | 11345* |
| Ferritin(μg/L) | 764 ± 217 | 781 ± 192 | 783 ± 191 | 646 ± 189* | 754 ± 220 | 634 ± 231* |
| T sat(%) | 18 ± 6.4 | 18.2 ± 5.8 | 20.6 ± 5.5 | 26.4 ± 4.1* | 19.8 ± 4.9 | 24.5 ± 3.2* |

* is $p < 0.05$

There was no difference in group 2 and 3. In conclusion, Our study has demonstrated that intravenous or oral ascorbic acid therapy can improve anemia, hyperferritinemia and EPO resistance in hemodialysis patients. The effect of intravenous and oral ascorbic acid are similar. Further studies are needed to determine ascorbic acid dosing optimization.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1387**

**Cumulative Safety Experience in a Cohort of Patients with End Stage Renal Disease (ESRD) on Hemodialysis Receiving Ferumoxytol** Premila Bhat, Joesan A. Gabaldon, Jodumutt Ganesh Bhat. *Atlantic Dialysis Management Services, LLC, Ridgewood, NY.*

Ferumoxytol is a novel intravenous (IV) iron characterized by a carbohydrate-coated superparamagnetic iron oxide particle shown to result in lower free iron levels than other IV iron formulations. Ferumoxytol has been studied in over 1500 Chronic Kidney Disease and ESRD patients with a low occurrence of serious adverse drug reactions. We report here our experience treating a cohort of ESRD patients receiving hemodialysis at a regional chain of hemodialysis centers. An anemia-management protocol using ferumoxytol for IV injection was implemented. Patients were treated with ferumoxytol (510 mg injection delivered at a rate of up to 30 mg/sec) if they had Hemoglobin <13 g/dL; Transferrin Saturation <30% or Ferritin <500ng/mL; and no documented allergies or intolerance to other intravenous irons. Adverse drug events were prospectively monitored and reported. 609 patients received at least one dose of ferumoxytol in the three months following implementation of the ferumoxytol-based strategy (total 1379 doses, mean 2.26 doses/ patient). Eight injection-related adverse drug events were recorded. Six of 8 events were mild and included itching/rash (n=2), nausea (n=2), burning sensation (n=1), and a single hypotensive event wherein the patient transiently lost consciousness. This patient's hypotension and unconsciousness resolved upon completion of ferumoxytol injection. No other interventions were performed, and the patient did not require hospitalization. There were two (n=2) anaphylactoid reactions treated with IV corticosteroids and antihistamines. Both patients were hospitalized but neither required mechanical ventilation or intensive care. Anaphylactoid reactions occurred with the patients' first and second doses of ferumoxytol, respectively. In conclusion, ferumoxytol appears to be generally well tolerated when used to treat iron deficiency anemia in dialysis patients. Most reactions were mild, and occurrence of injection-related anaphylaxis was 0.15%, consistent with the incidence of such events in clinical trials to date.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1388**

**Tissue Distribution of $^{14}$C-Peginesatide Following IV Administration in Albino and Pigmented Rats** Kathryn W. Woodburn,[1] Yoshihiko Tagawa,[2] Yuu Moriya,[2] Christopher P. Holmes.[1] *[1]Affymax Inc, Palo Alto, CA; [2]Takeda Pharmaceutical Company, Ltd, Yodogawa-ku, Osaka, Japan.*

**Background:** Hematide™/peginesatide is a PEGylated, investigational, peptide-based erythropoiesis-stimulating agent that was designed and engineered to stimulate specifically the erythropoietin receptor dimer that governs erythropoiesis. This study was conducted to evaluate the tissue distribution of a single IV dose of $^{14}$C-peginesatide in both albino and pigmented rats. **Methods:** Male Sprague-Dawley rats (albino) were administered a single dose of 5 mg/kg $^{14}$C-peginesatide and evaluated (3 animals per time point) at 0.25, 6, 24, 168, 336, 720 and 1440 h following dosing for the evaluation of tissue radioactivity. The same procedure was following for male Long Evans rats (pigmented), with plasma, skin and eyes being evaluated. **Results:** In albino rats, the plasma concentration of radioactivity was 130.7 μg equiv./mL at 0.25 h following dosing, which decreased to 64.1 μg equiv./mL by 24 h. The concentrations in the other tissues were much lower than in the plasma at these time points, suggesting limited distribution beyond the vascular compartment. At 336 h after administration to albino rats, localization of radioactivity was observed in the bone marrow (6.3 μg equiv./g) and sites of extramedullary hematopoiesis including the spleen (23.6 μg equiv./g), adrenal glands (9.2 μg equiv./g), liver (8.5 μg equiv./g), and kidney (4.5 μg equiv./g) compared to brain (0.1 μg equiv./g), spinal cord (0.07 μg equiv./g), and muscle (0.4 g equiv./g). Elimination of $^{14}$C-peginesatide derived radioactivity was prolonged as was present up to 1440 h postdose. In pigmented rats, the concentrations of radioactivity in the plasma, eyes and skin were comparable to those in the albino rats, indicating that $^{14}$C-peginesatide and related compounds have little affinity for melanin. **Conclusions:** The elimination of $^{14}$C-peginesatide-derived radioactivity was prolonged, and biodistribution occurred in the target site (bone marrow) and sites of extramedullary hematopoiesis.

**Inflammation and Other Modifiable Patient Characteristics Associated with ESA Dose: Results from the DOPPS** James P. Smith,[1] Jinyao Zhang,[2] Yun Li,[1] Hal Morgenstern,[1] Tadao Akizawa,[3] Joan Fort,[4] Friedrich K. Port,[1,2] Bruce M. Robinson.[1,2] *[1]University of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Showa University, Tokyo, Japan; [4]University Hospital Vall d'Hebron, Barcelona, Spain.*

Background: A better understanding of potentially modifiable patient characteristics that influence ESA dose may inform strategies to optimize ESA usage. Inflammation is a putative cause of higher ESA requirements, but this association largely derives from small cross-sectional and retrospective studies.

Methods: We investigated predictors of ESA dose in DOPPS 3 (2005-2008), an international, prospective cohort study. A linear mixed model was used to determine associations of mean weekly ESA dose (updated monthly) with CRP and other lab values from the prior month, adjusted for Hgb level, demographics, comorbidities, and dialysis facility (to account for discretionary dosing practices). Many facilities in DOPPS countries measure CRP by routine.

Results: The analysis included 2,535 pts (21,903 pt-months) from 7 European countries (85%), and Australia/NZ (15%). We excluded USA and Canada because of infrequent CRP measurement and Japan because of notably different ESA dosing practices. The median ESA dose was 9900 U/wk (IQR: 5250, 15250). Across increasing quartiles of CRP, the median ESA dose was 8250, 9000, 9900, and 13000 U/wk ($P<0.001$, test of trend accounting for country). In the adjusted model, higher ESA dose was predicted by younger age, higher weight, lower Hgb, lower TSAT, higher log-CRP, higher ferritin, and lower WBC (all $P \leq 0.01$). Neither albumin, creatinine, nor PTH was appreciably associated with ESA dose.

Conclusion: Inflammation was positively associated with ESA dose in this representative multinational sample of HD patients. Albumin, creatinine, and PTH do not predict ESA dose after controlling for confounders, however, suggesting that nutritional status and hyperparathyroidism may not contribute substantially to ESA dose requirements. Interventions to prevent or treat inflammation may reduce ESA requirements.

Disclosure of Financial Relationships: Research Funding: The DOPPS is administered by Arbor Research Collaborative for Health and is supported by scientific research grants from Amgen (since 1996), Kyowa Hakko Kirin (since 1999, in Japan), Genzyme (since 2009), and Abbott (since 2009), without restrictions on publications.

**F-PO1390**

**The Effect of Intravenous Ascorbic Acid in Continuous Hemodialysis Patients with Anemia** Hyun Lee Kim,[1] Byung Chul Shin,[2] Jung Hoon Chung.[1] *[1]Internal Medicine, Chosun University Hospital, Gwangju, Republic of Korea; [2]Internal Medicine, Seonam University Hospital, Gwangju, Republic of Korea.*

Hemodialysis patients with functional iron deficiency often develop resistance to recombinant human erythropoietin (EPO). Recent studies suggest that intravenous ascorbic acid administration could override EPO resistance in hemodialysis patients. This study was undertaken to test the effect of intravenous ascorbic acid in patients with hemodialysis accompanied with EPO-hyporesponsive anemia. A total of 35 patients (16 men, 19 women) with ESRD on hemodialysis were included in this study. The patients received 500 mg of intravenous Vitamin C with each dialysis session. The effects of Vitamin C on EPO were assessed during the study periods of 4months, and additional 3months follow up after the end of the study. The mean age was 54.6±12.3 years, and the mean duration of hemodialysis was 5.7±4.2 years. The main cause of renal disease was diabetic nephropathy. The end of the vitamine replacement, Hb levels significantly increased from 9.4 to 10.6 g/dL. Hct (27.5 to 31.6%), RBC mass (3.0 to 3.3×103 ug/L), TSAT (30.9 to 38.0%) also significantly increased. EPO dose (136.5 to 72.9 IU/kg/week) is significantly decreased. The 3months after the end of the study, no change in Hb (10.6 to 10.3 g/dL), EPO dose (72.9 to 101.2 IU/kg/week) was noted. But, Hct (31.6 to 29.4%), RBC mass (3.3 to 3.1×103 ug/L), serum iron (81.6 to 67.0 ug/dL), TSAT (38.0 to 30.9%) significantly decreased. There were no change in TIBC, ferritin, calcium, phosphorus, intact parathyroid hormone levels, Kt/V, CRP, aluminum and Vitamin B12. Intravenous ascorbic acid can be a potent and effective adjuvant therapy for hemodialysis patients with EPO-resistant anemia. And ascorbic acid can reduce the dosage of EPO for anemia correction.

**F-PO1391**

**Cinacalcet Hydrochloride Reduced the ESA Dose by Improving Inflammation on Dialysis Patients** Sato Megumi. *Nephrology, Satojunnkannkikanaika, Matsuyama City, Ehime, Japan.*

[Introduction)

High level of parathyroid hormone (PTH) is well known as a mortality risk factor independently from serum levels of calcium and phosphorus, however, one more important aspect of PTH is a cause of refractoriness to erithropoiesis stimulating agent (ESA). We evaluated the effects of cinacalcet hydrochloride (CH), a new medication for 2HPT, on the responsiveness to ESA.

[Methods)

Nineteen out of 157 chronic dialysis patients in our facility have been followed under the treatment of CH for 1 year based on our therapeutic policy for 2HPT (CH group). The rest 138 patients have been also followed as a control (Cont group). Serum levels of intact- PTH (i-PTH), albumin (Alb), high-sensitive CRP (hs-CRP) and the dosages of darbepoietin-alpha (DA; microgram/week) have been monitored before and 1 year after CH. The patients in each group were divided in to 3 subgroups by the pre-/post ratio in hs-CRP; subgroup 1(-10% >), subgroup 2(-10%˜+10%), subgroup 3(+10% <).

[Results)

In the CH group, the serum level of i-PTH was significantly reduced in each subgroup, whereas the dosage of DA was clearly decreased only in subgroup 1. The levels of Hb, Alb didn't change significantly in each subgroup (table 1) . In the Cont group, there were not significant changes in i-PTH, Hb and dosages of DA in each subgroup. Bone density, the iron saturation level and volume of parathyroid in the CH group did not change(Data not shown).

table 1 Parameters in CH group

| | n | i-PTH(pre) (pg/ml) | i-PTH(post) (pg/ml) | Hb(pre) (g/dl) | Hb(post) (g/dl) | DA(pre) (mcg/w) | DA(post) (mcg/w) |

[Conclusions)

The reduction of ESA dosage in the relation to the improvement of inflammation was only observed in the CH group. It suggests that CH improves responsiveness to ESA by improving the systemic inflammatory status.

**Reduced ESA Requirement by Continuous Delivery of Soluble Ferric Pyrophosphate (SFP) Via Dialysate in CKD-HD Patients** Ajay Gupta,[1] Richard C. Yocum,[1] Carrie D. Guss,[1] Rosemary Ouseph,[2] Rajiv Agarwal.[3] *[1]Rockwell Medical, Wixom, MI; [2]University of Louisville, Louisville, KY; [3]Indiana U, Indianapolis, IN.*

BACKGROUND: SFP is an investigational, water-soluble, non-carbohydrate, tightly complexed salt of iron (Fe) (III) electrostatically bonded to pyrophosphate for continuous maintenance Fe therapy. A double-blinded Phase II study randomized CKD-HD patients to placebo (standard dialysate) or dialysate with SFP given at each dialysis session for up to 26 wks, while prohibiting ESA dose changes and IV/oral Fe.

METHODS: Sufficient protocol-violation ESA dose changes allowed post hoc analyses comparing ESA in placebo group versus combined SFP dose groups for (1) relative ESA (rESA), the ESA dose at any time/baseline ESA dose (baseline was mean ESA dose over 2 wks prior to study), and (2) proportion of events when ESA dose changes ≥25% of the baseline dose.

RESULTS: SFP was well tolerated. Patients were Fe-replete as suggested by maintenance of Hgb in the placebo group despite withholding all Fe supplements. A pooled, longitudinal analysis of rESA as a continuous variable showed a 13% decrease in ESA dose for SFP relative to placebo at Week 24, ignoring dropouts ($p<0.05$). For all ESA dosing events on study, 72% were unchanged from baseline dose, 17% were dose decreases, and 11% were increases, with a trend favoring lower doses for SFP vs. placebo. After Week 8, rESA dose was decreased ≥25% from baseline in 21% of dosing events for placebo vs. 25% for SFP, and increased ≥25% in 8% for placebo vs. 4% for SFP ($p<0.05$). In the optimal SFP dose group (10 µg/dL, 1.8 µM), the estimated Hgb increase was 0.2 gm/dL/month ($p< 0.05$), even as rESA was reduced compared to placebo.

CONCLUSIONS: SFP administered in dialysate to Fe-replete CKD-HD patients decreased ESA dose requirements despite the protocol prohibition on ESA dose change. The Hgb increase and ESA sparing suggest SFP's physiologic mode of action, allowing Fe transfer directly to apo-transferrin, corrects functional Fe deficiency, thereby enhancing ESA responsiveness. SFP's full ESA-sparing effect will be assessed in a study allowing ESA dose change and is anticipated to be larger than observed in this study.

**Anaemia Management (AM) in Incident Hemodialysis (HD) Patients (pts): Impact of Predialysis Care** Jacques B. Rottembourg, A. Kadri, A. Dansaert. *Hemodialysis Unit, Diaverum Group, Paris, France.*

**Purpose:**AM in incident HD pts, and the effect of predialysis AM, merits attention. The aims of this retrospective study were to evaluate (1)AM in incident HD pts from their first dialysis (M0) and (2)the impact of predialysis care on AM, both during year 1 of dialysis.**Methods:**Hb, ESA dose and IV iron dose were (1)measured in year 1 of dialysis (2)compared between pts given IV iron therapy(IT) & ESA predialysis vs only oral IT & ESA.**Results:**60 pts received M0 in the unit in the last 6 years: mean(SD) age 60.1(16.8) years; 32% female; ESRD due to diabetes (29%), hypertension (23%), glomerulonephritis (20%), other (20%) and PKD (8%);96% had native arteriovenous fistula for M0.Pts received darbepoetin alfa (DA) once/2 weeks (Q2W) and IV IT weekly (QW).Of these 60 pts, 15 (25%) received IV IT predialysis (300mg iron as iron sucrose 2-4 times in the year predialysis):12 males, mean age 56.2(18.7) years at start. At start of dialysis, Hb was 10.1(1.5)g/dL vs 11.1(1.4) for pts without or with IV IT, respectively ($p<0.003$).

| n=60 Mean(SD) | M0 | M3 | M6 | M12 | p M6 vs M3 | p M12 vs M6 |
|---|---|---|---|---|---|---|

| M3:No IV IT(n=45) | 11.1(1.2) | | 105(48) | | 90(1.12) | |
| M3:IV IT(n=15) | 12.0(1.0) | | 76.6(32.2) | | 88.2(1.13) | |
| p | 0.006 | | 0.01 | | 0.002 | |
| M12:No IV IT(n=45) | 11.6(0.6) | | 106(51) | | 88.8(3.1) | |
| M12:IV IT(n=15) | 12.5(0.6) | | 59(28) | | 82.1(8.8) | |
| p | 0.0002 | | 0.0005 | | 0.04 | |

**Conclusion:** Incident HD pts typically have low Hb, requiring >6 months to reach Hb target with high doses of ESA and IV IT. Pts starting dialysis after predialysis DA and IV IT require lower doses of ESA and IV IT during year 1 of dialysis. Prospective studies are required to confirm these data.

**Effect of Vitamin B12 and Folic Acid Supplementation on Erythropoitin Requirements To Maintain Haemoglobin Levels** John P. Killen. *Renal Medicine, Cairns Base Hospital, Cairns, QLD, Australia.*

INTRODUCTION : Vitamin B12 (B12) is an important co-enzyme for DNA synthesis. Normally plasma levels are 150 to 650 pmol/L representing only 0.02 – 0.05% of total body B12. B12 has been used as a marker for haemodialysis middle molecule clearance with modern dialysis membranes and can be effectively removed with high flux membranes. B12 deficiency is known to cause erythropoietin resistance in haemodialysis patients. Large amounts of folic acid supplementation can mask the damaging effects of vitamin B12 deficiency.

AIM : This prospective study assessed the effect of intramuscular B12 and oral folate supplementation on erythropoietin requirements to maintain heamoglobin levels.

METHODS: All 135 haemodialysis patients in our unit were screened for eligibility in this prospective observational study. Initial levels of B12 and were assessed in January 2009 with routine blood examinations. 60 haemodialysis patients with a B12 level of less than 300 pmol/L were offered intramuscular injections of 1000 micrograms hydroxocobalamin (NeoB12) weekly for 3 weeks. Serum B12 and haemoglobin levels and erythropoietin requirements were observed over the following 15 months. No change in intravenous iron protocols occurred during the study period.

RESULTS: Initially, the 60 eligible haemodialysis patients had a mean B12 level of 222 pmol/L (range 88 – 299 pmol/L) and mean red cell folate of 793 nmol/L requiring a corresponding mean erythropoietin dose of 9900 units/week to maintain a mean haemoglobin of 120 g/L. At the end of the study period the mean B12 levels rose to 462 pmol/L and the average folate rose to 1418 nmol/L. The average erythropoietin requirement reduced to 6200 units/week ($p < 0.0005$) to maintain the average haemoglobin of 117 g/L ($p = 0.35$) with no change in the average transferrin saturation at 32% and 33% respectively ($p = 0.77$) during the study.

CONCLUSIONS: In this small prospective observational study, implementation of intramuscular B12 supplementation for haemodialysis patients with serum B12 levels less than 300 pmol/L with oral folic acid supplementation resulted in a significant reduction in erythropoietin requirements, whilst maintaining average haemoglobin concentrations.

**IV Iron Therapy Leads to Iron Overload in CKD-HD Patients** Ajay K. Singh,[1] Richard C. Yocum,[2] Carrie D. Guss,[2] Mark T. Smith,[3] Ajay Gupta.[2] *[1]Brigham & Women's Hosp., Newton, MA; [2]Rockwell Medical, Wixom, MI; [3]Nephrology Associates, Augusta, GA.*

BACKGROUND: Iron (Fe) loss from hemodialysis is 5-7 mg/session (~1 gm/yr). Most CKD-HD patients receive regular IV Fe in excess of actual iron loss, median dose 4.2 gm/yr (USRDS 2006). IV Fe stimulates hepcidin >20X, induces reticuloendothelial (RE) block limiting Fe availability, causing progressive buildup of Fe stores. Soluble ferric pyrophosphate (SFP) is an investigational, physiologic, soluble, non-carbohydrate, Fe(III) salt donating Fe directly to transferrin via dialysate, bypassing the RE system.

OBJECTIVE: Assess if withholding Fe in CKD-HD patients up to 26 weeks while ESA dose held nearly constant (mean increase 8.7%) led to Fe-restricted erythropoiesis in a double-blinded, randomized Phase II study of placebo dialysate vs. SFP dialysate.

METHODS: Parameters of erythropoietic activity and Fe status at study end compared to baseline in subset of patients randomized to placebo (N=26).

RESULTS: Patients at baseline were similar to the U.S. CKD-HD population based on mean values: age 58 yrs, epoetin 12,510 U/wk (N=21), darbepoetin 59 µg/wk (N=5), IV Fe over prior 2 months 466 mg, albumin 3.9 g/dL, and pre-dialysis lab values (table). Over an average 15.7 wks (median 11.2, range 0.1 -25.4 wks), ferritin decreased 22% ($p< 0.05$) suggesting mobilization of Fe from stores. No significant change in TSAT, CHr or Hgb. This suggests stored Fe was adequate to maintain erythropoiesis.

| | Hgb g/dL | CHr pg | Ferritin µg/L | Iron µg/dL | TIBC µg/dL | UIBC µg/dL | TSAT % |
|---|---|---|---|---|---|---|---|
| Baseline | 11.0 | 32.6 | 503 | 59 | 221 | 162 | 27 |
| Study End | 10.8 | 31.9 | 394 | 52 | 220 | 169 | 24 |
| Change | -0.2 | -0.7 | -109* | -7 | -1 | 7 | -3 |

*Denotes $p<0.05$ for change from baseline.

CONCLUSIONS: The absence of Fe-restricted erythropoiesis despite Fe withholding over 16 wks suggests CKD-HD patients receive excessive IV Fe that might contribute to Fe overload and Fe toxicity in the long-term. Future trials will evaluate SFP's ability to maintain Fe available for erythropoeisis without leading to Fe overload or exacerbating inflammation.

**Current Status of Erythropoietin Immunogenicity in Korean Dialysis Patients** Sung Jin Moon,[1] Sung-Kyu Ha,[1] Tae Won Lee,[2] Yang Wook Kim,[3] Seung-Ok Choi,[4] Tae-Hyun Yoo,[5] Kang Wook Lee,[6] Young-Il Jo,[7] Jin Kuk Kim,[8] Hyeong Cheon Park,[1] Eawha Kang,[9] Sug Kyun Shin.[9] *[1]Internal Medicine, Gangnam Severance Hospital, Korea; [2]Internal Medicine, Kyung Hee University Hospital, Korea; [3]Internal Medicine, Pusan Paik Hospital, Korea; [4]Internal Medicine, Wonju Christian Hospital, Korea; [5]Internal Medicine, Severance Hospital, Korea; [6]Internal Medicine, Chungnam National University Hospital, Korea; [7]Internal Medicine, Konkuk University Hospital, Korea; [8]Internal Medicine, Soon Chun Hyang University Hospital, Buchoen, Korea; [9]Internal Medicine, Ilsan Hospital, National Health Insurance Cooperation, Korea.*

Anti-erythropoietin (EPO) antibody positivity, clinically presented by pure-red cell aplasia is a rare disease. We published the new bridging ELISA method for detecting anti-EPO antibody, this year. Therefore, we aimed to examine the prevalence, clinical characteristics and risk factors of anti-EPO antibody positive ESRD patients. Eight hundred fourteen ESRD patients who used rHu-EPO for more that 6 months were recruited at 12 university based hospital in Korea. Serum, clinical and biochemical data of the patients were collected. The mean age was 57.6±13.3 years and sex ratio was 1:1. The causes of ESRD were DM (46.2%), HTN (36.5%), GN (7.4%). The mean dialysis duration was 54.0±46.4 months, and the number of hemodialysis (HD) patients was 576 (70.8%). The types of EPO were epo-alfa 67.9%, epo-beta 4.2%, dabepoietin-alfa 27.8%, respectively. Eight out of the 814 patients had anti-EPO antibody, the prevalence of EPO immunogenicity was 0.98%. Mean age of the patients was 64.3±5.4 years and sex ratio was 1:1. The number of HD patients was 7 and mean dialysis duration was 65 months. Six patients used epo-alfa. These patients had lower hemoglobin (9.6±1.4g/dL) levels and reticulocyte counts (1.3±0.8%).

We could identify 8 patients with anti-EPO antibody from 814 ones. Mainly positive was shown in patients with epo-alfa (75%). Risk factors for antibody formation have to be evaluated in further studies with larger scale.

Disclosure of Financial Relationships: nothing to disclose

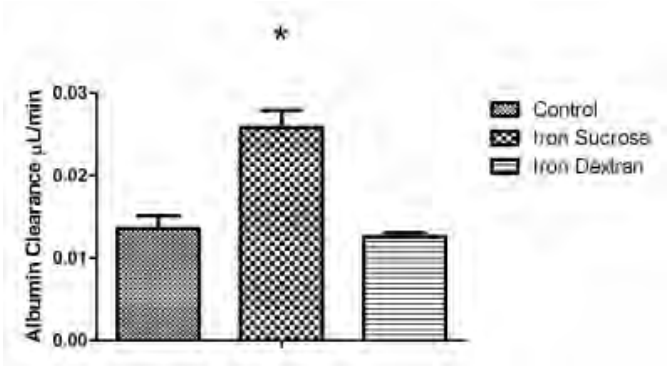
**Role of Intravenous Iron Compounds in Pathogenesis of Pulmonary Edema** Amy B. Pai, Arnold Johnson. *Albany College of Health of Health Sciences, Albany, NY.*

Pulmonary edema is a major complication associated with significant morbidity, mortality and hospitalization costs in hemodialysis patients. IV iron compounds induce ROS generation, which has been implicated in lung endothelial barrier dysfunction. It is unknown if these widely used agents affect lung permeability.

Rat lung microvessel endothelial cell (RLMEC) monolayers were cultured and treated with iron sucrose (IS) or low molecular weight iron dextran (ID) (0.05 mg/mL) for 24 hours. Clearance rate of Evans Blue-labeled albumin between 10 and 60 mins was assessed to determine permeability. ROS were quantitated in RLMEC treated with IS or ID (as above) for 30 minutes incubated with dihydroethidium (DHE) (10 µM, 0.5 h at 37°C). DHE fluorescence is reported as mean fluorescence intensity (MFI). Endothelial nitric oxide synthase (eNOS) activation was determined in lysate by immunochemistry and analyzed using the ratio of anti-p-eNOS-ser$^{1177}$ (an activation site) and p-eNOS-thr$^{495}$ (an inactivation site). Results are mean values ± SEM of $n > 3$ experiments.

Results: Incubation of RLMECM with IS induced significant endothelial barrier dysfunction compared to ID and untreated controls. (*$p<0.05$ for both comparisons, see Figure).



IS but not ID was associated with eNOS activation (mean ± SEM relative density units; 1.6 ± 0.31 and 0.88 ± 0.18 vs. control 0.83 ± 0.21, respectively, $p < 0.05$ IS vs. control and ID). Similarly, IS was associated with significant ROS generation, with an 85% increase in DHE fluorescence vs. untreated controls ($p < 0.05$, IS vs. controls). DHE fluorescence after ID treatment was not significantly different from untreated controls.

Iron sucrose but not iron dextran increased endothelial permeability to albumin, eNOS activation and ROS generation. These data indicate that IV iron has the potential to differentially induce lung injury via an eNOS/ROS mediated pathway.

**Reduction of Erythropoesis Stimulating Agent Requirements When Converting Patients from Epoetin beta (NeoRecormon) and Darbepoetin alpha (Aranesp) to Mircera in Haemodialysis Patients** Reena A. Popat,[1] Christopher J. Kirwan,[2] Martin J. Raftery,[2] Magdi Yaqoob.[2] *[1]Pharmacy & Medicines Management, Barts and The London NHS trust, United Kingdom; [2]Nephrology and Transplantation, Barts and The London NHS trust, United Kingdom.*

**Introduction:** Two studies (MAXIMA and PROTUS) have shown that patients on dialysis can successfully be converted from shorter acting ESA preperations (e.g. Aranesp and NeoRecormon) to Mircera whilst maintaining stable Hb. We report our experience of switching patients from NeoRecormon and Aranesp to Mircera in our haemodialysis (HD) unit.

**Method:** Patients were included in the study if maintained on the same ESA preparation and HD for the 6 months pre and post conversion to Mircera. Hb, PTH, ferritin, CRP and ESA dose (converted to mcg) were calculated for each patient pre and post conversion . Percentage of total Hb measurements greater than 10.5g.dL was also compared pre and post conversion.

**Results:** 130 patients had been converted to Mircera of which 107 met the inclusion criteria.

53 patients (33male), mean age 58.6 years, were converted from NeoRecormon to Mircera. There was no statistical difference in mean patient Hb pre and post conversion (10.8g.dL and 10.8g.dL respectively). The percentage of all Hb measurements greater than 10.5g.dL was not significantly different pre and post conversion (63.3% and 60.3%; $p>0.05$). However the mean ESA requirements did reduce significantly after conversion to Mircera (180mcg pre vs. 148mcg post; $p <0.001$).

54 patients (35 male), mean age 57.7 years, were converted from Aranesp to Mircera. There was no statistical difference in Hb pre and post conversion (10.7g.dl and 10.5 g.dL respectively). The percentage of all Hb measurements greater than 10.5g.dL was not significantly different pre and post conversion (61% and 52%; $p>0.05$). However the mean ESA requirements significantly reduced after conversion to Mircera (167mcg pre vs. 139mcg post; $p <0.001$).

Note: PTH, ferritin and CRP was not statistically different pre and post conversion to Mircera or between both groups.

**Conclusion:** Switching patients from shorter acting ESAs to Mircera in our HD population maintains haemoglobin control whilst reducing ESA requirements.

**F-PO1399**

**EPO Treatment at the Start of Hemodialysis Is More Beneficial Than at the End of Hemodialysis** Noritomo Itami,[1] Yasushi Shimonaka,[2] Taishi Nakashima,[1] Kazushi Tsuneyama.[1] *[1]Kidney Center, Nikko Memorial Hospital, Muroran, Hokkaido, Japan; [2]Product Research Dept., Chugai Pharmaceutical Co. Ltd., Japan.*

**Background and Aims**

Although erythroid progenitors require iron for their maturation after EPO stimulation, EPO is usually injected at the end of hemodialysis(HD) for renal anemia treatment as clinical guidelines suggest because EPO given at the start HD is supposed to be absorbed in the HD circuit decreasing its efficacy.

Previously, we have shown that EPO treatment at the start of HD could improve iron utilization and reduce EPO dose, while hemoglobin(Hb) level and iron treatment frequency were unaffected in a short pilot study. Here, we performed a longer study to confirm the beneficial impact of EPO treatment at the start of HD.

**Method**

Thirty six HD patients providing written informed consent were enrolled. At the beginning, EPO treatment was changed from the end of HD (Period I) to the start (Period II). Anemia treatment was carried out as usual. EPO dose was altered biweekly to maintain a target Hb level of 11-12g/dL. After 12 and 25 weeks, average EPO dose, clinical parameters and rate of operational incidents were examined.

**Results**

At the start of the study, mean Hb level was 10.99±0.85g/dL and was unchanged at week 12 and 25 (11.22±0.83g/dL and 11.05±0.83, p=0.16 and p=0.89). Frequency of iron treatment (28%, 33% and 17%, p=0.69 and p=0.40) and serum ferritin were also unchanged (174±113ng/mL, 190±130ng/mL and 176±109, p=0.46 and p=0.76). Average EPO dose in 2 weeks was significantly reduced from 4771±2528 IU/week in Period I to 3949±2140 IU/week at week 12 (p=0.048). At week 25, EPO dose remained reduced at 4412±2583IU/week, but not significantly (p=0.34). There were no operational incidents such as neglecting EPO injection in Period II.

**Conclusions**

Results indicate EPO treatment at the start of HD was more beneficial and effective than EPO treatment at the end of HD. It was suggested that improved iron utilization reduces EPO dose, although Hb level and iron treatment were unaffected. Moreover, more reliable EPO injection can be achieved because incidents at the start of HD were rare. Further study should provide information to establish an efficient EPO treatment.

### Erythropoietin Dose and Peritoneal Membrane Transport Status: A Dose Response Relationship

Sharad K. Ratanjee, James E. Jackson. *Renal Medicine, Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia.*

Aim: To determine if the dose of erythropoietin (Epo) used correlates with peritoneal transport status (TS) in peritoneal dialysis (PD) patients.

Background: Epo has demonstrated angiogenic activity, both via the Epo receptor and via upregulation of vascular endothelial growth factor VEGF/VEGF receptor and hence may contribute to peritoneal vasculopathy. Epo may also stimulate the epithelial-to-mesenchymal transition of peritoneal cells. These changes may predispose PD patients to the development of peritoneal membrane changes, including fibrosis, and effective increases in vascular peritoneal surface area leading to rapid TS and ultimately membrane failure.

Methods: A cross-sectional analysis was performed of 88 patients established on PD. The weekly equivalent Epo dose per kilogram body mass (WEED) was calculated. Peritoneal transport status was determined using the peritoneal equilibration test (PET) as popularised by Twardowski. Analysis of variance was performed with the following factors related to TS: body-mass index (BMI), haemoglobin (Hb), number of previous peritonitis episodes (PPE), CRP, serum albumin (alb), days on dialysis, age and WEED.

Results: On multivariate analysis five of the variables were unimportant (BMI, Hb, PPE, Alb, days on dialysis). Age and CRP were important as confounders of relationship of WEED to TS. A significant relationship between WEED and TS was shown on multivariate analysis (p=0.034). Similarly for age and TS (p=0.012). Each additional unit of WEED corresponded to an increase in TS by 0.029 (95% CI 0.002 – 0.057).

Conclusion: There is a significant correlation between the WEED and TS in PD patients in this cross-sectional study. Larger prospective longitudinal studies are needed to further evaluate this relationship.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1401

### Impact of Hemodialysis with Polysulfone Dialyzers on Red Blood Cell Lifespan in Chronic Hemodialysis Patients

Georges Ouellet,[1,2] Anja Kruse,[1,2] Garry J. Handelman,[3] Stephan Thijssen,[1,2] Peter Kotanko,[1,2] Nathan W. Levin.[1,2] *[1]Renal Research Institute; [2]Beth Israel Medical Center, New York, NY; [3]University of Massachusetts, Lowell, MA.*

**Background**

Red blood cell lifespan (RBCLS) is usually markedly reduced in uremia. RBCLS can be estimated by measuring endogenous carbon monoxide (ECO) production, which largely reflects the rate of heme degradation. A 20% acute intradialytic increase in ECO (ascribed to a reduction in RBCLS) has been reported with cellulose acetate membranes (Medina, 1994). We aimed to determine if hemodialysis (HD) with polysulfone membranes influences RBCLS.

**Methods**

We recruited non-smoking patients without inflammatory pulmonary disease receiving maintenance bicarbonate HD with Optiflux polysulfone dialyzers (Fresenius Medical Care, Waltham, MA). Hemoglobin (Hb) was measured pre-HD. Pre- and post-HD alveolar air samples were collected and analyzed for CO with a 910 Buck Scientific gas chromatograph (East Norwalk, CT). ECO production was computed by subtraction of environmental CO concentrations (home and dialysis unit) from alveolar CO levels. RBCLS was calculated from ECO levels (Strocchi, 1992). Intradialytic changes in ECO and RBCLS were assessed by paired samples t test. Data are shown as mean±SD.

**Results**

Nineteen patients (median age 69.2 years [range 32.6-82.5]; 68% male; 68% Black; blood flow 406±53 mL/min) were studied. Mean Hb was 11.4±1.0 g/dL. ECO levels and RBCLS did not change during HD (Table 1). Mean pre-HD RBCLS was not significantly different from that reported by Medina *et al* (P=0.6).

Table 1. Pre- and post-HD ECO and RBCLS

| | Pre-HD | Post-HD | P value |
|---|---|---|---|
| ECO (ppm) | 2.63±0.99 | 2.29±0.86 | 0.09 |
| RBCLS (days) | 75.3±27.7 | 77.1±25.8 | 0.67 |

**Conclusions**

In a group of 19 chronic HD patients, we found no significant changes in ECO levels and RBCLS from pre- to post-HD, suggesting that turnover of erythrocytes is not affected by HD. Improvements in dialysis technologies, especially progress in water quality and the use of more biocompatible membranes causing little complement activation, might explain the difference between our results and older reports.

Disclosure of Financial Relationships: nothing to disclose

### Switch from the Original Intravenous Iron Sucrose to an Iron Sucrose Similar Is Associated with Lower Hemoglobin (Hb) Levels in a Hemodialysis (HD) Population

Jacques B. Rottembourg,[1] A. Kadri,[1] E. Leonard,[1] A. Dansaert,[1] A. Lafuma.[2] *[1]Groupe Diavarum, Centre Suzanne Levy, Paris, France; [2]CEMKA/Eval, Bourg La Reine, France.*

**Purpose:** HD patients (pts) received ESAs and IV iron sucrose Venofer® (V) at our center with satisfactory results for 6 years. In June 2009, a switch was made to the IV iron sucrose similar FerMylan® (FM). Hb target was 11.5-12g/dL. **Methods:** The analysis compared two 27-week periods; Period 1 (P1): Dec 1, 2008-June 7, 2009 when pts received V, and Period 2 (P2): Jun 29, 2009-Jan 3, 2010 when they received FM. Inclusion criteria were ≥60 dialysis sessions per P and ≥1 IV iron treatment. Hb was assessed every two weeks, and serum ferritin, transferrin saturation (TSAT), CRP and Kt/V every three months. IV darbepoetin-a (DA) was given every two weeks and IV iron every week (25-100 mg iron). **Results:** 75 pts were analyzed (male 69%), mean age 63.415.2 years, mean dialysis duration 55 months.

| Values | P1 | P2 | p-value |
|---|---|---|---|
| Hb mean (SD) g/dL | 11.78 (0.99) | 11.48 (0.98) | 0.01 |
| Serum ferritin mean (SD) µg/L | 534 (328) | 495 (280) | 0.25 |
| TSAT mean (SD) % | 49.3 (11) | 24.5 (9) | <0.0001 |
| CRP mean (SD) mg/L | 6.4 (6.8) | 8.4 (10.5) | 0.15 |
| Kt/V mean | 1.41 (0.25) | 1.42 (0.24) | 0.80 |
| DA total dose per Period µg | 73510 | 82750 | |
| DAµg/kg/week per pt (SD) | 0.58 (0.52) | 0.66 (0.64) | 0.13 |
| Iron (ampoules/Period) | 923.0 | 1242.5 | 0.001 |
| Iron mean dose/pt per Period (SD) mg | 1231 (897) | 1657 (836) | 0.001 |

Hb levels were significantly lower with FM (P2) vs V (P1). To maintain Hb target, an increase of 12.6% in total DA dose and ~35% in total iron dose was required in P2. **Conclusions:** This analysis suggests that V and FM may not be therapeutically equivalent. Previously well-controlled patients required higher doses to maintain target Hb levels after switch from V to FM, with a resultant ~12% increase in total drug costs. In addition these findings have important implications related to the Medicare bundled payment rate for medications, and the Medicare quality incentive payment program for iron/anemia management in HD patients to be enacted in the near future.

### Correction of Anemia and Iron Metabolism in Chronic Renal Insufficiency. Are Cardio/Cerebrovascular Risks (CC-Risks) Avoidable?

Hannelore B. Hampl. *Nephrology, University, Berlin, Germany.*

Renal cardiac insufficiency is accompanied by anemia due to erythropoeitin (EPO)-iron deficiency. A suffered heart needs increased oxygen to improve. Therefore, full anemia correction with EPO/iron (iv) was added to adequate cardiac therapy with β-blockers, ACE-inhibitors, ARBs to investigate changes in leftventricular mass index(LVMI-regression?) and to investigate amounts of EPO/iron **on the way** to full anemia correction. We conducted this retrospective survey in 350 outdoor HD pats (age>68years)with this therapy(A). As controls served HD pats(N=350;age>67years) from different centers with low cardiac therapy and Hb of 12g/dl (B) and parameters of iron metabolism given by guidelines. **Results-A/B: Hb**(g/dl):11.5/**14.1p<0.001**; 11.6/12.2 n.s.; **LVMI**(g/m²)159.3/**131.2p<0.001**; 162.5/159.3n.s.; **LVEF**(%)58.9/**68.5p<0.001**; 59.3/59.3n.s.; **TSAT**(%):27.2/**46.5**;19.8/22.1n.s.; **Transferrin** (mg/dl):167.6/148.5 p<0.05; 165.6/147.1p<0.05; **Iron**(µ/dl):52.6/**75.2p<0.001**;40.5/5 0.2p<0.05; **Ferritin**(µg/L):500.7/**1537.0p<;0.001**; 200.8/550.1 p<0.05; **Thrombocyte counts**(mm³):310 000/**187 522p<0.001**; 319 000/ 309 000n.s. **In contrast, in B**: **iron was deficient, thrombocyte counts unchanged.** The applicated amount of EPO (Epoeitin-beta) was over 3 times higher (18 000IE pat/week) despite a lower Hb (12g/dl) than in A(5 500 IU pat/week; Hb14g/dl). The average observation time of 10years showed a low mortality ratio(A):16% by non cardiac reasons,10% by cardiac reasons in contrast to high mortality ratio in B. **Conclusion:** Full anemia correction did not increase risks, provided that effective cardiac medication and iron therapy (iv) is optimally applied during EPO therapy(A) to prevent iron deficiency which is well known for inducing **activated thrombocytosis being responsible for severe CC-risks**. Thrombocyte counts >than 300 000/mm³( B ) have a fourfold higher event ratio. Iron- values lower than 60 µg/dl are accompanied with a significantly increase in hazard ratio. The best survival is given by lowest EPO amounts. **A functional iron deficiency with activated thrombocytosis on the way of full anemia correction with EPO is a risk factor not taken in consideration until now!**

**F-PO1404**

**Chronic Oral Iron Supplementation Reduces Darbepoetin α Doses in Maintenance Hemodialysis Patients** Shinichi Suga,[1] Hironobu Kawai,[1] Tokuyuki Kitahara,[2] Yoshito Tsukada,[3] Kazue Ueki,[4] Tatsuhiko Sakamoto,[5] Keiju Hiromura,[6] Yoshihisa Nojima.[6] *[1]Nephrology, Saiseikai Maebashi Hosp., Gunma, Japan; [2]Medinice, Shibukawa Central Hosp., Gunma, Japan; [3]Medicine, Fujioka General Hosp., Gunma, Japan; [4]Nephrology, Toho Hosp., Gunma, Japan; [5]Medicine, Usui Hosp., Gunma, Japan; [6]Med. & Clin. Sci., Gunma Univ., Grad. Sch. Med., Gunma, Japan.*

The preferred rout of iron administration is intravenous in hemodialysis patients, partially because of their impaired iron absorption. Since iron absorption has been reported to be up-regulated in iron-deficient hemodialysis patients treated with recombinant human erythropoietin (NDT 13:82, 1998), we hypothesized that chronic oral iron supplementation is effective in iron-deficient hemodialysis patients with erythropoiesis-stimulating agents. We compared the efficacy of oral to intravenous iron for the chronic management of anemia in hemodialysis patients treated with darbepoetin α. Fifty-one hemodialysis patients with initial serum ferritin < 100 ng/ml and transferrin saturation (TSAT) < 30% were randomly assigned to one of two groups: those receiving oral iron therapy (40~50 mg/day, n = 32) and those receiving intravenous iron (100~105 mg once weekly, n = 19). At the end of 3 months, the mean Hgb showed no significant difference between the oral group and the intravenous group (11.3 ± 0.2 g/dl vs 11.0 ± 0.2 g/dl, respectively). However, the mean darbepoetin α dose was 32% lower in the oral group than in the intravenous group (14.6 ± 2.0 μg/wk vs 21.5 ± 4.0 μg/wk; P < 0.05). Although the mean serum ferritin was significantly lower in the oral group than in the intravenous group (57 ± 5 ng/ml vs 124 ± 10 ng/ml; P < 0.05), the mean TSAT and the mean serum iron were significantly higher in the oral group than in the intravenous group (TSAT: 34 ± 2 % vs 28 ± 2 %; P < 0.05) (iron: 80 ± 4 μg/dl vs 59 ± 4 μg/dl; P < 0.05). There was no significant difference in the withdrawal rate from the study due to drug-related adverse effects between two groups. We found that administering iron orally for chronic maintenance iron supplementation could result in effective erythropoiesis, at least in iron-deficient hemodialysis patients.

**F-PO1405**

**Comparison of Hemoglobin Variability between Erythropoiesis Stimulating Agents in Hemodialysis Patients** Tai Yeon Koo,[1] Jung-Sik Park,[1] Gheun-Ho Kim.[2] *[1]Internal Medicine, Division of Nephrology, Asan Medical Center, Seoul, Korea; [2]Internal Medicine, Division of Nephrology, Asan Medical Center, Seoul, Korea; [3]Internal Medicine, Division of Nephrology, Hanyang University College of Medicine, Seoul, Korea.*

**Background:** In hemodialysis patients, treatment of anemia with erythropoiesis-stimulating agents(ESAs) accompanies recurrent cyclic fluctuations in hemoglobin levels which may be associated with increased morbidity and mortality. It is conceivable that hemoglobin variability may be deferential according to different pharmacodynamic and pharmacokinetic properties in each ESA. This study was undertaken to examine whether differences exist in the hemoglobin variability according to the types of ESA. **Methods**: Clinical data were retrospectively analyzed from 72 patients on hemodialysis without acute illness. As parameters of hemoglobin variability, hemoglobin cycling, variance and SD/mean of hemoglobin were analyzed. Hemoglobin cycling was defined as the presence of cycles with amplitude >1.5 g/dL and lasting more than 2 months. **Results:** Hemoglobin cycling was present in 53 out of 72 hemodialysis patients. The number of hemoglobin cycling was 1.4±0.9 times/year. The amplitude and duration of hemoglobin cycling were 2.4±1.6 g/dL and 4.1±3.1 months, respectively. The number of ESA dose change including withdrawal of ESA was 3.7 ± 1.4 times/year, and the number of ESA withdrawal was 1.5±0.7 times/year. The frequency, amplitude, and velocity of hemoglobin cycling for patients receiving darbepoetin alfa (n=27) were greater than those for patients receiving epoetin beta (n=27). The variance and the SD/mean of hemoglobin for patients receiving darbepoetin alfa was greater than those for patients receiving epoetin beta. The hemoglobin cycling including frequency, amplitude and velocity, the variance of hemoglobin and the SD/mean of hemoglobin were not significantly different between patients receiving darbepoetin alfa and epoetin alpha.**Conclusions:** Hemoglobin variability is common in hemodialysis patients receiving ESAs. It may be deferential according to various ESAs, and epoetin beta may have less hemoglobin variability compared with darbepoetin alpha and epoetin alpha.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1406**

**Long-Term Analysis of Once-Monthly C.E.R.A. Maintainance in 293 Hemodialysis (HD) Patients within an Italian Setting** Francesco Locatelli. *Alessandro Manzoni Hospital, Lecco, Italy.*

**Purpose:** CARISMA is a Phase IIIB single-arm study providing long-term analysis of hemoglobin (Hb) maintenance following once-monthly (Q4W) administration of C.E.R.A. in HD patients (pts) with chronic kidney disease (CKD) converted from shorter-acting erythropoiesis-stimulating agents (ESAs) in a real-life clinical setting.

**Methods:** Adult HD pts receiving different schedules of epoetin alfa, beta, or darbepoetin alfa as maintenance therapy were converted to C.E.R.A. Q4W over a 16-week titration period prior to an 8-week evaluation period. Hb stability was defined by the following criteria A, B, and C, throughout the study: (A) average Hb levels within target range (10.0-12.0 g/dL); (B) average Hb levels ±1 g/dL from baseline. The proportion of pts attaining (A) and (B) was defined as a challenging end point; (A) or (B) was defined as overall stability; (C) was defined as fulfilling overall stability without Hb levels ≥0.5 g/dL outside of 10.0-12.0 g/dL. Safety and tolerability were examined throughout the study, including a long-term safety follow-up of 28 weeks.

**Results:** Pts (n=293) had a mean age of 66.4 (19-92) years with 41% having hypertension and 18% having diabetes at baseline; epoetin was received by 63.8% of pts and the remainder received darbepoetin alfa. Mean Hb levels during titration and evaluation were 11.4 g/dL and 11.1 g/dL, respectively. The most challenging end point (A+B) was achieved by 56% of pts, overall stability (A or B) by 82% of pts, and criterion C by 80% of pts, with mean Hb fluctuations of 0.26 g/dL at titration and 0.24 g/dL at evaluation. Pts received a median dose of 120 μg throughout the 24-week period; with an average of 2.3 dose changes per pt. C.E.R.A. Q4W was well tolerated with only 58% of pts reporting one adverse event.

**Conclusion:** These data show that conversion from different schedules of shorter-acting ESAs to C.E.R.A. Q4W is safe and effective in maintaining stable Hb levels in patients with CKD in a real-life clinical setting. Hb stability was achieved with fewer dose changes and pts demonstrated a safety profile similar to that observed with traditional ESAs.

**F-PO1407**

**Lower Erythropoietin Dose Utilization in Paricalcitol-Treated Patients Compared with Doxercalciferol-Treated Patients** Steven E. Marx, Samina Khan, Utpaul Audhya, Beverly A. Johns. *Abbott, Abbott Park, IL.*

OBJECTIVE: Erythropoietin incurs a significant cost in hemodialysis patients. We assessed erythropoietin utilization among hemodialysis patient receiving paricalcitol versus doxercalciferol.

METHODS: A historical cohort between 2004 and 2009 was used from a large dialysis organization. To enter the study cohort, hemodialysis patients were required to have a minimum of 10 doses of paricalcitol or doxercalciferol within 90 days, age >17, minimum 90 days pre-index, survive first 90 days after the index date, and have consistent records. Index date was the first dose of either paricalcitol or doxercalciferol. A total of 16,770 patients were assessed using a multivariate analysis adjusted for (1) age, gender, race, diabetes status, duration of dialysis, hemoglobin; (2) plus ferritin, and (3) plus study entry period. Additionally, 1,321 propensity matched patients using age, gender, race, and baseline hemoglobin were assessed as above. Additional subanalyses were performed replacing ferritin with iron saturation as well as adding baseline iPTH levels to propensity match.

RESULTS: Both multivariate and propensity matched analyses demonstrated statistically significant lower erythropoietin utilization.

Results

| Paricalcitol vs. Doxercalciferol | Adjusted 1 | Adjusted 2 | Adjusted 3 |
|---|---|---|---|
| Multivariate Analysis | n=15,449 vs. 1,321 | n=15,271 vs. 1,301 | n=15,271 vs. 1,301 |
| Parameter Estimates | -0.05 p<0.05 | -0.05 p<0.05 | -0.06 p<0.05 |
| Propensity Matched Analysis | n=1,321 vs. 1,321 | n=1,285 vs. 1,285 | n=1,285 vs. 1,285 |
| Parameter Estimates | -0.07 p<0.05 | -0.07 p<0.05 | -0.08 p<0.05 |

All subanalyses revealed similar results.

CONCLUSION: In this single dialysis provider organization, patients who received paricalcitol were associated with lower erythropoietin utilization compared to those on doxercalciferol. This is the first study to compare erythropoietin utilization among hemodialysis patients receiving paricalcitol versus doxercalciferol. Further prospective studies are required to confirm these results.

**F-PO1408**

**Prospective Multicentre Study of HX575 (Human Recombinant Epoetin alfa) Treatment in Patients with Chronic Kidney Disease (CKD) Applying a Target Hemoglobin (Hb) of 10-12 g/dL** Karsten Roth,[1] Francesco Locatelli,[2] Walter H. Hoerl.[3] *[1]Sandoz Biopharmaceuticals, Hexal AG, Holzkirchen, Germany; [2]Nephrology, Dialysis and Renal Transplant, Ospedale "Alessandro Manzoni", Lecco, Italy; [3]Medicine III, Division of Nephrology and Dialysis, University of Vienna, Vienna, Austria.*

The objective of this post-authorization study was to extend the safety database on HX575. Monitoring intravenous HX575 administrations in clinical practice covering 750 patient years should allow for the assessment of rare drug-related adverse events. HX575 (marketed as Binocrit®, Epoetin alfa Hexal®, and Abseamed®) was the first human recombinant epoetin alfa approved according to European biosimilar regulations in 2007.

**Methods:** This open, 6-month study was conducted at 114 sites in 10 European countries with a target enrolment of approximately 1,500 patients with CKD. HX575 dosing was according to label and medical practice with an Hb target concentration of 10-12 g/dL. An independent data safety monitoring board (DSMB) ensured accurate review and assessment of adverse events.

**Results:** 1695 patients who provided written informed consent were enrolled and received study medication; 1393 (82.2%) patients completed the study. The mean age at baseline was 61.8 years, 57% of patients were male. Most frequent primary underlying diseases were chronic glomerulonephritis (24.2%), diabetes mellitus (20.3%), and hypertension (14.0%).

Thrombotic vascular events were reported in 11.9% of patients (0.2612 per patient year). Tumor incidence was 1.4% (0.0299 per patient year). Two Suspected Unexpected Serious Adverse Reactions (SUSARs) were recorded: myelodysplastic syndrome with transformation into acute myeloid leukemia, a causal relationship to erythropoiesis-

stimulating agent (ESA) treatment was not suspected; and uncontrolled hypertension resulting in fatal cerebral hemorrhage, which was assessed as possibly related to ESA treatment. No subject developed anti-epoetin antibodies during the study.

**Conclusions:** No concerning safety findings were reported over a period covering 769 patient years. Intravenous ESA treatment with HX575 in anemic CKD patients was well tolerated and no signs of immunogenicity were observed.

Disclosure of Financial Relationships: Employer: Hexal AG, a Sandoz company (sponsor of the study).

### F-PO1409

**Toward Physiologic EPO and IV Iron Dosing in HD Patients: Patient-Centered and Data-Based** Jonathan Lorch,[1] Victor E. Pollak.[2] *[1]Rogosin Institute, Weill-Cornell Medical College, New York, NY; [2]MIQS Inc. & Department of Medicine, University of Colorado HSC, Denver, CO.*

EPO dosing has been driven by guidelines and changing Medicare regulations rather than patient physiologic responses. Recent US EPO dosing is high (17,996 units/week); Medicare changes now encourage reduced EPO doses. Long term HD patient survival was shown to be best with Hb >12 g/dl, TSAT >25%, moderate IV iron, relatively low EPO (BMC Nephrology 2009, 10:6). Retrospective analysis of prospectively collected individual patient data from 3 dialysis units (The Rogosin Institute, New York, NY) in a patient-centered EMR (MIQS, Inc., Boulder CO) showed that expected Hb change lagged EPO dose changes by many weeks. Over short (4-12 weeks) and long periods (8-12 years) EPO given to individual patients varied widely, sometimes within weeks, with no obvious reasons, and with high Hb variance. 25% of patients were iron insufficient (TSAT ≤25%). In unit A (265 patients) a new dosing model was initiated in February 2010; units B and C using the traditional dosing model served as controls. Objectives: Hb and iron sufficiency (TSAT persistently ≥25% and serum ferritin ≥300 µg/L), low Hb variance; modest/low EPO dosing. Method: evaluate EPO and iron status not more frequently than 4-8 weekly using a reporting tool for each patient that aggregates hematologic data and hematinic medications monthly for the prior 18 months. Actions: replete iron IV as needed; maintain, adjust downward, but do not stop EPO. Results: Unit A: in the first 18 weeks, Hb increased 10% from 11.1 to 12.2 g/dl. Hb variance decreased from 1.21 to 0.68 $g^2/dl^2$. IV iron given doubled from 14 to 28 mg/HD, and TSAT increased from 29.8 to 31.3% while EPO decreased from 17,300 to 15,200 units/week. Units B and C: EPO doses decreased by 13% and 14% to 19,000 and 17,600 units, but Hb was unchanged in unit B and decreased by 2% to 10.81 g/dl in unit C. Conclusion: The new dosing model facilitated orderly EPO reduction, increased Hb and iron sufficiency. The small EPO decrease in the first 18 study weeks is expected as EPO dose was changed at long intervals; a further decrease is anticipated with continued study and contained Hb swings.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1410

**Total and HMW Adiponectin Is Independently Associated with Brain Natriuric Peptide and Anemia in Chronic Hemodialysis Patients** Yasuhiro Abe, Kenji Ito, Maho Watanabe, Hitoshi Nakashima, Takao Saito. *Division of Nephrology and Rheumatology, Fukuoka University School of Medicine, Fukuoka, Japan.*

**Background**: A number of vasculo-protective role for adiponectin have been reported, including the promotion of angiogenesis, inhibition of atherosclerosis and ventricular hypertrophy. In contrast, higher, rather than lower, plasma adiponectin levels are associated with an increased risk of cardiovascular disease and mortality in patients with end-stage renal disease (ESRD). It is not yet elucidated the mechanism why high total adiponectin levels were associated with adverse outcome.

**Methods**: We measured the level of total and HMW adiponectins in 72 patients with HD patients with and without diabetes mellitus (age: 65+-9 years, time on HD: 94+-10 months, male/ female: 30/42), and examined the association between adiponectin and metabolic parameters.

**Results**: Female patients had significantly higher total, HMW adiponectin levels and HMW to total adiponectin ratio than those male patients did. The level of total and HMW adiponectins were positively correlated with those of HDL-C and brain natriuretic peptide (BNP) levels, and negatively associated with BMI, TG, high sensitive-CRP and hematocrit levels. In stepwise regression analyses, HMW adiponectin showed independent association with BMI (β=-0.244, P=0.006), HDL-C (β=0.372, P<0.001), hematocrit (β=-0.217 P=0.009) and BNP (β=0.247, P=0.002) as total adiponectin did.

**Conclusions**: Anemia and BNP level had independent influence on total and HMW adiponectin levels in chronic HD patients. This finding may partly be explained the 'adiponectin paradox' in ESRD.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1411

**Effect of Ergocalciferol on Anemia Management in End Stage Kidney Disease** Neenoo Khosla, Hongyan Du, Nisha N. Patel, L. Tammy Ho, Junine Darby Degraf, Stuart M. Sprague. *Nephrology, Northshore Universty Healthsystem, Evanston Hospital, Evanston, IL.*

Previous studies have demonstrated that lower 25 hydroxyvitamin D (25D) levels are independently associated with lower hemoglobin (Hb) concentrations in chronic kidney disease (CKD) patients. However, the effect of Vitamin D2 (Ergocalciferol) repletion on the anemia of patients with end stage kidney disease (ESKD) is unclear. Therefore, we sought to observe, in three hemodialysis centers, the effects of Ergocalciferol supplementation on Hb levels and erythropoietin (EPO) dosing requirements in patients with ESKD.

Patients from three hemodialysis centers were screened with baseline 25D values. In two centers patients with 25D levels <30 ng/ml were prescribed 50,000 units of Ergo weekly, while patients with levels>30 ng/ml were given 50,000 units monthly. In the third unit the patients were given Ergocalciferol 50,000 units weekly. Subjects were then followed prospectively on a monthly basis with quarterly vitamin D levels for six months. Important variables compared from baseline to month 6 included 25D, Hb, EPO dosing and mortality.

The change from month 0 to 6 was calculated from difference of values with assigned rank test to assess significance. Spearman's correlation coefficient was used to assess correlation.

Of the 132 patients, 25D levels increased significantly from an average of 23.2 ± 11.9 to 35.8 ± 15.6 (p= .0001). The absolute change in 25D was an average of 10.7 (median 9.0) (P= .0001). Total EPO dose significantly decreased at an average of 52,498 units monthly (median: 23,000, p = 0.001). Average Hb increased significantly by a mean value of 0.2 mg/dl (p=0.024). There was no significant change in albumin , ferritin or intravenous iron dosing during this same time period. Change in 25D level was not associated with change in mortality.

In a 6 month prospective study, administration of Ergocalciferol was associated with patients requiring lower doses of EPO with a corresponding increase in the achieved Hb.

**Clinical Evaluation of an Acetate-Free Dialysis Fluid Containing Citrate Used as a Dialysis Buffer – Central Dialysis Fluid Delivery System Used in 860 Patients** Junji Uchino, Toyohiko Yoshida. *Mihama Hospital, Chiba, Japan.*

Background: After being approved in Japan in 2007, acetate-free dialysis fluids have become popular, but reports on their use in central dialysis fluid-delivery systems are rare.

Objective: We aimed to evaluate the usefulness of an acetate-free dialysis fluid by assessing the changes induced by replacing the acetate-containing dialysis fluids (Kindaly AF2P and 2E, both containing 8 mEq/L acetate) with an acetate-free dialysis fluid (Carbostar-P [CP]) in 6 dialysis units of our hospital.

Patients and Methods: Subjects were 860 patients on maintenance dialysis, followed up for 7 to 14 months. AF2P and 2E were sequentially switched to CP, and changes in the quality of life (short form (SF)-36 score), treatment of anemia (amounts of erythropoiesis-stimulating agents (ESAs) and iron preparations used), and bone metabolism after switching were noted.

Results: Assessment of laboratory data after the switch revealed increased pH levels and HCO3 concentration. The levels of hemoglobin, total protein, and intact parathyroid hormone (i-PTH) increased after about 4 months of dialysis with CP. The SF-36 scores showed inhibition of the yearly decreases in values. ESAs were used in similar amounts, while the usage of iron preparations decreased markedly (25% to less than 10%). Among the 30 patients who had low i-PTH (< 60 pg/mL) levels for several months, 15 reached normal values.

Conclusions: The results showed that CP sufficiently decreased the degree of acidosis and had some other effects. In the future, the standards for the use of CP, including guidelines for the treatment of anemia, may require revision, and patients may require long-term monitoring.

**Comparison of Different Equations by Bioimpedance Method for Detection of Body Cell Mass** Li Zuo, Yanna Dou, Li Liu. *Renal Division, Peking University First Hospital, Beijing, China.*

**Introduction**

Body cell mass (BCM) encompasses the intracellular water (ICW) compartment. In fact, ICW are used as a close approximation of BCM. BCM has been deemed a key parameter for assessing nutrition status.

There are two equations by multi-frequency bioimpedance measurement for evaluation of ICW: Xitron second generation ICW volume equation (eq. 1) and BCS equation (eq. 2) $V_{ICW}=V_{ECW}*\{[\rho TBW*(R_E+R_I)/\rho ECW*R_I]^{2/3}-1\}$ (eq. 1) $ICW_{BCS}=K_{ICW}[H2*(BW^{1/2})/R_I]^{2/3}$. (eq. 2). To evaluate the accuracy of different equations, we hypothesized that ICW will not change during one hemodialysis session and a better equation can detect ICW accurately.

**Methods**

A total of 50 stable hemodialysis patients from the dialysis center of Peking University First Hospital were included in this study. Bioimpedance measurements were performed in HD patients before and after HD session by the same operator. ICW were calculated by XE and BCSE, respectively. Paired t-test was used to compare changes in ICW calculated using different equations before and after HD session.

**Results**

In total 50 HD patients (23 males and 27 females) were observed with 115 bioimpedance measurements. The average age was 54.6±13.9 years. The mean height was 165.4±8.8cm. ICW results are shown in Table 1. There is a significant difference between XE and BCSE in pre-HD and post-HD . And ICW calculated by XE increased significantly after HD. However, there is no significant change in ICW calculated by BCSE after HD session.

ICW Comparison between Xitron equation and BCS equation

| | ICW By XE | ICW By BCSE | p Value |
|---|---|---|---|
| Pre-HD | 15.61±5.17 | 17.55±4.42 | <0.01 |
| Post-HD | 16.25±5.40 | 17.61±4.40 | <0.01 |
| p Value | p <0.05 | NS | |

**Conclusion**

BCS equation is more stable than Xitron second generation equation in estimation of body cell mass estimation.

## F-PO1414

**Alignment of the Dialysate Sodium Concentration with the Serum Sodium: Role of Plasma Water Fraction and Donnan Effects** E. Lars Penne,[1,2] Jochen G. Raimann,[1,2] Len A. Usvyat,[1] Stephan Thijssen,[1,2] Nathan W. Levin,[1,2] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York; [2]Beth Israel Medical Center, New York.*

Low dialysate sodium (dNa) concentrations have been associated with intradialytic symptoms such as hypotensive episodes. High dNa concentrations may lead to intradialytic sodium loading, thirst and subsequent increased interdialytic weight gain and hypertension. Alignment of dNa with pre-dialysis serum sodium (sNa) has been proposed to minimize dialytic morbidity. The aim of the current study was to evaluate whether such alignment strategy would result in a stable sNa concentration over the hemodialysis (HD) treatment.

The relation between the change in sNa from the beginning to the end of the dialysis treatment (Post-Pre Sodium Difference; PPSD) and the sodium gradient (grNa = dNa – $sNa_{pre}$) was evaluated in 150 chronic HD patients (mean age 61 ± 16 [±SD], 56% male, 80% black and 53% diabetic) with and without correcting the sodium level for Donnan effects ($\alpha = 1.007 – 0.009 \times TP$) and plasma water fraction ($f_{pw} = 0.989 – 0.0047 \times TP$), where TP = total protein in g/dL (Gotch FA et al. Proc Clin Dial Trans Forum; 1980). Intradialytic diffusive sodium flux was considered to be zero if PPSD = 0 mEq/L. Sodium was measured on a mid-week dialysis session by indirect potentiometry.

The relation between PPSD and grNa was linear (PPSD = 0.75 x grNa + 1.2; r = 0.80, P<0.001). According to this regression equation PPSD would rise by 1.2 mEq/L (95% CI 0.8 to 1.6) in a patient with grNa=0 mEq/L. Correction of the grNa for Donnan effects and plasma water fraction ($grNa_{corr}$) resulted in a shift of the regression line to the right. Alignment of the dNa based on the $grNa_{corr}$ resulted in a PPSD = -0.3 mEq/L (95% CI -0.7 to 0.2). Additional corrections for intradialytic changes of TP or total ultrafiltration volume did not change the results materially.

These analyses suggest that Donnan effects and plasma water fraction should be taken into account when aligning dNa with sNa. As a clinical rule of a thumb, dNa level should be 1 to 2 mEq/L lower than the pre-dialysis sNa to maintain a stable sNa concentration over the dialysis treatment. These findings need confirmation in a prospective study.

**Relationship between Ionized Calcium Concentration and Activated Clotting Time in Citrate Anticoagulated Blood** Dieter Falkenhagen,[1] Stephan Thijssen,[2] Martin Brandl,[1] Jens Hartmann,[1] Karin Strobl.[1] *[1]Department of Clinical Medicine and Biotechnology, Danube University, Krems, Austria; [2]Renal Research Institute, New York, NY.*

**Background:**

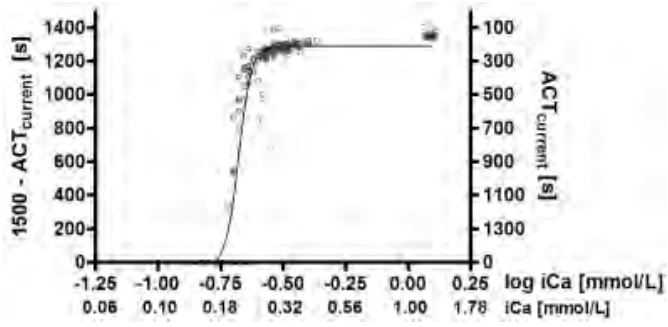
Regional citrate anticoagulation (AC) offers multiple advantages over systemic heparin AC in hemodialysis (HD) patients. An accurate characterization of the relationship between ionized calcium (iCa) level and degree of AC is valuable when modeling citrate AC.

**Methods:**

Whole blood samples were obtained from 10 healthy subjects and citrated with concentrations ranging from 2.75 to 6.5 mmol/L. iCa and activated clotting times (ACT) were measured for each sample. Coagulability was defined as maximum ACT (1500 seconds) minus ACT of current aliquot. The relationship between coagulability and log iCa was displayed, and the data were fitted to a variable-slope sigmoidal dose-response function (Y = bottom + (top-bottom)/(1+10^((logEC50-X)*(hill slope))), where X is the log iCa concentration and Y is the response (coagulability).

**Results:**

Baseline ACT was: min 121s; max 157s; median 148.5s. The relationship between coagulability and log iCa is displayed in Figure 1. The global fit estimates for this relationship are presented in Table 1. Goodness of fit was excellent, with $R^2$=0.93.



Best-fit values for sigmoidal dose-response relationship between blood coagulability [s] and log serum ionized calcium level [mmol/L].

| Parameter | Best-fit value |
|---|---|
| Bottom | 0 |
| Top | 1288 |
| LogEC50 | -0.6776 |
| Hill slope | 17.83 |
| EC50 | 0.2101 |

**Conclusion:**

The relationship between coagulability and iCa levels is non-linear, as previously shown by Falkenhagen et al. [1] and is described by the presented equation with very good accuracy. This characterization is of value for modeling AC during regional citrate AC in HD.

## F-PO1416

**Citrasate®: Effects on Hemodialysis Adequacy and Heparin N Requirements** Jeffrey J. Sands,[1] Peter Kotanko,[2] Jonathan H. Segal,[3] Chiang-Hong Ho,[1] Amy Young,[4] Mary Carter,[2] Olga Sergeyeva,[2] Lisa Korth,[4] Eileen Maunsell,[1] Yueping Zhu,[1] Mahesh Krishnan,[4] Jose A. Diaz-Buxo.[1] *[1]Fresenius; [2]RRINY; [3]U Mich; [4]DaVita.*

Citrasate (C) contains citrate instead of acetate as in standard bicarbonate (B) dialysate. C is reported to improve clearance and decrease heparin requirements due to local, non-systemic anticoagulant effects in the dialyzer.

Methods: We prospectively evaluated HD pts over consecutive 2-week periods (P): Baseline-bicarbonate dialysate+standard (100%) dose heparin N (H), P1-Citrasate+100% H, P2-Citrasate+80% H, P3-Citrasate+67% H. Dialyzer clearance (mean KECN) and spKt/V were measured by ionic dialysance and clotting by dialyzer/line replacement or treatment termination. The predefined primary endpoint was non-inferiority of mean KECN between baseline and P2. $\beta$=0.1 at $\alpha$=0.05 required 100 pts to conclude non-inferiority with -8% margin (expected mean -5%, SD=10%).

Results: The cohort comprised 148 subjects: 60% male, 45% white, 49% black, 46% diabetic, 22% on antiplatelets, age 59±15 yrs, vintage 3.7±3.2 yrs, 60% AVF, 22% AVG, 19% catheters.

| | B+100% H | C+100% H | C+80% H | C+67% H | P |
|---|---|---|---|---|---|
| N | 148 | 134 | 117 | 101 | |
| Heparin N (u) | 3707±1423 | 3762±1431 | 3019±1148 | 2528±955 | |
| Heparin N (u/Kg) | 47.2±16.9 | 47.8±16.8 | 38.4±13.6 | 32.2±11.4 | |
| Mean KECN (mL/min) | 248±25.5 | 248±24.4 | 248±24.6 | 250±22.7 | NS |
| % Change Mean KECN | | 0.5 (-0.6, 1.6) | 0.6 (-0.7, 1.9) | 0.4 (-1.0, 1.9) | |
| % Decreased Mean KECN > 8% | | 6.7 (3.1, 12.4) | 5.1 (1.9, 10.8) | 9.9 (4.8, 17.5) | |
| spKt/V | 1.54±.24 | 1.54±.22 | 1.54±.23 | 1.56±.24 | NS |
| % spKt/V < 1.2 | 5.4 (2.4,10.4) | 6.0 (2.6, 11.4) | 6.0 (2.4, 11.9) | 4.0 (1.1, 9.8) | |
| % Clotted Dialyzer/Lines | 2.6 (0.4, 5.8) | 4.3 (1.2, 8.5) | 3.4 (0.9, 8.5) | 4.0 (1.1, 9.8) | |

(95% CI)

There was no difference in study related AEs or post HD time to hemostasis.

Conclusion: Citrasate + 80% heparin N maintained HD adequacy and met the primary endpoint of non-inferiority of mean KECN when compared to bicarbonate dialysis with standard dose heparin N. Dialyzer clearance was similar with 20% to 33% heparin reduction with no significant difference in clotting of dialyzers/lines or AEs.

## F-PO1417

**Thrombocytopenia Associated with One Type of Modified Polysulfone Hemodialysis Membrane** Srilatha Nadipineni, Jean Lee, Avrum Gillespie, Jesse M. Goldman. *Section of Nephrology, Temple University School of Medicine, Philadelphia, PA.*

Polysulfone membranes have been noted to activate platelets, depending on their composition and configuration . One case of thrombocytopenia has been linked to the Fresenius Optiflux polysulfone membrane. We wish to report five cases of persistent thrombocytopenia associated with the Fresenius Optiflux dialysis membrane.

table1

| Patient | 1 | 2 | 3 | 4 | 5 |
|---|---|---|---|---|---|
| ESRD diagnosis | Hypertension | Diabetes | Diabetes | Hypertension | FSGS |
| Ethnicity | Hispanic | Hispanic | African American | African American | African American |
| Age (yrs) | 66 | 43 | 66 | 63 | 30 |
| Sex | female | male | female | male | female |
| Initial Platelet Count | 218K | 121K | 113K | 186K | 176K |
| Plt s 24 -48 hrs post Fresenius Optiflux | 66K | 46K | 53K | 72K | 66K |
| Plt s 24-48 hrs post second membrane | 205K | 158K | 103K | 135K | 182K |
| Second Membrane | Baxter Xenium | Baxter Xenium | Baxter Xenium | Asahi Rexeed | Asahi Rexeed |
| HIT Antibody | Negative | Negative | Negative x 2 | Negative x 2 | not done |

The patients were on hemodialysis in 3 different units All cases occurred in a two year period .Peripheral blood smears showed decreased platelets without clumping The coagulation profile was normal. Platelet counts were lowest immediately post dialysis. No bleeding or thrombosis was associated with the low platelet count.

Platelet counts did not improve with heparin free dialysis. Medication review did not reveal any platelet lowering drugs. When Patients 1,2,3 were rechallenged with the Fresenius Optiflux membrane, the platelet count fell to less than 60,000. Once back on the Baxter Xenium dialyzer, the platelets counts recovered to greater than 100,000. The Baxter Xenium membrane is polyethersulfone and the Asahi Rexeed is a polysulfone modified to prevent platelet activation.

**Conclusions**: The Fresenius Optiflux membrane was associated with persistent thrombocytopenia in five hemodialysis patients. Platelet counts improved with other polysulfone dialysis membranes.

Further investigation is needed to determine the mechanisms of thrombocytopenia, and possible long term consequences. The thrombocytopenia associated with the Fresenius Optiflux polysulfone membrane may be confused with heparin induced thrombocytopenia or idiopathic thrombocytopenia.

Disclosure of Financial Relationships: nothing to disclose

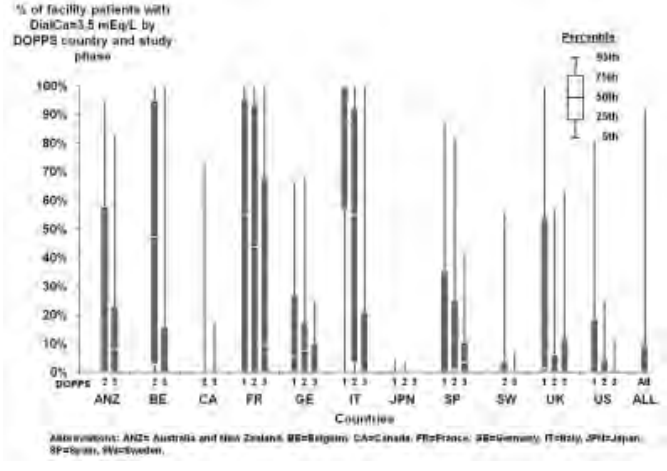
## F-PO1418

**High Dialysate Calcium (DialCa) Is Associated with Mortality in the DOPPS** Francesca Tentori,[1] Lin Tong,[1] Brenda W. Gillespie,[2] Hal Morgenstern,[2] Ronald L. Pisoni,[1] Friedrich K. Port,[1] Bruce M. Robinson,[1,2] Jean Ethier,[3] Michel Y. Jadoul,[4] Takashi Akiba,[5] Juergen Bommer.[6] *[1]Arbor Research; [2]Univ. of M; [3]Center Hosp. de Univ. of Montreal; [4]Univ. of Louvain; [5]Tokyo Women's Medical Univ.; [6]Dialysezentrum Heidelberg.*

Exposure to exogenous calcium (Ca) in the dialysate or from phosphate binders may contribute to vascular calcifications. We postulated that exposure to high levels of Ca may lead to increased mortality.

Data were from 34,575 patients (pts) with DialCa = 2, 2.5, 3, or 3.5 mEq/l from 869 facilities in 12 DOPPS countries. The associations of high DialCa (3.5 mEq/l ) with mortality (all-cause=ACM; cardiovascular=CVM; sudden death=SD) were examined in adjusted Cox models. To reduce bias due to unmeasured confounders, an instrumental variable (IV) approach was also used.

Use of DialCa (mEq/l) was: 2 = 3.4%, 2.5 = 42.2%, 3 = 40.2%, and 3.5 = 3.4% of patients. Facility use of DialCa=3.5 was variable, but fell over time (Figure). Serum Ca and comorbidities were similar across DialCa levels. Compared to lower DialCa, pts on DialCa=3.5 had higher ACM (hazard ratio=1.09 [95% CI=1.01-1.18], p=0.03), CVM (1.12 [1.00-1.26], p=0.05), and SD (1.23 [1.04-1.46], p<0.01). The association of DialCa=3.5 with higher CVM and SD was stronger among pts on ca-based phosphate binders (p<0.01). No interactions were found with low PTH and vitamin D use. DialCa=3.5 was also associated with mortality in IV models (ACM: 1.04 [0.92-1.17], p=0.56; CVM: 1.10 [0.92-1.33], p=0.29; SD:1.32 [1.01-1.73], p=0.04). No difference in mortality were observed for patients on DialCa=2, 2.5 or 3 vs. 3.5 mEq/l.



DialCa=3.5 mEq/l was associated with elevated mortality, especially in pts on Ca-based binders, supporting a detrimental effect of Ca load on outcomes. Exposure over time to lower DialCa levels (i.e. ≤ 3.0 mEq/l) requires additional study.

Disclosure of Financial Relationships: Research Funding: The DOPPS is administered by Arbor Research Collaborative for Health and is supported by scientific research grants from Amgen (since 1996), Kyowa Hakko Kirin (since 1999, in Japan), Genzyme (since 2009), and Abbott (since 2009), without restrictions on publications.

## F-PO1419

**Prediction of Normal Hydration State in Hemodialysis Patients Using Calf Resistivity** Fansan Zhu, Peter Kotanko, Nathan W. Levin. *Renal Research Institute, New York, NY.*

The inability to predict dry weight (DW) makes prescriptions of post dialysis weight difficult and usually subjective. We have previously reported (Zhu et al., Physiol Meas, 2008) the use of calf bioimpedance spectroscopy (cBIS) to estimate DW defined by two criteria: 1) Intradialytic flattening of the calf resistance curve measured continuously during the whole hemodialysis (HD) treatment, and 2) Achieving normalized resistivity (nRho) in the range of healthy subjects. The aim of this study was to model the relationship between differences in nRho and in post HD weights (PWt) between baseline (BL) and at actual DW which was established by the criteria above.

nRho at BL and actual DW were analyzed in chronic HD patients. In randomly selected patients (group 1) a regression model was developed to describe the relationship between nRho and excess fluid volume (ExFV). ExFV is defined as the difference between PWt at BL and actual DW. The regression model was then applied to a different group of HD patients (group 2) to predict DW. Predicted DW was calculated as PWt at any time minus ExFV [eq 1].

We studied 27 patients, 15 in group 1 and 12 in group 2. Regression analysis in group 1 related ExFV to ΔnRho: ExFV=0.504* ΔnRho+0.295 ($R^2$=0.61, p<0.001). Applying this regression model together with [eq 1] in group 2 resulted in an excellent prediction DW as determined by the independent criteria mentioned above ($R^2$=0.989, p<0.0001; Figure 1 (a)). In Bland Altman analysis no systematic bias was observed (p > 0.05; Figure 1(b)).

Using a model relating differences in calf resistivity and post dialysis weight at any time it is possible to predict what appears to be a close approximation to actual DW as determined by an independent method. This information is useful in that it provides objective targets for post dialysis weight prescription over time to achieve dry weight.

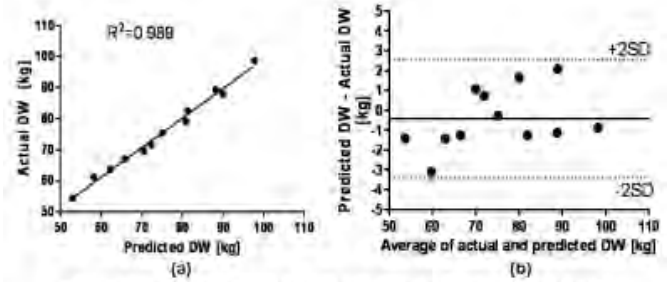


Fig.1 Correlation and Bland-Altman analysis for group2 patient (n=12)

## F-PO1420

**Improving Hemodialysis Adequacy, Anticoagulation and Dialyzer Efficiency with Streamline Bloodlines** Sharon Lynn Haas, Manohar Ahuja. *Milwaukee Nephrologists, Milwaukee, WI.*

The performance of conventional hemodialysis (HD) bloodlines is typically constrained by traditional technology that involves blood-air contact and arterial pressure (AP) limits caused by circuit turbulence. We evaluated a patented bloodline (Streamline® (SL) from Medisystems®) with reduced circuit turbulence and blood-air contact eliminated. We hypothesized that this newer technology using SL would deliver higher blood flows (Qb) at lower AP, which would enable efficient use of dialyzers while maintaining HD adequacy (Kt/V≥1.4); and lower heparin dosage & cost due to less frequent clotting of system.

Sixty seven patients were measured on lab draw days in 2 periods: 1) Pre-SL period using Fresenius Combiset® bloodlines; and 2) Post-SL period using SL after a 2 month transition. Rx adjustments were made to Qb, dialyzer type and heparin dose (based on rinseback quality). Single pool (sp) Kt/V, delivered Qb, average AP, and dialyzers were recorded for both periods. Dialyzer profile consisted of standard Fresenius and Asahi single-use dialyzers. Other Rx variables such as needle sizes, access types, dialysate rates, and HD times were not modified. Total heparin purchases were tracked over 12 months, and normalized by number of HDs performed/month. The results are shown in Table 1. Statistical significance was calculated using paired t-test where appropriate.

Table 1

| | Pre-SL | Post-SL | % Improvement | P value |
|---|---|---|---|---|
| Average Qb, ml/min | 431 | 453 | 5 | 0.003 |
| % patients with improved Qb | - | 43 | NA | - |
| Average AP, mmHg | -209 | -179 | 16 | <0.001 |
| % patients with improved AP | - | 70 | NA | - |
| Average spKt/V | 1.50 | 1.59 | 6 | 0.024 |
| % patients spKt/V>1.2 | 88 | 93 | 5 | - |
| % patients spKt/V>1.4 | 66 | 76 | 10 | - |
| % patients spKt/V>1.6 | 37 | 51 | 14 | - |
| Dialyzer cost/HD | $12.64 | $10.12 | 20 ($2.52) | <0.001 |
| Heparin cost/HD* | $1.64 | $0.70 | 57 ($0.96) | - |

*3-month rolling average cost based on total heparin purchased. Pre-SL = Mar to Apr 2009; Post-SL = Jan to Mar 2010

*In conclusion* , with SL use, we did increase Qb rates while reducing AP. The resultant improved HD adequacy allowed us to maximize dialyzer efficiency. We also did significantly lower heparin usage and cost/HD.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1421

**Serum Magnesium and Muscle Cramps in Chronic Hemodialysis Patients** Patrick Lynch, Heesuck Suh, Mersema Abate, Nand K. Wadhwa. *Division of Nephrology, SUNY, Stony Brook, NY.*

Muscle cramps are common adverse events among patients receiving chronic hemodialysis (HD). Serum magnesium (MG) levels have been implicated in muscle cramps associated with pregnancy, the elderly, and with restless leg syndrome. We hypothesized that magnesium may play a role in muscle cramps, particularly during HD treatment. The objective of the study was to evaluate prevalence of muscle cramps and its association with serum magnesium levels in HD patients. We conducted a survey of 108 chronic HD patients. 85 Patients (55 males and 30 females) participated in the survey. The mean age of participants was 60.0 ± 16.6 years (range 25-90 years). A single nephrology fellow conducted an in-person questionnaire with each participant. The severity of cramps was evaluated on a 0-10 scale, with 10 rated as maximal severity. Routine monthly pre-dialysis laboratory data were used for analysis. Sixty-two (73%) patients, 41 male and 21 female reported having muscle cramps. The mean age of patients with muscle cramps was 59.2 ± 16.7 years vs. 62.0 ± 16.5 years in patients without cramps. Fifty-seven (92%) patients reported cramps on their dialysis days while 26 (42%) reported cramps on their non-dialysis days. Forty (65%) patients report having muscle cramps during their HD treatment session and 29 (47%) patients had cramps after their session. Only 27% of patients with cramps informed their nephrologist. In contrast, 60% of patients inform a nurse or a dialysis technician. The mean KT/V, pre dialysis serum BUN, creatinine, sodium, potassium, calcium, phosphorus and albumin were not significantly different between the two groups. The mean pre-dialysis serum MG of 1.89 ± 0.34 mg/dl in the group with cramps was not significantly different from 1.84 ± 0.33 mg/dl in the group without cramps. However, the pre-dialysis serum MG level was inversely correlated (r= -0.29; p=0.02) to the severity of muscle cramps. No statistically significant difference in muscle cramps was found in relation to gender, race, diabetes and ESRD etiology. In conclusion, data suggest that serum MG may plays a role in muscle cramps in HD patients.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1422

**Bioimpedance Guided Reduction of Post-Dialysis Target Weight Does Not Lead to Increased Intradialytic Hypotension in Chronic Hemodialysis Patients** Samer Rateb Abbas,[1,2] E. Lars Penne,[1,2] Fansan Zhu,[1] Jochen G. Raimann,[1,2] Li Liu,[1,2] Stephan Thijssen,[1,2] Nathan W. Levin,[1,2] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York; [2]Beth Israel Medical Care, New York.*

Treatment of overhydration is often suboptimal due to the current notion that reducing the post-hemodialysis (HD) target weight may increase the frequency of intradialytic hypotension (IDH). The aim of the present study was to investigate whether a reduction of the post-HD target weight towards dry weight, as assessed by continuous calf bioimpedance spectroscopy (cBIS), increased the risk of IDH.

In stable HD patients the post-HD target weight was gradually reduced over time until dry weight, as defined by cBIS (DWcBIS), was achieved (Zhu, Physiol Meas, 2008). IDH was defined by K/DOQI and EBPG (symptomatic drop of systolic blood pressure ≥20mmHg requiring staff intervention). Treatments were stratified in quartiles of the degree of overhydration (i.e. the difference between post-dialysis weight and DWcBIS). The frequency of IDH was analyzed for each of these quartiles.

We studied 289 HD treatments in 28 patients (57% male, age 54±12). Twenty patients (71%) were overhydrated at baseline and post-HD target weight was gradually decreased over a median period of 5 weeks (interquartile range: 2 to 9) until DWcBIS was reached. Clinical post-HD target weight was 1.2±1.7 L above DWcBIS (P=0.001). IDH occurred in 10% of the treatments, with no significant differences between quartiles of overhydration (<0.4 L above DWcBIS: 11%; 0.4 to 1.1 L above DWcBIS: 7%; 1.2 to 1.9 L above DWcBIS: 13%; > 1.9 L above DWcBIS: 10%, P=0.63).

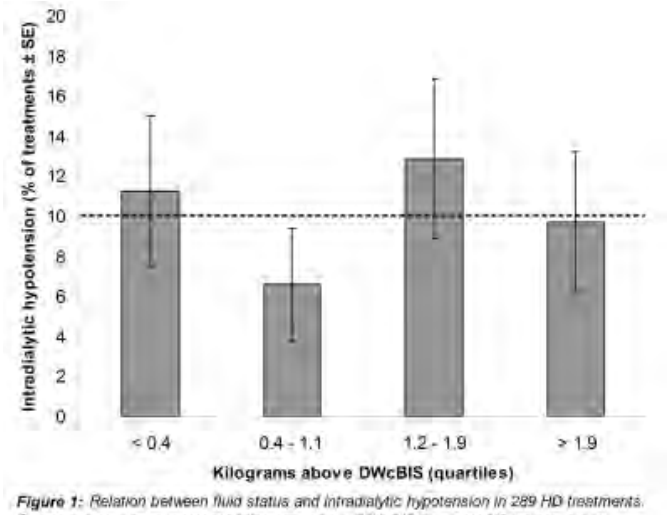

***Figure 1:*** *Relation between fluid status and intradialytic hypotension in 289 HD treatments. Categories on x-axes represent kilograms above DWcBIS (i.e. post-HD weight minus DWcBIS). P=0.63 for differences between groups. Dashed line respresents overall mean.*

The study supports the notion that fluid overload is highly prevalent among chronic HD patients. cBIS is a valuable method to estimate dry weight in HD patients. In overhydrated patients post-HD target weight can be safely lowered to DWcBIS without increasing the risk of IDH.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1423

**Comparison of Measurement of Change in State of Body Hydration in Hemodialysis Patients by Segmental and Whole Body Bioimpedance Methods** Samer Rateb Abbas,[1,2] Fansan Zhu,[1] Laura Rosales,[1] Dayvett A. Ulloa,[1,2] Murat H. Sipahioglu,[1,2] Mary Carter,[1,2] Peter Kotanko,[1,2] Nathan W. Levin.[1,2] *[1]Renal Research Institute, New Nork; [2]Beth Israel Medical Care, New York.*

The aim of this study was to compare calf, chest and whole body bioimpedance techniques in the assessment of changes in hydration state in hemodialysis (HD) patients.

Chronic HD patients were studied pre-HD and post-HD on two occasions in the same week: at the highest (hiWT) and at the lowest pre-HD weight (loWT). In addition, healthy controls (HC) were studied on one occasion. In each subject the following bioimpedance measurements were done to assess changes in fluid volumes: a) Calf bioimpedance spectroscopy (cBIS) to determine calf resistivity (nRho, W $m^3$/kg) (Xitron) in the supine position; b) ZOE fluid monitor (Zo, W) (Noninvasive Medical Technologies) to assess chest fluid volume in the sitting position; c) DF50 (ImpediMed) to measure whole body resistance (R50, W) , reactance (Xc50, W) , and phase angle (PA50, degree) at 50 kHz in the supine position.

We studied 54 HD patients (25f; age 63±16 yrs) and 54 HC (27f; age 35±10 yrs). Calf nRho increased significantly from pre- to post-HD and from hiWT to loWT. Zo increased significantly from pre- to post-HD but did not differ between hiWT and loWT. R50, Xc50 increased significantly from pre- to post- HD both at hiWT and loWT. In HD patients pre-HD R50 did not differ from HC. PA50 increased between pre- and post-HD at loWT..

| | Weight[kg] | Calf nRho[Ωm³/kg] | Zo[Ω] | PA50[°] | R50[Ω] | Xc50[Ω] |
|---|---|---|---|---|---|---|
| Pre-HD hiWT | 74.5±18# | 0.125±0.03*# | 21.4±4.6 | 4.9±6 | 525±84# | 36.7±11*# |
| Post-HD hiWT | 71.7±18# | 0.155±0.04*# | 23±4.3* | 4.9±2.4* | 609±118*# | 50.9±23* |
| Pre-HD loWT | 73.4±18 | 0.14±0.04* | 22.2±3.7 | 4.4±1.4* | 557±94 | 42.8±13* |
| Post-HD loWT | 71±18 | 0.17±0.05 | 23.9±4.3* | 5±1.9* | 650±112* | 57.1±23 |
| Healthy Controls | 75.3±16 | 0.19±0.03 | 22.4±3.7 | 6.2±0.8 | 551±84 | 58.8±7.6 |

# P<0.05 hiWT vs loWT * P<0.05 HD pts vs HC

Calf bioimpedance is more sensitive than ZOE and DF50 for assessing change in hydration and thus appears to be the preferred method for measuring the state of body hydration.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1424

**Cystatin C Reduction Ratio Depends on Normalized Blood Liters Processed and Fluid Removal during Hemodialysis** Shih-Han S. Huang,[1] Guido Filler,[2] Robert M. Lindsay.[1] *[1]Department of Medicine, Division of Nephrology, London Health Sciences Centre, London, ON, Canada; [2]Department of Pediatrics, London Health Sciences Centre, London, ON, Canada.*

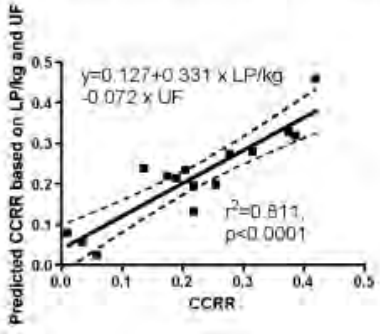
*Purpose:* A negative correlation between the weekly standard Kt/V (urea), an index of dialytic sufficiency, and serum cystatin C level (CysC) in functionally anephric dialysis patients was demonstrated. Our objective was to measure the pre-dialysis CysC reduction ratio (CCRR) and to compare it with other indices of dialytic function.

*Methods:* In a pilot cross-sectional study of 15 functionally anephric patients on conventional high-flux high-efficiency hemodialysis thrice per week, CysC levels were

drawn pre-, mid- and post- dialysis over one week. CCRR was compared with single pool Kt/V (Sp Kt/V) using urea kinetic modeling (UKM), urea reduction ratio (URR), creatinine reduction ratio (CRR), normalized liters processed (LP/kg) and ultrafiltration volume (UF). Normally distributed data (Shapiro-Wilks test) were described as mean one standard deviation; otherwise as median and interquartile range.

*Results:* The mean pre- and post- CysC levels were 6.0±1.0 mg/L and 4.7±1.1 mg/L (p=0.002). The Sp Kt/V and Std Kt/V were 1.5±0.2 and 2.6 (2.2, 2.7). The URR, the CRR and the CCRR were 70.2±9.0 %, 64.5±8.2 % and 26.1±11.8 % (p≤0.002), respectively. There was no correlation between the CCRR and the Sp Kt/V, URR and CRR while CCRR correlated with LP/kg ($r^2$=0.459, p=0.006) and UF ($r^2$=-0.524, p=0.002). Multiple regression analysis with these two parameters provided a model that explained 81% of the variance ($r^2$=0.811, p<0.001).

Figure 3. Correlation Analysis of the measured Cystatin C Reduction Rate (CCRR) and the calculated CCRR based on a model using the ultrafiltration volume (UF [L]) and the normalized Liters processed (LP/kg [L/ kg]). The model explained 81% of the variance



*Conclusion:* Our data suggest that normalized liters processed and ultrafiltration volume explain most of the variance of CCRR. Therefore, CCRR may be an excellent way to monitor dialysis efficiency for low molecular weight proteins.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1425**

**Impacts of Diabetic Foot Checks on Amputations and Hospitalizations in Incident Hemodialysis Patients** Lynn Saunders, Len A. Usvyat, Paul Balter, Lisa Bocklud Harvey, Heather J. Ansede, Nathan W. Levin, Peter Kotanko, Paul M. Zabetakis. *Renal Research Institute, NY, NY.*

Diabetic hemodialysis (HD) patients (pts) experience high incidence of leg or toe amputations. In recent yrs, foot checks in pts with diabetes mellitus (DM) became a routine procedure in RRI clinics. Previous analyses in prevalent DM HD pts have shown that foot checks decrease risk of amputations (Saunders, ERA 2010). This study assesses whether foot checks affect amputations & number of hospitalizations in incident DM HD pts.

We reviewed all RRI DM HD pts who started first dialysis b/n Jan 1, 2001 and Apr 30, 2010. Only pts who survived first 12 mns were included. The number of foot checks done in the first 12 mns was counted ("baseline prd"). Pts' leg and toe amputations after the baseline prd were noted ("follow up prd"). A logistic regression model was built with amputation in the follow up prd as an outcome variable & number of foot checks, race, ethnicity, age & gender as predictors.

N=3057 incident DM pts (53% male, 47% black, 43% white, mean age [SD]: 63.1 [12.5] years). In multivariate logistic regression the number of foot checks (odds ratio 0.87 [95% CI: 0.81-0.94]) and male gender (odds ratio 1.49 [95% CI: 1.05-2.12]) predicted amputations.

Hospital admissions (P<0.05) & hospital days (P<0.05) were lower in pts who received more than 10 foot checks in the first yr of dialysis.

| Number of foot checks in year 1 | Hospital Admissions per pt yr | Hospital Days per pt yr |
|---|---|---|
| ≤10 | 1.50 | 10.73 |
| >10 | 1.32 | 6.73 |

Foot checks in DM HD pts are crucial component of quality care in dialysis clinics. In RRI pts the likelihood of amputation was reduced by 13% per every foot check performed in the first yr of HD. Male pts have notably higher incidence of amputations. While some reduction in hospitalization may be attributed to lower incidence of amputations, overall improvement in hospital admission & days is also notable when monthly foot checks are part of a standard clinic operating procedure.

**Quantifying and Predicting the Impact of Hemodialysis on Drug Exposure: Application to Saxagliptin** Liping Zhang, David W. Boulton, Marc Pfister. *Research and Development, Bristol-Myers Squibb, Princeton, NJ.*

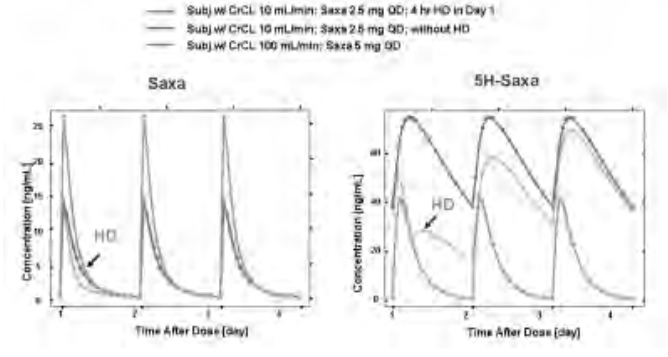
**Background:** The new draft FDA guidance requires PK studies be conducted for renally excreted medicines in subjects under both HD and non-HD conditions to determine the contribution of HD to the elimination of the drug and active metabolites. Yet clinical study designs (often single dose administrated before HD session) do not necessarily represent patient care (multiple doses administrated at varying times relative to HD sessions).

**Objective:** Using saxagliptin (Saxa) and its active metabolite, 5-hydoxy saxagliptin (5H-Saxa) exposure modeling as an example, this work demonstrates how modeling and simulation (M&S) can be used to quantify and predict HD effects on drug exposure in clinical studies and in patient care.

**Methods:** Plasma concentrations of Saxa and 5H-Saxa from 39 subjects with normal renal function, mild, moderate, severe renal impairment, or ESRD undergoing HD were quantified after a single dose of 10-mg Saxa. Nonlinear mixed effect modeling was applied to differentiate the contribution of HD and renal/non-renal clearance of Saxa and 5H-Saxa.

**Results:** The model-estimated mean clearances of Saxa and 5H-saxa contributed by HD are 23.7 (14.9-32.5) and 3.67 (2.96-4.38) L/h, respectively. For an ESRD subject with creatinine clearance of 10 mL/min, clearance of Saxa and 5H-Saxa will increase during HD treatment by 1.7 and 6.5 fold, respectively. The expected concentration profiles of Saxa and 5H-Saxa in subjects receiving 3 HD sessions a week are presented in Figure 1.

**Figure 1. Simulated steady state concentration profiles of Saxa and 5H-Saxa After HD on Day 1**



The total active moiety after Saxa administration in ESRD patients undergoing HD is estimated.

**Conclusion:** Using data collected from a standard single-dose renal impairment study, pharmacometric M&S can provide an efficient way to quantify and predict the impact of HD on drug exposure in the clinical setting.

**Does Individualized Sodium Concentration of Dialysate Fit All Hemodialysis Patients?** Eun Sook Jung,[1] Ji Yong Jung,[2] Kook-Hwan Oh,[1] Yon Su Kim,[1] Curie Ahn,[1] Jin Suk Han,[1] Suhnggwon Kim,[1] Kwon Wook Joo.[1] [1]*Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea;* [2]*Internal Medicine, Gachon University of Medicine and Science, Incheon, Republic of Korea.*

Most dialysis units adopt a single default dialysate sodium prescription. No single dialysate will provide isonatremic dialysis to all patients and an individualized approach seems to be more physiologic. We investigated the clinical impact and safety of an individualized dialysate sodium prescription. Twenty-six chronic maintenance hemodialysis (HD) patients were enrolled. During the standard period (3 weeks), all the subjects underwent nine consecutive HD sessions with the dialysate sodium concentration of 136 (16 pateints) or 138 mEq/L (10 patients). During the individualized period (3 weeks), they underwent nine HD sessions with the individualized dialysate sodium concentrations set to match the patient's average midweek pre-HD serum sodium concentration during the standard period. The patients were divided into three groups: average midweek pre-HD serum sodium concentration was lower than (group 1, n=7), equal to (group 2, n=6), and higher than (group 3, n=13) the standard dialysate sodium concentration. Pre-HD serum sodium concentration did not change during the entire study period in all groups. In group 1, pre-HD diastolic blood pressures decreased (70.8±11.0 vs. 66.9±8.4 mmHg; P<0.05) and intradialytic hypotensive episodes and nursing interventions increased significantly after dialysate sodium individualization. In group 2, no significant differences were observed in all parameters. In group 3, interdialytic weight gain increased significantly during the individualized period (2.0±0.5 kg vs. 2.3±0.4 kg; P<0.05). Thirst scores in 7 patients whose dialysate sodium was increased by 4 mEq/L were increased (6.4±1.5 vs. 7.6±1.5; p<0.05).

Individualization of dialysate sodium concentration based on patient's serum sodium has little benefit for the chronic stable HD patients with their baseline dialysate sodium concentration of 136-138 mEq/L. An individualized dialysate sodium prescription does not fit all HD patients ant it may be considered only in the selected patients.

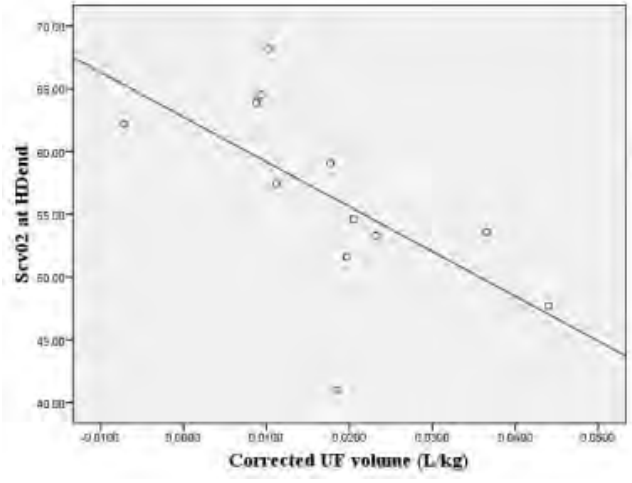
**Central Venous Oxygen Saturation: A Potential New Marker for Circulatory Stress in Haemodialysis Patients** Laura E. A. Harrison,[1] Nicholas M. Selby,[1] Chris W. McIntyre.[1,2] *[1]Department of Renal Medicine, Royal Derby Hospital, United Kingdom; [2]School of Graduate Entry Medicine and Health, University of Nottingham, United Kingdom.*

Haemodialysis (HD) results in significant circulatory effects with subsequent ischaemic end-organ dysfunction. Central venous oxygen saturation ($ScvO_2$), utilised as a composite marker of oxygen delivery/consumption, can predict prognosis in heart failure and septic shock. We aimed to measure $ScvO_2$ during HD and assess its potential in identifying patients experiencing significant circulatory stress.

12 established HD patients utilising tunnelled internal jugular central venous catheters were studied. Central venous samples were drawn from the arterial line in the first and last 10 minutes of HD with immediate blood gas analysis, allowing direct measurement of right atrial $SO_2$. Blood pressure (BP) and heart rate (HR) were measured pre, post and every 15 minutes during HD with weight and ultrafiltration (UF) volumes recorded.

Patient age was 67±16 yrs and dialysis vintage 20 months [IQR 9-24]. At HD initiation, $ScvO_2$ was 63.5±13% (cf quoted normal value of 70%), and during HD it fell further to 56.4 ±8% (p=0.04). UF volume inversely correlated to $ScvO_2$ (r= -0.680, p=0.015). Correcting UF volume for body weight strengthened this association (r= -0.769, p=0.003) (see figure 1). Absolute and $\Delta ScvO_2$ did not correlate with age, pre or post SBP and HR, nor BP reduction during HD (although mean reduction in SBP was only 9±20 mmHg).



This study demonstrates $ScvO_2$ sampling is practical, with potential clinical utility as an indicator of circulatory stress during HD. Increasing UF volume, previously indicated as the principal driver of cardiac stress in HD, was strongly associated with $ScvO_2$ values at the end of dialysis. Additional study is needed to further define the clinical utility of $ScvO_2$ monitoring in optimising the cardiovascular response to HD.

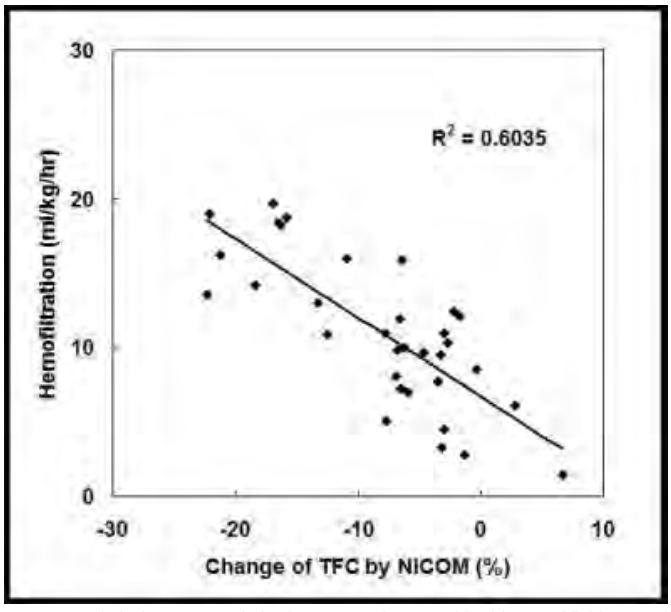
**Characterization of Cardiovascular Health for Chronic Dialysis Using Continuous Non-Invasive Monitoring** Jose F. Bernardo,[1] Hyung Kook Kim,[2] Michael R. Pinsky.[2] *[1]Medicine/Renal-Electrolyte Division, University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Critical Care Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA.*

The principle of fluid removal during intermittent hemodialysis (IHD) is to induce a relative hypovolemic state by ultrafiltration followed by refilling of the vascular space from the interstitial and cellular compartments (plasma refill rate). However, if the ultrafiltration rate (UFR) greatly exceeds the plasma refill rate then hypovolemic cardiovascular collapse may ensue. The objective of this study was to determine if progressive changes in arterial pressure, cardiac output (flow) and related cardiovascular status using the bioreactance non-invasive cardiac output monitor (NICOM)(Cheetah Medical, Tel Aviv) can tract UFR and identify the onset of cardiovascular insufficiency during routine IHD. The NICOM reports CO, stroke volume index, ventricular ejection time, cardiac contractility and TFC. We hypothesized that steady state thoracic fluid content (TFC) and the change in cardiac output (CO) would parallel total volume removal during IHD. These parameters were measured over the course of IHD in 20 chronic dialysis patients on two separate consecutive treatment days corresponding to weekend and weekday interval. Seven runs were lost because of technical reasons. Of the remaining 33 runs, there was no relation between change in CO and the UFR or day of dialysis. However, change in TFC inversely correlated with UFR (r=0.6, p<0.001) but not with total amount of fluid removal.



We conclude that NICOM-derived measures of TFC could guide rate of fluid removal during dialysis whereas measures of flow appear to be insensitive to dialysis-induced fluid removal. A larger prospective clinical trial would be needed to address this issue.

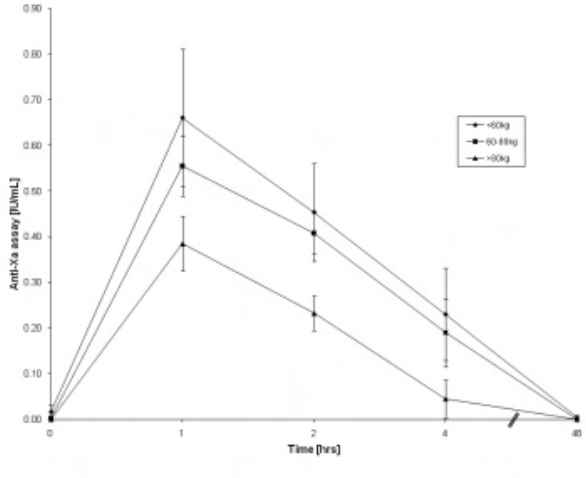
**F-PO1430**

**Tinzaparin Pharmacokinetics in South Asian Hemodialysis Patients** Albert J. Power,[1] Mike Laffan,[2] Claire Edwards,[1] David Taube,[1] Neill D. Duncan.[1] *[1]Imperial College Kidney & Transplant Institute, West London Renal & Transplant Centre, Hammersmith Hospital, London, United Kingdom; [2]Department of Haematology, Imperial College, London, United Kingdom.*

30% strokes in dialysis patients are hemorrhagic in origin, are associated with worse prognosis and may relate to hemodialysis [HD] circuit anticoagulation. We noted an increase in hemorrhagic stroke at our center on conversion from unfractionated heparin to fixed-dose tinzaparin for circuit anticoagulation [as per European recommendations] which appeared limited to South Asian patients. We therefore examined the influence of ethnicity on the anticoagulant effect of tinzaparin.

We prospectively studied tinzaparin 2500 IU [Innohep®, Leo Pharma, UK] given once via the arterial limb of the HD circuit at initiation of HD. 12 patients dialyzing via central venous catheters grouped according to dry weight [<60, 60-80 & >80kg] had heparin-free HD 72 hrs prior to study with the catheter lumens locked with 46.7% citrate. Coagulation profile [prothrombin time, APTT and fibrinogen], antithrombin-III and anti-Xa assays were performed at 0, 1, 2, 4 and 48hrs from HD start.



Anti-Xa levels peaked at 1 hour reaching 0.66±0.15, 0.56±0.07 & 0.39±0.06 IU/ml in the <60, 60-80 & >80kg groups respectively and with parallel increases in APTT [54±8, 41±6 & 33±4 secs]. Tinzaparin use and initiation of HD had no significant effect on antithrombin-III levels [mean 0.85±0.15 vs 0.86±0.18 IU/l, p=0.7]. There was no significant change in prothrombin time or fibrinogen levels. Tinzaparin exerted no anticoagulant effect extending into the next HD session and no patient experienced catheter dysfunction during the study.

Fixed-dose tinzaparin appears to exert a predictable weight-dependent anticoagulant effect that needs to be considered in patients of higher hemorrhagic risk. White and African-Caribbean patients are currently under evaluation.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1431**

**Lowering Dialysate Na Prescription in Patients Undergoing Nocturnal Center HD: Effect on Interdialytic Weight Gain and Blood Pressure** Jair Munoz Mendoza,[1,2] Sumi Sun,[2] Sheila Doss,[2] Brigitte Schiller.[1,2] *[1]Department of Nephrology, Stanford University, Palo Alto, CA; [2]Satellite Healthcare, Mountain View, CA.*

Patients on nocturnal in center hemodialysis (HD) frequently increase interdialytic weight gain (IDWG) over time, supposedly due to more liberalized fluid intake with longer dialysis. We examined whether dialyzing patients against a lower dialysate sodium (Na) concentration closer to the patient's pre-dialysis plasma Na (average of three monthly results) would reduce IDWG.

Fifteen patients were included in this QA project. Patients were told that changes in dialysate prescription would be made, but were blinded to timing to avoid a bias towards over reporting of adverse events (hypotension, cramps). After at least three months observation with "standard" (Na=140mEq/L) therapy, dialysate Na concentration were lowered to 136 or 134mEq/L with gradual biweekly changes. The results from the last two weeks of each prescription were compared by paired t-test.

The mean pre-HD plasma Na during the standard Na phase was 136mEq/L (range 129 to 141mEq/L). IDWG decreased significantly from 4.2 ± 0.8 with standard dialysate Na to 3.6 ± 0.6 with lower dialysate Na concentration ($p<0.004$). Pre-HD MAP and SBP also decreased with lower dialysate Na -6.6 ± 12 ($p=0.05$) and -8.3 ± 15 ($p=0.05$), respectively. Furthermore, a reduction in pre-HD DBP was noted (89.6 ± 11.6 vs 83.9 ± 10.6; $p=0.06$), while no difference in post-HD MAP ($p=0.48$), post-HD SBP ($p=0.60$) and post-HD DBP ($p=0.43$) was found. There was only one episode of intradialytic hypotension requiring saline in each phase. The pre-HD plasma Na was unchanged in both phases ($p=0.99$), while post-HD plasma Na decreased -3.7 ± 1.9mEq/L with lower dialysate Na prescription ($p<0.0001$).

Decreasing dialysate Na from standard 140mEq concentration in extended time center HD resulted in decreased IDWG, reduced post-HD plasma Na and reduction in pre-dialytic BP without increasing intradialytic adverse events. These preliminary data require confirmation in more subjects undergoing conventional thrice weekly HD.

**F-PO1432**

**Extracellular Resistance Changes in the Calf and Whole Body in Different Hydration State during Ultrafiltration** Li Liu, Yanna Dou, Li Zuo. *Renal Division, Peking University First Hospital, Beijing, China.*

**Purpose** Monitoring fluid removal in the calf by bioimpedance technique during ultrafiltration (UF) has been suggested to determine normal hydration status (NH) in hemodialysis (HD) patients [Zhu F, Physiol Meas, 2008]. The aim of the study was to explore the relationship between fluid removal in the calf and whole body (WB) during UF.

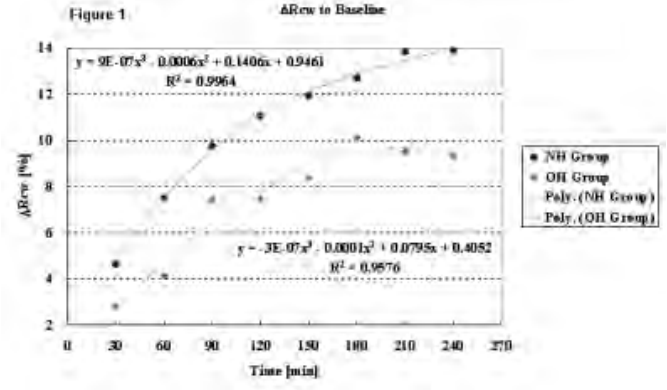
**Methods** Twenty HD patients (11F), aged 56 years, were enrolled. Removal of fluid in WB or calf was represented by change in extracellular resistance ($wR_E$ and $cR_E$) were measured by a Hydra 4200 and modified Hydra device every 30 min during HD respectively. Ratio of $cR_E/wR_E$ was used to indicate fluid distribution between calf and WB. All measurements were divided into two groups according to calf resistivity (nRho<18) defined as over-hydration (OH) and nRho>18 defined as normal hydration (NH). Change in ratio of $cR_E/wR_E$ (ΔRcw) % from baseline (time '0') to time 't' was calculated by formula: $(Rcw_t-Rcw_0)/Rcw_0*100\%$. Average ΔRcw for every 30 minutes in all measurements was calculated in OH and NH respectively. Polynomial regression with 3 orders was performed to distinguish difference in the curve of average ΔRcw between OH and NH during HD.

**Results** Among 25 measurements, 12 were in NH group and 13 in OH group. Both cRe and wRe increased continuously over time during hemodialysis session (Table 1). Figure 1 shows that mean of ΔRcw increased. However, the curve was trend to be flattening during the last hour in OH but increased continuously in NH during UF.

Table 1 Change in Extracellular Resistance in Calf and Whole Body over Time

| | OH Group | | NH Group | |
|---|---|---|---|---|
| Time [min] | $cR_E$ (ohm) | $wR_E$ (ohm) | $cR_E$ (ohm) | $wR_E$ (ohm) |
| 0 | 39.97±7.94 | 536±107 | 43.46±8.12 | 606±77 |
| 30 | 42.35±9.22 | 551±113 | 47.01±8.74 | 624±82 |
| 60 | 44.14±9.51 | 567±116 | 49.82±9.50 | 642±84 |
| 90 | 45.80±10.35 | 575±125 | 52.09±9.80 | 658±84 |
| 120 | 47.39±10.40 | 599±139 | 54.40±10.16 | 680±91 |
| 150 | 49.08±10.94 | 614±145 | 56.76±10.58 | 703±96 |
| 180 | 51.18±11.40 | 634±152 | 58.95±10.37 | 727±103 |
| 210 | 52.85±12.06 | 659±163 | 61.43±11.11 | 749±110 |
| 240 | 54.45±13.03 | 675±168 | 63.17±11.60 | 771±117 |

Figure 1



**Conclusion** Fluid was removed more quickly and continuously from calf than other segments which confirmed that hydration in the calf is relatively higher than the average hydration in whole body. This suggests that normal hydration can be determined more accurately by using calf bioimpedance approach in HD patients.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1433**

**Effect of Elevating Calcium Concentration of Dialysate To Treat Intra-Dialytic Hypotension: A Cross-Over Self-Control Trial** Zi Li, Ping Fu. *Department of Medicine-Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

**BACKGROUND:** Symptomatic intra-dialysis hypotension (IDH) continues to be a common problem. With the use of low calcium (Ca) concentration dialysate in our dialysis center for 5 years, several patients developed IDH occasionally or frequently. Even after multiple therapeutic strategies were induced, IDH still happened in some patients. In this study, we investigated the changes in haemodynamic parameters induced by calcium concentration of dialysis fluid in IDH patients. **METHODS:** Single-blinded, crossover design was used. Nineteen maintainance hemodialysis patients with IDH were randomized into two groups, beginning by changing the calcium concentration in dialysate either to 1.25mmol/L or 1.75mmol/L. The first 2-week intervention phase was followed by two-week of wash out with calcium concentration in dialysate as 1.5mmol/L, switching round the calcium concentration compared to the initial randomization, by a second 2-week intervention phase. **RESULTS:** Eighteen patients finished the trial except one patient withdrew due to hypercalcemia. Compared to low calcium concentration (1.25mmol/L), medium and high calcium concentration (1.5mmol/L and 1.75mmol/L respectively) elevated intradialytic systolic blood pressure (SBP) and heart rate ($P<0.05$), decrease the maximum decrease of SBP (the difference between predialytic SBP and the lowest intradialytic SBP), decrease the events of symptomatic IDH. Compared to medium concentration, high calcium concentration dialysate only had lower incident of intradialytic intravenous fluid infusion. No sever disorder of electrolyte were found. **CONCLUSION:** Medium calcium concentration dialysate can effectively improve the hemodynamic stability in IDH patients. Clinical trial with larger sample and longer follew-up is needed.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1434**

**Elevated Plasma Brain Natriuretic Peptide (BNP) Levels in Hemo-Dialysis (HD) Patients with Sleep Apnea (SA)** Robert L. Benz,[1,3,6] Rob J. Mathews,[1] Mark R. Pressman,[4,6] Michael M. Chernick,[5] Albert A. Keshgegian.[2,3,6] *[1]Nephrology, Lankenau Hospital, Wynnewood, PA; [2]Pathology, Lankenau Hospital, Wynnewood, PA; [3]Mainline Health, Wynnewood, PA; [4]Pulmonary & Sleep Medicine, Lankenau Hospital, Wynnewood, PA; [5]Biostatistics, Lankenau Institute for Medical Research, Wynnewood, PA; [6]Lankenau Institute for Medical Research, Wynnewood, PA.*

**Background**: BNP is elevated in volume overload states. In HD patients, BNP can be elevated in the absence of overt circulatory overload. SA causes pulmonary hypertension and circulatory patho-physiology which could stimulate BNP from overstretched myocardial tissue. We evaluated BNP levels in HD patients with SA to determine whether SA may contribute to elevated BNP.

**Methods**: 22 SA patients on maintenance high-flux HD without evidence of overt circulatory overload were studied. Volume status was assessed by history, exam, and weight measurements. SA was assessed by prior polysomnography (PSG) and all underwent confirmatory PSG followed by pre/post-dialysis (1st of week) and pre-next dialysis (mid-week) measurements of BNP.

**Results**: 19/22 SA, HD patients had elevated BNP levels. Mean KT/V was 1.66. Mean group post-HD weights matched mean group EDW goal. Mean (1st of week) pre-HD BNP was 846.2pgm/ml; mean post-HD BNP was 895.4 pgm/ml; and mean pre mid-week BNP level was 755.2 pg/ml (nl<100pgm/ml). Mean apnea-hypopnea index (AHI) was 40.94 events/hour. There was no correlation between AHI and BNP [p=0.856, 0.991, and 0.938 (pre/post/pre) respectively].

**Conclusion**: Plasma BNP is elevated in HD patients with SA despite the absence of overt circulatory overload. There was no correlation between BNP levels and AHI, likely eliminating SA as a causative factor of elevated BNP. This data suggests that alternative causes for elevated BNP be investigated in HD patients in the absence of circulatory overload despite the presence of SA.

**F-PO1435**

**Negative Sodium Gradients Are Associated with Greater Sodium Removal without Adversely Affecting Inter-Dialytic Weight Gain: Support for an Individualisation of Dialysate Sodium** Aghogho Odudu,[1] Maarten W. Taal,[1] Richard J. Fluck,[1] Chris W. McIntyre.[2] *[1]Renal Medicine, Royal Derby Hospital, United Kingdom; [2]School of Graduate Entry Medicine and Health, University of Nottingham, United Kingdom.*

**Background.** Larger inter-dialytic weight gains (IDWG) and higher ultrafiltration volumes and rates are associated with cardiac morbidity and mortality. Control of IDWG is a key therapeutic aim. The sodium set-point hypothesis predicts that the gradient between serum sodium (SNa) and dialysate sodium (DNa) is a major driver of thirst and IDWG. A positive sodium gradient (GNa = DNa - SNa), results in sodium loading and increased IDWG, but the effects of a negative gradient have been subjected to only limited study.

**Methods.** 19 chronic HD patients were studied over four weeks, dialysed against a constant 136 mmol/l dialysate Na concentration. 15 were anuric and 4 had urine output <150 ml/day. We used continuous on-line conductivity monitoring, ion-specific electrodes and a validated sodium kinetic model to calculate sodium gradients and related this to both ionic mass balance (IMB), IDWG, and blood pressure.

**Results.** A full dataset was available for 214 treatment sessions. The mean+/- SD are presented. GNa was -6.1+/-3.8 mmol/l, IMB 347+/- 146 mmol, UF volume 1.9+/-0.9l, IDWG 2.7+/-1.4%, pre-HD systolic BP 142+/-25 and diastolic BP 83+/-17 mmHg. Inter-patient variation in IMB was much greater than intra-patient variation. There was a reasonable correlation of negative gradients with higher ionic mass balance (r =0.59, p<0.01). There was no detectable effect on IDWG or BP.

**Conclusion.** Negative sodium gradients enhance sodium removal without increasing intra-dialytic hypotension. There was no detectable effect on IDWG.

**Relevance.** This study needs to be confirmed in a larger population but suggests that having dialysate sodium set lower than plasma sodium may enhance diffusive removal of sodium without adverse effects. Use of on-line conductivity monitoring makes this operationally feasible.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1436**

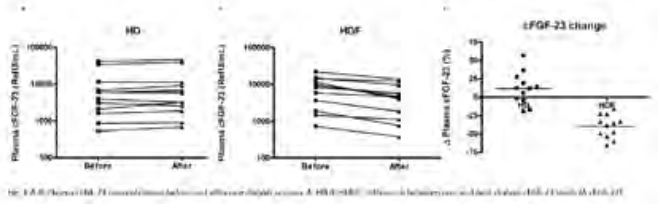
**Fibroblast Growth Factor 23 Is Effectively Removed by Online Hemodiafiltration, but Not by Low-Flux Hemodialysis** Claire H. Den Hoedt,[1,2] Marinus A. Van Den Dorpel,[1] Marc G. Vervloet,[3] Albert H. Mazairac,[2] Neelke C. Van Der Weerd,[3] Muriel Grooteman,[3] E. Lars Penne,[2,3] Michiel Bots,[4] Peter J. Blankestijn,[2] Pieter M. Ter Wee.[3] *[1]Maasstad Hospital, Rotterdam; [2]UMCU, Utrecht; [3]VUmc, Amsterdam; [4]Julius Center, Utrecht, Netherlands.*

**Background.** Fibroblast Growth Factor 23 (FGF-23, ±27 kDa) is strongly associated with increased mortality in dialysis patients. If causality exists, methods to lower FGF23 can have beneficial effects on outcome.

**Purpose.** To investigate whether FGF-23 is more effectively removed by online hemodiafiltration (HDF) than by low-flux hemodialysis (HD).

**Methods.** Blood samples were obtained at the beginning and end of 1 dialysis session in 12 HDF and 12 HD patients. Both full-length FGF-23 (iFGF-23) and C-terminal FGF-23 (cFGF-23, ±12 kDa) were measured. FGF-23 levels are depicted as medians (total ranges). Differences were analyzed by Mann-Whitney tests.

**Results.** cFGF-23 changed from 5030 RefU/mL (531-42319) to 4549 RefU/mL (678-47268) in HD patients and from 8449 RefU/mL (717-22018) to 4540 RefU/mL (378-13635) in HDF. Pre dialysis levels did not differ between the two groups (p=0.5). During HD, cFGF-23 did not change (+12% (-19 to +57)), whereas it decreased during HDF (-37% (-65 to -15)) (p<0.001, for difference in Δ change). iFGF-23 remained stable during HD (+11%) and decreased significantly during HDF (-28%) (p<0.001). Residual kidney function, weight- and calcium change were the same in the 2 groups. Phosphate and PTH levels decreased significantly more in HDF, but did not explain the change in FGF-23.



**Conclusions.** FGF-23 is effectively removed by HDF but not by low flux HD. In view of the possible adverse actions of FGF-23 in the development of cardiovascular disease, removal by HDF may be beneficial. Further studies are needed to elucidate the long-term effects of increased FGF removal.

**Cytokine Production of Peripheral Blood Mononuclear Cells after Exposure to Endotoxin during High Flux Hemodialysis** Kearkiat Praditpornsilpa, Khajohn Tiranathanagul, Somchai Eiam-Ong. *Division of Nephrology, Chulalongkorn University, Bangkok, Thailand.*

The back filtration of endotoxin across high-flux membranes to blood compartment causes activation of inflammatory cells and inflammation. Question has been raised what endotoxin contamination limit have the least inflammatory cells stimulation. We investigated the effect of dialysate endotoxin contamination by cytokines release from peripheral blood mononuclear cells (PBMCs) after endotoxin exposure.

**Methods:**

Four different levels of endotoxin contaminated hemodialysis (HD) centers where endotoxin in dialysate was monthly monitored by limulus amoebocyte lysate kinetic turbidimetric assay were recruited in this study (0.001 EU/mL in HD center 1, 0.026 EU/mL in HD center 2, 0.558 EU/mL in HD center 3, and 1.960 EU/mL in HD center 4). PBMCs from HD patients who met the inclusion/exclusion criteria were separated and measured the spontaneous cytokines production after HD ( case = 26, 25, 20, and 20 in HD center 1, 2, 3, and 4 respectively). The criteria included patients who had no current infection, had no previous kidney transplantation, had no malignancy or autoimmune disease, and had negative test for HIV Ab, HBsAg and anti-HCV.

**Results:**

There were significant differences of mean IL-6, IL-1beta, and IL-1Ra level spontaneously released from the PBMCs after HD session among patients from HD centers. The higher endotoxin exposure had higher inflammatory cell activation. Cytokines released from the PBMCs were highest in HD center 4 where endotoxin contamintion was highest. There were no statistically significant differences of cytokine release between two ultrapure dialysate (endotoxin level < 0.03 EU/mL) centers (HD center1 and HD center 2).

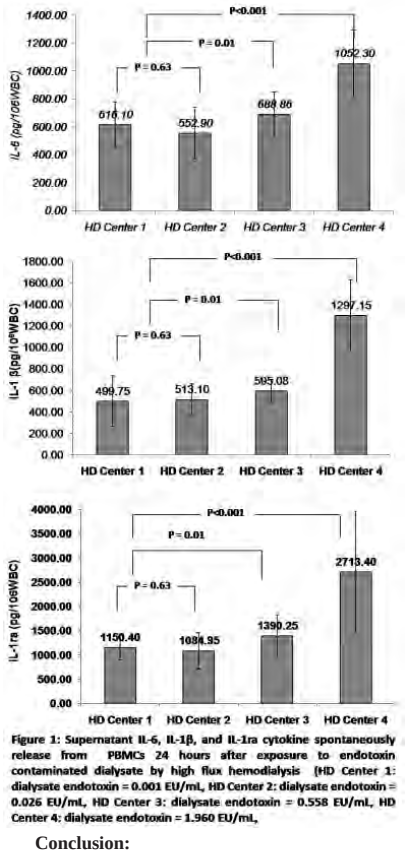

**Figure 1: Supernatant IL-6, IL-1β, and IL-1ra cytokine spontaneously release from PBMCs 24 hours after exposure to endotoxin contaminated dialysate by high flux hemodialysis (HD Center 1: dialysate endotoxin = 0.001 EU/mL, HD Center 2: dialysate endotoxin = 0.026 EU/mL, HD Center 3: dialysate endotoxin = 0.558 EU/mL, HD Center 4: dialysate endotoxin = 1.960 EU/mL,**

**Conclusion:**

Endotoxin < 2 EU/mL as recommended by AAMI can be inadequate. The ultrapure dialysate should be a minimal endotoxin contamination allowed in HD.

## F-PO1438

**Left Ventricular Torsion Is an Early Marker of Myocardial Dysfunction in Incident Haemodialysis Patients** Aghogho Odudu,[1] Mohamed Tarek Eldehni,[1] Chris W. McIntyre.[2] [1]*Renal Medicine, Royal Derby Hospital, United Kingdom;* [2]*School of Graduate Entry Medicine and Health, University of Nottingham, United Kingdom.*

Contractile coherence is essential for normal ventricular ejection, this can be assessed by measuring ventricular synchrony and the degree of rotational displacement over a cardiac cycle. Such defective ventricular contractile function can exist in the presence of superficially normal systolic function, with preserved ejection fraction (EF). Appreciation of the importance of synchronous ventricular contraction in haemodialysis (HD) patients has been limited to prevalent populations using echocardiography based techniques limited by low resolution and high degrees of operator dependence. We report a pilot study utilising cardiac magnetic resonance (CMR) myocardial tagging of patients new to HD. This utilises a magnetized grid allowing three-dimensional quantification of intra-myocardial motion with high spatial and temporal resolution.

11 HD patients (exposed to HD <90 days) were studied on a post-HD day using a 1.5T MR scanner. Conventional CMR techniques were combined with a 7mm grid tag applied with a spatial modulation of magnetization sequence in 3 short axis slices evenly distributed over the LV. Harmonic phase images were computed using a semi-automated software. Peak absolute rotation was calculated and compared to published values in healthy volunteers.

The mean ±SD of values are presented. Global LV function was normal (EF 69±15%) with only 1 subject with EF<50%. There was a high degree of LVH (LVMI 97.7±25m$^2$) The degree of rotation increased from base to apex whilst basal to mid-ventricular rotation was similar to values in non-uraemic controls(4.1°Vs 3.8° & -4.2° Vs-4.4° respectively). Mean peak apical rotation was significantly lower than non-uraemic controls (6.9° Vs 10.5°, p>0.05).

Conclusion: Incident HD patients are not characterised by global LV dysfunction more typical of patients established on HD. However study of LV torsion reveals subclinical disordered contraction despite preserved EF. The significance of the relationship to HD tolerability and susceptibility to recurrent HD-induced cardiac injury awaits further elucidation.

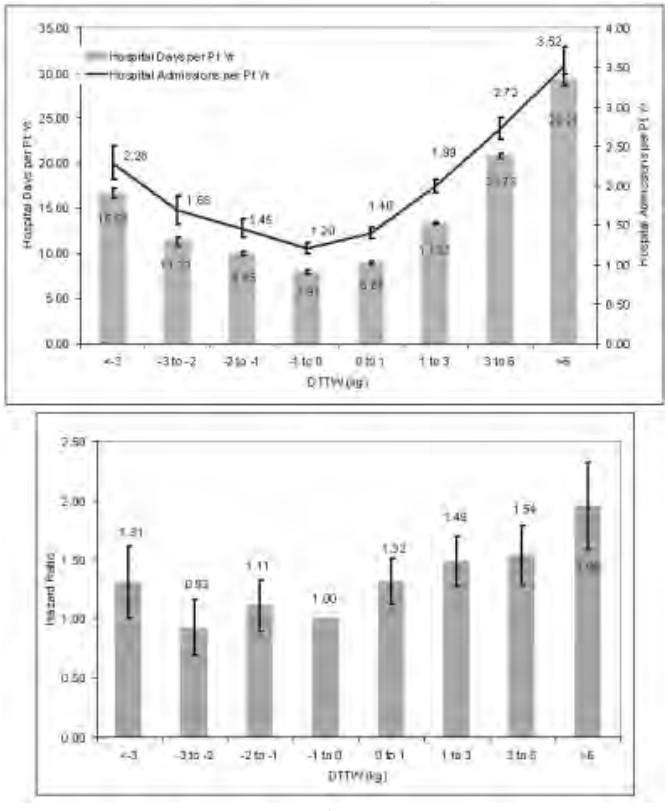
**Failure To Achieve Prescribed Target Weight in Chronic Hemodialysis Patients Is Associated with Poor Outcomes** Len A. Usvyat,[1] Balaji Gandhi,[2] Nathan W. Levin,[1] Peter Kotanko.[1] [1]*Renal Research Institute, NY, NY;* [2]*Fresenius Medical Care North America, Waltham, MA.*

Overhydration is prevalent in the vast majority of chronic hemodialysis (HD) patients (pts). Post-HD target weight (TW) is prescribed by nephrologists primarily based on clinical evaluation. Unfortunately, TW is frequently not achieved. This study evaluates the impact of the difference between achieved post-HD weight and prescribed TW (delta to target weight, DTTW) on hospitalizations and mortality.

We studied HD pts treated in RRI clinics in 2007 ("study prd"). Achieved post-HD weight and laboratory parameters were computed as avg for the study prd. Pts were stratified according to DTTW (in kg): DTTW<-3, DTTW-3 to -2, DTTW-2 to -1, DTTW-1 to 0, DTTW0 to 1, DTTW1 to 3, DTTW3 to 6, DTTW>6.

6,440 pts were studied (4% with DTTW<-3, 4% with DTTW-3 to -2, 8% with DTTW-2 to -1, 19% with DTTW-1 to 0, 23% with DTTW0 to 1, 25% with DTTW1 to 3, 12% with DTTW3 to 6, 5% with DTTW>6). Both number of hospital admissions (ADM) and LOS showed a U-shaped relationship with highest ADM and hospital days in the DTTW>6 group and lowest in the DTTW-1 to 0 cohort. Both ADM and LOS were 3x higher in DTTW>6 compared to DTTW-1 to 0.

Cox survival analysis with adjustment for age, gender, race, albumin, and sodium gradient (dialysate Na - serum Na), also demonstrated a U-shaped relationship with best survival in DTTW-2 to -1, DTTW-1 to 0, and DTTW0 to 1 groups (no statistical differences b/n those groups). HR was nearly 2-times higher in DTTW>6 than in the reference group (DTTW-1 to 0).



This study accentuates the importance of reaching TW. In order to achieve TW in some pts txt time has to be extended. An important consideration is the fact that TW may still be greater than the true "dry weight" in many pts. Means to objectively define dry weight are necessary to elucidate this issue further.

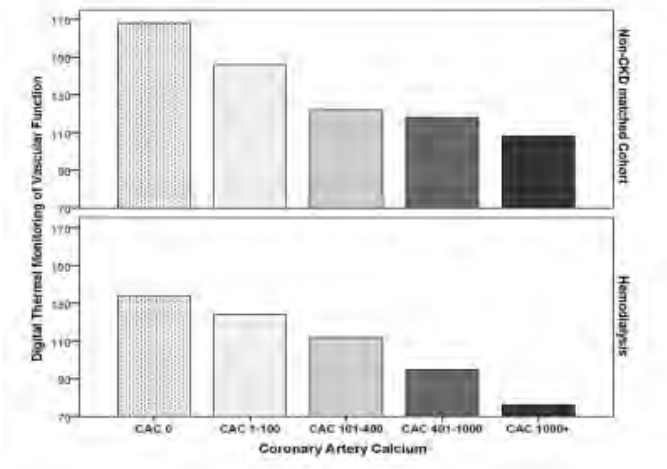
## F-PO1440

**Vascular Dysfunction and Coronary Artery Calcium Increase with the Presence of End Stage Renal Disease** Irfan Zeb, Naser Ahmadi, Jennie Jing, Ramanath B. Dukkipati, Matthew Jay Budoff, Kamyar Kalantar-Zadeh. *Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA.*

Cardiovascular (CV) morbidity and mortality is comon among maintenance hemodialysis (MHD) patients (pts), which increase with the presence and severity of coronary artery calcium (CAC). We investigated the association of vascular dysfunction measured by digital thermal monitoring (DTM) with severity of CAC in MHD pts compared to a matched cohort without CKD. Study population consisted of 105 MHD pts (age: 57±12, males: 49%) and 105 age, gender and traditional CV risk factor matched non-CKD subjects. All pts underwent CAC and DTM. Area under the temperature curve (TMP-AUC), DTM index of vascular function were assessed through a 5-minute arm-cuff reactive

hyperemia test. TMP-AUC decreased significantly from Non-CKD to MHD pts (143±80 vs. 114±72, p=0.001). CAC (Agatston score) increased from Non-CDK (240±332) to MHD pts (525±425)(p=0.0001). After adjustment for age, gender, DM, HTN, lipid, smoking, ethnicity and race, the risk for each standard deviation decrease in TMP-AUC was 1.46 (95%CI 1.12-1.93,p=0.007) in MHD pts compared to non-CKD. TMP-AUC decreased with increasing CAC (0,1-100,101-400,401-1000 & 1000+) which was significantly higher in MHD pts compared with Non-CKD (P<0.05). The relative risk of increase in CAC from 0 to 1-100, 101-400, 401-1000 and 1000+ was 5.29 (95%CI 1.82-15.38,p=0.002), 7.49 (95%CI 2.45-22.85,p=0.0001), 10.88 (95%CI 3.82-31.03,p=0.0001), and 13.98 (95%CI 4.86-40.14,p=0.0001) in MHD pts compared to Non-CKD, respectively.



In MHD pts, higher rate of vascular dysfunction and coronary atherosclerosis exist compared to non-CKD; and vascular dysfunction increases with the severity of coronary atherosclerosis in MHD pts, independent of conventional risk factors, suggesting the importance of subclinical atherosclerosis assessment in MHD pts.

**F-PO1441**

**Compliance to Phosphate Binders: An Observational Multi-Centre Study** Monique M. Elseviers, Sofie Alida Marcel Huybrechts, Yoleen Philomena Margueritte Van Camp, Marc E. De Broe. *Nursing Science, Univ. Antwerp, Belgium.*

This study aimed to map compliance to phosphate binders (PBs) in the hemodialysis (HD) population using the electronic Medication Event Monitoring System (MEMS) and to determine patients characteristics related to non-compliance.

Compliance to PBs was evaluated in 3 Belgian and 1 Dutch dialysis centre. All adult patients treated with PBs, in chronic HD for more than 3 months and without mental disorders were asked for participation. Compliance was measured using MEMS-V Track-Cap devices (Aardex Ltd, CH). In addition, a pill count method (adding each week a changing number of extra pills while refilling the medication box) was used to test compliance. Non-compliance was defined as a registered intake <80% of prescribed doses.

A cohort of 216 patients (out of 276 meeting the inclusion criteria) was followed during a period of 14 weeks. Mean age was 67 years (range 21-90), 57% were males, mean HD treatment was 47 months (range 3-189). Patients had a mean pill burden of 14 pills per day (range 2-35) with 33% of patients taking more than one PB. PBs studied were calcium carbonate, sevelamer and lanthanum in 45, 45 and 10% of patients, resp., with a mean intake of 5.4 (range 1-12) PB pills per day. Electronic monitoring revealed a compliance of 68% (range 58-74% per centre) compared to 85% using pill count, both showing a decreasing trend after one month of observation. Compliance was slightly negatively related to mean serum phosphorus (r=-.179; p=.009) and did not show a relationship with mean serum calcium levels (r=0.051; p=0.462). In HD patients, non-compliance was significantly influenced by younger age (OR=1.96), taste complaints of PBs (OR=7.15), nausea related to PB intake (OR 4.19) and a high PB pill burden (OR=2.74).

Only two thirds of HD patients had an acceptable level of compliance to PBs. Main risk factors for non-compliance were associated with complaints related to PB use.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1442**

**Bioimpedance Spectroscopy (BIS): Clinical Application To Evaluate Acute Extracellular Water (ECW) Changes and Overhydration (OH) in Hemodialysis** Mauricio Paredes-Fernandez, Klearly M. Tinoco, Ricardo Correa-Rotter. *Instituto Nacional de Ciencias Médicas y Nutrición.*

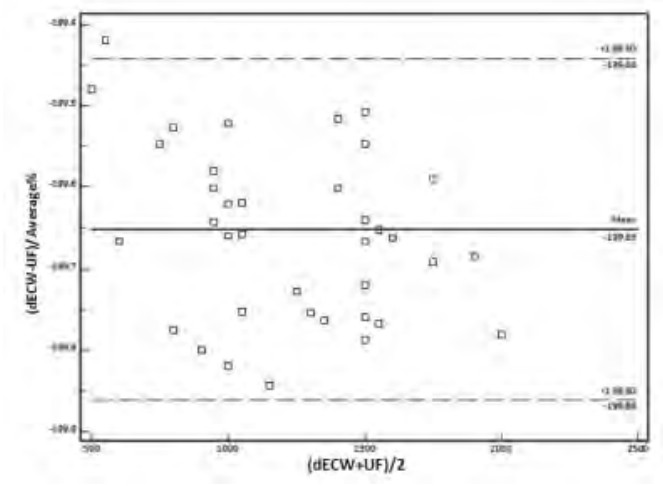
Dry weight estimation is crucial in HD prescription. Multifrequency bioimpedance spectroscopy (BIS) assesses hydration status estimating ECW and OH. For clinical application, BIS must be accurate enough to assess acute variations of volume status, almost exclusive to ECW, without showing artifactual intracellular water (ICW) modifications (as usually happens with other bioimpedance techniques).

Purpose: To estimate OH and determine BIS sensitivity to acute volume variations during HD and to compare hydration status of HD patients with normal controls.

METHODS: We employed a BIS device (Body Composition Monitor (BCM) Fresenius Medical Care) to measure pre and post HD ECW and OH in chronic adult HD patients and compared ECW reduction to net UF. Measured ECW minus calculated ECW (formula for Mexican people= 0.007594+0.03557BSA+0.001229BMI+0.008608gender (0=female,1=male) provides an objective evaluation of ECW expansion (diECW).

RESULTS: We studied 42 HD pts. (age 45.9±16.5 y, 66% males), follow up 41±32 mo. Basal ECW was 0.09±0.01 L/cm (0.07 to 0.16) and significantly greater to that measured in healthy individuals [0.09±0.01 L/cm, (0.06 to 0.13), p=0.03]. UF reduced significantly ECW(16.12±3.8 L preHD vs 14.2±3.6 L postHD, p=0.01) but did not affect ICW (16.5±3.7 L preHD vs 16.6±4.0 L postHD, p=0.91). Basal and final diECW showed good correlation with pre and postHD OH(R=0.88, P<0.001 and r=0.9, p<0.001).

ECW reduction and OH showed good correlations with UF (r=0.7, p<0.001 and r=0.70, p<0.001). ECW reduction and UF had a mean difference of 199.6 mL between them(Bland Altman graph.)



DISCUSSION: BIS accurately estimates acute ECW variations as shown in correlation to net UF. As expected, variations are restricted to ECW. OH or diECW could be used interchangeably to assess fluid status.

**Mass Spectroscopy Reveals Numerous Uremic Solutes Produced by Colon Bacteria** Timothy W. Meyer,[1] Pavel A. Aronov,[1] Natalie Plummer,[1] Susan Holmes,[1] Thomas H. Hostetter.[2] *[1]Stanford University & VA Palo Alto, Palo Alto; [2]Albert Einstein College of Medicine, New York.*

Potentially important uremic solutes are produced in the colon by bacteria acting on foodstuffs which escape digestion in the small intestine. This study employed mass spectroscopy (MS) to identify such solutes. Plasma was collected from 7 normal subjects and, prior to dialysis treatment, from 15 ESRD patients of whom 6 had total colectomies and 9 had intact colons. Analysis by UPLC (C18, reverse phase) coupled to high accuracy MS (orbitrap) revealed 1075 chemical features characterized by retention time and mass/charge ratio. Of these, 56 features were absent or found in significantly reduced concentration in patients with colectomies (p<0.05 after adjustment for multiple comparisons). Online databases (HMDB, Madison, Metlin) revealed candidate compounds corresponding to only 27 of these features. The identify of 4 features which accumulate in ESRD patients wth intact colons but are largely absent in those without colons has so far been confirmed by UPLC/MS of chemical standards:

| | Plasma Ratio Colectomy HD vs Intact Colon HD | Plasma Ratio Intact Colon HD vs Normal Control |
|---|---|---|
| p-cresol sulfate | 0.02 | 11 |
| indoxyl sulfate | 0.01 | 45 |
| phenylacetyl-L-glutamine | 0.05 | 77 |
| 5-hydroxyindole | 0.11 | 4 |

This list includes p-cresol sulfate and indoxyl sulfate which have previously been identified as of colonic origin along with an additional indole and a phenyl compound, presumably derived from tryptophan and phenylalanine/tyrosine, respectively. Of note, the plasma concentrations of two other indoles, indole-3-acetic acid and indole-3-lactic acid were not lower in patients with colectomies. These results indicate that colon bacteria produce a remarkably large number of uremic solutes, many of which are not included in current metabolomic databases. Further work is required to elucidate their structures and potential contributions to uremic illness.

**F-PO1444**

**Phosphate Binders: A Nurse Lead Intervention To Improve Compliance** Monique M. Elseviers, Yoleen Philomena Margueritte Van Camp, Sofie Alida Marcel Huybrechts. *Nursing Sciences, Univ. Antwerp, Belgium.*

This study aims to compare the baseline compliance to phosphate binders (PBs) blindly controlled by the Medication Event Monitoring System (MEMS) to the results obtained by a nurse lead intervention focusing on medication knowledge and personalized support.

In 4 dialysis centres, all adult patients treated with PBs, in chronic HD for more than 3 months and without mental disorders, were asked for participation. Compliance was measured during a period of 14 weeks using MEMS devices. Non-compliance was defined as a registered intake <80% of prescribed doses. An interventional study was set up in an additional Belgian centre using identical inclusion and observation methods. In the latter centre, 4 weeks after the start of the observation period, a nurse visited all participating patients, offering an information chart and an individualized explanation about PBs. Thereafter, she contacted all participants bi-weekly for a personalized talk about compliance.

In the total cohort of 257 patients (including 216 baseline and 41 intervention patients), mean age was 67.5 years (range 21-90), 59% were males, mean HD treatment was 47 months (range 3-267). Patients had a mean pill burden of 14 pills per day (range 2-35) with 33% of patients taking more than one PB. PBs studied were calcium carbonate, sevelamer and lanthanum in 46, 42 and 12% of patients, respectively with a mean intake of 3.9 (range 1-9) PB pills per day. In the baseline cohort, compliance decreased from a mean of 85% in week 1 to 76% in week 14. In contrast, in the intervention group compliance increased from a mean of 82% to 94%. Interrupted time series analysis revealed that the decreasing trend of compliance in the baseline cohort with a slope of -0.782 (95% CI -1.07--0.489) significantly differed from the slope of 0.672 (95% CI -0.13-1.40) in the intervention group. During the intervention study, serum phosphorus levels decreased from 4.8 to 4.6 mg/dL (p=0.110) and knowledge about PBs increased from a mean score of 53 to 75%.

Although non-compliance to PBs was frequently observed in HD patients, a nurse lead program of education and close follow-up of PB intake is worth considering to improve compliance.

**F-PO1445**

**Dialysate Sodium (Na) 2 to 10 mEq/L Higher Than Plasma Na during Hemodialysis (HD) Increases Interdialytic Na Accumulation** Marcia L. Keen,[1] Frank A. Gotch.[2] *[1]ML Keen & Associates, Moorpark, CA; [2]University of California, San Francisco, CA.*

Sodium (Na) intake in HD patients is assumed to primarily reflect dietary Na intake. Few data are available to determine the relative contribution of dialysate Na ($J_DNa$) to total Na intake ($J_TNa$) in HD patients. It has been reported that individual HD patients may have plasma Na set points ($C_{sp}Na$), which range from 135 to 145 mEq/L (Keen, Int J Artif Organs, 2007). These data have been re-analyzed to determine the relative contributions of $J_DNa$ and $J_{Diet}Na$ to total interdialytic Na accumulation ($J_TNa$).

Methods: Data consisted of monthly pre/post plasma Na ($C_{p0}Na$, $C_{pt}Na$) and urea kinetic modeling for 1 year in 57 HD patients. Dialysate Na was 143 mEq/L, which produced Na gradients of 0 to 8 mEq/L. Twelve sets of values for pre/post urea volumes ($V_0$,$V_t$) and $J_DNa$, $J_{Diet}Na$ were calculated per patient. From known osmotic equilibrium in extracellular and intracellular volumes ($V_e$,$V_i$), anatomical distribution of K in $V_i$ and Na in $V_e$ and $C_{sp}Na=C_{p0}Na$, normal total body osmotically active cation, $TBC=C_{sp}Na*V_t$ was calculated. Mass balance, $J_DNa = (C_{pt}Na-C_{sp}Na)*Vt$ and $J_{Diet}Na=(C_{sp}Na-C_{pt}Na)*V_t+C_{sp}Na*(V_0-V_t)$ as functions of the gradient from dialysate to blood ($\Delta CNa$) could be calculated. A single pool variable volume kinetic model was used to calculate $J_DNa$ and $J_{Diet}Na$ as continuous functions over wide ranges of $\Delta CNa$ and interdialytic weight gain (IDWG).

Results (M±SD): $V_tT=30.6\pm8.7$; $(V_0T-V_tT)=2.2\pm1.0$; $J_{diet}Na=3.0\pm1.1$ and ≠ f($\Delta CNa$); $J_dNa=0.18(\Delta CNa)-0.10$, $r^2 = .62$, $p<0.001$. The results of modeling these data are shown below.

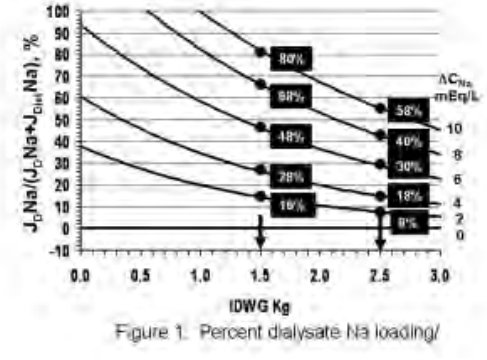

Figure 1. Percent dialysate Na loading/

Conclusion: These data quantify and differentiate the effect of $J_DNa$ and $J_{Diet}Na$ on Na loading in HD. Each 5 mEq/L $\Delta CNa$ was equivalent to a $J_{diet}Na$ of 1 gm/day, supporting the importance of prescribing $\Delta CNa=0$ to avoid chronic Na overload in HD patients.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1446**

**Relationship of Change in Relative Blood Volume and Hydration State in Hemodialysis Patients** Fansan Zhu, Samer Rateb Abbas, Li Liu, Murat H. Sipahioglu, Jochen G. Raimann, Laura Rosales, Peter Kotanko, Nathan W. Levin. *Renal Research Institute, New York, NY.*

Relative blood volume (RBV) monitoring has been suggested as a simple approach to monitoring hydration state during hemodialysis (HD) treatments. However, high variability in nadir RBV ($RBV_{min}$) and RBV slope ($RBV_{slope}$) during HD complicates its clinical use. This study investigated the relationship between $RBV_{min}$ and $RBV_{slope}$ with ultrafiltration rate (UFR) and hydration state as determined by calf bioimpedance spectroscopy (cBIS).

Post-HD weights were gradually decreased in 40 chronic HD patients with the aim to reach dry weight (DW) as defined by cBIS (Zhu, et al., Physiol Meas, 2008). Continuous RBV monitoring (BVM, Fresenius) and cBIS (Xitron) were done during HD. Calf normalized resistivity (nRho) measured by cBIS was calculated as an indicator of hydration state. Correlations of $RBV_{min}$ and $RBV_{slope}$ with UFR and Pre-, Post-HD weight, and nRho were calculated for each patient. Patients were divided into two groups: DW (n= 23; 248 treatments) and Non-DW (n=17; 260 treatments) who did not reach dry weight.

$RBV_{min}$ (DW: 85.3±6.6; non-DW: 85.8±5.7 %) and $RBV_{slope}$ (DW: 5.1±5.6; non-DW: 4.2±1.4 %/hour) did not differ between DW and non-DW patients. In patients who eventually reached DW, neither $RBV_{min}$ (overhydration:83.8±4.5 ; at DW: 85.3±6.6 %) nor $RBV_{slope}$ (overhydration: 3.9±1.6; at DW: 5.1±5.6 %/hour) differed between the overhydrated state and DW. A significant correlation between a) $RBV_{min}$ and UFR ($R^2$=0.58, $p<0.01$), b) $RBV_{min}$ and UFR together with Pre-HD weight (multiple $R^2$=0.60, $p<0.05$) and c) $RBV_{min}$ and UFR together with Post-HD nRho (multiple $R^2$=0.68, $p<0.05$) was observed in 50 % (a), 50 % (b), and 45 % (c) of patients, respectively. $RBV_{min}$ correlated with Post-HD nRho in only 10% of the patients significantly ($R^2$=0.66). $RBV_{slope}$ correlated with UFR in 17.5%, Pre-HD weight in 5%, Post-HD weight in 22.5% and nRho in 22.5 % of patients significantly.

Changes in RBV are associated with multiple factors such as degree of UFR, variability of hydration state and efficiency of plasma refilling. RBV is not useful for estimating hydration but can indicate appropriate UFR in individual treatments.

**F-PO1447**

**The Effects of Hemodialysis Circuit on Platelet-Derived Microparticles and Platelet Factor 4 in Hemodialysis Patients** Takanobu Imada,[1] Sanae Kikuchi,[1] Hideki Yamahara,[1] Hiroya Masaki,[2] Mitsushige Nishikawa,[1] Toshiji Iwasaka.[1] *[1]Department of Medicine II, Kansai Medical University, Osaka, Japan; [2]Department of Laboratory Medicine and Clinical Sciences, Kansai Medical University, Osaka, Japan.*

BACKGROUND: Platelet-delived microparticles (PDMP) and platelet factor 4 (PF-4) are released from activated platelet. Activated platelets are thought to play a role in the mediation of platelets-leukocyte interaction for atherosclerosis. Hemodialysis (HD) patient always receives stimulation in extracorporeal circulation. In this study, we investigate that the effect of HD on circulating levels of PDMP and PF-4 in HD patients, and we improvement of HD circuit. METHOD: Nine patients were selected from among patients admitted to our hospital for treatment of HD. The study protocol was approved by our institutional review boad and written informed consent was obtained from each patient prior to the start of the trial. Each patient was measured using four kinds of HD circuits. Blood samples from patients were collected into tubes before and after HD from HD circuit. PDMP levels were measured using an enzyme-linked immunosorbent assay (ELISA). RESULTS: Mean PDMP level was 34.9 U/ml before HD. After HD, PDMP level was 3.05±0.47 times greater than before HD (p=0.004). Mean PF-4 level was 24.6 ng/ml. After HD, PF-4 level was 2.56±1.26 times greater than before HD (p=0.0007). The changing rate of PF-4 level was able to be reduced in predominance by changing the form of air-trap chamber in dialysis circuit into the tornado from perpendicular type (1.58±0.85 in tornado type vs. 3.93±0.73 in perpendicular type, P=0.029). CONCLUSION: Our results clearly indicated that HD activated the patient's platelet. This result suggests that non-physiological HD promotes not only the blood loss by coagulation but atherosclerosis. Interestingly, reform a part of HD circuit has possibility of improvement of this problem.

**F-PO1448**

**Dialysis Dose Scaled to Body Surface Area and Patient Mortality** Sylvia Paz B. Ramirez,[1] Rajiv Saran,[2] Alissa Kapke,[1] Robert A. Wolfe,[1] Jeffrey Pearson,[1] Friedrich K. Port,[1] Richard Hirth,[2] J. M. Messana,[2] John T. Daugirdas.[3] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Kidney Epidemiology & Cost Center, University of Michigan, Ann Arbor, MI; [3]University of Illinois College of Medicine, Chicago, IL.*

Previous analyses have shown survival benefit with higher dialysis dose for women but not men. We postulated that dialysis dose normalized for body surface area (S) as opposed to total body water (V) could potentially explain this finding and also be a better predictor of mortality since the ratio V/S differs by sex. A cohort of prevalent thrice-weekly HD patients from the CMS 2008 ESRD CPM Project with at least 6 months since start of ESRD (N=7216) was analyzed. Single pool (sp) Kt/V was calculated using Daugirdas II formula, standardized (std) Kt/V was calculated per Leypoldt (2004), and surface area normalized (SAN) measure (SAN-stdKt/V) was calculated per Daugirdas (2008) by multiplying stdKt/V by Vant/S (Watson/Dubois) and dividing by mean Vant/S (20.5). Patients were grouped into quintiles and Cox regression hazard ratios for mortality during the subsequent year

were calculated censoring at transplant or 12/31/08 (referent=males in quintile 1). Similar to prior studies, the highest quintile of spKt/V appeared to benefit females but not males (stdKt/V results similar, not shown); using SAN-stdKt/V benefits of increasing dialysis dose were more consistent for the sexes. While all measures predicted mortality, the spKt/V model (likelihood ratio chi-square or LR$\chi^2$:23.1, 9df; p=.006) and stdKt/V model (LR$\chi^2$:23.8, 9df; p=.005) were both outperformed by the SAN-stdKt/V model (LR$\chi^2$:108.8, 9df; p<.0001). Scaling dialysis dose to S shows benefits of higher doses for both sexes and better association with mortality risk; hence, measures of dialysis adequacy scaled to S may be superior to those scaled to V.

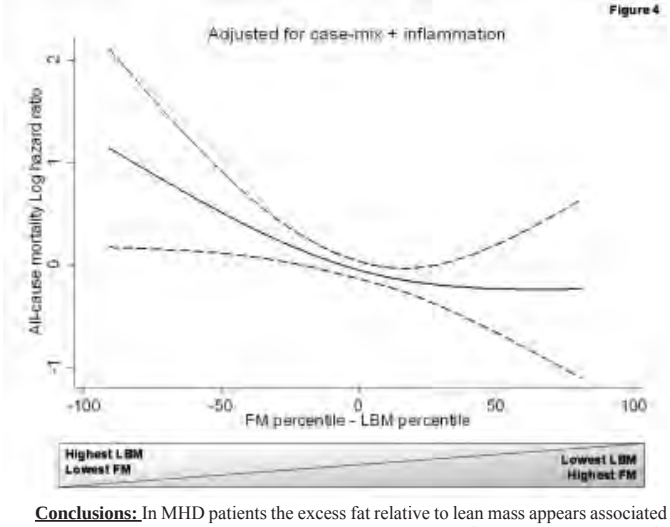
**F-PO1449**

**Survival Advantage of Excess Fat Relative to Lean Body Mass in Long-Term Hemodialysis Patients** Nazanin Noori,[1] Csaba P. Kovesdy,[2] Ramanath B. Dukkipati,[1] Uyen Duong,[1] Rachelle Bross,[1] Antigone Oreopoulos,[4] Deborah A. Benner,[3] Joel D. Kopple,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]Salem VA Medical Center, Salem, VA; [3]Davita, Lakewood, CO.*

**Background:** Several studies have suggested that maintenance hemodialysis patients (MHD) with higher body mass index (BMI) enjoy a survival advantage. It is not clear whether lean body mass (LBM) or fat mass (FM) confers this survival benefit. **Methods**: Using near infrared (NIR) technology we measured body compositions in 732 MHD patients and ranked them twice, once according to their absolute FM or then LBM (in kg) and assigned a percentile score to each patient within each gender group, i.e., a number between 0 (lowest) and 100 (highest FM or LBM). The difference between the two percentile scores (FM percentile minus LBM percentile) in each patient yielded a number between –100 (indicating a patient with lowest FM but highest LBM) and + 100 (indicating a patient with highest FM and lowest LBM). The Cox survival regression was modeled using cubic spline for the "FM minus LBM percentiles" after adjustment for case-mix and inflammatory markers. **Results:** A relatively linear and downgoing trend towards greater survival was observed with higher excess fat relative to lean mass (Figure).

Figure 4



**Conclusions:** In MHD patients the excess fat relative to lean mass appears associated with greater survival. Clinical trials to examine the outcomes of interventions that modify body composition in MHD patients are indicated.

**F-PO1450**

**Elevated Serum Ferritin Level May Determine the Seroconversion Rates to 2009 Influenza A (H1N1) Vaccination in Hemodialysis (HD) Patients** Hyeong Cheon Park,[1] Sang Hun Lee,[1] Areum Kim,[2] Sung Jin Moon,[1] Jung Eun Lee,[3] Jae Myun Lee,[2] Sung-Kyu Ha.[1] *[1]Internal Medicine, Gangnam Severance Hospital, College of Medicine, Yonsei University, Korea; [2]Microbiology and Brain Korea 21 Project for Medical Science, College of Medicine, Yonsei University, Korea; [3]Internal Medicine, Yongin Severance Hospital, Yongin, Korea.*

End stage renal disease patients on HD are at risk for higher case-fatality ratios than healthy subjects. Therefore, HD patients demand more accurate determination of seroconversion rates after vaccination. The aim of the study was to investigate the seroresponsiveness and parameters affecting antibody response after 2009 Influenza A (H1N1) vaccination in HD patients. Clinically stable HD patients (n=102, age 20-80 yrs) were enrolled. Patients received Influenza A vaccine [strain A/ California/ 7/ 2009 NYMC X-179 (H1N1), Green Cross, Seoul, Korea] by intramuscular injection and seroconversion was determined using ELISA method *(FLUAb™* kit, ATGEN, Seoul, Korea). Baseline assessment showed 17 seropositive patients. Other patients (n=85) were assessed for seroconversion rates one month after vaccination. Demographic and other biochemical parameters were also assessed. After Influenza A (H1N1) vaccination, about 1/3 of the patients (n=28) showed positive seroconversion (Group 1) whereas the other patients (n=57, Group 2) showed no significant increase in antibody titers. Both groups showed comparable demographic and biochemical parameters except that Group 1 showed significantly higher serum ferritin level compared to Group2 (257 ± 211 *vs.*183 ± 125 ng/ml, respectively, p=0.008). In binary logistic regression analysis, high serum ferritin level was independent parameter related to better seroresponse rate [Odds ratio (OR) 1.004, 95% Confidence Interval (CI) 1.001-1.008, *p*=0.026]. Patients with high ferritin levels (>400 ng/ml) was strongly related to higher seroresponse rate (OR 12.1, 95% CI, 1.6-92.1, *p*=0.016). In conclusion, our results suggest that elevated serum ferritin levels may predict stronger seroconversion rate after 2009 Influenza A (H1N1) vaccination in HD patients.

**Natriuretic Peptides (NP) and Fluid Status in Hemodialysis (HD)** Elena Mancini, Emanuele Mambelli, Antonio Bellasi, Antonio Santoro. *S.Orsola-Malpighi, Bologna, Italy.*

To assess the usefulness of NP as biomarkers of the fluid status in the HD patient, we evaluated the behaviour of adrenomedullin and atrial natriuretic peptide (ADM, ANP) in 50 randomly selected HD patients (28 conventional HD, 23 hemodiafiltration, HDF).

Due to the short half-life of the peptides, we measured their prercusors (medium region pro-ADM and pro-ANP, molecular weight 2,460 and 4,000 daltons; IF assay, Brahms Kriptor) pre- and post a mid-week HD session. Dry body weight had been clinically determined. The interdialytic body weight increase was the measure for fluid overload, the ultrafiltration (UF) volume for fluid removal. Any relationship between the peptide levels or their changes, and fluid overload/removal and blood pressure values was studied.

The basal levels (proADM 3.6±1.8 mmol/L; proANP 836.1±438 pmol/L) did not correlate either each other (R=0.06) or with pre-HD fluid overload (ADM: r=0.11 and ANP: r=0.03) or blood pressure.

Both decreased significantly during HD (proADM: from 3.6±1.8 to 1.8±1.4 mmol/L, p<0.0001; proANP: from 836.1±438 to 599.8 +456 pmol/L, p< 0.0001) but their pre-to-post HD % changes did not correlate with UF.

The % change of both the peptides was significantly lower in HD (low flux membranes) than HDF (high flux membranes) in spite of similar UF. However, the pre-dialysis levels were comparable.

Main results

| | HD | HDF | p |
|---|---|---|---|
| Pre-dialysis ADM ( mol/L) | 3.6 ± 1.5 | 3.7 ± 2.1 | NS |
| Pre-to-post dialysis ADM (%) | -37.4 ± 20.7 | -64.7 ±14.8 | <0.0001 |
| Pre-dialysis ANP (pmol/L) | 890.1 ± 495 | 770.4 ± 357 | NS |
| Pre-to-post dialysis ANP (%) | -15.8 ± 24.6 | -49.13 ± 16 | <0.0001 |
| UF (L) | 1.83 ± 0.9 | 1.9 ± 1.3 | NS |

The correlations between pre or post-HD peptide levels and pre or post-HD blood pressure were not significant.

These data do not support the hypothesis of an association between the fluid status *per se* and NP levels. Moreover, in spite of a greater reduction ratio of the NP levels with the convective-diffusive techniques, pre-dialysis values in HDF patients are not lower than in HD, suggesting a multiple control of their concentration. The use of the NP precursors in the day-by-day clinical setting still needs further studies.

**Modulation of Von Willebrand Factor, Von Willebrand Factor Propeptide, and ADAMTS-13 in End-Stage Renal Disease** Vinod K. Bansal,[1] Rachael Davis,[2] Evangelos Litinas,[2] Debra Hoppensteadt,[2] Jawed Fareed.[2] *[1]Department of Nephrology, Loyola University Medical Center, Maywood, IL; [2]Department of Pathology, Loyola University Medical Center, Maywood, IL.*

End-Stage Renal Disease (ESRD) is a complex syndrome in which systemic vascular pathophysiologic changes contribute to adverse cardiovascular and cerebrovascular manifestations due to thrombotic activation. Von Willebrand Factor (vWF) plays a well known role in platelet aggregation and has been shown to be upregulated in many

thromboembolic conditions. However in many conditions, the role of von Willebrand Factor Propeptide (vWFpp), a peptide cleaved prior to assembly of active vWF multimers, and ADAMTS-13, the enzyme responsible for disassembly and deactivation of vWF multimers, have not been examined. The purpose of this study is to better characterize the relationship among vWF, vWFpp, and ADAMTS-13 as it relates to ESRD. Plasma samples from 51 patients with ESRD were collected prior to maintenance hemodialysis. A group of 50 normal individuals, both male and female, was included as control. Concentrations of vWF and vWFpp were quantified using the GTI® vWF & Propeptide Assay. A separate assay was used to measure ADAMTS-13 in these samples (GTI®). This data as well as the ratio of vWF:vWFpp were analyzed using the Mann-Whitney U test. Compared to the controls, there was an upregulation of all three analytes in patients with ESRD. Levels of vWF were increased 1.3 fold, (mean 128 ± 69 U/dL, range 9.2 to 308) compared to control (mean 101 ± 60, range 22 to 332). Similarly, there was a 1.6 fold increase in both vWFpp (mean 148 ± 92, range 8.0 to 361) compared to (mean 92 ± 23, range 60 to 163) and ADAMTS-13 (mean 131 ± 27, range 67 to 150) compared to (mean 84 ± 22, range 36 to 128). However, the ratio of vWFpp:vWF (mean 1.2 ± 0.6, range 0.4 to 3.3) was unchanged compared to control (mean 1.2 ± 0.7, range 0.4 to 3.6). This study shows an increase in vWFpp and further validates the upregulation of vWF in ESRD. The normal vWFpp:vWF ratio implies an increased production in vWF in response to endothelial damage without any apparent alteration in vWF degradation or clearance.

### Calf Bioimpedance Ratio Improves Dry Weight Assessment and Blood Pressure Control in Hemodialysis Patients

Yi-Lun Zhou, Jing Liu, Fang Sun, Li-Jie Ma, Bin Han, Yang Shen, T. G. Cui. *Department of Nephrology, Chao-Yang Hospital, Capital Medical University, Beijing, China.*

**Backgroud** Chronic fluid overload due to over-estimation of dry weight (DW) is the major factor in the development of hypertension in hemodialysis (HD) patients. Under physiological conditions, the ratio of extracellular volume to total body water remains tightly regulated, and the ratio of impedance at high frequency to impedance at low frequency is positively related to the ratio of extracellular volume to total body water. The present study was undertaken to investigate whether bioimpedance ratio in the calf (Calf-BR = impedance at 200 kHz / impedance at 5 kHz, as measured by bioimpedance spectroscopy) could be a useful hydration marker for estimation of DW and facilitate better control of blood pressure in HD patients.

**Methods** A multifrequency bioimpedance spectrum analyzer device (BodyStat, UK) was used to measure impedance in right calf . Target range of Calf-BR was derived from 157 healthy Chinese subjects. Post-dialysis Calf-BR was measured in 117 stable, non-edematous HD patients. Those with Calf-BR (s) above target range, had their DW gradually reduced under the guidance of Calf-BR. Home blood pressure was recorded in the mean time.

**Results** The Calf-BR was normally distributed and increased with age, but was independent of BMI and gender in both healthy subjects and dialysis patients. HD patients with Calf-BR above age-stratified target range had significantly higher home blood pressure, in spite of more antihypertensive treatments ($P$=0.058). The patients who reached the target range of Calf-BR by decreasing DW, had their home systolic and diastolic blood pressure significantly decreased ($P$<0.001, and $P$=0.001, respectively), along with reduction in antihypertensive medications ($P$=0.012).

**Conclusions** Modification of bioimpedance technique by the measurement of impedance ratio in the calf (Calf-BR) was a simple and practical method in assessing body fluid status. Recognition and correction of chronic fluid overload based on age-stratified Calf-BR is helpful in hypertension control in Chinese HD patients.

### Smoking and End Stage Kidney Disease: A Systematic Review of Mortality, Cardiovascular Morbidity, and Arteriovenous Access Patency

Scott E. Liebman, Steven P. Lamontagne. *Medicine, University of Rochester Medical Center, Rochester, NY.*

**Background and objectives:** Dialysis patients have a large burden of vascular morbidity and mortality due to both traditional and non-traditional risk factors. Despite its detrimental effects in the general population, smoking has not been well studied in dialysis patients. We systematically reviewed smoking and adverse vascular and arteriovenous (AV) access outcomes in dialysis patients to summarize the current state of knowledge.

**Design, setting, participants, & measurements**: The MEDLINE database was searched for prospective articles examining smoking and vascular disease or AV access in dialysis patients. Of 1397 articles retrieved, 25 were appropriate for inclusion in this review. Three studies specifically examined the association between smoking and adverse vascular outcomes, and one examined smoking and AV fistula failure. In the remainder, smoking was analyzed as a covariate.

**Results:** The three studies examining mortality and vascular outcomes encompassed over 5,000 patients. They all demonstrated a higher all cause mortality in current smokers compared with lifetime non smokers (RR= 1.22-1.37). The risk of former smokers compared with current smokers was less clear. Smoking was also found to increase the risk of new onset heart failure and peripheral vascular disease, but not cerebrovascular or ischemic heart disease. The fourth study, a small, single center report, demonstrated higher rates of fistula failure in smokers.

**Conclusions**- The available data, although scant, support an association between smoking and adverse outcomes in dialysis patients. Dialysis patients should be counseled on smoking cessation. It is not clear how the relative risk of smoking compares with other factors known to impact morbidity and mortality in dialysis patients.

### Risk Factors for Sudden Cardiac Death Using a Competing Risk Approach

Shani Shastri, Navdeep Tangri, Hocine Tighiouart, Alfred K. Cheung, Gerald J. Beck, Gary Eknoyan, Mark J. Sarnak. *Tufts Medical Center.*

**Introduction:** Sudden cardiac death (SCD) accounts for ~60% of cardiac deaths in hemodialysis (HD) patients. There are few data on risk factors for, or prediction equations, to estimate SCD in HD patients.

**Methods:** The Hemodialysis (HEMO) Study was a randomized trial involving 1,846 HD patients testing the effect of dialysis dose and membrane flux on all-cause mortality. For this analysis, deaths were classified into SCD (adjudicated as a secondary outcome), non-sudden cardiac and non-cardiac death. Risk factors were evaluated using cause-specific Cox proportional hazard models and model performance was assessed using Cox models that allowed adjustment for competing risks of death.

**Results:** During a median follow-up of 2.5 years, there were 808 deaths (46.3%). 23%, 61%, and 17% were due to SCD, non-sudden cardiac, and non-cardiac deaths, respectively. Adjusted cause-specific hazard ratios are shown in the Table. The naïve Cox model overestimated the risk of SCD compared to the competing risk model by 10%. The 3-year C-statistic was 0.75 and calibration was adequate ($\chi^2$ 15.02, p 0.09).

**Conclusion:** Risk factors for various causes of mortality differ in HD patients. We present a predictive model for SCD that incorporates easily collected variables with good discrimination and calibration. The model takes into account competing causes of death thus estimating the true risk of SCD. External validation of the model is required.

### Different Cardiac Systolic and Diastolic Functions among Patients Undergoing Maintenance Hemodialysis and Peritoneal Dialysis

Chi-Ting Su,[1,2] Kuan-Yu Hung,[1] Kwan-Dun Wu.[1] *[1]Renal Division, Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; [2]Renal Division, Internal Medicine, National Taiwan University Hospital, YunLin Branch, DouLiou, Taiwan.*

**Purpose**-Evaluate systolic and diastolic function in patients undergoing hemodialysis (HD) and peritoneal dialysis (PD) by two-dimensional (2D) speckle tracking echocardiography (STE).

**Methods**- We conducted a prospective study in adult patients (mean age: 62 years) who were receiving long-term dialysis for end-stage renal disease (ESRD). Of these patients, HD patients underwent a thrice weekly maintenance scheme, and PD patients had kept on a regular program. Each subject received conventional echocardiography, TDI, and STE to evaluate cardiac functions. We checked the levels of cardiac troponin T (cTnT), high sensitivity C-reactive protein (hs-CRP), interleukin-6 (IL-6), resistin, Cystatin-C, and plasminogen activator inhibitor-1 (PAI-1).

**Results**- Eighty-two patients were enrolled,60 on HD and the remaining undergoing PD. There were no differences in serum levels of cTnT, hs-CRP, IL-6, resistin, cyctatin-C, and left ventricular (LV) systolic functions by conventional echocardiographic and TDI parameters among two groups. With adjustment for age, sex, and co-morbidities by multivariate analysis, HD patients had higher mitral annular E/e' ratio, presenting poor diastolic functions ($p$<0.001). By STE, circumferential strain rate was less negative in PD patients, indicating worse systolic functions ($p$<0.001) despite no detectable difference in LV ejection fraction ($p$=0.993) between groups. Interestingly, patients on PD presented with lower PAI-1($p$=0.001),indicating less severity of cardiac fibrosis. PD patients had higher serum cholesterol and albumin ($p$<0.001).

**Conclusions**-Among ESRD patients, cardiac diastolic functions were better among those undergoing PD with less severity of cardiac fibrosis and lower serum PAI-1 levels. However, HD patients presented with better systolic cardiac contractility by speckle tracking echocardiography. Taken together, no promising dialysis modality would warrant better cardiac functions in patients undergoing renal replacement therapy.

**F-PO1457**

**Predictors and Mortality of Incident Atrial Fibrillation in Hemodialysis Patients** Keiko Nishi, Shouichi Fujimoto, Kazuo Kitamura. *Dialysis Division, University of Miyazaki Hospital, Miyazaki, Japan.*

**Background:** The prevalence and incidence of atrial fibrillation (AF) in hemodialysis (HD) patients are increased. The purpose of this study is to indentify the risk factors including predictive value of electrocardiographic assessment associated with incident AF and to establish the influence of AF on mortality in patients with maintenance HD.

**Method:** A cohort of 299 patients (age, 63.1 ± 14.0 years; men, 59.2%; duration of HD, 80.3 ± 77.7 months) on HD therapy in two centers was retrospectively analyzed between December 2004 and December 2009. An electrocardiogram was scheduled to be carried out on at least a quarterly basis and also at any time that the patient had any cardiac symptoms. Cox proportional hazard analysis was used to determine independent predictors of incident AF after identifying associated variables including clinical, laboratory and electrocardiographic parameters by stepwise procedures. The Kaplan-Meier test was used for analysis of survival.

**Results:** Thirty-seven patients had AF at enrollement. Of the 262 patients who were in sinus rhythm (SR) at enrollement, 45 patients newly developed AF during a follow-up time of five years. In multivaliate analysis, lower hemoglobin level (hazard ratio [HR], 0.72; 95% confidence interval [CI], 0.52 to 0.99) and the presence of P-terminal force > 0.04 mm⁄sec suggesting left atrial enlargement (HR, 2.94; 95% CI, 1.51 to 6.02), premature atrial contractions (HR,7.51; 95 % CI, 3.40 to18.50) and strain pattern (HR, 2.46; 95% CI, 1.19 to 4.84) as electrocardiographic findings were independently associated with new-onset AF in HD patients. The survival curves show a significant difference between the patients with presence or incidence of AF and those who maintained SR. Three year survival rate of patients with incident AF and those maintained SR was 71.4% and 85.6%, respectively.

**Conclusion:** AF is frequent in HD patients and they have poor prognosis compared with those without. Left atrial enlargement, premature atrial contractions and strain pattern as electrocardiographic findings, in addition to lower hemoglobin level, may predict new-onset AF in HD patients.

**F-PO1458**

**Increased Plasma S100A12 Level Is Associated with Cardiovascular Diseases in Non-Diabetic Hemodialysis Patients** Yasukiyo Mori,[1] Yayoi Shiotsu,[1] Atsushi Kosaki.[2] *[1]Department of Cardiology and Nephrology, Kyoto Prefectural University of Medicine, Kyoto, Japan; [2]Department of Medicine II, Kansai Medical University, Hirakata, Japan.*

S100A12, also called EN-RAGE, is an endogenous ligand for the receptor for advanced glycation end products (RAGE). Our working hypothesis is that S100A12 protein might contribute to the development of atherosclerosis. Cardiovascular disease (CVD) due to atherosclerosis remains the major cause of morbidity and mortality in the patient with chronic kidney disease (CKD), particularly in the hemodialysis (HD) patients. We have already showed that plasma S100A12 level was more than twice as high in HD patients and the intima-media thickness (IMT) of carotid artery correlated with the plasma S100A12 level, suggesting that plasma S100A12 level is associated with atherosclerosis as a complication of CKD (Mori Y and Kosaki A et al. Am J Nephrol 2009;29:18-24). Moreover, we confirmed the higher level of plasma S100A12 in our larger cross-sectional study to assess the association between plasma S100A12 levels and CVD on 550 hemodialysis (HD) patients including diabetic nephropathy. However, it is well established that the prevalence of CVD in diabetic HD patients remains the highest among all primary diagnoses. In the present study, we focused on the association of plasma S100A12 level with the prevalence of CVD in non-diabetic hemodialysis patients(n=348). The analysis resulted in 1) plasma S100A12 level in non-diabetic hemodialysis patients with CVD (n=97, 32.1±2.96 ng/ml) was significantly higher than those without CVD (n=251, 17.8±0.80 ng/ml) ($p<0.001$), and 2) 10ng/ml increase in plasma S100A12 level (OR, 1.597; 95% CI, 1.343 to 1.898, $p<0.001$) as well as the history of smoking (OR, 2.115; 95% CI, 1.017 to 4.398, $p=0.045$) and age (OR, 1.028; 95% CI, 1.006-1.051, $p=0.011$) were identified as the independent factors associated with the prevalence of CVD in stepwise regression analysis. These results suggest that plasma S100A12 protein may be a novel predictor for CVD events in non-diabetic HD patients.

**F-PO1459**

**Serum β2-Microglobulin Levels Predict Cardiovascular and All-Cause Mortality in End-Stage Renal Disease Patients on Chronic Hemodialysis** Hirotake Kasuga,[1] Tetsuya Yamada,[2] Nobumasa Nakamura,[1] Ryo Takahashi,[1] Keiko Kimura,[1] Takanobu Toriyama,[1] Seiichi Matsuo,[3] Hirohisa Kawahara.[1] *[1]Internal Medicine, Division of Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; [2]Seto Kyoritsu Clinic, Seto, Japan; [3]Nagoya University Hospital, Nagoya, Japan.*

**Background:** β2-microglobulin (β2-MG) is a middle-molecule uremic toxin, and the serum levels elevate according with progression of renal insufficiency. In ESRD patients on chronic HD, serum β2-MG concentration is thought to be a surrogate marker which reflects both residual renal function and adequate HD therapy. However, the association of β2-MG levels with clinical outcome has not been fully evaluated in this population. We investigated whether serum β2-MG levels could predict cardiovascular (CV) and all-cause mortality in HD patients.

**Methods:** A total of 363 stable HD patients (male 61%, age 59±12 years, diabetes 25.7%, duration of HD 7.3±6.2 years) were enrolled. All patients were undergoing maintain HD therapy using high-flux membrane dialyzer. Serum β2-MG levels were measured in blood samples before and after HD session. The patients were divided into tertiles according to serum β2-MG levels before HD session; tertile 1 (T1): <31.6mg/L (n=121), T2: 31.6-37.3mg/L (n=121) and T3: >37.3mg/L (n=121), and were followed for 6 years.

**Results:** Baseline variables were comparable among tertiles. Reduction rate of β2-MG during HD session was 28.6%, 19.3% and 17.4% in T1, T2 and T3 groups, respectively ($p<0.0001$). During follow-up period (55±24months), 102 patients (28.1%) died including CV death (12.7%). Six-year event-free survival rates were 93.7%, 87.8% and 80.5% for CV mortality ($p=0.0019$) and 79.7%, 77.3% and 65.7% for all-cause death ($p=0.0019$) in T1, T2 and T3, respectively. After adjustment for gender, age, traditional risk factors, history of CV disease, hemoglobin, albumin and C-reactive protein, elevated serum β2-MG levels were independent predictors for CV mortality [HR 4.96, $p=0.0021$ for T3 vs. T1] and for all-cause death (HR 2.35, $p=0.0040$ for T3 vs. T1), respectively.

**Conclusion:** Elevated serum β2-MG levels could strongly predict both CV and all-cause mortality in ESRD patients on HD.

Disclosure of Financial Relationships: nothing to disclose

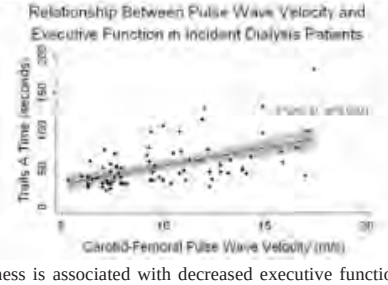
**F-PO1460**

**Arterial Stiffness Is Associated with Impairments in Executive Function in Incident Hemodialysis Patients: The Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) Study** Stephen M. Sozio,[1] Bernard G. Jaar,[1] Tariq Shafi,[1] Lucy A. Meoni,[1] Julia J. Scialla,[1] Wen Hong Linda Kao,[1] Rulan S. Parekh.[2] *[1]Johns Hopkins University; [2]University of Toronto.*

Accelerated arterial calcification and subsequent vascular stiffness is common in patients with ESRD, and likely contributes to clinical cardiovascular events. We hypothesize that vascular stiffness leads to disease in the cerebral vasculature and could manifest subclinically as cognitive impairment. We investigated the cross-sectional association of carotid-femoral pulse wave velocity (PWV), a non-invasive measure of arterial stiffness, with both global cognitive function (Modified Mini-Mental Status Exam [3MSE]) and executive function (Trails A and Trails B) in an incident hemodialysis cohort of the first 176 PACE participants. PWV was measured using the Sphygmocor PVx System; all clinical and cognitive tests were performed in a quiet room on an interdialytic day. Linear and logistic regressions were used to assess the independent associations of PWV with global cognitive function and executive function. Mean age was 55 years with 54% male, 65% African-American, 48% with diabetes, 46% with prior atherosclerotic cardiovascular disease (ASCVD), and mean PWV 10.2 m/s (range 5.2-17.8). A total of 12% of participants had global cognitive impairment by 3MSE. Higher PWV was not associated with global cognitive function but was significantly associated with longer times for executive function in both Trails A and Trails B in unadjusted analyses. After adjusting for CVD risk factors, PWV remained significantly associated with longer Trails A time.

| Executive Function Test | Beta Coefficient (95% CI) for Cognitive Score versus PWV in Incident Dialysis Patients§ | | |
|---|---|---|---|
| | Unadjusted | Model 1* | Model 2** |
| Trails A Time (range 21-181 sec) | **4.80 (2.96, 6.63)‡** | **2.99 (0.92, 5.07)‡** | **2.84 (0.27, 5.42)†** |
| Trails B Time (range 45-300 sec) | **8.68 (2.99, 14.37)‡** | 2.08 (-3.72, 7.88) | 1.63 (-5.72, 8.98) |

§Difference in cognitive score (seconds) per each m/s difference in PWV
*Model 1: Adjusted for age, sex, race
**Model 2: Model 1 plus diabetes mellitus, prior ASCVD, SBP, DBP
†p<0.05
‡p<0.01



Arterial stiffness is associated with decreased executive function among incident dialysis patients, independent of other CVD risk factors including blood pressure. Further studies are warranted to assess interventions to target vascular stiffness.

**Myeloid-Related Protein 8/14 Predicts All-Cause Mortality in Peritoneal Dialysis Patients** Bonnie Kwan, Peter Yam-Kau Poon, Kai Ming Chow, Philip K. T. Li, Cheuk-Chun Szeto. *Dept of Medicine, Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong.*

Background & Aim: Myeloid-related protein (MRP) 8/14 complex, also termed calprotectin, is a marker of phagocyte activation. Studies have found that MRP 8/14 complex is increased systemically and is a potential biomarker for acute coronary syndrome in the general population.

We aim to examine the use of MRP 8/14 complex in the prediction of future cardiovascular events and all-cause mortality among patients on peritoneal dialysis. We aim to study the significance of MRP 8 and MRP 14 on the outcome of patients on peritoneal dialysis (PD).

Method: We retrospectively studied patients commenced on PD from January 2007 – December 2008. Dialysis records, demographic data and past medical history were obtained from medical records, while stored serum were analysed for MRP 8/14 complex levels.

Results: A total of 104 patients were recruited into the study. Fifty-nine were male. Mean age 57.4±11.9 years old. Mean duration of dialysis 7.8±31.0 months. MRP 8/14 level was 4.47±5.77 µg/ml. MRP 8/14 did not differ significantly between males/females, diabetics/non-diabetics, with/without past history of coronary artery disease, cerebrovascular disease or peripheral vascular disease. The subjects were divided into 4 quartiles according to MRP level. Actuarial survival was significantly different among the MRP 8/14 quartiles (p=0.003), while there was no significant difference among the quartiles for technique survival (p=0.255) or cardiovascular survival (p=0.136). MRP 8/14 quartiles was found to be a significant factor in multivariate analysis of actuarial survival (adjusted hazard ratio 3.52, 95% CI 1.203-10.294) after adjusting for residual renal function, KT/V, albumin, subjective global assessment, Charlson's score, age, duration of dialysis and diabetes.

Conclusion: MRP levels were found to be predictive of all-cause mortality in PD patients. In our current study MRP levels were not found to be predictive of cardiovascular mortality. This could be related to confounding effects from the many cardiovascular risk factors in PD patients. Further studies with more subjects are needed.

Disclosure of Financial Relationships: nothing to disclose

**Survival of US Dialysis Patients Receiving Cardiac Valvular Replacement for Bacterial Endocarditis** Charles A. Herzog, David T. Gilbertson. *CVSSC, USRDS, Minneapolis, MN.*

**Background:** Dialysis pts with bacterial endocarditis (BE) have poor long-term survival, with a previously reported one year mortality of 62%. Although cardiac valvular surgery is a key aspect of therapy of left-sided endocarditis, there are no published data on the long-term survival of dialysis pts with BE undergoing heart valve replacement surgery.

We searched the records of the United States Renal Data System database to identify 11,125 dialysis pts hospitalized for BE in 2004-2007, and the subset of 1267 pts receiving cardiac valvular replacement surgery. Long-term survival was estimated by Kaplan-Meier method and independent predictors of death were examined in a Cox model.

**Results:** Valve surgery cohort characteristics: 24% <45yrs, 54% 45-64yrs, 16% 65-74 yrs, 6% 75+ yrs, 50% white, 47% black, 60% male, 36% Diabetic ESRD, 98% hemodialysis, 46% aortic(AVR), 45% mitral (MVR), 9% both (AVR+MVR), 44% tissue valves. In-hospital mortality was 13.7 %. The tables show estimated survival and predictors of death in pts undergoing surgery (age 45-64, male, white, hemodialysis, non-diabetic ESRD, tissue valve, MVR is reference) with hazard ratio (HR).

**Conclusion:** Dialysis patients undergoing left-sided cardiac valvular replacement for bacterial endocarditis have high long term mortality. Selected dialysis pts with BE may potentially benefit from surgery. Survival is not related to valve selection (tissue vs non-tissue).

| | Survival (%) | | |
|---|---|---|---|
| Yrs | Tissue | Non-Tissue | No valve surgery |
| 0.5 | 59.4 | 59.6 | 48.5 |
| 1 | 48.0 | 49.6 | 39.0 |

**Cinacalcet Can Reduce a Drop in Intradialytic Blood Pressure (BP) in Hemodialysis (HD) Patients** Terumi Morita,[1] Akira Furusu,[2] Kinichi Izumikawa,[3] Shigeru Kohno.[4] *[1]Nephrology, Izumikawa Hospital, Minamishimabara, Japan; [2]Nagasaki University, Nagasaki, Japan; [3]Izumikawa Hospital, Minamishimabarashi, Japan; [4]Nagasaki University, Nagasaki, Japan.*

Background; A drop in BP during HD session is reported to be a major risk factor for cardiac death in HD patients. Recent experimental studies have shown the expression of calcium-sensing receptor on heart muscle and vascular cells, and suggest that cinacalcet has cardioprotective effects and stabilizes BP. Purpose; To evaluate the effects of cinacalcet on improving intradialytic BP drop in HD patients. Subjects and Methods; From February 2008 to May 2010, 22 outpatients on maintenance HD who had average intradialytic BP drop > 20% were enrolled in this study after appropriate IC. One year after the start of cinacalcet treatment at dose of 25-75 mg, intradialytic BP profile, parameters for ultrasound cardiographiy, serum PTH and heart rate variability (HRV), a measure of the autonomic nervous system function, were compared. Results; As shown in [Table], the average intradialytic BP drop was drastically improved, whereas and HRV stayed the same, indicating the autonomic nervous system function was not contributing factor. Parameters for cardiac function tended to improve, but not significant. Conclusions; Our data showed that cinacalcet can stabilize intradialytic BP, suggesting it may potentially have cardioprotective effects in HD patients.

Change of intradialytic BP profiles after cinacalcet treatment

| | Before | After | p-value |
|---|---|---|---|
| average BP drop | 28.6±14.7 | 16.8±12.8 | 0.0017 |
| EF | **** | **** | 0.12 |
| LVDd | **** | **** | 0.09 |

**Geographic Variation in Cardioprotective Antihypertensive Medication Usage in Dialysis Patients** James B. Wetmore,[1] Jonathan D. Mahnken,[2] Qingjiang Hou,[2] Edward F. Ellerbeck,[3] Sally K. Rigler,[3] John Spertus,[4] Theresa I. Shireman.[3] *[1]Medicine, Division of Nephrology and Hypertension, University of Kansas Medical Center, Kansas City, KS; [2]Biostatistics, University of Kansas Medical Center, Kansas City, KS; [3]Preventive Medicine and Public Health, University of Kansas Medical Center, Kansas City, KS; [4]St Luke's Mid America Heart Institute, University of Missouri - Kansas City, Kansas City, MO.*

**Introduction:** Antihypertensive agents with cardioprotective properties are commonly prescribed in dialysis patients. However, little is known about clinical and geographic factors associated with their use.

**Methods:** We conducted a national, cross-sectional retrospective analysis of prescription drug claims for dually-eligible (Medicare-Medicaid) chronic dialysis patients diagnosed with hypertension to assess the prevalence of cardioprotective antihypertensive medication use, to examine how the use of these agents was associated with various demographic and clinical factors, and to determine how use varied by state across the US.

**Results:** Of 41,656 dialysis patients with hypertension, 77.7% received at least one angiotensin covenverting enzyme inhibitor / angiotensin receptor blocker (ACEI/ARB), beta-blocker, or calcium channel blocker (CCB) during the period studied. CCBs were the most commonly-used agent (48.9%), followed by ACEI/ARBs (44.8%) and beta-blockers (44.0%). In multivariate analyses, older age, male sex, Caucasian race, high body mass index, and poor functional status were associated with less use of each of the classes of agent studied, as was self-care dialysis. There was substantial state-by-state variation in use of all classes of agents, with roughly 2.5-fold differences in adjusted rate ratios between the highest- and lowest-prescribing states.

**Conclusions:** Relatively modest numbers of hypertensive dialysis patients are treated with antihypertensive drugs having cardioprotective properties. Moreover, substantial variability across states was observed. There appears to be an opportunity to improve the use of cardioprotective anti-hypertensive medications and to support more standardized practice patterns.

**Novel Insights into Calciphylaxis: The International Calcific Uremic Arteriolopathy (CUA) Registry** Vincent Brandenburg,[1] Jurgen Floege,[2] Markus Ketteler.[3] *[1]Cardiology, RWTH University Hospital Aachen, Aachen, Germany; [2]Nephrology, RWTH University Hospital Aachen, Aachen, Germany; [3]Nephrology, Klinikum Coburg, Coburg, Germany.*

**INTRODUCTION AND AIMS:** Calcific uremic arteriolopathy (CUA, calciphylaxis) is a rare disease associated with high morbidity and mortality. The aim of the International Collaborative Calciphylaxis network (ICCN) was to establish an online registry to collect data about incidence and risk factors for CUA. Thereafter, we tried to gain overview about current treatment strategies. This data collection is intended to be the basis for future prospective treatment trials.

**METHODS:** The internet-based registry allows online notification of all cases of established or suspected CUA (www.calciphylaxie.de). A comprehensive data base including various parameters was established (patient characteristics, laboratory data,

clinical background and presentation as well as therapeutic strategies). Follow-up of the patients is planned by regular queries of long-term outcome.

**RESULTS:** Altogether 110 patients with CUA have been documented until 06/2010: 65 female (59%); 48 diabetics (43%); mean age was 66 +/-14 (20-89) years. N= 52 (57%) were treated with coumadins. Focussing on dialysis pts (n=84, 76%) mean serum total calcium was 2.3+/-0.4 mmol/L, mean serum phosphorus: 2.0+/-0.9 mmol/L. PTH levels varied broadly between undetectably low and > 1200 pg/ml, mean 260 +/- 270 pg/mL. According to KDOQI PTH target levels (150 to 300 pg/mL) 32% were below, 22% within and 46% above target range. Among the most frequently recorded therapeutic procedures were: intensifying dialysis modality, hyperparathyroidism control, i.v. sodium-thiosulfate application, lowering calcium burden by reducing dialysate calcium and / or reducing oral calcium-containing phosphate-binders, systemic antibiotics, and stopping oral anticoagulation.

**CONCLUSIONS:** CUA is a rare complication predominantly occurring in dialysis pts. PTH levels vary substantially and are below 300 pg/ml in 2/3 of cases. The present internet based ICCN registry is a valuable tool to collect data upon CUA cases and may become a basis for prospective systematic evaluations of treatment modalities in the near future.

**Cardiovascular Disease and Cognition in Hemodialysis** Daniel E. Weiner, Lena M. Giang, Brian T. Agganis, Tammy Scott, Hocine Tighiouart, Mark J. Sarnak. *Tufts Medical Center, Boston, MA.*

Cardiovascular disease (CVD) and cognitive impairment are both common in patients with kidney failure. Given the high prevalence of vascular disease in hemodialysis patients and the proposed role of microvascular disease on cognitive function, particularly cognitive domains that incorporate attention, processing and executive functions, we hypothesized that prevalent systemic cardiovascular disease would be associated with worse cognitive performance in hemodialysis patients and identify individuals with a high burden of cognitive impairment.

The Cognition and Dialysis Study is an ongoing investigation of cognitive impairment and its risk factors in 5 Boston area DCI hemodialysis units. After excluding 48 individuals with history of clinical stroke, we evaluated the cross-sectional association between CVD and cognitive functioning. Principle components analysis reduced tests to either processing speed/executive function or memory domains. Multivariable models adjust for age, sex, education, and race as well as any variables with p<0.2 after these adjustments.

Among 200 participants, mean (SD) age was 62 (18) years and 75 (38%) had CVD; of these 13 had peripheral vascular disease only, 34 had coronary disease only and 28 had both. Individuals with CVD were older, more likely to be men, diabetic, and current or former smokers. In adjusted models, individuals with CVD performed 0.46 standard deviations worse (p=0.0003) on tests assessing executive function and processing speed, while there was no difference in performance on tests of memory (Table).

In conclusion, performance on tests of executive function and processing speed is worse in hemodialysis patients with CVD.

Table. Association between CVD and cognitive function

| Cognitive Test/Component | Function Tested | Test Scores | | Multivariable | |
|---|---|---|---|---|---|
| | | No CVD | CVD | Beta | p-value |
| Executive Factor | *Composite of 'executive' tests* | 0.37 ± 0.92 | -0.42 ± 0.85 | -0.46 | 0.0003 |
| Memory Factor | *Composite of memory tests* | 0.15 ± 1.00 | -0.09 ± 1.08 | 0.15 | 0.32 |
| Mini-Mental State Exam | *Screen* | 26.9 ± 2.7 | 26.5 ± 3.0 | 0.3 | 0.46 |
| Short Delayed Recall | *Working memory, recognition, and memory* | 5.4 ± 2.9 | 4.3 ± 3.2 | 0.2 | 0.63 |
| Delayed Recall | | 5.0 ± 2.8 | 4.1 ± 2.9 | 0.3 | 0.54 |
| Recognition | | 21.6 ± 2.6 | 20.3 ± 3.3 | -0.3 | 0.53 |
| Block Design | *Executive function, processing speed and attention* | 30.1 ± 11.2 | 22.1 ± 9.1 | -4.7 | 0.001 |
| Digit Symbol Coding | | 47.0 ± 18.5 | 32.9 ± 12.2 | -4.1 | 0.07 |
| Trails A | | 49.5 ± 26.6 | 70.2 ± 40.1 | 8.4 | 0.08 |
| Trails B (Completers) | | 122.5 ± 62.7 | 164.0 ± 61.9 | 23.5 | 0.10 |
| Trails B (Non-Completion) | | 15.2% | 30.7% | | |

Results are mean ± standard deviation. Individual test results represent number or percent correct except Trails A and B which are reported in seconds required to complete the task. Factor scores by definition have mean of 0 ± 1 for the population, with positive numbers consistent with better performance. Positive beta-coefficients are consistent with worse performance on Trails A and Trails B, while negative beta-coefficients are consistent with worse performance on all other tests, including the factors

**High Plasma Levels of Fibroblast Growth Factor-23 Are Associated with Left Ventricular Dysfunction in Dialysis Patients** Jessica B. Kendrick,[1] Jacob Joseph,[2] James S. Kaufman,[2] Alfred K. Cheung,[3,4] Tom H. Greene,[4] William L. Roberts,[4] Zahi Rafeq,[2] Gerard John Smits,[1] Michel B. Chonchol.[1] *[1]University of Colorado Denver Health Sciences Center, Denver, CO; [2]VA Boston Healthcare System, Boston, MA; [3]VASLCHCS, Salt Lake City, UT; [4]University of Utah, Salt Lake City, UT.*

Purpose: Fibroblast growth factor-23 (FGF-23) levels are elevated in dialysis patients. FGFs receptors have been implicated in the pathogenesis of atherosclerosis. We tested the hypothesis that high FGF-23 levels are associated with left ventricular dysfunction in dialysis patients.

Methods: The Homocysteine Study was a randomized trial, which evaluated the effects of folic acid and B vitamins on all-cause mortality in dialysis patients with elevated homocysteine levels. We identified 110 dialysis participants in this study who had echocardiograms performed for clinical indications during the study follow-up. FGF-23 levels were measured in stored baseline plasma samples. Multivariate regression analyses were performed to evaluate whether FGF-23 levels were associated with a lower ejection fraction (EF) independently of other covariates that might influence systolic function.

Results: Participants had a mean age of 60±11 years. The median (IQR) FGF-23 level and mean EF at baseline were 4632 [1384-14997] RU/mL and 50±13 %, respectively. Median follow-up time was 1.9 years. Higher FGF-23 levels were associated with lower EF. After adjustment for baseline EF, age, race, sex, hypertension, diabetes, history of cardiovascular disease, body mass index, calcium, phosphorus, 25-hydroxyvitamin D, calcitriol and intact PTH levels, for every log10 increase in FGF-23, EF decreased by 8% (p=0.004). Higher FGF-23 levels were also independently associated with an EF < 40% in multivariate analysis. For every log10 increase in FGF-23, there was a 6-fold increased risk of an EF <40% (odds ratio 6.3, 95% CI 1.04 to 40.1; p=0.04).

Conclusion: Higher plasma FGF-23 level is independently associated with systolic dysfunction in dialysis patients. Findings should be confirmed in studies where echocardiograms are protocol-based rather than selected by clinical indication.

## F-PO1468

**Brain Natriuretic Peptide and Echocardiographic Evaluation on Patients with End Stage Renal Disease on Hemodialysis: 4-Year's Clinical Follow-Up** Jinil Yoo, Lin N. Lwin, Hugo J. Villanueva, Donjeta Sulaj, Khashayar Sehhat. *Neprology, Montefiore Medical Center, North Division, New York Medical College, Bronx, NY.*

Brain natriuretic peptide (BNP) is considered to be a marker of cardiac dysfunction and its level has shown a predictive value on congestive heart failure (CHF) and cardiac events. The presence of left ventricular hypertrophy (LVH) and LV dysfunction on echocardiogram (ECHO) is also known to be associated with a high cardiac morbidity and mortality.

We obtained pre dialysis plasma BNP levels and post dialysis ECHO at their prescribed dry weight on 45 of 54 patients (pts) in a hospital-based dialysis unit. There were 15 African Americans(33%), 11 Hispanics(24%), 12 non-Hispanic Caribbeans(27%), 4 Caucasians(9%), 3 Asians(7%); avarage age of 63 years, 24 diabetics(53%), 42 hypertensives(93%), 18(40%) with history of coronary artery disease, and avarage on HD of 3.6 years. The following diagram is the summary of our pts mortality rate (MR) based on ejection fraction (EF : %) calculated from ECHO and plasma BNP level, during 4-year's clinical follow up after the BNP and ECHO.

| BNP levels→ | BNP ≤ 100 pg/mL | | BNP ≥ 200 pg/mL | |
|---|---|---|---|---|
| Ejection Fraction(%) ↓ | Pts distribution | Mortality N(%) | Pts distribution | Mortality N(%) |
| EF ≤ 50 | 1/9(11%) | 0 | 8/9(89%) | 6/8(75%) |
| EF > 50 to ≤ 58 | 8/18(44%) | 4/8(50%) | 8/18(44%) | 5/8(63%) |
| EF ≥ 59 | 8/18(44%) | 2/8(25%) | 5/18(28%) | 2/5(40%) |

In this observational study, 26 of 45 pts(58%) had BNP level ≥ 100 pg/mL (higher than the normal reference level) and EF less than 59 in 27 of 45 pts(60%). During the 4-year's observation, the first group of patients with BNP ≥ 200 and EF ≤ 50 had MR of 75%(6/8) while the 3rd group with BNP ≤ 100 and EF ≥ 59 having MR of 25%(2/8). The primary cause of death among the first group was cardiac origin in all, but the cause of death from the 3rd group was non-cardiac origin. All of 3 pts who had no LVH on ECHO had BNP level < 65 pg/mL and all of 4 pts with dilated LVH on ECHO had BNP level > 200 pg/mL. We believe that utility of plasma BNP and ECHO testing may enhance early recognition of asymptomatic cardiac dysfunction and guide us to lessen cardiac events to our pts.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1469

**Impact of Co-Infection with Hepatitis B and C and Human Immuno Deficiency Viruses on Survival in Hemodialysis Patients** Moro O. Salifu,[1] Rahul Jindal,[2] Amarpali Brar,[1] Win Kyaw,[1] Dominic S. Raj.[3] *[1]Medicine, Division of Nephrology, SUNY Downstate Medical Center, Brooklyn, NY; [2]Organ Transplant Program, Walter Reed Army Medical Center, Washington, DC; [3]Division of Renal Disease and Hypertension, The George Washington University, Washington, DC.*

Background: The prevalence of hepatitis viruses and human immunodeficiency virus (HIV) co-infection among maintenance hemodialysis patients and their impact on survival is unknown.

Methods: Data from the United States Renal Data System from January 2000 to December 2001, with at least 3 years of follow-up was analyzed. The study population was categorized based on the viral status at the time of initiation of dialysis. Survival analysis and hazard functions were used to estimate the risk of death over time.

Results: Among the 146,717 incident hemodialysis patients studied, the prevalence of hepatitis B virus (HBV), hepatitis C (HCV), HIV and HCV+HIV were 1.0%, 15.5%, 1.4% and 0.2% respectively. During the observation period 51.1% of the patients died. All cause mortality was higher in patients with HCV (AHR 1.22; 95% CI 1.18-1.27) and HCV+HIV (AHR 1.49; 95% CI 1.17-1.88), but lower in HBV patients (AHR 0.43; 95% CI 0.35-0.52) compared to those without viral disease. The risk for cardiovascular mortality was higher in patients with HCV and compared to other groups (HR 1.47; 1.43-1.50). Death due to liver disease was uncommon, but infection-related mortality was increased in HCV (HR 2.70; 95% CI 2.55-2.78), HIV (HR 2.75; 95% CI 2.47-3.07) and HCV+HIV (HR 3.28; 95% CI 2.50-4.26) patients.

Conclusion: HCV and HBV status have opposing effect on survival among hemodialysis patients. The mortality risk associated with HIV varies with co-existing HBV and HCV. Thus, co-infection status is important for risk assessment as well as for planning therapeutic intervention.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1470**

**Increased Serum ADMA Level Associated with Pulmonary Hypertension in Patients on Hemodialysis** Qianmei Sun,[1] Juan Meng,[2] Zhongxin Li,[1] Wei Jiang,[3] Karl L. Womer.[4] *[1]Departments of Nephrology, Beijing ChaoYang Hospital, Capital Medical University, Beijing, China; [2]Department of Rheumatology, Beijing ChaoYang Hospital, Capital Medical University, Beijing, China; [3]Department of Ultrasonic Medicine, Beijing ChaoYang Hospital, Capital Medical University, Beijing, China; [4]Department of Medicine, Division of Nephrology, Johns Hopkins University School of Medicine, Baltimore, MD.*

**Background** Pulmonary hypertension (PH) in patients with end-stage renal disease (ESRD) on hemodialysis is a newly described entity, with the pathogenesis considered to be ESRD-related endothelial dysfunction. Asymmetrical dimethylarginine (ADMA) is an endogenous nitric oxide (NO) inhibitor. Increased serum concentrations of ADMA may contribute to endothelial dysfunction in patients with pulmonary vascular disease. The present study was undertaken to determine whether a relationship exists between serum ADMA and PH in patients undergoing hemodialysis (HD).

**Methods** The incidence of PH was prospectively estimated by Doppler echocardiography in 69 patients with ESRD receiving long-term HD within 2h of completion of HD. PH was defined as pulmonary artery systolic pressure (sPAP)>35mmHg, as determined by Doppler echocardiography using the modified Bemouli equation. Serum ADMA levels were measured by enzyme-linked immunosorbent assay (ELISA) method. The relationship between ADMA and PAP was then analyzed.

**Results** PH was detected in 31.9% of patients receiving HD. Mean sPAP in the PH group was 40.79±12.32 mmHg compared to 24.81±4.54 mmHg in patients without PH (P<0.001), Patients with PH had significantly higher cardiac output (6.41±0.74 vs 5.08±0.61 L/min/m2; P<0.001 by ANOVA). Serum ADMA levels were significantly elevated in patients with PH compared with those without PH and 25 matched control subjects (1.32±0.15μmol/L vs 0.99±0.19μmol/L vs 0.22±0.05μmol/L; P<0.001). Multiple regression analysis showed that sPAP was independently related to ADMA and arterio-venous fistula (AVF) flow (P<0.01).

**Conclusions** Increased ADMA levels and their positive association with PAP suggests that the NO pathway is involved in the development of pulmonary hypertension in patients on haemodialysis.

**F-PO1471**

**Sudden Cardiac Death in Dialysis Patients from a Meta-Analysis of Cardiac Arrests on Dialysis Units** Darren Green, David I. New, Philip A. Kalra. *Department of Renal Medicine, Salford Royal Hospital, Salford, United Kingdom.*

Sudden cardiac death (SCD) is a major cause of mortality in dialysis patients. The use of implanted cardioverter-defibrillator devices (ICD) in these patients is contentious as studies suggest that survival with ICD is poor relative to other patients. Whether this is because they suffer less shockable rhythms (VF/VT) is not known, as the relative proportion of VF /VT arrests has not been studied in these patients, whereas it is known to be 75-80% in the general population.

Studies have been published on the outcome of cardiac arrests on dialysis units. However, none focus on the arrest rhythm. The purpose of this meta-analysis was to determine the proportion of dialysis-associated cardiac arrests that were of cardiac origin and whether the cardiac arrest rhythm was mostly VF/VT as in the general population.

A pubmed search for "dialysis cardiac arrest" included 9 cohort studies with data quantifying the outcome of cardiac arrests on dialysis units. Of these, 2 were excluded for giving little data about the study population, 1 was excluded as it referred to a cluster of deaths caused by a dialyzer reaction, and 2 referred to the same population. This left 5 study populations. Data was collected of cardiac arrests in chronic haemodialysis patients without a do not resuscitate order.

There were 1325 cardiac arrests covering 24,875,998 dialysis sessions. Where the cause of cardiac arrest was documented, 79.8% (485 of 608) of events were of a cardiac cause. These data equate to an approximate SCD event rate of 61 per 1000 patient years. 57.5% had VF/VT as the arrest rhythm.

This study suggests that SCD may be less likely to be caused a by shockable rhythm in dialysis patients compared to the general population. This may contribute to their poorer survival with ICD. However, if 57% of SCD in dialysis patients is due to VF/VT, the meta-analysis suggests that these events alone will occur at a rate of 35 events per 1000 patient years, which is as much as 20 times greater than the rate in the general population. Dialysis patients are therefore very high risk for SCD which may respond to ICD therapy, making them a worthy target for risk stratification for ICD use.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1472**

**Intravenous Erythropoetin Does Not Influence Intradialytic Hypertension** Albert J. Power, Kakit Chan, Seema Singh, Peter Hill, David Taube, Neill D. Duncan. *Imperial College Kidney & Transplant Institute, West London Renal & Transplant Centre, Hammersmith Hospital, London, United Kingdom.*

Intradialytic hypertension [IDH] confers a 22% increased risk of hospitalization or death per 10mmHg postdialysis increase in systolic blood pressure [BP]. Intravenous [IV] and not subcutaneous erythropoetin [EPO] elevates endothelin-1 levels and mean arterial pressure 30 mins after administration and has been hypothesized to contribute to IDH. However there are no large studies on this in clinical practice.

In this retrospective cohort study of 166 patients established [>90d] on hemodialysis [HD] and receiving protocolised care at 1 dialysis unit at our center Jan-Dec 2009, EPO [darbepoetin] was given IV 1hr into dialysis weekly and adjusted to target hemoglobin [Hb] 10.5-12.5g/dL. The dialysis prescription was tailored to target postdialysis BP≤130/80mmHg with ultrafiltration [UF] to euvolemia and subsequent antihypertensive use. IDH was defined with precedent as ≥15mmHg increase in postdialysis MAP from predialysis levels.

We examined 20407 sessions in all patients [mean age 66.4±14.0 yrs, 57% male, 42% diabetic, 57% hypertensive] using mixed effects models to account for repeat measures. Mean pre & postdialysis BP was 140±24/78±14mmHg & 136±24/75±14mmHg respectively. 6800 EPO doses were given [mean 0.60±0.35mcg/kg] with mean predialysis Hb 12.2±1.0g/dL, ferritin 278±112ng/mL. Overall IDH occurred in 13.7% sessions and clustered with ≥20% prevalence in 21% of the cohort.

IV EPO was not associated with absolute changes in MAP [p=0.2] or odds of IDH [OR 0.9, p=0.3]. UF volume reduced MAP by 1.6mmHg/liter UF [p<0.001] and odds of IDH by 14% per liter. Older age associated with intradialytic rise in MAP [1.4mmHg/10yrs age, p=0.002] and increased odds of IDH by 10% per decade [p=0.03]. Patient ethnicity, major comorbid diagnoses, dry weight and Hb had no significant effect on intradialytic change of MAP or IDH.

This large comprehensive study demonstrates no association of IV EPO use with IDH and MAP changes which are predominantly associated with UF volume and patient age.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1473**

**Association between Left Ventricular Diastolic Dysfunction by Color Tissue Doppler Imaging and Vascular Calcification on Plain Radiographs in Dialysis Patients** Won Suk An,[1] Sung Hyun Son,[2] Young Ki Son,[1] Seong Eun Kim,[1] Ki Hyun Kim.[1] *[1]Internal Medicine, Dong-A University, Busan, Republic of Korea; [2]Internal Medicine, BHS Han Seo Hospital, Busan, Republic of Korea.*

Diastolic dysfunction is frequently associated with left ventricular (LV) hypertrophy, indicating future cardiovascular events and vascular calcification (VC) is known to be associated with coronary artery disease (CAD) in dialysis patients. The aim of the present study was to determine the possible interrelationship between LV diastolic dysfunction by tissue Doppler imaging (TDI) and vascular calcification on plain radiographs in dialysis patients. We recruited 36 hemodialysis (HD) patients and 22 peritoneal dialysis (PD) patients. We checked the plain radiographic films of the feet, hands, pelvis and lateral lumbar spine and evaluated VC scores with previously reported methods. Pulse-wave Doppler examination of mitral inflow and TDI of the lateral mitral annulus was performed. The ratio of the mitral inflow early diastolic filling velocity (E) to the mitral annular early diastolic velocity measured by tissue Doppler (E') was used as an estimation of mean left atrial pressure (E/E'). The mean age of the patients was 55.7±10.4 years, dialysis duration was 40.5±29.5 months and E/E' was 11.0±4.0. The mean age, dialysis duration, the prevalence of VC on plain radiographs, E/E' and cardiac valvular calcifications were not significantly different in HD patients compared to PD patients. Patients who showed the abdominal aortic calcifications (AACs) scores >5 or VC scores of the pelvis and hands >3 had higher E/E' than patients without significant VC in dialysis patients. Positive associations were found between AACs scores >5 (r=0.371, p=0.009) , VC scores of the pelvis and hands >3 (r=0.412, p=0.004), CAD (r=0.305, p=0.037), left atrial volume (r=0.635, p<0.001), CRP (r=0.318, p=0.030) and E/E' in dialysis patients. Positive associations were found between AACs scores >5, E/E' (r=0.547, p=0.028) and cardiac valvular calcification in PD patients.These results suggest that diastolic LV dysfunction may be associated with VC on plain radiographs in dialysis patients.

**F-PO1474**

**The Relationship of the Course of Depression Symptoms with the Left Ventricular Mass Index and Left Ventricular Filling Pressure in Chronic Hemodialysis Patients** Biro Kim,[1] Yongkyun Kim,[2] Jihee Lim,[3] Minyoung Kim,[3] Cheolwhee Park,[3] Ho-Cheol Song,[2] Yongsoo Kim,[3] Euy-Jin Choi,[2] Yoonsik Chang,[1] Bumsoon Choi.[3] *[1]Division of Nephrology, Department of Internal Medicine, The Catholic University of Korea, Yeouido, St. Mary's Hospital, Republic of Korea; [2]Division of Nephrology, Department of Internal Medicine, The Catholic University of Korea, Bucheon, St. Mary's Hospital, Republic of Korea; [3]Division of Nephrology, Department of Internal Medicine, The Catholic University of Korea, Seoul, St.Mary's Hospital, Republic of Korea.*

*Introduction*: Multiple measurements of depression symptoms were more predictive of cardiovascular mortality than a single time measurement performed at baseline. The aim of this study is to evaluate the association of the course of depression symptoms, based on repeated assessments of depression symptoms over time, with left ventricular mass index (LVMI) and left ventricular filling pressure (LVFP) in patients on hemodialysis (HD).

*Methods*: Sixty-one patients on HD were prospectively assessed the level of depression symptoms using the Beck Depression Inventory (BDI) at baseline and three intervals (5, 10, 15 months). Doppler echocardiographic examinations were performed at the end of follow-up.

*Results*: At the end of follow-up, the patients were divided into three groups according to their course of depression symptoms: the non-depression (n = 21), the intermittent depression (n = 23), and the persistent depression symptoms group (n = 17). LVMI and LVFP were significantly increased in the persistent depression symptoms group compared to those of the non-depression symptoms group and the intermittent depression symptoms group. Persistent depression symptoms was independently associated with LVMI (β-coefficient = 0.347, $P$ = 0.017) and LVFP (β-coefficient = 0.274, $P$ = 0.048) after adjustment for age, gender, systolic blood pressure, diastolic blood pressure, diabetes and interdialytic weight gain.

*Conclusions*: In our study, persistent depression symptoms were associated with LV hypertrophy and diastolic dysfunction. Our data may provide a more complete understanding of cardiovascular risk associated with depression symptoms in the patients on HD.

**Serum Levels of proANP and Albumin Are Independent Predictors of Mortality in the High Risk Patients (Elderly and Diabetics) Treated by Hemodialysis (HD) and Continuous Peritoneal Dialysis (CAPD) in 4 Year Prospective Observation** Madziarska Katarzyna,[1] Waclaw Weyde,[1] Katarzyna Gosek,[2] Waclaw Kopec,[1] Jozef Penar,[1] Magdalena Krajewska,[1] Mariusz Kusztal,[1] Tomasz Golebiowski,[1] Ewa Zukowska-Szczechowska,[2] Marian Klinger.[1] *[1]Nephrology Transplantation Medicine, Wroclaw Medical University, Wroclaw, Poland; [2]Diabetology Nephrology, Medical University of Silesia, Zabrze.*

The undecided issue remains what type of dialysis (HD or CAPD) offers the long-term survival benefit in the highest risk of ESRD patients (pts). The aim of study was to compare survival in groups of 86 pts consisted of diabetics and elderly (>70 yrs) dependent on modality of dialysis (HD–46 pts, CAPD–40 pts; 41F, 45 M). The second goal was to identify the factors independently affecting the survival in 4 yrs prospective observation. The clinical pts characteristics: median age 73.5 yrs, 71% diabetics, 59% elderly, 30% of pts with both risk factors, median time on dialysis 17 months, and residual diuresis 550ml. There were no differences between HD and CAPD pts in these features. However, the distinctive element between HD and CAPD subgroups were lower albumin concentration ($p<0.002$) and higher cholesterol level ($p<0.001$) in CAPD pts. In addition, the following laboratory parameters were determined in all patients: pro-ANP, NT–proBNP, CRP and IL-6. All standard indices of dialysis care (BP, HGB, BMI, Kt/V) were also analysed. In prospective observation 53 pts (62%) survived 20 months, and 27 pts 50 months (last point of the observation). No effect of dialysis modality was discerned. In univariate linear model the survival was significantly associated with elevated CRP ($p= 0.05$), higher pro-ANP ($p= 0.005$), and lower albumin level ($p= 0.013$). The effect of higher pro-ANP ($p= 0.018$), and lower albumin ($p= 0.013$) was left as independent variable in the Cox regression model.

Conclusion: In high risk cohort of prevalent dialysis patients the type of dialysis modality does not influence the poor survival in 4 year prospective observation. The independent negative prognostic factors are reduced albumin level, and as the novel finding higher plasma pro-ANP reflecting volume status and cardiac performance.

**F-PO1476**

**Prevalence of Chronic Atrial Fibrillation in Dually-Eligible Dialysis Patients** James B. Wetmore,[1] Edward F. Ellerbeck,[2] Sally K. Rigler,[3] Jonathan D. Mahnken,[5] Qingjiang Hou,[5] John Spertus,[4] Theresa I. Shireman.[2] *[1]Medicine, Division of Nephrology, University of Kansas Medical Center, Kansas City, KS; [2]Preventive Medicine and Public Health, University of Kansas Medical Center, Kansas City, KS; [3]Medicine, University of Kansas Medical Center, Kansas City, KS; [4]St Luke's Mid American Heart Institute, University of Missouri - Kansas City, Kansas City, MO; [5]Biostatistics, University of Kansas Medical Center, Kansas City, KS.*

A rigorous claims-based approach for identifcation of chronc atrial fibrillation (CAF) in dually-eligible (Medicare-Medicaid) chronic dialysis patients has never been undertaken. We performed a retrospective cohort analysis of 123,615 dually-eligible patients undergoing chronic dialysis between January 1, 2001 and December 31, 2002. To be classified as having CAF, individuals had to have at least 3 AF Medicare claims (at least 2 of which were outpatient claims) a minimum of 30 days apart. Claims likely to represent transient AF or to be attributable to valvular heart disease or hyperthyroidism were eliminated.

The 2-year period prevalence of CAF was approximately 5.5 %, ranging from 3.6% in females aged 55-59 years to 13.2% in males over age 80. In multivariable analysis, age (adjusted prevalence rate ratio [APRR] 1.57 per decade), male sex (1.21), Caucasian race (approximately 2.0 relative to other groups), coronary artery disease (1.22), and congestive heart failure (1.61) were significantly associated with increased prevalence of CAF (all $p < 0.0001$). Hypertension, however, was associated with significantly lower likelihood of CAF (0.89, $p = 0.006$).

The 2-year period prevalence rate of CAF in dually-eligible dialysis patients is approximately 5.5%. This estimate is lower than typically reported, probably because we employed a strategy to eliminate individuals likely to have transient or secondary causes of AF. Nevertheless, this rate is substantially higher than that of the general population across all strata of age, demonstrating that CAF is a major problem in dialysis patients. The apparent "paradoxical" association of hypertension with a lower rate of CAF must be investigated.

**Severity of Heart Failure Predicts Outcomes and Health-Related Quality of Life in Maintenance Hemodialysis Patients in the HEMO Study** Kelly V. Liang,[1] Francis Pike,[2] Christos Argyropoulos,[1] Lisa Weissfeld,[2] Jeffrey Teuteberg,[3] Mary Amanda Dew,[4] Mark L. Unruh.[1] *[1]Renal-Electrolyte, University of Pittsburgh, Pittsburgh, PA; [2]Biostatistics, University of Pittsburgh, Pittsburgh, PA; [3]Cardiology, University of Pittsburgh, Pittsburgh, PA; [4]Psychiatry, Psychology, & Epidemiology, University of Pittsburgh, Pittsburgh, PA.*

**Background:** Cardiac disease is the leading cause of death among United States prevalent hemodialysis (HD) patients. We assessed the extent to which severity of congestive heart failure (CHF) influences morbidity and mortality, and health-related quality of life (HRQOL), in HD patients.

**Methods:** Using the database from the HEMO Study, which randomized 1846 HD patients to either high or low dose and flux interventions, we examined the relationship between CHF severity and mortality with Cox proportional hazards models. The relationship between CHF severity and HRQOL scores were modeled via linear regression.

**Results:** CHF was present in 40% of the total HD patients. Increasing severity of CHF was associated with greater age, higher proportion with diabetes, and lower serum albumin levels (all $p <0.0001$). Unadjusted hazard ratios for all-cause mortality were 1.61, 2.05, and 2.73 for mild, moderate, and severe CHF, respectively ($p <0.0001$). All-cause, cardiac, and infectious mortality and cardiac hospitalizations all increased with increasing severity of CHF. Increasing CHF severity was associated with decrements in HRQOL indices, particularly in physical functioning, and sleep quality.

**Conclusions:** Increasing severity of CHF is associated with increased mortality, cardiac hospitalizations, and worse HRQOL, especially in perceived physical limitations. These findings underscore both the need to assess disease severity and the importance of treatment to prevent progression of CHF in the HD population.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1478**

**Differences in Serious Adverse Event Reporting Rates from IV Iron by Country** George R. Bailie,[1] Walter H. Hoerl,[2] Jan-Jaap Verhoef.[3] *[1]Albany College of Pharmacy & Health Sciences, Albany, NY; [2]Medical University of Vienna, Austria; [3]University of Utrecht, Netherlands.*

Adverse event (AE) reporting varies between Europe (Eur) and N. America (NA). We examined serious AE (SAE) by population exposed to IV iron (Fe) products.

Methods: We extracted SAE (anaphylaxis/oid) from IV Fe AE reports in Eur and NA between 1Q03 to 2Q09 from Uppsala Monitoring Center. IMS Health Fe sales data were standardized to 100 mg dose equivalents. Fe use reported as gram of Fe/million population/yr (GFe/mil/y) using census data (www.prb.org). SAE rates derived as total # SAE/GFe/mil/y.

Results: Iron sucrose (IS) was used by all countries, ferric gluconate (FG) by 8, low MW iron dextran (ID) by 12, IS similars (ISS) by 3. For countries using a product, use ranged hugely: for IS from 1 (Ire) to 5349 (Swi); FG from 0.2 (Pol) to 7488 (Ita, where some use of FG is oral); ID from 0.1 (Swi) to 256 (Ire). Many countries under-reported SAE despite

much Fe use (Table). ISS SAE were not separated from IS. SAE rates ranged from $1.7x10^{-3}$ (IS, Swe) to $305x10^{-3}$ (ID, UK). IS and FG had similar SAE rates in Eur and NA but FG rate was much higher in NA. Greatest SAE rates were for ID in Eur and NA.

IVFe use and serious AE

| | IS | | ISS | FG | | ID | |
|---|---|---|---|---|---|---|---|
| Eur | Fe use | SAE # (rate)* | Fe use | Fe use | SAE # (rate) | Fe use | SAE # (rate) |
| Fra | 1870 | 9 (4.8) | 37 | | | | |
| Ger | 231 | 4 (17.3) | | 1990 | 6 (3.0) | 119 | 26 (219.2) |
| Ita | 21 | | | 7488 | 26 (3.5) | 11 | |
| Pol | 478 | | | | | 120 | 1 (8.3) |
| Spa | 1875 | | 334 | 3.0 | | 39 | |
| Swe | 1751 | 3 (1.7) | | | | 51 | 3 (59.0) |
| Swi | 5349 | 53 (9.9) | | | | | |
| Tur | 1572 | 9 (5.7) | 155 | | | 175 | 1 (5.7) |
| UK | 929 | 12 (12.9) | | | | 79 | 24 (305.3) |
| All Eur (16 countries) | 17475 | 92 (5.3) | 526 | 11176 | 34 (3.0) | 866 | 61 (70.4) |
| NA | | | | | | | |
| US | 2351 | 31 (13.2) | | 1313 | 90 (68.6) | 243 | 108 (444.1) |
| Can | 196 | 3 (15.3) | | 130 | 2 (15.4) | 367 | 23 (62.7) |
| All NA | 2547 | 34 (13.3) | | 1443 | 92 (63.8) | 610 | 131 (214.8) |
| **All Eur + NA** | **20022** | **126 (6.3)** | | **12618** | **126 (10.0)** | **1476** | **192 (130.1)** |

*# for total period; rate is $x10^{-3}$

Conclusions: Inter-country SAE reporting rates vary drastically; may be due to IV Fe use in different therapeutic areas or clinical settings, or varied reporting procedures. Generally, SAE rates were highest for ID and lowest for IS.

### F-PO1479

**Worsening Severity of Peripheral Vascular Disease Associated with Poor Outcomes in Hemodialysis: Findings from the HEMO Study** Patrick Ifesinachi Emelife, Tao Liu, Lindsay J. Proud, Alan J. Rosenbaum, Ryan M. Stephenson, Raymond J. Vergona, Mark L. Unruh. *University of Pittsburgh.*

Background: The contribution of peripheral vascular disease (PVD) to the morbidity and mortality of patients undergoing maintenance hemodialysis remains largely unexplored. This study aimsto describe the distribution of PVD according to its severity and to assess the risk factors associated with increased severity of PVD. Additionally, our study assessed the extent to which PVD was associated with health-related quality of life and long-term survival among a prevalent hemodialysis population.

Methods: Secondary data analysis was performed on 1846 prevalent hemodialysis patients from the HEMOStudy. PVD severity, as defined by the Index of Co-Existent Disease (ICED), was the exposure variable. The relationship between PVD and selected demographic, clinical and laboratory values was examined. Primary outcomes included health-related quality of life as measured by the SF36 and KDQOL Sleep Quality Index as well as all-cause mortality.

Results: The relative frequency of PVD severity was 1372 without PVD (73.6%), 150 with mild PVD (8.1%), 221 with moderate PVD (12.0%), and 103 with severe PVD (6.0%). Factors associated with more severe PVD included older age (P<0.0001), white race (P<0.0001), smoking (P=0.03), drug use (P=0.01), disability (P=0.019), diabetes (P<0.0001), ischemic heart disease (P<0.0001) cerebrovascular disease (P<0.0001), and higher diastolic blood pressure (P<0.0001). The severity of PVD was associated with decreased Physical Function , Role Physical, General Health, Vitality, and Social Function (all p< 0.01). Increased PVD severity was strongly associated with an increased risk of death compared to no PVD; mild PVD HR 1.3; 95% CI (1.03, 1.63), moderate PVD HR 1.35; 95% CI (1.1,1.64), and severe PVD 1.45; 95% CI (1.12,1.87) after adjustment for demographic and clinical variables.

Conclusions: Since severe PVD is a commonly observed in hemodialysis patients, our study identified modifiable risk factors that predisposed patients to PVD. These findings emphasize the need for evaluation of the benefits of more aggressive treatment for PVD in patients on hemodialysis.

### F-PO1480

**Chronic HCV Infection Independently Increased Mortality Risks for Cardiovascular and Liver Disease-Related Death in Hemodialysis Patients, While Past HCV Infection Did Not** Masaki Ohsawa,[#1] Yosuke Fujishima.[#2] *[1]Hygiene and Preventive Medicine, Iwate Medical University, Morioka, Japan; [2]Department of Urology, Iwate Medical University, Morioka, Japan.*

Whether past hepatitis C virus (HCV) infection or chronic HCV infection contributes to an increase in mortality among hemodialysis patients (HD pts) has not been clarified. A total of 1214 HD pts were enrolled. Numbers of deaths (total death (TD), cardiovascular death (CVD), infectious disease-related death (ID) and liver disease-related death (LD)) and crude and age-adjusted (based on WHO standard population) mortality rates (/1000 patient-years) were estimated in HCV infection status groups (never, HCV antibody negative; past infection, HCV antibody positive and HCV antigen negative; chronic infection, HCV antigen positive), and multivariate-adjusted hazard ratios (HRs) and their 95% confidence intervals (95% CIs) for death attributable to past HCV infection or chronic HCV infection were estimated using Cox's regression model after adjustment for risk factors. The observed patient-years were 4734 patient-years. Mean follow-up period was 3.9 years. A total of 457 patients died during the five-year observation period. Numbers of deaths, crude and age-adjusted mortality rates and HRs (95% CIs) for each cause of death among HD pts are shown in the table.

Number of death, crude and age-adjusted mortality rates and hazard ratios (95%CIs) by groups according to HCV infection status

| Cause of death | HCV status | Number of death | crude mortality | age-adjusted mortality | HR (95%CI) |
|---|---|---|---|---|---|
| TD | never (n=1080) | 393 | 91.4 | 31.2 | 1 |
| | past (n=55) | 25 | 123.0 | 36.1 | 1.73 (1.14-2.64) |
| | chronic (n=79) | 39 | 137.2 | 83.1 | 2.21 (1.56-3.12) |
| CVD | never | 190 | 44.2 | 16.7 | 1 |
| | past | 9 | 44.3 | 12.3 | 1.22 (0.60-2.50) |
| | chronic | 17 | 59.8 | 23.3 | 2.29 (1.16-4.53) |
| ID | never | 103 | 23.9 | 6.4 | 1 |
| | past | 8 | 39.4 | 9.5 | 2.48 (1.17-5.29) |
| | chronic | 10 | 35.2 | 14.4 | 2.29 (1.16-4.53) |
| LD | never | 5 | 1.2 | 0.3 | 1 |
| | past | 1 | 4.9 | 1.0 | 2.77 (0.27-28.9) |
| | chronic | 4 | 14.1 | 32.3 | 11.5 (2.31-56.9) |

Chronic HCV infection independently increased mortality risks for TD, CVD, ID and LD among hemodialysis patients, while past HCV infection did not increase risks for CVD and LD.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1481

**The Relation between Glutathione S-Transferase M1 Polymorphism and the Clinical Outcome of Chinese PD Patients** Peter Yam-Kau Poon,[1] Cheuk-Chun Szeto,[1] Bonnie Kwan,[1] Kai Ming Chow,[2] Philip K. T. Li.[2] *[1]Department of Medicine & Therapeutics, The Chinese University of Hong Kong, Shatin, Hong Kong; [2]Department of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, Hong Kong.*

Objective To investigate the effect of glutathione S-transferase M1 (GST M1) gene (-)/(+) polymorphism on the survival of patients undergoing peritoneal dialysis (PD). Methods We studied 441 new PD patients (232 males, mean age 56.6 ± 13.5 years). GST M1 gene (-)/(+) genotyping was determined by multiplex polymerase chain reaction (PCR) using primer pairs for both GST M1 gene and β-globulin gene. All patients were then followed for an average of 41.4 ± 18.2 months for survival study. Results The 5-year actuarial survival of patients with GST M1(-) (N = 267) and GST M1(+) (N = 174) genotype are 51.4% and 69.1% respectively (log rank test, p = 0.017). The 5-year technique survival of GST M1(-) and GST M1(+) genotypes were 39.0% and 53.6% respectively (p = 0.051). Multivariate Cox regression analysis showed that only total Kt/V, Charlson's comorbidity index and the presence of pre-existing diabetes are the independent predictors of actuarial survival, while the GST genotype did not appear in the final model. However, for patients ages >70 years, GST M1(+) genotype (N = 30) had significantly better actuarial survival (62.5% vs 26.2%, p = 0.012) and technique survival (55.1% vs 21.9%, p = 0.024) than GST M1(-) genotype (N = 56). Multivariate analysis showed that the GST genotype was an independent predictor of actuarial survival (adjusted hazard ratio [AHR] 0.243, 95% confidence interval [CI] 0.063 – 0.944, p = 0.041) and technique survival (AHR 0.243, 95%CI 0.063 – 0.944, p = 0.041). In patients <70 years, the GST genotype had no effect on actuarial or technique survival. Conclusion GST M1(+) genotype apparently confers a survival advantage to elderly PD patients. Since both natural aging and the process of PD result in the accumulation of oxidative stress, it is possible that the presence of anti-oxidative enzyme GST could have a protective effect on elderly PD patients, but the detailed mechanism deserves further investigation.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1482

**The Relation between Human Oxoguanine-DNA Glycosylase-1 Polymorphism and the Clinical Outcome of Chinese PD Patients** Peter Yam-Kau Poon,[1] Cheuk-Chun Szeto,[1] Bonnie Kwan,[1] Kai Ming Chow,[2] Philip K. T. Li.[2] *[1]Department of Medicine & Therapeutics, The Chinese University of Hong Kong, Shatin, Hong Kong; [2]Department of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, Hong Kong.*

Objective To investigate the effect of human oxoguanine-DNA glycosylase 1 (hOGG1) gene C1245G polymorphism on the survival of patients undergoing peritoneal dialysis (PD). Methods We studied 441 new PD subjects (232 males, mean age 56.6 ± 13.5 years). hOGG1 C1245G genotyping was determined by polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP). All patients were then followed for an average of 41.4 ± 18.2 months for cardiovascular events. Results For the entire cohort, there was no significant difference in the 5-year event-free survival between CC (N = 73) and CG+GG (N = 368) genotypes (42.9% vs 33.2% respectively; log rank test, p = 0.120). However, for patients with baseline serum C-reactive protein (CRP) levels ≤5.0 mg/L, 5-year event-free survival of CC patients (N = 40) were significantly higher than that of CG+GG patients (N = 200) (50.3% vs 31.9% respectively, p = 0.046). Multivariate Cox regression analysis showed that both the hOGG1 genotype (adjusted hazard ratio [AHR] 3.989; 95% confidence interval [CI] 1.445 to 11.013; p = 0.008) and Charlson's comorbidity index (AHR 1.266; 95%CI 1.127 to 1.422; p < 0.001) were independent predictors of the 5-year event-free survival. In contrast, there was no significant difference in 5-year event-free survival between the CC (N = 10) and CG+GG genotypes (N = 49) for patients with baseline CRP >5.0 mg/L (26.7% vs 30.2% respectively, p = 0.9). Conclusions In PD patients with no systemic inflammation, hOGG1 1245CC genotype had a lower risk of cardiovascular event than those with CG or GG genotypes. The protective effect of hOGG1 1245CC genotype,

however, disappeared in PD patients with feature of systemic inflammation. Our results suggest a complex interaction between the enzyme hOGG1, which has a DNA repairing activity, and the systemic inflammatory state in the pathogenesis of cardiovascular disease of PD patients.

## F-PO1483

**Study of the Relationship between Fluid Overload and Autonomic Response during Hemodyalisis** Manuela Ferrario,[1] Ulrich Moissl,[2] Francesco Garzotto,[3] Maria Gabriella Signorini,[1] Dinna N. Cruz,[3] Flavio Basso,[3] Alessandra Brendolan,[3] Federico Nalesso,[3] Ciro Tetta,[2] Sergio Cerutti,[1] Claudio Ronco.[3] *[1]Politecnico di Milano, Milano, Italy; [2]Fresenius Medical Care Deutschland GmbH, Germany; [3]San Bortolo Hospital, Vicenza, Italy.*

**Background.** Fluid overload (FO) is an important and independent predictor of mortality in chronic hemodialysis (HD) patients [Wizemann V. et al., 2009]. The aim of this study was to investigate the relationship between FO and the autonomic response to the HD, estimated from Heart rate variability (HRV) .

**Methods.** 80 patients were recruited from the dialysis unit of San Bortolo Hospital, Vicenza, Italy. 24 hr ECG Holter recordings were performed once for each patient starting before the HD treatment, immediately after fluid overload ($FO_{pre}$) was assessed with a whole body bioimpedance spectroscopy device (BCM, Fresenius Medical Care, Germany). Heart rate variability (HRV) was analyzed with time domain parameters and frequency domain indices [Task Force, Circulation, 1996]. Mean values of time and frequency domain indices of HRV were calculated for the first 30 minutes and last 30 minutes of HD, and for the entire HD session [Task Force, Circulation, 1996].

**Results.**

Table 1: Pearson Coefficients (HRV indices vs FOpre/ECW%)

| | all pts | diabetic pts | non diabetic pts |
|---|---|---|---|
| **SDANN** | rho= -0.40 Pval=0.002 | rho=-0.16, Pval= 0.552 | rho=-0.51 Pval=0.001 |
| **VLF** | rho=-0.31 Pval=0.020 | rho=-0.28, Pval= 0.302 | rho=-0.39, Pval=0.015 |
| **HF%** | rho= +0.33 Pval=0.012 | rho=+0.56, Pval=0.024 | rho=+0.30, Pval=0.062 |

SDANN estimated over the entire HD was significantly different between overhydrated (FO>2.5l) and non-overhydrated patients (FO<=2.5L) both for D and ND pts (T-test p-value<0.05).

**Conclusion.** These results for the first time demonstrate that there is a link between fluid status and autonomic function. Heart rate variability as a marker of autonomic function significantly changes with rising fluid overload. Diabetic and non-diabetic patients present different correlations between FO and HRV indices.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1484

**The Effects of Long-Term Administration of Cinacalcet on Left Ventricular Function in Hemodialysis (HD) Patients** Jyunichiro Hashiguchi,[1] Miwa Shirahama,[1] Masao Aoyagi,[1] Yoshiaki Lee,[1] Takashi Harada,[1] Satoshi Funakoshi,[1] Mineaki Kitamura,[2] Akira Furusu,[2] Shigeru Kohno.[2] *[1]Dialysis Center, Sakuramachi Clinic, Nagasaki, Japan; [2]Department of Internal Medicine, Nagasaki University Graduate School of Medicine, Nagasaki, Japan; [3]Department of Diabetis, Jikei University, Tokyo, Japan.*

Background; The expression of the calcium-sensing receptor (CaSR) on heart muscle and vascular cells has been well-documented, and calcimimetics have become a potential candidate for cardiovascular intervention. Purpose; To evaluate the effects of cinacalcet on cardiac function when administered over a long term period of 5 years. Subjects and Methods; From April 2004 to March 2010, 12 HD outpatients with secondary hyperparathyroidism were enrolled in this study after appropriate IC, and were monitored using various parameters including yearly examined ultrasound cardiography over > 5 years from the start of cinacalcet administration. There were two groups; Group 1 continuing cinacalcet administration for > 5years (n=7), group 2 stopped cinacalcet administration < 1 year due to poor compliance (n=5). Results; There was no significant difference between the two groups in age, interdialytic weight gain (IWG) or HD vintage. As shown in Table 1, significant suppression was observed in the tei index and the LVDd, while an increase was observed in the LVPW of the group that continued administration of cinacalcet > 5 years.

Change in the left ventricular parameters by cinacalcet treatment in 5 years (%)

| | group 1 | group 2 | p value |
|---|---|---|---|
| average ΔEF | -4.5±4.8 | -5.5±6.1 | NS |
| average Δtei index | -18.5±9.9 | +13.7±12.8 | 0.024 |
| average ΔLVDd | -4.3±3.9 | +8.8±7.9 | 0.041 |
| average ΔLVPW | +26.8±9.0 | +2.8±7.5 | 0.0019 |

Conclusions; Our results indicate the potential effects of cinacalcet on protecting left ventricular function in HD patients.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1485

**Undiagnosed Renal Artery Stenosis in Patients Evaluated for Kidney Transplant** Samer Bani-Hani,[1] Vinaya Rao,[2,4] Min Min Mya,[3] Ahmed I. Al-Absi,[4] Maung Mya.[2,4] *[1]Int. Med, UTHSC, Memphis; [2]Transplant Institute, Methodist University Hospital, Memphis; [3]EMCare, Memphis; [4]Nephrology, University of Tennessee Health Science Center, Memphis.*

Back ground: Renal artery stenosis(RAS) accounts for only 0.8% of primary diagnoses as the cause of prevalent ESRD in 2007. RAS is likely underdiagnosed as physicians are hesitant to use contrast agents in patients(pts) with advanced chronic kidney disease.

Objective: To examine the prevalence of undiagnosed RAS in ESRD pts evaluated for renal transplant.

Method: Retrospective analysis of CT angiogram(CTA) in pts evaluated for renal transplant in a single center.

Results: There were 483 kidney transplant recipients from Jan, 2005 to Oct,2009 who had CTA as part of their pretransplant evaluations in our center. Two pts who had stent placement for RAS before the pretransplant evaluation were excluded from the study. Pts' demographics were: mean age 48 y, male 302, female 179, white 152, African American 317 and other races 12. RAS was present in 14 (2.9%) pts. All pts had hypertension. RAS was significantly associated with age and peripheral vascular disease(PVD). Contrary to our expectation, RAS was not significantly associated with diabetes, hyperlipidemia and history of cerebrovascular accidents(CVA).

| | **RAS**: yes | **RAS**: No | **P** |
|---|---|---|---|
| | N (%) | N(%) | |
| **Total**: 481 | 14 (2.9) | 467 (97.1) | |
| **Age** | 55.85 | 47.82 | 0.004 |
| **Gender**: Male | 8 (57.1) | 294 (63) | 0.658 |
| Female | 6 (42.9) | 173 (37) | |
| **Race**: white | 5 (35.7) | 147 (31.5) | 0.801 |
| Black | 9 (64.3) | 308 (65.9) | |
| other | 0 (0) | 12 (2.6) | |
| **Diabetes**: Yes | 5 (35.7) | 142 (30.4) | 0.671 |
| No | 9 (64.3) | 325 (69.6) | |
| **Hyperlipidemia**: Yes | 6 (42.8) | 158 (33.8) | 0.483 |
| No | 8 (57.2) | 309 (66.2) | |
| **PVD**: Yes | 1 (7.1) | 5 (1.1) | 0.044 |
| No | 13 (92.9) | 462 (98.9) | |
| **CVA**:Yes | 0 (0) | 23 (4.9) | 0.137 |
| No | 14 (100) | 444 (95.1) | |

Conclusion. Undiagnosed RAS was present in 2.9% of pts evaluated for renal transplant. RAS was significantly associated with age and PVD but not with diabetes, hyperlipidemia and history of CVA.

## F-PO1486

**Effect of Carnitine Supplementation on Carnitine Levels and Left Ventricular Performance in Children on Chronic Hemodialysis** Kristen Sgambat, Ahmad Ellini, Lowell Frank, Craig Sable, Asha Moudgil. *Nephrology and Cardiology, Children National Medical Center, Washington, DC.*

**Background:** Carnitine is essential for transport of fatty acids into mitochondria and plays a key role in beta-oxidation and energy production in the myocardium. Carnitine deficiency may occur in patients on chronic hemodialysis (HD) due to its removal by dialysis and inadequate dietary intake; this may contribute to cardiomyopathy. We assessed carnitine levels and cardiac response to carnitine supplementation by standard echocardiography including more sensitive parameters including left ventricular (LV) strain and strain rate.

**Methods**: The carnitine levels (total and free carnitine and acyl: free carntine ratio) and cardiac function of 8 children (mean age 12.9 years, range 9 – 17 years) on chronic HD were assessed before and after carnitine (20mg/kg/dose) infusion 3 times a week for 6 months. Standard echocardiographic measures of LV size, systolic and diastolic function as well as circumferential, radial, and longitudinal strain and strain rate analysis using speckle tracking were performed.

**Results**: Total (50 ± 36 vs. 267 ± 36 μmol/l) and free carnitine (29 ± 23 vs. 160 ± 23 μmol/l) levels increased significantly ($p < 0.001$), whereas acyl:free ratio remained unchanged (0.72 ± 0.14 vs. 0.69 ± 0.14) after carnitine supplementation. There were no significant changes in standard echocardiographic measures of LV function including end diastolic dimension, mass index, ejection fraction, shortening fraction and mitral E/A and E/E' ratios after carnitine supplementation. However, there was a significant ($p = 0.025$) improvement in longitudinal strain rate (-1.46 ± 0.33 vs. -1.91 ± 0.37) after supplementation. This difference remained significant ($p = 0.013$)after controlling for interdialytic weight gain and blood pressure. There were no significant differences in other strain/ strain rate parameters.

**Conclusion:** Carnitine supplementation improved total and free carnitine levels in children on chronic HD without affecting acyl:free carnitine ratio. LV performance improved after supplementation as assessed by strain rate analysis that was not obvious by standard echocardiographic measures.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1487**

**Ankle Brachial Index, Vascular Calcifications and Mortality in Dialysis Patients** Patricia Quadros Branco,[1] Teresa Adragao,[2] Ana Pires,[3] Rui Castro.[4] *[1]SPD Diaverum, Portugal; [2]NCE Diaverum, Portugal; [3]NC LAV Diaverum, Portugal; [4]Tecsam Vila Real, Portugal.*

The ankle brachial index (ABI) is a non-invasive method to evaluate peripheral artery disease (PAD). ABI<0.9 diagnoses PAD; ABI>1.3 is a false-negative caused by non-compressible arteries. The aim of this study was to evaluate the association between ABI with vascular calcifications (VC) and with mortality, in hemodialysis (HD) pts.

We studied 219 HD pts (60% male; 20% diabetic). At baseline, ABI was evaluated by a doppler device. VC were evaluated by 2 methods: the abdominal aorta calcification score (AACS) in a lateral plain X-ray of the abdominal aorta and the simple vascular CS (SVCS) in plain X-ray of pelvis and hands. VC were also classified by their anatomical localization in main vessels (aorta, iliac-femoral) and in collateral or distal vessels (pelvic , radial or digital) The cut-off values for the different VC scores in relation with ABI were determined by ROC curve analysis. Biochemical parameters were time averaged for the 6 months preceding ABI evaluation.

An ABI <0.9, an ABI >1.3 or a normal ABI were found, respectively in 90 (41%), in 42 (19%) and in 87 (40%) pts. AACS >6 and SVCS >3 were found, respectively, in 98 (45%) and 95 (43%) pts. The adjusted risk for having an ABI<0.9 was 2.9 (p≤0.001) for AACS>6; 3.5 (p≤0.001) for SVCS>3 and 4.4(p<0.001) for iliac-femoral CS>3. The adjusted risk for having an ABI>1.3 was 3.4 (p=0.001) for hands CS >2 and 3.5 (p=0.001) for pelvic CS >2. After a follow-up of 29±7 months, 50 (23%) pts died. Adjusting for age, diabetes and HD duration, an ABI<0.9 and an ABI>1.3 were associated with mortality (HR=3.4; p=0.001 and HR=2.9; p=0.029, respectively).

In conclusion, both low and high ABI were independent predictors of mortality. VC in main arteries were associated with an ABI<0.9. VC in collateral and distal arteries were associated with an ABI>1.3. The hypothesis that the correction of factors associated with development of vascular calcifications might have an impact on PAD outcomes needs to be evaluated.

**F-PO1488**

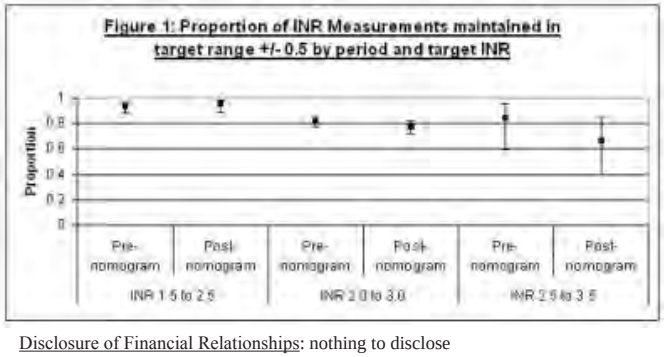
**Evaluation of a Warfarin Nomogram for Anticoagulation in Hemodialysis Patients** Benjamin Ka Thomson, Jianguo Zhang, Jennifer M. MacRae, Megan Alicia Manning, Brenda Hemmelgarn. *Internal Medicine, Division of Nephrology, Department of Internal Medicine, Calgary, AB, Canada.*

Introduction: Outpatient warfarin nomograms to guide warfarin dosing have been shown to improve INR control, compared to physician directed therapy. The effectiveness of these nomograms in the hemodialysis population is unknown. The purpose of this study was to evaluate the adequacy of anticoagulation using an electronic warfarin nomogram administered by nurses in the outpatient hemodialysis population, compared to physician directed therapy.

Methods: The study population included all patients on hemodialysis treated with warfarin in Calgary Alberta. Two five-month time periods were compared: a pre-period prior to implementation of the nomogram and a post-period following implementation of the nurse directed, electronic warfarin nomogram. The primary endpoint was adequacy of anticoagulation (proportion of INR measurements within target 0.5). Secondary outcomes included frequency of INR testing and adverse events.

Results: Overall 67 patients in the pre- period and 55 in the post-period were included (with 40 patients in both periods). Using generalized linear mixed models, the adequacy of INR control was similar in both periods, for all target INR levels: target INR 1.5 to 2.5 (pre 93.6%; post 95.6%, p=0.953); INR 2.0 to 3.0 (pre 82.2%; post 77.4%, p=0.202) and; INR 2.5 to 3.5 (pre 84.3%; post 66.8%, p=0.287).The mean number of INR measurements per patient decreased significantly from pre (30.5) to post (22.3) (p=0.003). There were 3 bleeding events in each of the pre and post periods.

Limitations and Conclusions: Our study was limited by its single centre location and pre-post design. Our results suggest that a nurse directed electronic warfarin anticoagulation nomogram achieves adequacy of INR control similar to that of physician directed therapy among hemodialysis patients.



Disclosure of Financial Relationships: nothing to disclose

**F-PO1489**

**Leptin and Volume Status in Hemodialysis Patients: Preliminary Data** Sejoong Kim,[1] Eun Sook Jung,[2] Hayne C. Park,[2] Hajeong Lee,[2] Jiyoon Sung,[1] Sun Young Na,[1] Ho Jun Chin,[2] Jin Suk Han,[2] Kwon Wook Joo.[2] *[1]Internal Medicine, Gachon University of Medicine and Science, Incheon, Korea; [2]Internal Medicine, Seoul National University College of Medicine, Seoul, Korea.*

*Background:* Adipokines are related to cardiovascular outcome in hemodialysis (HD) patients. Both fluid overload and dehydration are also linked to an increased cardiovascular morbidity in HD patients. However, the association between adipokines and volume status has not been investigated yet.

*Methods:* We enrolled 120 patients who received more than 3-month hemodialysis in major 3 dialysis centers. According to the amount of fluid overload, which was provided by the body composition moniter (BCM, Fresenius Medical Care Korea), we divided into 3 groups: overhydrated group (fluid overload ≥ 1.1L), normohydrated group (-1.1L ≤ fluid overload < 1.1L), and dehydrated group (fluid overload < -1.1L). We also measured the adipokines (leptin, adiponectin, and resistin) and inflammation (interleukin-6, and monocyte chemotactic protein-1).

*Results:* The proportion of the overhydrated group was 36.9% (45/120), and that of the dehydrated group was 18% (22/120). Serum levels of leptin in the dehydrated group was higher, compared to the other groups ($P$ = 0.001). Serum levels of adiponectin, resistin, interleukin-6, and monocyte chemotactic protein-1 were not different among the three groups. Serum leptin levels were negatively correlated with the absolute amount of fluid overoload, controlled for age, gender, and fat contents (coefficient β=-0.427, $P$=0.007).

*Conclusion:*

We found that leptin levels may be strongly associated with volume overload in hemodialysis patients. Further prospective interventional trials could be needed to evaluate serial changes of leptin with volume status.

**Characteristics of Revascularization Treatment for Arteriosclerosis Obliterans in Patients with and without Hemodialysis** Junichi Hoshino,[1, 4] Keiichi Sumida,[1] Rikako Hiramatsu,[1] Fumi Takemoto,[2] Kunihiro Yamagata,[3] Yoshifumi Ubara.[1] *[1]Nephrology Center, Toranomon Hospital, Minato-ku, Tokyo, Japan; [2]Department of Nephrology, Jichi Medical University, Shimotsuke, Tochigi, Japan; [3]Department of Nephrology, University of Tsukuba, Tsukuba, Ibaraki, Japan; [4]Terasaki Foundation Laboratory, Los Angeles, CA.*

Background: Limb ischemia is a major complication in patients who are receiving dialysis (HD). Here we identified distinctive features and factors affecting the outcome of HD patients with limb ischemia.

Methods and Results: We retrospectively compared 180 consecutive symptomatic limb ischemic patients who were or were not receiving HD and who successfully underwent surgical bypass grafting (bypass, n=75) or endovascular angioplasty (PTA, n=105) at our hospital. The endpoint of this study was amputation of the ischemic leg or death.

Median follow-up was 2.25 years. The amputation-free survivals of HD patients (68.3%, 53.3%, and 40.0% at 1,3 and 5 years) were significantly lower than that of non-HD patients (90.9%, 84.9% and 78.0%, p<0.0001). In bypass group, amputation-free survivals of HD patients (79.3%, 44.3%, and 14.8%) were significantly lower than those of non-HD patients (90.1%, 84.7%, and 80.9%, p=0.0002), whether the graft was patent or not (p=0.32). On the other hand, in PTA group, amputation-free survivals of HD patients (all 62.1%) were lower than those of non-HD patients (91.4%, 85.1%, and 75.2%, p=0.03) with significantly lower patency rate (59.6%, 34.8%, and 23.2%, p=0.0004). Predictors of amputation-free survival differed between HD and non-HD patients; predictors were diabetes mellitus {HR(hazard ratio), 8.34[95%CI, 1.91 to 46.98]} and gender (HR, 0.19[95%CI, 0.06 to 0.63]) in HD patients, while they were Fontaine classification (HR, 6.12[95%CI, 1.99 to 15.75]) and hyperlipidemia (HR, 0.36[95%CI, 0.12 to 0.94)in non-HD patients. Infectious death rate was higher in HD patients than non-HD patients (53% vs 22%, p<0.05)

Conclusions: This study clearly showed poorer prognosis in HD patients than non-HD patients especially after bypass surgery, whether the graft was patent or not.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1491**

**Black Ethnicity Predicts Better Survival on Renal Replacement Therapy Despite Greater Deprivation and Diabetes** Satish Jayawardene, Chris Jones, Nicholas Cole, Andrew Cai, Michael Bedford, Hugh S. Cairns. *Renal Unit, King's College Hospital, London, United Kingdom.*

Background: Black ethnicity is known to carry a survival benefit on renal replacement therapy (RRT). It is unclear if this benefit is affected by deprivation, as it is linked to poorer outcome and assumed to be worse in ethnic minorities.

Aim: To describe survival of black vs white RRT patients and the effect of deprivation and other traditional risk factors for death.

Method: Retrospective analysis of the 1340 patients of white or black race starting RRT in one renal unit between 1996-2008. Deprivation was calculated matching patient postcodes to area scores of the UK Index of Multiple Deprivation 2007. Patient comorbidity and demographics were extracted from the unit database. Survival comparison between groups used Cox's Proportional Hazard models and Hazard Ratios (HR).

Results: During the time period 952 white and 388 black patients started RRT. Black patients were significantly younger than whites at RRT start, though with more diabetes (DM) and worse deprivation scores. Black race was associated with a significant survival benefit even after adjustment for age, sex, deprivation, transplantation and DM (HR 0.51, 95%CI 0.41-0.65, p<0.001).

Demographics of RRT patients (values are means & standard deviations or numbers & percentages)

| | White (952(71%)) | Black (388(29%)) | All RRT (1340(100%)) | P |
|---|---|---|---|---|
| Male Gender | 583(61%) | 229(59%) | 812(61%) | 0.45 |
| Age at RRT start | 62(16) | 54(16) | 60(16) | <0.001 |
| ESRF cause: Diabetes | 248(26%) | 132(34%) | 380(28%) | 0.003 |
| ESRF cause: Hypertension | 69(7%) | 78(20%) | 147(11%) | <0.001 |
| ESRF cause: Ischaemia | 83(9%) | 5(1%) | 88(7%) | <0.001 |
| Deprivation score (higher score = more deprived) | 24(14) | 35(11) | 28(14) | <0.001 |
| Death | 554(58%) | 137(35%) | 691(52%) | <0.001 |
| Transplanted | 170(18%) | 74(19%) | 244(18%) | 0.61 |

Conclusion: In this study the better survival of black patients on RRT outweighed the possible adverse effect of deprivation and DM on survival. More work is needed to assess the cause of this significant benefit.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1492

**Prevalence and Correlates of Orgasmic Function, Intercourse Satisfaction, Sexual Desire and Overall Satisfaction in a Men on Hemodialysis: A Multi-National Cross-Sectional Study** Mariacristina Vecchio,[1] Giorgia De Berardis,[1] Valeria Maria Saglimbene,[1] Marinella Ruospo,[1] David W. Johnson,[2] Jorgen B. A. Hegbrant,[3] Giovanni F. M. Strippoli.[1,3] *[1]Mario Negri Sud Consortium; [2]University of Queensland; [3]Diaverum Medical Scientific Office.*

Although sexual dysfunctions in men include orgasmic problems, intercourse dissatisfaction, sexual desire and overall satisfaction abnormalities, only erectile problems have been generally studied. In this cross-sectional study, we have evaluated the remaining aspects of sexual dysfunction in men receiving hemodialysis.

Patients were identified in 27 hemodialysis clinics selected randomly within a collaborative network. All domains of sexual dysfunction were assessed anonymously with the International Index of Erectile Function (IIEF-15) questionnaire. Multivariate logistic regression was used to determine correlates of the different domains of sexual dysfunction and data are presented as adjusted odds ratio (AOR) and 95% confidence intervals (CI) .

Overall, 1056 (60%) of 1611 eligible men responded. Of these, 773 (73%) men reported orgasmic dysfunction, 927 (88%) sexual desire dysfunction, 957 (91%) intercourse dissatisfaction and 790 (75%) overall dissatisfaction. Results on key correlates of these adverse sexuality outcomes identified by multivariate analyses are reported in the table.

## F-PO1493

**Ankle-Brachial Index Can Predict Mortality among Incident Patients in Hemodialysis** Zaida Noemy Cabrera Jimenez, Joao Egidio Romao, Jr., Benedito J. Pereira, Rodrigo B. Oliveira, Sonia Cristina S. Makida, Rosilene M. Elias. *Nephrology, University of Sao Paulo School of Medicine, Sao Paulo, SP, Brazil.*

**Background and Hypothesis:** Patients in hemodialysis have a high risk of mortality. Ankle-brachial index (ABI) is a non-invasive method reported to be useful in predicting mortality both in general population and prevalent hemodialysis patients (by detecting peripheral arterial disease). However, an analysis of ABI is lacking for incident patients in hemodialysis. We hypothesize that altered ABI can predict risk of death in incident patients on hemodialysis.

**Methods**: We prospectively followed 119 (83 men; age 53.1 ± 18.8 years old.) consecutive incident hemodialysis patients. Patients were prospectively followed until either death or end of period of observation up to 24 months. Patients were stratified into three groups according to ABI (<0.9; 0.9-1.3; >1.3) measured at entry by an oscilometric method.

**Results:** The mean ABI or all patients was 1.17 ± 0.22. There were 34 deaths occurring during the follow-up which mean duration of 12.7 ± 7 months. Table 1 shows characteristics of the three groups, regarding demographic and clinical variables. Highest mortality rate was observed in ABI <0.9 and >1.3. The survival curve analysis revealed that ABI 0.9-1.3 group had better outcomes than ABI <0.9 and ABI >1.3 groups (log-rank test p= 0.0096). There was no difference in survival between ABI <0.9 and >1.3 groups (log-rank test p= 0.694).

Demographic and clinical characteristics of the three groups

| | ABI < 0.9 | ABI 0.9-1.3 | ABI >1.3 | p |
|---|---|---|---|---|
| Age | 65 ± 17 | 53 ± 18 | 49 ± 19 | 0.030 |
| Sex male/female | 9/4 | 47/15 | 27/7 | 0.546 |
| Diabetes yes/no | 8/5 | 29/43 | 13/21 | 0.313 |
| Smoking yes/no | 4/9 | 23/49 | 10/24 | 0.966 |
| Death, n (%) | 7 (53.8) | 13 (18) | 14 (41.2) | 0.004 |

**Conclusion:** Our findings indicate that pathological ABI was a good predictor of risk of mortality among incident patients in hemodialysis. Screening patients by a simple ABI measurement can help to identify a high-risk group for increased mortality.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1494

**Seasonal and Circadian Variability in Body Temperature in Chronic Hemodialysis Patients** Stephan Thijssen,[1] Len A. Usvyat,[1] Frank Van der Sande,[2] Jeroen Kooman,[2] Nathan W. Levin,[1] Peter Kotanko.[1] *[1]Renal Research Institute, NY, NY; [2]Maastricht University Medical Centre, Maastricht, Netherlands.*

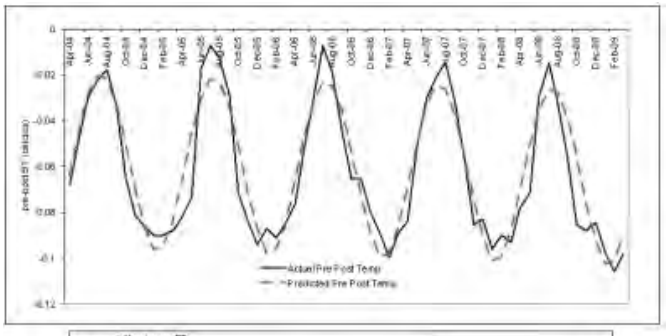
In hemodialysis (HD) patients, body temperature (BT) follows circannual and circadian rhythms. The aim of the present study was to assess seasonal and circadian variations in BT and intradialytic Δ in BT across diverse climatic US regions.

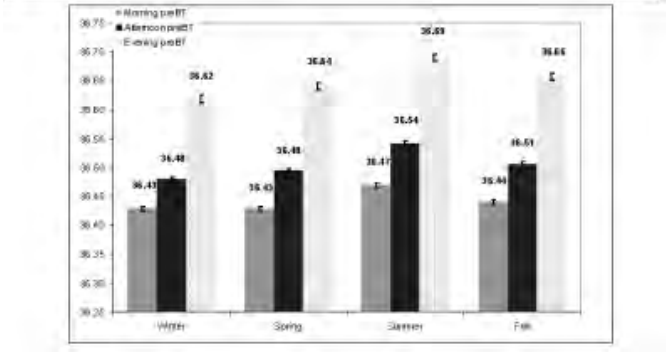
We reviewed data on HD pts treated in RRI clinics b/n Apr 1, 2004 and Mar 31, 2009. Seasons were defined on a calendar basis. Pre-dialysis BT (preBT) and post-dialysis BT (postBT) were recorded per txt. Intradialytic change in BT (BT) = preBT – postBT.

Cosinor analysis was conducted to test for seasonality in preBT and ΔBT. RRI clinics were grouped in distinct climate groups: continental, mediterranean, and subtropical. Consideration was given to the dialysis shift.

10,303 pts were studied (55% male, 49% black, 49% diabetic, avg age [stdev]: 60.5 [15.5] years). Across all climatic zones, preBT (in ºC) was lowest in the winter (mean [95% CI]): continental (36.49 [0.002]), mediterranean (36.37 [0.013]), subtropical (36.08 [0.01]). preBT was consistently highest in summer: continental (36.55 [0.002]), mediterranean (36.46 [0.012]), subtropical (36.08 [0.01]). Notably, in mediterranean & subtropical climates, where the magnitude of difference of outside temp is much smaller across seasons, BT varied suggesting a pattern independent of ambient temp.

Cosinor analysis over a 5 yr period demonstrated a seasonal component of preBT and ΔBT. Increase in ΔBT was largest in winter and smallest in summer.





Analysis of preBT by shift showed that morning pts have the lowest preBT across seasons while evening pts have highest preBT (fig).

This study demonstrates a seasonal influence on preBT and ΔBT. Morning pts in the winter experience the highest intradialytic increase in BT while evening summer pts experience the small ΔBT.

**Is Smoking a Risk Factor for Cardiovascular Events in HD Patients?** Ioannis (John) E. Droulias, Andreas Soloukides, Stamatina Papakonstantinou, Rainer Fischer, George Zervas, Efi Dampolia, Stylianos Zerefos, Dimitrios Valis, Nicolaos Zerefos. *Renal Unit"Hygeia" Hospital, Athens, Greece.*

**Introduction:** Atherosclerotic cardiovascular disease is a multifactorial condition including genetic factors, hyperlipidemia, hypertension, systemic inflammation and haemodynamic factors. It has already been showed by the Framingham Study and other studies, that the majority of causes of atherosclerotic disease are attributed to varying lifetime habits. Surprisingly, the influence of smoking in HD patients has so far received little attention concerning cardiovascular events in dialysis population, a group at monumental cardiovascular risk.

Aim: We have tried to study associations between smoking, new-onset cardiovascular outcomes and mortality in 120 patients of our Renal Unit who were followed for 5 years (2004-2009)

Methods-Results: Of the participants, 20 patients (16,6%) were lifetime smokers, 43 patients were lifetime nonsmokers (35,9%), 33 patients (27,5%) had quit smoking for more than 1 year, 15 patients (12,5%) were current smokers - new onset less than 6 months, 6 patients (5%) had quit smoking less than 1 year ago while 3 patients (2,5%) were lost in the follow-up. Patients were followed until 31 December 2009. When adjustment was made for baseline age, demographic variables, mode of dialysis therapy, and comorbidity, smoking status was associated with new-onset congestive heart failure (adjusted hazard ratio 1,59, P=0,004), new-onset peripheral vascular disease (adjusted hazard ratio 1,68, P=0,001) and mortality (adjusted hazards ratio 1,37, P<0,001). Former smokers, in contrast, had adjusted event risks similar to lifelong nonsmokers.

Conclusion: Smoking is a major, modifiable, cardiovascular risk factor in patients starting dialysis therapy. Discontinuation of above factor reduces the risk.

**Relationship of Mitral Annular Calcification and Coronary Artery Calcification in Hemodialysis Subjects** Ronney Sami Shantouf, Naser Ahmadi, Irfan Zeb, Jennie Jing, Matthew Jay Budoff, Kamyar Kalantar-Zadeh. *Medicine, LABiomed at Harbor-UCLA, Torrance, CA.*

Introduction: Vascular calcification is common among maintenance hemodialysis (MHD) subjects. This study aims to look at the relationship of mitral annular calcification (MAC) and coronary artery calcification (CAC) in hemodialysis subjects.

Methods: One hundred and sixty six MHD subjects, age 54±14 years, underwent cardiac CT. Both CAC and MAC scores were calculated. Subjects were categorized into three groups, CAC 0, CAC 1-100, and CAC 100+. Prevalence and extent of MAC was determined for each category. Adjusted odds ratio for the presence of MAC was determined using linear regression analysis.

Results: The prevalence and MAC score increased among CAC categories [CAC 0, MAC 5%, MAC score 1±7; CAC 1-100, MAC 24%, MAC Score 92±242; CAC 100+, MAC 45%, MAC Score 575±1558; prevalence of MAC p=0.002, MAC Score p=0.0001]. CAC 1-100 and CAC 100+ category demonstrated a higher likelihood of MAC with odds ratios of 5.27 [1.16-25.33, p=0.02] and 13.91 [1.76-59.60, p=0.01] when compared to CAC 0 after adjusting for age, gender, diabetes, hypertension, hyperlipidemia, family history of heart disease, smoking, vintage, dialysis dose, and mineral metabolism (table not shown).

Conclusion: The prevalence and likelihood of MAC increases as CAC scores increase in MHD subjects.

MAC Prevalence and Score among CAC categories

| Variable | CAC 0 N=18 | CAC 1-100 N=48 | CAC 100+ N=100 | P value |
|---|---|---|---|---|
| Prevalence of MAC | 5% | 24% | 45% | 0.002 |
| MAC score | 1±7 | 92±242 | 575±1558 | 0.0001 |

Disclosure of Financial Relationships: nothing to disclose

**F-PO1497**

**Ankle-Arm Index (AAI) as Predictor of Mortality on Hemodialysis** Jair Miguel,[1,2] Jorge Strogoff-de-Matos,[1] Luiz T. Naveiro,[1] Claudia M. Miguel,[1,2] Jocemir R. Lugon.[1] *[1]Universidade Federal Fluminense, Niteroi, RJ, Brazil; [2]Clinefron, Padua, RJ, Brazil.*

Aim: to assess the predictive value of AAI to risk of death among patients on maintenance hemodialysis (HD).

Material and methods: 478 patients prevalent on HD, from 6 dialysis facilities, underwent AAI measurement using mercury column sfigmomanometer and portable Doppler (10 MHz, Super Dupplex, Huntleigh Technology, Inc. NJ). Patients were divided into 3 groups, according to AAI (low: <0.9, normal: 0.9 to 1.3, and high: >1.3) and were followed for a 36-month period. Survival rate was assessed by Kaplan-Meier method and comparison between curves by Log-Rank test. Risk of death for each group was calculated using Cox proportional model, with adjustment to age, gender, diabetes status, smoking, and ultra-sensitive C reactive protein, having the normal group as reference.

Results: Participants were 54 (18 to 75) years old, 56% males, and 17% diabetics. The prevalence of low, normal and high AAI were 26.8%, 64.6% and 8.6%, respectively. The 3-year survival rate was lower in the groups with low AAI (60.3%, P <0.0001) and high AAI (69.0%, P= 0.034) than in the group with normal AAI (82.3%). After adjustment to variables, the presence of low AAI persisted to be significantly associated with the risk of death (hazard ratio [HR]= 1.78, 95% confidence interval [CI] 1.14 to 2.79; P= 0.012). High AAI presented a trend toward increasing the risk of death (HR= 1.94, 95% CI 0.99 to 3.80; P= 0.054).

Conclusion: Low AAI was found to be an important risk factor to death among HD patients. Despite the small number of patients with high AAI, that variable seems to have an impact on mortality, but statistical significance was not reached.

Disclosure of Financial Relationships: nothing to disclose

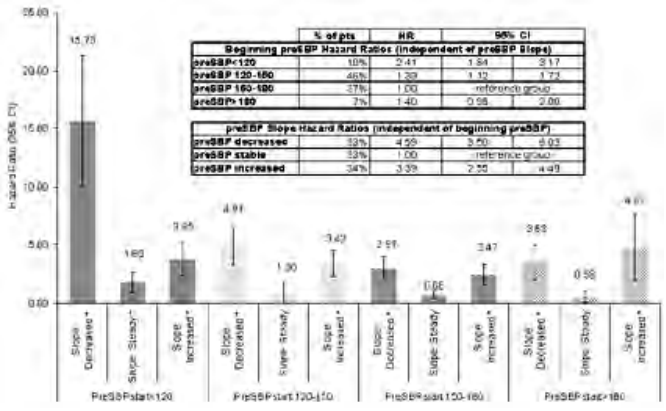
**F-PO1498**

**Patterns of Systolic Blood Pressure Change Affect Patient Outcomes in Incident Hemodialysis Patients** Len A. Usvyat, Peter Kotanko, Nathan W. Levin. *Renal Research Institute, NY, NY.*

The U-shaped curve relating blood pressure (BP) to outcomes in hemodialysis (HD) patients (pts) can be explained by the high mortality with both low systolic BP (Li AJKD 2006) and the hypertension on the left and right sides of the curve, respectively. We attempted to analyze this further.

We reviewed data of all RRI in-center HD pts starting dialysis b/n Jan 2000 and Dec 2009. Pts' pre-dialysis systolic blood pressures (preSBPSTART) were computed per pt as avg of first 30 days; the slope of BP change (preSBPSLOPE) was computed by linear regression using preSBP values in year one. Pts are stratified based on preSBPSTART and preSBPSLOPE (increased, decreased, stable).

N=7077 (56% male, 39% black, 53% white, 53% diabetic, age (SD) 62.2 (15.8)). Initial BPs predicted mortality, with worst survival in preSBPSTART<120 (HR=2.4; 95% CI 1.8-3.2) & preSBPSTART 150-180 with the lowest relative risk (table in fig). In all BP ranges, decreases in BP are associated with increased mortality (table in fig); survival was best in pts with stable BP. When the results of preSBPSTART and preSBPSLOPE are combined, pts with SBP<120 and decreasing slope have the highest HR of 15.7 [10.2-21.7] compared to the ref group of steady preSBPSLOPE and preSBPSTART 120-150 (fig).



Both upward and downward changes in BP have an unfavorable affect on survival. We hypothesize that declines in BP are due to progressive cardiomyopathy. This is reinforced by the lowest BP pts having the highest mortality. The adverse affect of increase in BP, possibly due to persistent overhydration is not surprising. However, the clinical problem presented by these data is that an apparently normal BP (as a result of decease in BP) may be misinterpreted as being satisfactory clinical situation when severe cardiac disease may be underlying the "normal" BP level.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1499**

**Arterial Stiffness in HD Patients Correlates with Early Cognitive Deficits** James B. Post, Kel G. Morin, Dwindally Rosado-Rivera, John P. Handrakis, Mary C. Sano, Ann M. Spungen. *Research & Development, James J. Peters VAMC, Bronx, NY.*

Despite extensive vascular disease and cerebrovascular morbidity in hemodialysis (HD) patients, little is known about the risk of arterial stiffness and its relation to early cognitive deficits. The purpose of our study was to compare arterial stiffness and cognitive function in HD patients with no clinical evidence of cerebrovascular disease (CVD) and appropriate controls matched for age, diabetes, hypertension, BMI, and hyperlipidemia. In 37 HD and 18 control subjects, the MMSE and detailed neuropsychological tests were performed to assess each of the following cognitive domains: Attention & mental processing speed (AMP), Executive function (EXF), Language (LAN), and Memory (MEM). Arterial stiffness was measured as common carotid artery pulsatility index (PI) using a B mode ultrasound and Pulse Wave Doppler portable unit. Composite domain scores were calculated by adding up the T scores of all tests assessed within each domain. Comparisons were made using t-tests, chi-squared tests, and regression models where applicable. There were no significant differences between HD and controls in age 62±10 vs. 63±11 y, years of education, ethnicity, hypertension, BMI, diabetes, or hyperlipidemia. In controls, mean PI was lower than the HD group 1.7±0.3 cm/s vs. 2.1±0.4 cm/s (p=.0005). HD was a significant risk factor for having an elevated PI (>1.8 cm/s) independent of other cardiovascular risk factors (p=.03). HD conferred an 8.8 fold increased risk of having an elevated PI (p=.001). In HD patients, PI correlated with AMP, independent of other risk factors (r=-.58, p=.04), and years on HD (r=.37, p=.02). In controls, there was no correlation between PI and cognitive function. All subjects had a MMSE score ≥26. HD patients had significantly lower composite scores in all domains: AMP 177±30 vs. 215±34 (p=.0001), EXF 114±20 vs. 129±20 (p=.01), LAN 78±12 vs. 99±11 (p<.0001), and MEM 169±27 vs. 189±29 (p=.01). Our results suggest that HD patients without clinical evidence of CVD demonstrate increased arterial stiffness which may be related to early cognitive deficits.

**F-PO1500**

**Characteristics of Chronic Hemodialysis Patients with Hypertension: Baseline Data of the OCTOPUS Study** Kunitoshi Iseki. *Dialysis Unit, University Hospital of the Ryukyus, Nishihara, Okinawa, Japan.*

Background: Hypertension is one of the culprits of poor survival in chronic hemodialysis (HD) patients, but the benefit of treatment and the target levels are not shown by prospective randomized clinical trial (RCT).

Methods: We, Okinawa Dialysis Study (OKIDS) group, are conducting a multicenter, randomized, parallel study of angiotensin receptor blockade (Olmesartan) in HD patients: Olmesartan Clinical Trial in Okinawan Patients Under OKIDS (OCTOPUS, CRG010600030). OCTOPUS is the first prospective intervention study to examine the benefits, if any, of treatment of hypertension with the target pre-HD blood pressure (BP) levels of 140/90 mm Hg. Patients were randomized into those with the use of renin-angiotensin system (RAS) inhibitors such as ARB and angiotensin converting enzyme inhibitors as RAS (+) and those without RAS inhibitors as RAS (-); the former uses Olmesartan and or other non-RAS antihypertensive drugs and the latter uses conventional antihypertensive drugs but not any RAS inhibitors. Randomization was done using sex and the primary renal disease (diabetes mellitus).

Results: A total of 469 chronic HD patients, N=235 in RAS (+) and N=234 in RAS (-), was registered during June 2006 and June 2008 in Okinawa, Japan. Subjects were 62% men, mean age 59.6 years, HD duration of 88 months, pre-HD systolic BP 159.1 mm Hg, pre-HD diastolic BP 80.7 mm Hg, and pulse rate 77.7 beats per minute. Data of home BP were available for 210 patients. Home and pre-HD systolic and diastolic BP, and pulse rate were significantly lower at home than those obtained at pre-HD state (paired t-test). However, there were no differences between the groups. Follow-up will end on June 2011.

Conclusions: In the OCTOPUS study, the baseline data were similar between those assigned to treat hypertension with RAS (+) and RAS (-). It may prove or disprove the merit of treatment of hypertension and the superiority of ARB as a treatment choice.

**F-PO1501**

**State-Level Geographic Variation in Statin Exposure among Dually Eligible ESRD Patients** Theresa I. Shireman,[1] James B. Wetmore,[1] Jonathan D. Mahnken,[1] Qingjiang Hou,[1] Sally K. Rigler,[1] John Spertus,[2] Edward F. Ellerbeck.[1] *[1]University of Kansas Medical Center, Kansas City, KS; [2]St. Luke's Mid-American Heart Institute, Kansas City, MO.*

HMG-CoA reductase inhibitors (statins) are a cornerstone of therapy for individuals with cardiovascular disease (CVD). We examined the prevalence of and factors associated with statin use among publicly insured dialysis patients. In a retrospective, cross-sectional sample of dually-eligible (Medicare - Medicaid) dialysis patients, we linked national Medicaid prescription claims data from 2002 with USRDS baseline data, derived from the CMS 2728 Medical Evidence Form, to examine how statin use was associated with various demographic and risk behavior factors, functional status, comorbidity, and dialysis modality. We also explored how use varied across states. Among 49,466 dialysis patients, 23.9% received a statin prescription [56.3%, atorvastatin; 28.7%, simvastatin; 11.2%, pravastatin; 3.9%, fluvastatin or lovastatin]. For persons with diabetes, 31.2% received statins compared to 16.3% of those without (p<0.001). For persons with CAD, 35.5% received statins compared to 21.1% of those without (p<0.001). Persons with higher BMIs had progressively higher rates of statin exposure (p<0.001). Caucasians also had higher exposure rates (28.9%) than African-Americans (20.2%) and Hispanics or other races (25.0% and 25.9%, respectively; p<0.001). In the multivariable analysis, male sex, non-Caucasian race, HF, substance abuse, and poor functional status were associated with less use of statins, while diabetes, CAD, hypertension, and prior CVA were associated with higher exposure. There was also substantial state-by-state variation: when adjusted for patient level factors, the adjusted rate ratios showed a 2.7-fold difference between the highest- and lowest-prescribing states. Statin exposure was generally lower than expected in dialysis patients, given the prevalence of known cardiac risk factors, although use was higher among persons with key risk factors. Noted variations in exposure by race, sex, and state of residence suggest areas for future research.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1502**

**Echocardiographic Evaluation of Left Ventricular Dysfunction and 4-Year's Follow-Up for Patients with End Stage Renal Disease on Hemodialysis** Jinil Yoo, Hugo J. Villanueva, Lin N. Lwin, Yisfalem W. Alamdew, Khashayar Sehhat. *Nephrology, Montefiore Medical Center, North Division, New York Medical College, Bronx, NY.*

A high cardiac morbidity and mortality is known to exist among patients (Pts) with endstage renal disease (ESRD) on hemodialysis (HD), especially with presence of left ventricular hypertrophy (LVH). The echocardiogram (ECHO) was performed at their prescribed dry weight, on 54 of a total 64 Pts who agreed to be enrolled. There were 18 African Americans (33%), 15 Hispanics (28%), 12 non-Hispanic Caribbeans (22%), 4 Caucasians (7%), 5 Asians (9%); average age of 63 years, 29 diabetics (54%), 50 hypertensives (93%), and average HD of 3.8 years. The following diagram is the summary of our Pts' ECHO findings and mortality rates based on LV systolic function (ejection fraction: EF%) and ECHO characteristics of LVH during 4-year's clinical follow-up after the initial ECHO.

| LV systolic function (EF %) | Distribution of Pts | Mortality rate (4 years) | ECHO characterstics | Distribution of Pts | Mortality rate ( 4 years) |
|---|---|---|---|---|---|
| EF ≤50 | 9/54(17%) | 7/9(78%) | Dilated LVH | 4/54(7.5%) | 3/4(75%) |
| EF >50 to <59 | 22/54(41%) | 11/22(50%) | Concentric LVH | 46/54(85%) | 18/46(39%) |
| EF ≥59 | 23/54(43%) | 4/23(17%) | Normal | 4/54(7.5%) | 1/4(25%) |

The initial ECHO study revealed LVH in 50/54 (93%), predominantly of concentric type, significant systolic dysfunction (EF≤50) in 9/54 (17%), EF≥59 in 23/54 (43%) and ECHO-Doppler evidence of diastolic dysfunction in 50/54 (93%). During the following 4 years' observation, the mortality rate (MR) on Pts with EF≤50 reached 78% (7/9) Vs 17% (4/23) on Pts with EF≥59, and MR on Pts with with dilated LVH leading to 75% (3/4) Vs 39% (18/46) on Pts with concentric LVH. The primary cause of death among Pts with EF<59 is cardiac 72% (13/18), CVA 11% (2/18) and malignancies 11% (2/18).

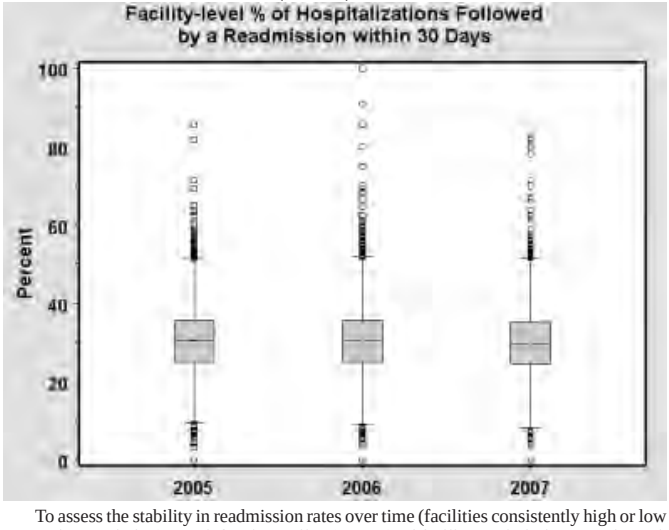
We believe that the majority of patients reaching ESRD develop LVH with significant systolic and/or diastolic dysfunction, which contributes to the extremely high cardiac morbidity and mortality. We feel that initial ECHO evaluation is beneficial to all Pts entering ESRD stage for the prognostic implications and therapeutic endeavor to decrease adverse cardiac events.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1503**

**30-Day Hospital Readmission among Dialysis Patients: Influence of Dialysis Facilities Versus Hospitals** Marc Turenne,[2] S. Hunter,[1] Robert A. Wolfe,[2] T. H. Shearon,[1] Jeffrey Pearson,[2] John Kalbfleisch,[1] Claudia Dahlerus,[2] John R. C. Wheeler,[1] J. M. Messana,[1] Richard Hirth.[1] *[1]Univ of Michigan KECC; [2]Arbor Research.*

Hospital readmission is a relatively common occurrence in the ESRD population. In 2007, 31.7% of hospitalizations among Medicare dialysis patients were followed by a readmission within 30 days. There may be a role for multiple providers, including hospitals and dialysis facilities, in preventing readmissions. Using Medicare claims, we examined inpatient hospitalizations for dialysis patients in 2005-2007. There is substantial variation in readmission rates across facilities (n=5,050).



To assess the stability in readmission rates over time (facilities consistently high or low vs. random variation), we defined quartiles (Q1-Q4) of facility readmission rates in each year. This yielded: 5.4% of facilities remained in Q4 for all 3 years, while 22.2% remained in Q3 or Q4, 4.6% remained in Q1, and 20.8% remained in Q1 or Q2.

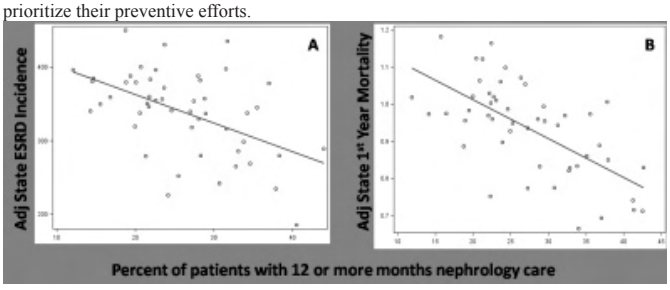
Using 2007 data (n=378,480 claims), we used a generalized linear model with a logit link to model readmission within 30 days, with random effects for facility and hospital. Fixed effects included patient age, race, sex, and diabetes. Facility and hospital random effects were both highly significant based on likelihood ratio tests ($p<0.0001$). The estimated SD in readmission rates was 4.5% across facilities and 4.3% across hospitals. The patient-level adjustments had little impact on the results. The results suggest that dialysis facilities and hospitals provide nearly equal components to the variation in readmissions. The potential influence of dialysis facilities over hospital readmissions may be an opportunity to reduce their high frequency among ESRD patients. Factors that cause readmissions and policies that might encourage facilities or other providers to prevent them should be explored further.

Disclosure of Financial Relationships: Research Funding: The Dialysis Outcomes and Practice Patterns Study (DOPPS) is administered by Arbor Research Collaborative for Health and is supported by scientific research grants from Amgen (since 1996), Kyowa Hakko Kirin (since 1999, in Japan), Genzyme (since 2009), and Abbott (since 2009), without restrictions on publications.

**F-PO1504**

**Longer Nephrologist-Driven Care Associated with Lower Mortality and Lower Incidence of End Stage Renal Disease in the United States** Elizabeth Hedgeman,[1] N. A. Lueth,[1] T. H. Shearon,[1] Brenda W. Gillespie,[1] Laura C. Plantinga,[2] Neil R. Powe,[2] Nilka Rios Burrows,[3] Desmond Williams,[3] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of California San Francisco, San Francisco, CA; [3]Centers for Disease Control and Prevention, Atlanta, GA.*

The Healthy People guidelines recommend individuals with declining kidney function receive care from a nephrologist a minimum of 12 months prior to the start of ESRD. Using data from the Centers for Medicare and Medicaid Services' Form 2728, we assessed pre-ESRD data in > 260,000 individuals beginning ESRD therapy during 2005-2007. Nationwide, 24.4% of patients had been under the care of a nephrologist for ≥12 months. In most instances, ≥ 12 months of care from a nephrologist was associated with better health and preparedness outcomes than 6-12 months of care (fistula at start, higher albumin, higher hemoglobin, transplant options discussed, all odds ratios were $p<0.05$). Importantly, ≥12 months of nephrology care was associated with a significant reduction of first-year mortality after ESRD onset (adjusted Hazard Ratio=0.58, $p<0.0001$). Wide variation was observed in the duration of nephrology care prior to ESRD onset by state of residence at time of ESRD start. Both incidence rates of ESRD ($R^2=0.25$, $p<0.001$) as well as the first-year standardized mortality ratios ($R^2=0.40$, $p<0.001$) were lower in states with greater proportions of individuals with ≥12 or more months of nephrology care (Figure; panels A and B). Nephrology care for ≥12 months in advance of ESRD has the potential both to reduce the incidence of ESRD in the country as well as mortality after ESRD onset. Further research to investigate factors underlying observed geographic disparities is needed to improve care of patients with CKD and allow public health authorities to prioritize their preventive efforts.



Disclosure of Financial Relationships: nothing to disclose

**F-PO1505**

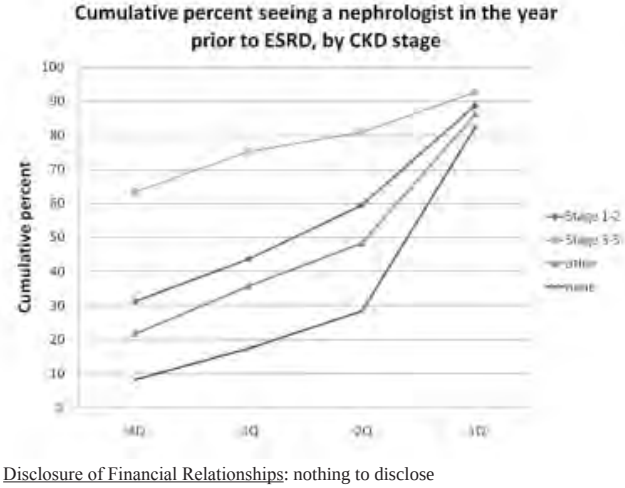
**Frequency of Nephrologist Claims Prior to ESRD Initiation by CKD Stage** David A. Zaun,[1] David T. Gilbertson,[1,2] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

This study investigates the cumulative percent of CKD patients that visit a nephrologist prior to ESRD using Medicare data. Patients included were age 67+ incident ESRD in 2008. Nephrologist claims were studied 12 months prior to ESRD and CKD stage was defined from two years to a year prior to ESRD. CKD stage was grouped into four categories: stage 3-5 CKD (a stage 3, 4, or 5 claim), stage 1-2 CKD (a stage 1 or 2 claim), other (a non stage specific CKD claim); and no CKD (no CKD claims).

Many patients are not recognized to have CKD a year prior to ESRD: 27.6% with no CKD, 1.8% with stage 1-2 CKD, 53.8% with stage 3-5 CKD, and 16.8% with other CKD. Some patients not recognized to have CKD likely had CKD. Many patients are not referred to a nephrologist: 20% with stage 3-5 CKD, 40% with stage 1-2 CKD, 50% with non stage specific CKD, and 70% with no CKD were still not referred to a nephrologist 3 months prior to ESRD.

The percent of patients seeing a nephrologist one year to three quarters prior to ESRD was different across groups: 8.2% with no CKD, 21.8% with non stage specific CKD, 31.3% with stage 1-2 CKD, and 63.5% with stage 3-5 CKD. By the time patients reached ESRD the percent seeing a nephrologist within the year prior to ESRD was similar across the groups: 82.6% with no CKD, 86.4% with non stage specific CKD, 88.9% with stage 1-2 CKD, and 92.7% with stage 3-5 CKD. This is higher than historically seen in the Medical Evidence Form.

There is a large percentage of patients not recognized as having CKD, any stage, 12 to 24 months prior to ESRD. Many patients do not see a nephrologist until the quarter prior to ESRD. Although there is a dramatic increase in the percent of patients with nephrologist claims in the quarter prior to ESRD, there is little time to address CKD care, manage risk factors, and plan for ESRD treatment.



Disclosure of Financial Relationships: nothing to disclose

**F-PO1506**

**Medicare Part D Enrollment and Medication Use and Costs in US Dialysis Patients in 2007** Eric D. Weinhandl,[1] Benjamin L. Howell,[2] Wendy L. St. Peter,[1,3] Christopher Powers,[2] James P. Ebben,[1] Diane L. Frankenfield.[2] *[1]U.S. Renal Data System, MMRF, Minneapolis, MN; [2]ORDI, CMS, Baltimore, MD; [3]Univ. of Minnesota, Minneapolis, MN.*

**Background**: Studies have found that dialysis patients take 11-12 medications at any point in time. The Medicare Part D drug benefit may assist patients in acquiring medication. Predictors of enrollment and descriptors of use are largely unknown. **Methods**: We used data from the United States Renal Data System to assess enrollment in and use of the Part

D benefit in prevalent dialysis patients in 2007. We included dialysis patients alive on Jan 1, 2007, who continued dialysis and carried Medicare Parts A and B during all of 2007 (*N*=196,101). **Results**: Full-year enrollment was 69.2%. From logistic regression, factors positively associated with enrollment included younger age; female gender; black *vs.* white race; hypertension *vs.* diabetes as primary end-stage renal disease [ESRD] cause; shorter ESRD duration; presence of cardiovascular (excepting dysrhythmia and ischemic heart disease), gastrointestinal, and liver disease, along with COPD and diabetes; and absence of cancer and dysrhythmia. There was also geographic variability. In patients with full-year enrollment, 80.0% received low-income subsidy (LIS). Younger age, female gender, and black *vs.* white race were positively associated with LIS receipt. In patients receiving LIS, 95.5% took ≥1 medication, and mean cumulative medications were 13.6 (standard deviation [SD], 7.4). Corresponding estimates in patients not receiving LIS were 93.4% and 11.3 (6.4). Gross drug costs (GDC) per patient per year (PPPY) were higher in patients receiving LIS *vs.* not, although out-of-pocket [OOP] costs PPPY were lower.

| | GDC PPPY† | % with >$2400 GDC | % with >$5451 GDC | OOP costs PPPY† |
|---|---|---|---|---|
| with LIS | $6694 (6186) | 74.9 | 47.6 | $113 (224) |
| without LIS | $4181 (4386) | 60.8 | 15.3 | $1549 (1341) |

†mean (SD)

**Conclusion**: There is high variability in Part D enrollment across patient factors, although most patients enrolled in Part D used the benefit. While high prevalence of LIS may mitigate concern about medication accessibility in the coverage gap, substantial out-of-pocket costs in patients without LIS may preclude appropriate treatment.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1507

### Hemodialysis (HD) Patients Utilizing Kidney Specialty Pharmacy Have Higher Medication Adherence, Fewer Hospitalizations and Lower Healthcare Costs

Harold J. Manley, Steven Wang, Allen R. Nissenson. *DaVita Inc., Denver, CO.*

HD patients' medication adherence and healthcare utilization patterns based upon pharmacy type selection (chain, independent, or specialty) are unknown. In 2004, DaVita Rx (DVA Rx), a kidney specialty pharmacy began operations serving dialysis patients by providing prescription services within the dialysis clinic. We hypothesized that HD patient's medication adherence and healthcare utilization are impacted by pharmacy selection. We evaluated HD patient medication adherence and per member per month (PMPM) healthcare costs and hospitalization rate (per member per thousand days, PMPT) based on pharmacy type (e.g., chain, independent, DVA Rx)

METHODS: We conducted a retrospective review of all pharmacy (Rx) and medical claims for 750 HD patients from 1/06 to 6/09 enrolled in an ESRD Medicare Demonstration project. Patients who filled >70% of all prescriptions using a specific pharmacy type were assigned to a specific group. We calculated medication adherence behavior using medication possession ratio (MPR): MPR = Σ Medication Day's Supply/(# Days between the first fill & the last refill + Day's supply last refill). We used a multivariate analysis to estimate pharmacy type effect on MPR, PMPM costs, and PMPT hospitalization rates after controlling for confounding variables.

RESULTS: 472 HD patients were assigned into a specific pharmacy type (62 DVA Rx; 355 Chain, 55 Independent). DVA Rx patients had more patients with MPR values > 0.8 than either pharmacy type: DVA RX 84.0%, Chain 37.9%, Independent 46.9% ($p<0.003$). Utilizing a 1:1 propensity match, DVA Rx patients had lower PMPT and PMPM costs compared to non-DVA Rx patients (Table).

| | DaVita Rx (N=59) | Non-DaVita (N=59) |
|---|---|---|
| Medical PMPM | $4,477 | $4,791 |
| Medication PMPM | $637 | $745 |
| Total Cost | $5,114 | $5,536 |
| Admits PMPT | 1024 | 1435 |

CONCLUSION: Use of DVA Rx kidney specialty pharmacy by HD patients was associated with higher medication adherence rates, fewer hospitalizations, and lower total healthcare costs compared to those filling their prescriptions at a chain or independent pharmacy.

Note: This is a DaVita analysis of CMS demonstration experience; CMS will conduct an independent evaluation.

## F-PO1508

### Financial Evaluation of the Centers for Medicare & Medicaid Services (CMS) End-Stage Renal Disease (ESRD) Disease Management (DM) Demonstration

Sylvia Paz B. Ramirez,[1] Sean M. Lyons,[2] W. Pete Welch,[2] Christine Cheu,[1] Jeffrey Pearson,[1] Claudia Dahlerus,[1] Tania Chowdhury,[1] Brett Lantz,[1] Sabrina K. Gomes,[1] Friedrich K. Port.[1] *[1]Arbor Research; [2]Lewin.*

We examined: 1) to what extent did CMS pay more for enrollees in 3 DM Organizations (DMOs) than had they remained in fee-for-service (FFS) and 2) are there savings to DMOs resulting from differences in service utilization.

Propensity score matching identified a comparison FFS population to minimize selection bias; multiple regression adjusted for remaining differences in observed factors, including age, sex, race, Hispanic ethnicity, geography, Medicaid status, new enrollee status, ESRD vintage, comorbidity, and ESRD cause. Costs for DMO enrollees had they remained in FFS were estimated from comparison group claims. Capitated Medicare payments to DMOs were compared to these estimated costs. Estimated savings to DMOs were the product of utilization difference (FFS-DMO) and FFS cost for hospital admissions, skilled nursing facility (SNF) stays, emergency department (ED) visits, and physician (MD) visits.

Mean capitated payments for DMO patients ($6,551 per patient per month) exceeded the estimated cost of remaining in FFS ($5,776), a mean difference of $774 or a 13.4% higher cost to Medicare. Capitated payments were higher: 11.2% in DMO A, 10.9% in DMO B, and 14.7% in DMO C. Estimated savings differed by DMO. DMO C experienced savings primarily due to fewer hospital admissions. For DMO A, excess hospitalizations fell over time.

| | DMO A | | | | DMO B | | | | DMO C | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | 2006 | 2007 | 2008 | 2006-2008 | 2006 | 2007 | 2008 | 2006-2008 | 2006 | 2007 | 2008 | 2006-2008 |
| Hospital Admissions | -$1,951 | -$2,624 | -$391 | -$1,564 | -$3,097 | $769 | -$3,655 | -$1,822 | $1,411 | $490 | $3,238 | $1,575 |
| SNF Stays | $956 | $944 | $506 | $765 | -$73 | $723 | -$102 | $229 | $983 | $1,295 | $1,231 | $1,217 |
| ED Visits | $146 | $50 | $211 | $136 | -$90 | $136 | $269 | $167 | $33 | -$43 | $35 | -$5 |
| MD Visits | $336 | $289 | $119 | $224 | $77 | $104 | $56 | $78 | $96 | $118 | $192 | $135 |
| Est. Total Savings | -$513 | -$1,349 | $445 | -$472 | -$3,183 | $1,732 | -$3,432 | -$1,294 | $2,523 | $1,860 | $4,695 | $2,927 |
| Est. Total Savings % | -9.6% | -17% | 5% | -9% | -45% | 25% | -43% | -20% | 33% | 24% | 59% | 37% |

CMS paid more under Medicare Advantage than it would have had patients remained in FFS consistent with studies of Medicare managed care programs. There was marked variation in cost savings and losses by DMO; one DMO demonstrated consistent reduction in hospitalization admissions which translated to cost savings. DM has potential to reduce costs by reducing service utilization.

## F-PO1509

### Utilization of High Cost Services in the Centers for Medicare & Medicaid Services End Stage Renal Disease (ESRD) Disease Management (DM) Demonstration

Sylvia Paz B. Ramirez, Jeffrey Pearson, Christine Cheu, Claudia Dahlerus, Tania Chowdhury, Brett Lantz, Sabrina K. Gomes, Friedrich K. Port. *Arbor Research.*

Hospitalization rates for ESRD patients (pts) have changed little since 1980. ESRD is an ideal target for DM because of comorbidities, fragmented patient (pt) management, high morbidity and mortality, and use of high cost services.

Each DM Organization (DMO) developed a program with clinical interventions and focus areas. DMO in-center hemodialysis pts were compared with similar pts in traditional fee-for-service (FFS) Medicare using propensity score matching on age, sex, race, Hispanic ethnicity, geography, Medicaid status, new enrollee status, ESRD vintage, comorbidity, and ESRD cause. Services evaluated included hospital admissions, readmissions, length of hospital stay (LOS), total hospital days (TD), physician (MD) visits, emergency department (ED) visits, and skilled nursing facility (SNF) stays.

For 2006, 2007, and 2008, respectively, the analyses included 242; 408; and 415 pts in DMO A; 78; 170; and 191 pts in DMO B; and 529; 959; and 612 pts in DMO C. Corresponding numbers of FFS pts were included as controls. Overall there were marginally fewer admissions, MD visits, ED visits, and SNF stays but more readmissions, TD, and longer LOS. DMO C had fewer admissions than FFS: in 2008, 12% (and 19% fewer readmissions). DMO A reduced excess admissions and readmissions by 2008 when rates became very similar to FFS. Admission and readmission rates in DMO B fluctuated suggesting unstable estimates due to fewer pts. All three DMOs had longer LOS and TD than FFS. Generally, DMOs had fewer MD and ED visits and SNF stays than FFS.

| | DMO A | | | | DMO B | | | | DMO C | | | | All | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | 2006 | 2007 | 2008 | All | 2006 | 2007 | 2008 | All | 2006 | 2007 | 2008 | All | 2006 | 2007 | 2008 | All |
| Hospital Admissions | -8% | -10% | -1% | -6% | -17% | -4% | -17% | -10% | -6% | -2% | -12% | -7% | -2% | -6% | -8% | -6% |
| Total Hospital Days (TD) | +15% | +12% | +24% | +26% | +74% | +17% | +75% | +54% | -8% | +21% | +12% | +15% | +15% | +23% | +25% | +23% |
| Readmissions | -8% | +18% | +12% | +14% | +91% | -4% | +51% | +40% | -9% | -3% | -19% | -10% | -2% | -2% | -1% | +1% |
| LOS | +7% | +20% | +29% | +18% | +48% | +22% | +49% | +40% | +16% | +24% | +28% | +24% | +17% | +19% | +29% | +24% |
| MD Visits | -48% | -37% | -15% | -30% | -18% | -22% | -10% | -14% | -17% | -18% | -27% | -20% | -28% | -23% | -21% | -23% |
| ED Visits | -24% | -7% | -26% | -19% | +9% | -11% | -24% | -14% | -4% | -5% | -3% | -1% | -8% | +6% | -11% | -6% |
| SNF Stays | -41% | -36% | -22% | -32% | +12% | -51% | +7% | -13% | -57% | -57% | -49% | -53% | -47% | -52% | -34% | -44% |

DM may reduce use of costly services. Admission and readmission rates were persistently lower in DMO C. Hospital use was greater in DMOs A and B, though a trend toward reduced admissions over time was seen in DMO A.

Disclosure of Financial Relationships: Research Funding: Arbor Research receives funding for DOPPS from Amgen, Kyowa Hakko Kirin, Abbot and Genzyme.

## F-PO1510

### Characteristics of Dialysis Facilities Losing Income under the CMS Proposed Payment System

Fredric O. Finkelstein, Alan S. Kliger. *Hospital of St. Raphael, Yale.*

**Background**. CMS reported the average dialysis facility will lose an average of 2% Medicare income in 2011 under a new proposed payment system (PPS). Estimates suggest some types of facilities will lose more income than others but variances were not reported. Independent facilities will be more vulnerable to large payment reductions and treatment quality may be jeopardized. Our objective was to analyze the range of payment losses and characteristics of facilities predicted to sustain the greatest losses.

**Method**. We merged the CMS Payment flat file with the 2009 CMS Dialysis Compare file enhanced with US Census data. Amount of predicted loss (PPS income 2007 - Medicare payments in quintiles) was tabulated by type of facility: large dialysis organization (LDO), Regional, Independent, Hospital; number of treatments: <3000,3000-9999,>10,000; census region; urban/suburban/rural; and % minority in zip code population.

**Results**. The 2007 CMS flat file identified 4921 facilities: 60.7% were LDOs, 15.3% Regional chains, 11.2% Independent, 9.6% hospital; 3.3% unknown. In 2009, the CMS provider files indicated that the number of LDO facilities grew by approximately 10% from 2007. The following results are classification current in 2009. The top quintile (N=985) of income losers under the PPS will lose a median average of 10.8% on a median income of $1.65 million. Loses will be higher for LDOs (625, -11.4%) and lower for Independents (102, -7.8%). Top losers were concentrated in the South Atlantic (30.8%) and South Central

(30.6%) census regions. Compared to all Independent facilities those in the high loss quintile were more likely to be rural and performing 3000 – 9999 treatments.

**Conclusions**. Large numbers of facilities will lose far more than an average of 2% Medicare income under the bundled model putting them at risk of failure. Losses were not evenly distributed. Failure of at risk facilities could selectively reduce access to care.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1511

**Integrated Care Management (ICM) Is Associated with Improved Patient Mortality: Results from the CMS ESRD Disease Management Demonstration Project** Stephen D. McMurray, Peter F. Sauer, Robert E. Farrell. *Integrated Care Management, Fresenius Medical Care, Walthan, MA.*

Fresenius Medical Care Health Plan (FMCHP) participated in the CMS ESRD Disease Management Demonstration project. CMS implemented the demonstration to test the effectiveness of an integrated care program & enhanced benefits provided to ESRD patients enrolled in disease specific Medicare Advantage plans. We were able to provide additional benefits (AB) and services to members beyond those available in FFS Medicare with the hypothesis that we could decrease mortality in this vulnerable population. The AB include home tele-health devices, Kidney Tel nurse, nutritional supplements, flexible benefit plan, transportation support and free glucometers and test strips. The results are from data collected from patients enrolled in the program 2006-2009. The mortality results were compared to the most recent USRDS data reports. Table 1 lists the results.

FMCHP Mortality as Compared to USRDS: Deaths per 100/pt yrs

| USRDS | FMCHP 2006 | FMCHP 2007 | FMCHP 2008 | FMCHP 2009 |
|---|---|---|---|---|
| 21.2 | 11.5 | 9.46 | 10.8 | 8.5 |

Note: FMCHP is participating in a CMS demonstration, this is an FMCHP analysis of CMS demonstration experience, and CMS will conduct an independent evaluation

The mortality rate for the FMCHP population has consistently been half the most recent USRDS mortality rate of 21.2 deaths per 100 /pt yrs.

Summary: ICM and the provision of additional benefits reduced mortality in the ESRD Medicare patients as compared to FFS Medicare.

Disclosure of Financial Relationships: Employer: Fresenius Medical Care; Ownership: Fresenius Medical Care.

### F-PO1512

**Pharmacy Management Improves Facility Performance** Richard Mutell, Steven M. Wilson, Carey Colson, Tracy Jack Mayne, Josh Golomb. *DaVita Inc., Denver, CO.*

ESRD patients take an average of 8-11 oral medications per day. Research has shown that pharmacy management can improve patient outcomes, but this has been largely unexplored in ESRD patients. The purpose of this study is to assess the impact of pharmacy management on the facility-level DaVita Quality Index (DQI), a measure previously shown to predict hospitalizations and mortality.

Methods: This was retrospective analysis of 1945 HD dialysis facilities from 1/1/09 to 4/30/10 at a US dialysis organization. Pharmacy management included insurance management, prescription fulfillment, adherence support, and coordination of care with physicians and facility staff. DQI is a composite variable of weighted P, Ca, PTH, albumin, hemoglobin, KT/V, vaccination rates, and vascular access. The mineral and bone disease (MBD) component includes weighted P, PTH and Ca measures. The independent variable in all analyses was the percent of facility patients enrolled in pharmacy management. The primary outcomes were facility-level DQI and MBD scores, and percent of patients with P, PTH and Ca in KDOQI recommended ranges. Analyses were conducted using a Generalized Linear Mixed Model.

Results: Over the course of the study, mean pharmacy management enrollment increased from 11.9%-19.0%. There was a positive and statistically significant relationship between proportion of patients enrolled in pharmacy management and facility-level DQI & MBD scores, and percent of patients in KDOQI range for P and PTH. There was no significant effect on Ca.

| | beta (SE) | p-value |
|---|---|---|
| DQI score | 0.05 (0.007) | <0.001 |
| MBD score | 0.01 (0.003) | <0.001 |
| % P ≤ 5.5 mg/dL | 0.07(0.015) | <0.001 |
| % PTH 150-300 pg/nl | 0.006 (0.018) | <0.001 |
| % Ca<9.5 mg/dL | -0.01 (0.012) | 0.27 |

Conclusions: The burden of treatment, including a high number of medications and daily pill consumption, creates a high potential for inadequate compliance and persistence on important medications. Pharmacy management that focuses on access and adherence can improve important outcomes in dialysis care.

Disclosure of Financial Relationships: Employer: DaVita, Inc.

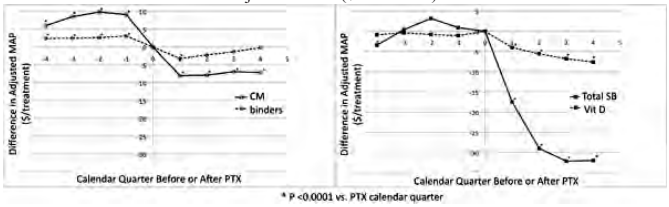
### F-PO1513

**Relationship between Parathyroidectomy (PTX) and Medicare Allowable Payment (MAP) for Separately Billed Services (SB) in Chronic Dialysis Patients** J. M. Messana,[1] Richard Hirth,[1] Marc Turenne,[2] K. Sleeman,[1] Jeffrey Pearson,[1] Jesse L. Roach,[1] John R. C. Wheeler.[1] *[1]Kidney Epidemiology & Cost Center, U Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Given the cost of calcimimetics (CM) and vitamin D analogs (vit D), inclusion of these drugs in an ESRD payment bundle could create financial incentives to perform more PTX in dialysis patients. To define the magnitude of this incentive, we used 2006-08 Medicare Claims data to model total SB and injectable vit D costs and Medicare Part D costs for CM, oral vit D and phosphorus binders (binders) for 4 calendar quarters before and after PTX.

Patients were included in the analysis if Medicare dialysis and Part D claims were available in 4 or more consecutive quarters before and after a quarter with a PTX claim. SB services, including injectable medications, labs and Part D Claims for vit D, CM and binders were calculated for each patient as ($/treatment/quarter). Linear regression models adjusted for age, sex, race and comorbidities were used to estimate MAP for SB and Part D services before and after PTX. (n= 1644; pt quarters= 14895)

Estimated Differences in Adjusted MAP ($/treatment) for SB and Selected Part D



* P <0.0001 vs. PTX calendar quarter

PTX is associated with sustained reduction in SB MAP for at least one year after surgery. Only a fraction of this reduction is explained by vit D use. In addition, CM and binder cost also decreased after PTX. The magnitude and duration of total SB savings will create financial incentives to perform PTX in an expanded bundle, whether or not Part D drugs are included. The combination of cost savings and possible improved survival associated with PTX (Kestenbaum, Kidney Int, 2004) suggests that additional cost-effectiveness analysis is warranted. In addition, PTX rates should be monitored closely after implementation of the expanded payment bundle.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1514

**Disease Management (DM) and Patient-Centered Outcomes in the Centers for Medicare and Medicaid Services (CMS) End Stage Renal Disease (ESRD) DM Demonstration** Claudia Dahlerus,[1] Sylvia Paz B. Ramirez,[1] Brett Lantz,[1] Caitlin C. Oppenheimer,[2] Alycia Infante,[2] Elizabeth Hargrave,[2] Jeffrey Pearson,[1] Christine Cheu,[1] Tania Chowdhury,[1] Sabrina K. Gomes,[1] Friedrich K. Port.[1] *[1]Arbor Research; [2]NORC.*

We evaluated the impact of the DM Demonstration on QoL and patient (pt) satisfaction for pts enrolled in 3 DM organizations (DMOs) 20062008.

The QualityMetric Short Form 12v2 or SF-36 survey collected QoL data. US DOPPS comparison pts completed the Kidney Disease Quality of Life survey. A 5 point change in the Mental Component Summary (MCS) or Physical Component Summary (PCS) composite scores was clinically meaningful. Baseline scores were compared to scores at ≥12 mos. Adjusted changes in scores were assessed with repeated measures linear mixed models controlling for baseline demographic and clinical variables.

Pt satisfaction data were collected from focus groups (2006), follow-up telephone interviews (2007), and a different sample of enrollees in 2008.

Baseline DMO QoL response rates were 17% - 87% for pts completing ≥1 survey; follow-up at 12 mos was 27% - 59%. Adjusted MCS and PCS scores did not change significantly for DMOs A and C, similar to the US DOPPS. DMO B had statistically significant but not clinically meaningful declines in adjusted scores.

Table 1

| | MCS | | PCS | |
|---|---|---|---|---|
| DMO | Change[1] | p-value | Change | p-value |
| A | 0.79 | 0.69 | -0.15 | 0.93 |
| B | -1.47 | <0.01 | -1.09 | <0.01 |
| C | 0.46 | 0.29 | -0.07 | 0.85 |
| All | -0.02 | 0.96 | -0.29 | 0.33 |
| US DOPPS | 0.28 | 0.51 | 0.01 | 0.99 |

[1]on 100-point scale

Results indicate overall pt satisfaction with DMO services (2006 = 4.6, 2007 = 4.6, 2008 = 4.5, on a 5-point scale). Overall satisfaction with DMO A increased by 2008 and decreased slightly with DMO C. Main reasons for disenrollment were misunderstandings about DMO plan services, and cost/billing issues.

Findings for enrollees suggest no clear impact of DM improving QoL. High satisfaction was observed among pts interviewed who remained in the DMOs. Separate data suggest disenrollment may be related to poor health, with sicker enrollees more likely to disenroll.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1515**

**Use and Costs of Anti-Diabetic Medications in U.S. Adult Dialysis Patients with Medicare Part D, 2007**

Wendy L. St. Peter,[1,3] Christopher Powers,[2] Eric D. Weinhandl,[1] Benjamin L. Howell,[2] James P. Ebben,[1] Diane L. Frankenfield.[2]
*[1]USRDS Coordinating Center, MMRF, Mpls, MN; [2]ORDI, CMS, Baltimore, MD; [3]College of Pharmacy, University of MN, Mpls, MN.*

**Background:** Nearly 52% of prevalent dialysis patients (pts) in 2007 had diabetes mellitus (DM) as primary end-stage renal disease (ESRD) cause or a comorbid condition. Metformin and exenatide are contraindicated and other diabetes drugs should be used with caution in severe kidney disease. **Methods:** We used Part D data in Medicare's Chronic Condition Warehouse linked to administrative data from the United States Renal Data System to assess the use and costs of insulin and oral anti-diabetic medications in prevalent adult dialysis patients with DM in the U.S. in 2007. All adult pts alive on Dec 31, 2007 with Part D coverage during all of 2007 were included in the study (n=93,540). **Results:** Insulin was used by 52% of pts, with 16% using rapid, 13% short, 12% intermediate, 24% long-acting and 17% pre-mixed insulin. Use of insulin was higher in younger (< 65 yr), female, White, and Hispanic pts, as well as in those with shorter dialysis duration. Sulfonylureas were the most commonly used oral agents (18%) followed by thiazolidinediones (TZDs) (13%). Metformin was used in 0.7% of pts and exenatide in 0.1% of pts. Medications to be used with caution (chlorpropamide, tolazamide, tolbutamide) were used by < 0.2% of pts. Sulfonylurea use was higher in older (≥ 45 yr), White, Asian/Pacific Islander, and Hispanic pts.; use was lower in those with longer dialysis duration. TZD use was higher in older (≥ 45 yr), American Indian/Alaska Native, Asian/Pacific Islander and Hispanic pts. Across ESRD Networks, there was variation in use of insulin (47-57%), sulfonlyureas (15-26%) and TZDs (9-21%). During 2007, average total costs per patient per year was about $660 for insulin, $88 for sulfonylureas, and $1088 for TZDs. Average out-of-pocket cost per prescription was $9.26 for insulin, $2.49 for sulfonylureas, and $12.67 for TZDs. **Conclusions:** Despite contraindications, metformin and exenatide are being used in some dialysis patients. Variation exists in approaches to anti-diabetic drug treatment in adult Medicare beneficiaries receiving dialysis.

**F-PO1516**

**Calcium-Based Phosphate Binders Are Associated with Better Outcomes in Haemodialysis Patients: Results from the French ARNOS Study**

Guillaume Jean,[1] X. Moreau-Gaudry,[2] Denis Fouque.[3] *[1]Hémodialyse, Centre de Rein Artificiel, Tassin, France; [2]Hémodialyse, AGDUC, Montélimar, France; [3]Néphrologie Hémodialyse, Hôpital Edouard Herriot, Lyon, France.*

**Background:** A short-term favourable effect of phosphate binders (PB) on incident HD has recently been reported (1). The association between the use of calcium-based phosphate binders (CBPB) and risk for vascular calcification remains unclear.

**Objective:** To assess the impact of prescribing PB, using CBPB or sevelamer HCl (SV), on survival in a French HD cohort.

**Methods:** Baseline PB prescription was recorded using a cross-sectional analysis of patients in 25 centres from the regional ARNOS French cohort. A prospective 42-month survival analysis study was performed according to PB, CBPB (Caco3) and SV, using crude and adjusted models.

**Results:** In July 2005, 1347 HD patients (mean age, 67.3 ± 14 years) on dialysis since 63 ± 75 months were included in this study. CBPB was prescribed in 55% of cases, SV was prescribed in 42% of cases, a mixed PB was prescribed in 24% of cases, and 26% of all patients were not prescribed PB. By using crude survival analysis, we found that compared to the group without PB prescription, the group prescribed with PB was associated with less mortality: hazards ratio (HR), 0.69 [0.57–0.89]; in case of CBPB: HR, 0.7 [0.6–0.85], and in the case of SV: HR, 0.8 [0.67–0.96]. Using Cox proportional model adjusted for age, dialysis vintage, gender, diabetes, calcaemia, phosphataemia, PTH, and comorbidities, PB prescription was found to be associated with less mortality (HR, 0.7 [0.5–0.83]), especially in the case of CBPB (HR, 0.64 [0.4–0.78]), but not in the case of SV (HR, 1.13 [0.92–1.3]). A mixed PB prescription was not associated with outcomes (HR, 0.92 [0.7-1.18]).

**Conclusion:** PB prescription is associated with a favourable effect on survival in a French HD population. This favourable impact is mainly associated with the prescription of calcium carbonate. Further studies are needed to confirm these results in dialysis patients.

**F-PO1517**

**Use and Costs of Phosphate Binders in U.S. Dialysis Patients with Medicare Part D in 2007**

Wendy L. St. Peter,[1,3] Christopher Powers,[2] Eric D. Weinhandl,[1] Benjamin L. Howell,[2] James P. Ebben,[1] Diane L. Frankenfield.[2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]ORDI, CMS, Baltimore, MD; [3]College of Pharmacy, University of Minnesota.*

**Background:** Management of hyperphosphatemia in dialysis patients (pts) has been associated with lower mortality risk. Use of phosphate binders is an important component of managing hyperphosphatemia. **Methods:** We assessed use and costs of selected phosphate binders in adult U.S. dialysis pts in 2007 with Part D data from Medicare's Chronic Condition Warehouse linked to administrative data from the United States Renal Data System. All pts alive on December 31, 2007, with Part D coverage during all of 2007, were included (n=169,443). **Results:** Overall, 79% of pts used the following phosphate binders, with 50%, 39% and 13% using sevelamer, calcium acetate (CA), and lanthanum, respectively. Binder use was higher in younger (< 65 yr), female, Asian/Pacific Islander, and Hispanic pts, as well as in those with longer dialysis duration (≥ 2 yr) and pts dialyzing in for-profit facilities. There was also variation in binder use by facility affiliation, with pts dialyzing in the facilities of a large dialysis organization (LDO) having highest binder use. CA use was higher in White, Asian/Pacific Islander, and Hispanic pts, as well as in those dialyzing in DCI facilities. CA use decreased as dialysis vintage increased. For both sevelamer and lanthanum, use was higher in younger (< 65 yr) pts, as well as in those with greater dialysis duration and in pts dialyzing in LDO facilities. Across ESRD Networks, binder use ranged from 68 to 84% (CA 32 to 57%; sevelamer 38 to 64%; lanthanum 9 to 21%). Average total cost per person per year was about $2007 for all phosphate binders, with $420 for CA, $2442 for sevelamer, and $1596 for lanthanum. Average out-of-pocket cost per prescription was $17.39 for all phosphate binders, $11.39 for CA, $20.79 for sevelamer and $21.49 for lanthanum. **Conclusions:** Despite highest total cost per patient per year, sevelamer was the predominant phosphate binder used in 2007. Part D data from 2007 indicate there was variation in use of phosphate binders by geographic region, in addition to some patient and facility characteristics.

**Factors Associated with Cinacalcet Initiation in Hemodialysis (HD) Patients**

Wendy L. St. Peter,[1,2] David A. Zaun,[1] Craig Solid,[1] Ryan D. Kilpatrick,[3] Jiannong Liu,[1] Kimberly M. Nieman,[1] Britt B. Newsome.[4] *[1]Chronic Disease Research Group, MMRF, Minneapolis, MN; [2]U of MN; [3]Amgen, Inc., Thousand Oaks, CA; [4]Denver Nephrologists, P.C., CO.*

**Background:** Many dialysis patients (pts) receive cinacalcet for secondary hyperparathyroidism. Objectives of this study were to describe pt characteristics and predictors associated with cinacalcet prescription to inform case-mix adjustment pertaining to cinacalcet inclusion in proposed end-stage renal disease (ESRD) prospective payment system (PPS). **Methods:** We used a linked DaVita and Centers for Medicare and Medicaid Services dataset with 45,589 prevalent HD pts in August 2004 with follow-up through July 2007. Pts had Medicare as primary payer and used IV vitamin D in baseline period (Aug. 1 to Oct. 31, 2004). Pts with modality change or kidney transplant were excluded. Pts were grouped by parathyroid hormone (PTH) baseline categories (<150, 150-300, >300-600, >600 pg/mL). Adjusted Cox regression was used to predict time to cinacalcet initiation. **Results:** 17,576 non-cinacalcet and 7,674 cinacalcet pts were included. Cinacalcet pts were younger, had longer vintage, were more often African American (AA), used more AV fistulas, had higher median PTH, mean corrected calcium and phosphorus, lower comorbidity burden, slightly higher albumin, higher hemoglobin, lower WBC, higher weekly IV vitamin D and daily phosphate binder doses, more consistent IV vitamin D use, less diabetes as ESRD cause. Characteristics in cinacalcet pts and nonusers varied by PTH category at baseline, e.g. in PTH>600 pg/mL category, consistency of IV vitamin D use was higher in nonusers. Initial doses >30 mg/day were more often prescribed in younger, higher vintage, and AA pts. Lower doses were more often prescribed in pts with diabetes. The strongest predictors of cinacalcet prescription were younger age, female gender, African-American race, vintage 5 years, higher body mass index, AV fistula use, PTH >300 pg/mL, corrected calcium >10.2 mg/dL, phosphorus 5 mg/dL, and sevelamer >7200 mg/day. **Conclusions:** Cinacalcet is preferentially used in AAs. Payment policy for ESRD-related oral medications under PPS should take this into account.

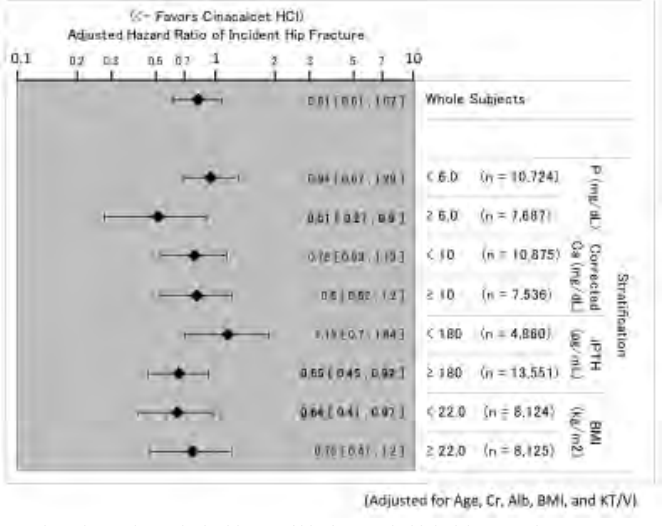
**One-Year Administration of Cinacalcet HCl and Effect on Hazard Ratio of Incident Hip Fracture in Large Japanese Hemodalysis Cohort** Naohiko Fujii, Takayuki Hamano, Masatomo Taniguchi, Takashi Shigematsu, Shigeru Nakai, Kunitoshi Iseki, Yoshiharu Tsubakihara. *Nephrology Department, Committee of Renal Data Registry of the Japanese Society for Dialysis Therapy, Tokyo, Japan.*

Cinacalcet reduces the incidence of bone fracture according to the combined analysis of four randomized clinical trials (KI 2005). It is not clear whether we have similar results in daily practice, or in the real world.

We used the nationwide Japanese Renal Data Registry surveyed at the end of year of 2007 and 2009. The prevalence of hip fracture was studied in these surveys, making it possible to calculate the incidence of hip fracture for 2 years by subtraction in those who had never experienced hip fracture at the time of 2007. Cinacalcet became available at the beginning of 2008 in Japan. The prescription of cinacalcet was retrospectively studied at the end of 2009. Enrolled patients are those who underwent HD 3 times/week and had been dialyzed for at least 1 year. Those who had a history of peritoneal dialysis, kidney transplantation, parathyroidectomy, or PEIT for hyperparathyroidism were excluded from the analysis. As a per-protocol analysis, we treated patients as treated who had been receiving this drug for more than 1 year. We made matched control group of patients who had never received this drug using propensity score based on the data collected at the end of 2007, when cinacalcet was not available.

Cinacalcet Group consists of 6,137 patients and 12,274 control patients were selected (1:2 matching). Cox regression model revealed that hazard ratio (HR) of incident fracture in cinacalcet treated patients was 0.81 (95% C.I. 0.61, 1.07). In subgroup analysis for those with intact PTH>180 pg/mL, or serum phosphate>6.0 mg/dL, and BMI<22.0, the HR was significantly lower than 1.0.



Cinacalcet reduces the incidence of hip fracture in high risk HD patients.

**F-PO1520**

**Cinacalcet Hydrochrolide Reduces Mortality in Hemodialysis Patients with Secondary Hyperparathyroidism** Takayuki Hamano, Naohiko Fujii, Masatomo Taniguchi, Takashi Shigematsu, Shigeru Nakai, Kunitoshi Iseki, Yoshiharu Tsubakihara. *Committee of Renal Data Registry of the Japanese Society for Dialysis Therapy, Tokyo, Japan.*

Pooled analysis of four randomized controlled trials revealed that cinacalcet reduces cardiovascular hospitalization in dialysis patients with secondary hyperparathyroidism. However, it is not known whether it reduces mortality in the real world.

We used the nationwide dialysis registry (Japanese Renal Data Registry) surveyed at the end of year of 2007, 2008, and 2009. The number of surveyed patients was 290,675 at the end of 2009. The prescription of cinacalcet was retrospectively studied at the end of 2009. Enrolled patients are those who underwent hemodialysis 3 times/week and had been dialyzed for at least 2 years. Prior to analysis, we excluded those with a history of parathyroidectomy or percutaneous ethanol injection therapy. In intention to treat analysis, we treated these patients as treated who have ever received cinacalcet (Cin Group). Therefore, even patients who had quitted this drug because of adverse effect were included in Cin Group. We made matched control group of patients who had never received this drug using propensity score based on the data collected at the end of 2007, when cinacalcet was not available in Japan. Age, sex, dialysis vintage, diabetic status, serum creatinine, albumin, corrected calcium, phosphate, PTH, CRP, BMI, Kt/V, history of amputation, bone fracture, congestive heart failure, myocardial infarction were matched. Cin Group consists of 5,278 patients and 10,556 control patients were selected (1:2 matching). One-year all-cause mortality (from the end of 2008 to the end of 2009) was compared between control group and Cin Group. Cox proportional hazard model revealed that hazard ratio of cinacalcet was 0.41 (95% CI 0.20, 0.84, P value 0.01). Using Poisson regression model did not alter the result at all.

These results indicate for the first time that cinacalcet reduces mortality in hemodialysis patients with secondary hyperparathyroidism in the real world. Future studies will be needed as to which therapy is more beneficial in reducing mortality, cinacalcet or parathyroidectomy.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1521**

**Efficacy and Safety of Paricalcitol Injection (PC) and Maxacalcitol Injection (OCT) in Subjects with Secondary Hyperparathyroidism Receiving Hemodialysis (HD)** Tadao Akizawa,[1] Michael Amdahl,[2] Samina Khan,[2] Utpaul Audhya.[2] *[1]Showa University School of Medicine, Representative of ABT-358 Study Group; [2]Abbott Laboratories.*

**Purpose:** The Japanese Society for Dialysis Therapy recommends an intact parathyroid hormone (iPTH) level between 60 and 180 pg/mL for HD patients. This study compared the efficacy and safety of PC to OCT in Japanese HD subjects with SHPT.

**Methods:**

This was an open-label, multi-center, 12-week study. Eligible subjects (iPTH: ≥300 pg/mL, Ca 8.4 ≤ - <10.2 mg/dL, and P ≤6.5 mg/dL after washout) were allocated to PC or OCT treatment groups in a 1:2 ratio (PC to OCT) based on iPTH at screening. Study drug was injected 3 times a week. The PC group received an initial dose of 2 µg, with dose adjustments in 1 µg increments. The OCT group received an initial dose of 5 µg or 10 µg based on iPTH (<500 pg/mL, and ≥500 pg/mL), with dose adjustments in 2.5 µg increments. The OCT was not held per label for an iPTH level <150 pg/mL in this study. Subjects were titrated to an iPTH level of 60-180 pg/mL. Efficacy was assessed in 45 subjects who completed ≥8 weeks of therapy. Safety was evaluated in all subjects. Efficacy assessments used the mean iPTH value during the last 3 weeks of treatment.

**Results:**

Of the 47 subjects, 14 received PC and 33 received OCT. Three subjects were withdrawn due to adverse events (1 PC and 2 OCT subjects). Efficacy rates in PC group were higher than those in the OCT group in all predefined efficacy endpoints (Table 1). The incidence rates of hypercalcemia (Ca >11.5 mg/dL or 2 consecutive values ≥11.0 mg/dL) in PC and OCT groups were 0% and 9.1%. The incident rates of hyperphosphatemia (2 consecutive values ≥7.0 mg/dl) in PC and OCT groups were 14.3% and 12.1%.

Table: Efficacy of PC Group Compared to OCT Group

| Efficacy endpoints | PC %(n) | OCT %(n) |
|---|---|---|
| Proportion of subjects with ≥ 50% reduction in iPTH | 53.8 (7/13) | 37.5 (12/32) |
| Proportion of subjects with iPTH target range of 60-180 pg/mL | 30.8 (4/13) | 15.6 (5/32) |
| Proportion of subjects with ≥ 50% reduction in iPTH and without hypercalcemia | 53.8 (7/13) | 34.4 (11/32) |
| Proportion of subjects with iPTH target range of 60-180 pg/mL and without hypercalcemia | 30.8 (4/13) | 12.5 (4/32) |

**Conclusion:**

The study suggests that PC has better efficacy and less hypercalcemia compared to OCT. These findings must be confirmed in a larger study.

**Active Vitamin D3 (VitD) Administration and Insulin Resistance in Chronic Hemodialysis (CHD) Patients** Adriana Hung,[1,2] Mary B. Sundell,[1] Natalia E. Plotnikova,[1] Aihua Bian,[2] Ayumi Shintani,[2] Edward Siew,[1] Charles D. Ellis,[1] Feng Sha,[1] T. Alp Ikizler.[1,2] *[1]Medicine, Vanderbilt University, TN; [2]Biostatistics, Vanderbilt University, TN; [3]Nashville VA, TN.*

Background: Active vitamin D administration in CHD patients has been the mainstay to control secondary hyperparathyroidism. However it has been recently recognized that Vitamin D deficiency is linked to increased cardiovascular risk both in the general population and in CHD patients. One of the postulated metabolic mechanisms implicated in the increased risk include its effects on insulin resistance (IR).

Design: In a pilot double blinded randomized clinical trial, 10 prevalent CHD patients (52.9 years old, 100% African American, 33% females, 33% with history of diabetes, body mass index 34.8 kg/m2) on stable VitD treatment were taken off their VitD for 8 weeks. iPTH levels were kept at baseline levels (within 10%) by administration of Cinacalcet as needed. At the end of 8 weeks, patients were randomly assigned to continue Cinacalcet or to restart an active vitamin D analog. The primary outcome was insulin resistance assessed by glucose disposal rate (GDR) measured by hyperinsulinemic euglycemic clamp (HEGC). Other important measures included other indirect indices of IR and serum adipokines.

Results: PTH levels were not associated with GDR at baseline (p=0.7). There was no detectable change in the GDR after withholding VitD at Week 8; p=0.7). There was also no effect of treatment assignment on GDR (Week 8 to Week 16 period; p=0.8). Similar results were achieved using more practical indices of IR such as HOMA, HOMA AD, leptin-adiponectin ratio (LAR) or QUICKI. Propensity scores were used in all analysis to balance clinical characteristics between groups and prevent selection bias.

Conclusion: This study showed no effect of Vitamin D on IR measured by HEGC or on indirect indices of IR while on a background of Cinacalcet.

### F-PO1523

**Decreased Epoetin Utilization Associated with Conversion to Ferumoxytol IV Iron Protocol** Amit Sharma,[1] Betsy J. Lahue.[2] *[1]Boise Kidney and Hypertension Institute, Boise, ID; [2]AMAG Pharmaceuticals, Lexington, MA.*

**Purpose**: To evaluate drug utilization and anemia outcomes with conversion to a new IV iron protocol.

**Methods**: A retrospective chart review selected chronic hemodialysis patients receiving ferric gluconate or ferumoxytol from May 2009-May 2010 at two clinics. Demographics, iron indices, hemoglobin values, IV iron and epoetin (EPO) doses were collected; patients with no lab values were excluded. Conversion was defined as the date when >80% of the unit's patients received ferumoxytol; January 2010 for Site 1, October 2009 for Site 2. Descriptive statistics were generated to compare values in pre- and post-conversion months.

**Results**: Review of 167 charts identified 155 patients for study, 85.2% received ≥ 1 IV iron dose. Site 1 had 8 months of pre-conversion data and 5 months post, while site 2 had 5 months pre- and 8 months post data. Compared to site 2, site 1 population was slightly older (63 v. 62 years), had similar dialysis vintage (1.5 median years), had more female patients (51% v. 45%) and had more patients of Caucasian ethnicity (82% v. 66%). Anemia management protocols for EPO and IV iron were identical for site 1 and 2. Comparing pre and post conversion values for all months available, both units used less EPO per patient; the mean monthly EPO (IU) total dose was reduced 19% at Site 1 (41,760 pre v. 33,929 post p=.08) and 26% in Site 2 (75,227 pre v. 55,538 post, p<0.01). Comparing cumulative IV iron utilization for equal time frames (5 months pre and 5 months post), following conversion the total grams consumed decreased by 27% in Site 1 and increased by 40% in site 2. Pooling the 2 sites, 5 month iron utilization increased 18% (123 g pre to 145 g post). Iron indices remained stable post conversion, the mean unit hemoglobins (g/dL) were consistent (11.2 pre to 11.2 post, p=.75) and mean TSATs increased slightly (33% pre to 36% post).

**Conclusions**: In hemodialysis patients, changing IV iron protocol from ferric gluconate maintenance to ferumoxytol bolus was associated with increased total iron use and decreased EPO utilization while maintaining anemia outcome parameters within target ranges.

### F-PO1524

**Increased Ferumoxytol Utilization Associated with Decreased Total Anemia Treatment Utilization** Amit Sharma,[1] Betsy J. Lahue,[2] Kellie Y. Becker,[3] Denise Vanvalkenburgh.[3] *[1]Boise Kidney and Hypertension Institute, Boise, ID; [2]AMAG Pharmaceuticals, Lexington, MA; [3]Liberty Dialysis, Mercer Island, WA.*

**Purpose:** To evaluate the impact of implementing a ferumoxytol protocol for treatment of iron deficiency anemia on the utilization of iron, epoetin (EPO) and anemia outcomes.

**Methods:** Anemia treatment utilization was collected across a medium-sized dialysis organization (MDO) from October 2009 through March 2010. Data abstracted was summarized at unit level on monthly and quarterly basis including total patients treated, proportion treated with each anemia drug, total IV doses, total EPO units, and unit hemoglobin labs. Total utilization across MDO sites and mean hemoglobin values per clinic per quarter were compared.

**Results:** From October to December 2009 (Q4), ferumoxtol treatment was 4% of the iron administrations and 22% of total MDO IV iron grams consumed. During Q4 2009, ferric gluconate and iron sucrose comprised 96% of IV iron administrations (47% and 31% of grams, respectively). From January to March 2010 (Q1), ferumoxytol use doubled to 48% of total grams. Comparing Q4 2009 to Q1 2010, the MDO treated more patients (4576 v. 5221) with a higher proportion of patients receiving treatments of iron (53% v. 65%) and EPO (86% to 94%). Total anemia drug utilization decreased for both iron and EPO from Q4 to Q1, with units consumed per treated patient decreasing by 20% for EPO (214,138 to 170,341 IU) and 29% iron (1316 to 933 mg). Hemoglobin values were available for approximately 90% of the patients Q4 and Q1, demonstrating similar proportions of unit population met targets (77% v 78% Hbg 10-12 g/dL, 5% v. 5% Hbg<10 g/dL).

**Conclusions:** As a MDO implemented broader ferumoxytol use and increased patients treated for anemia, treatment utilization decreased and unit populations remained within desired anemia management parameters. Results suggest increased efficiency in anemia treatment protocols, however further research is required to determine ferumoxytol's impact on per patient utilization.

Disclosure of Financial Relationships: Consultancy: Amgen, AmagResearch Funding: AMAG, AFFYMAX, Luitpold, AMGEN; Honoraria: AMGEN, AMAG; Scientific Advisor: AMAG, AMGEN.

### F-PO1525

**Current Status of Dialysis Initiation and Survival in Japan: Effect of Transfer and Facility** Norio Hanafusa, Hiroshi Nishi, Kunihiro Yamagata, Toshio Shinoda, Kunitoshi Iseki, Yoshiharu Tsubakihara. *The Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan.*

**Background:** Little is known about the dynamics and the relationship on survival in Japanese incident hemodialysis (HD) patients.

**Study protocol:** Observational retrospective study using Japanese Society for Dialysis Therapy (JSDT) registry data.

**Methods:** We used a standard analysis file from the JSDT registry database (JRDR-09104). All incident HD patients in 2006 were included (N=34,682). The outcome was examined in 2007. The status of transfer was evaluated as comparing both the HD initiated unit and the year-end HD unit in 2006. We examined relationship between the dynamics of the patients and one-year mortality using logistic analyses adjusted for age, sex and others. We excluded those without pertinent information.

**Results:** A total of 32,398 were included in this study and 86.2% of them started HD at hospital and the rest of them at clinics. The vast majority of the facilities (81.1%) had one or more incident patients. Those who were transferred from the original HD unit during 2006 were 40.8%. The "hospital HD initiation" and "remained at the original HD unit" groups were significantly poor survival, OR 3.84: 95% CI 2.78–5.44 and OR 7.19: 95% CI 4.48–12.5, respectively. Both groups experienced significantly higher rates of death from infection (both p<0.05). Those who began HD at hospitals and remained at the original HD unit showed higher mortality rate at shorter duration of HD. However, in other groups of incident HD patients the causes of death were evenly distributed and lower rate of mortality

**Discussion:** This is the first report on the dynamics of incident HD patients and the relation between the patient dynamics and the survival in Japan. Nursing home residents were reportedly poorest survival after initiating HD [NEJM 361:1539, 2009]. The dynamics of incident HD might warrant further information that covers more socio-economic conditions.

**Conclusions:** Results showed that the dynamics of incident HD patients has impact on survival. Reasons for poorer survival among incident HD patients who did not move remained to be determined.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1526

**White Blood Cell Count Relates to Dialysate Glucose Concentration in Chronic Hemodialysis Patients** Jochen G. Raimann,[1,2] Len A. Usvyat,[1] Stephan Thijssen,[1,2] Nathan W. Levin,[1] Peter Kotanko.[1,2] *[1]RRI, NY; [2]BIMC, NY.*

**Background**

In 2009, over the course of several months, all US hemodialysis (HD) clinics of the Renal Research Institute comprehensively switched dialysates from 200 mg/dL glucose (G200) to 100 mg/dL glucose (G100). Dialysate glucose concentrations above the serum glucose level can lead to diffusive shifts of glucose and raise the serum level (Schneditz, ASAIO 2010). Elevated serum glucose induces oxidative stress and secretion of pro-inflammatory cytokines (e.g. TNF-α, IL-6, IL-8). This is particularly pronounced after acute short-term hyperglycemia (Esposito, Circulation 2002) and may lead to an increase of WBC (van Oostrom, J Lipid Res 2003). The present study investigates the relationship between the switch from G200 to G100 and WBC and neutrophil-lymphocyte ratio (NLR) in chronic HD patients.

**Methods**

WBC and NLR were obtained six months before ($M_{-6}$) and six months after ($M_{+6}$) the change from G200 to G100. Individual differences in WBC and NLR between $M_{+6}$ and $M_{-6}$ were assessed by paired T-test and by multivariate analysis adjusted for age, dialysis vintage, gender, race, diabetes status, change in dialysate to serum sodium gradient, equilibrated normalized protein catabolic rate (enPCR) and post HD weight. A 12 months interval was chosen to account for potential seasonal variability in patient parameters. Data are displayed as mean±SD.

**Results**

We enrolled 1664 patients (age 61±15 yrs, vintage 4±3 yrs, 755 Blacks, 829 diabetic subjects). Univariate analysis showed significant differences of WBC ($M_{-6}$: 6.7±2.1 * $10^3$/$mm^3$ vs. $M_{+6}$: 6.6±2.2 * $10^3$/$mm^3$; P<0.01), but no significant differences of NLR ($M_{-6}$: 3.3±3.3 vs. $M_{+6}$: 3.5±2.4; P=0.14). This drop in WBC remains significant after multivariate adjustment (change in WBC between $M_{-6}$ and $M_{+6}$: -0.11 * $10^3$/$mm^3$ (95% CI -0.12 to -0.10; P<0.001).

**Conclusion**

This study reveals a small but significant decline of WBC following the reduction of dialysate glucose from 200 to 100 mg/dL. We hypothesize that this decline in WBC is related to the reduced prevalence of dialysis-induced hyperglycemia with the use of G100 dialysates.

**F-PO1527**

**Blood Pressure Prevalence and Control in the General Population and the Incidence of Renal Replacement Therapy (RRT): An Ecological Study of 192 Health Areas** Clare I. Castledine,[1] Julie A. Gilg,[1] Charles Tomson,[2] David Ansell,[1] Fergus J. Caskey.[2,3] *[1]UK Renal Registry, Bristol, United Kingdom; [2]Richard Bright Renal Unit, Southmead Hospital, Bristol, United Kingdom; [3]Clinical Science North Bristol, University of Bristol, United Kingdom.*

**Introduction:** UK healthcare is commissioned via 192 health areas. The UK Renal Registry (UKRR) collects data electronically on all RRT patients and has reported UK-wide variation in RRT incidence. Since 2004 the Quality Outcomes Framework (QOF), a pay-for-performance scheme for primary care physicians, provides data on the prevalence and control of hypertension in the general population.

**Methods:** An ecological design was used, with each health area contributing an observation. RRT incidence per area in 2007-2008 was obtained from the UKRR database and standardised for age and gender. The prevalence of known hypertension in the general population and the percentage of patients achieving BP<150/90 in each health area were obtained from QOF.

**Results:** The 192 health areas had a median population of 255,900 (IQR, 184,000-390,000). There was an average of 6642 new patients starting RRT each year. Each 1% point rise in hypertension prevalence was associated with 2% higher incidence of RRT (incidence rate ratio (IRR) 1.02, 95%CI 1.01-1.03 p<0.0001). After adjustment for area-level ethnicity and socio-economic deprivation the IRR was 1.06, 95%CI 1.05-1.07 p<0.0001 and after adjustment for life expectancy & cancer mortality IRR was 1.08, 95%CI 1.06-1.1 p<0.0001. Each 1% point rise in percentage of hypertensive patients achieving BP<150/90 was associated with reduced RRT risk (IRR 0.94, 95%CI 0.93-0.95 p<0.0001). After adjustment for area-level ethnicity and deprivation each 1% point rise was associated with an IRR of 0.93,95%CI 0.92-0.94 p<0.0001 and after adjustment for life expectancy/cancer mortality IRR was 0.95 ,95%CI 0.94-0.96p<0.0001.

**Conclusions:** In the UK a 1% point increase in hypertension prevalence was associated with up to 8% higher RRT incidence. Furthermore every 1% point increase in the percentage of registered hypertensive patients achieving moderate BP control was associated with 5% fewer patients commencing RRT.

**F-PO1528**

**Hemodialysis in a Satellite Unit: Clinical Performance Target Attainment and Health-Related Quality of Life** Michael Diamant,[1,2] Ann Young,[1,2] Kerri Gallo,[1] Wang Xi,[3] Rita Suri,[1,3] Amit X. Garg,[1,2,3] Louise M. Moist.[1,2,3] *[1]Division of Nephrology, Department of Medicine, London Health Sciences Centre, London, ON, Canada; [2]Epidemiology & Biostatistics, Schulich School of Medicine and Dentistry, University of Western Ontario, London, ON, Canada; [3]Schulich School of Medicine and Dentistry, University of Western Ontario, London, ON, Canada.*

Background and Objectives: In Canada, patients are increasingly receiving hemodialysis in satellite units, which are closer to their community but further from tertiary care hospitals and their nephrologists. The process of care is different in the satellites with fewer visits from nephrologists and reliance on remote communication. The objective of this study is to compare clinical performance target attainment and health related quality of life (HRQOL) in patients receiving hemodialysis in satellite versus in-centre units.

Design, setting, participants, and measures: The London Health Sciences Centre in London, Ontario, Canada has both tertiary care centre and satellite hemodialysis units. All eligible patients who received dialysis treatment at one of these units as of July 24, 2008 were enrolled into a cross-sectional study (n=522). Patient attainment of hemoglobin, albumin, calcium-phosphate (Ca-P) product, Kt/V, and vascular access targets were compared. Participants were also administered the Kidney Disease Quality of Life Short-FormTM questionnaire.

Results: Patients in both units had similar demographics while in-centre patients had a higher comorbidity index score (5.4 vs. 4.6 [p= 0.005]). Satellite patients were more likely to attain clinical performance targets for albumin (adjusted odds ratio [OR]= 4.87 [2.13, 11.14]), hemoglobin (OR=1.59 [1.08, 2.35]), and Ca-P product (OR=2.02 [1.14, 3.60]), as well as for multiple targets (p < 0.05). HRQOL scores were largely similar between groups.

Conclusions: Patients receiving hemodialysis in a satellite unit were just as likely, or more likely, to demonstrate attainment of clinical performance targets as those dialyzing in-centre, while maintaining a similar HRQOL. This supports the increased use of satellite units to provide care closer to the patient's community.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1529**

**Novel MRSA Reduction Practices in Inpatient Renal Care** Mark G. Parker,[1] August Valenti,[1] Sheila Parker,[1] Rosalie Blenkhorn,[1] Michelle Duval,[1] Curt Lindberg,[2] Mark Munger,[2] Peter Chingos,[1] Kimberly Harvey,[1] Bradley N. Doebbeling.[3] *[1]Maine Medical Center, Portland, ME; [2]Plexus Institute, Bordertown, NJ; [3]Regenstrief Institute, Indianapolis, IN.*

The MRSA Reduction Collaborative is an AHRQ-funded seven hospital Quality Improvement consortium tasked to study the application of systems improvement and positive deviance to reduce MRSA transmission. In July 2009, Maine Medical Center introduced Toyota LEAN methods and social/behavioral change dialogues on the medical renal floor and inpatient dialysis unit to identify effective practices to reduce MRSA transmission. A core group facilitates identification and implementation of prevention strategies determined by frontline personnel. Process and outcome measures include total practice changes, hand hygiene compliance, admission and discharge nasal and peri-rectal MRSA screening rates, and new asymptomatic conversions to MRSA carriage. Since the introduction of the collaborative, at least 90 practice changes have been implemented. Staff compliance with hand hygiene prior to patient encounters has increased from 77% to 90.5% ($p$=.0001). Admission and discharge MRSA screening rates have increased from 61.6% to 90.5% ($p$<.0001) and 68.5% to 77.3% ( $p$=.0043), respectively. Conversions have fallen from 1.49/1000 patient days immediately prior to intervention to 0.80/1000 patient days over the most recent two quarters. Poisson model estimates for MRSA conversions revealed that in the period since the intervention(s), there has been an 11% ( $p$=.570) decrease in the expected number of MRSA conversions, an estimate of about .89 (95% CI .61-1.32) conversions per quarter year compared to about 1.01 (95% CI .72-1.31) prior to the collaborative. A combined LEAN and positive deviance approach for reduced MRSA transmission has resulted in quantifiable process improvement on an acute care nephrology floor and dialysis unit. Though reduction in MRSA transmission is not yet definitively demonstrated in these preliminary analyses, lack of increase in the incidence of new MRSA transmissions in the context of intensified screening suggests the potential efficacy of this strategy.

**Small Solute Clearance in Obese Pediatric HD Patients** Colin T. White,[1] Diane L. Frankenfield,[2] Stuart Goldstein,[3] Cherry Mammen,[1] Alicia M. Neu.[4] *[1]BC Children's Hospital; [2]Centers for Medicaid & Medicare Services; [3]Cincinnati Children's Hospital and Medical Center; [4]Johns Hopkins Medical Institutions.*

CMS' ESRD Clinical Performance Measures Project collected data on all prevalent in-center pediatric (0- <18 yrs) HD pts since 2000. Utilizing 2000-2008 data, we assessed the relationships between body mass index standard deviation score (BMI SDS) and achievement of NKF/KDOQI HD adequacy targets (spKt/V≥1.2). Demographic, clinical & anthropometric characteristics of the population were compared across years. Pts with BMI <85% were compared to overweight (85%< BMI<95%) & obese (BMI >95%) pts. Logistic regression modeling with spKt/V as the outcome was performed with age, race, gender, ethnicity, post dialysis BMI SDS, dialysis vintage, time delivered and access type as covariates. 3399 unique pt had data submitted > 1 study year. Obesity prevalence did not vary by year (9.7-12%). Table 1 describes relevant characteristics of the 3 cohorts. The final regression model excluded all patients with a dialysis vintage <6 months. In the final fully adjusted model, overweight (adjusted odds ratio 0.61, [95% CI 0.41, 0.91]) or obese (0.27, [0.20,0.38]) pts were less likely to achieve spKt/V≥1.2. Male gender (0.57 [0.44,0.75]) and use of catheter as access (0.61 [0.45,0.81]) were associated with a decreased likelihood of achieving a spKt/V≥1.2. High percentages of pediatric HD pts in the US are overweight or obese & less likely to achieve NKF/KDOQI thrice weekly HD adequacy targets for small solute clearance. Our data suggest longer dialysis times will be required to achieve a spKt/V≥1.2 in these populations.

| | BMI Percentile | | | |
|---|---|---|---|---|

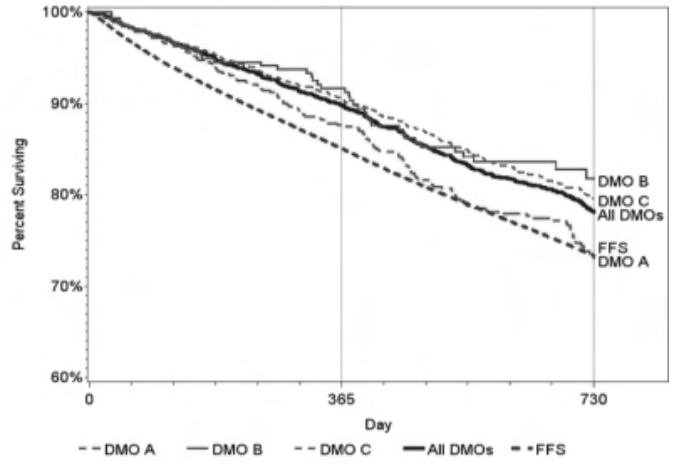
**F-PO1531**

**Hospitalization, Survival and Transplant-Related Outcomes in the Centers for Medicare & Medicaid Services End-Stage Renal Disease (ESRD) Disease Management (DM) Demonstration** Jeffrey Pearson, Sylvia Paz B. Ramirez, Charlotte J. Arrington, Christine Cheu, Claudia Dahlerus, Tania Chowdhury, Brett Lantz, Sabrina K. Gomes, Friedrich K. Port. *Arbor Research.*

ESRD is an ideal target for DM due to complex comorbidities, fragmentation of care, and high morbidity, mortality, and costs. This analysis presents the impact of DM by three DM Organizations (DMOs) on hospitalization, survival and transplant-related outcomes.

Each DMO developed its own DM programs with different clinical interventions and focus areas. Clinical outcomes of patients (pts) enrolled in each DMO between 2006 and 2008 were compared with pts in traditional fee-for-service (FFS) Medicare during the same period and in the same states. Cox models were used for survival, hospitalization and transplantation percentages adjusting for pt age, sex, race, Hispanic ethnicity, cause of ESRD, ESRD vintage, modality, previous failed transplant, state of residence and comorbidity.

There were 2,364 dialysis pts in the Demonstration: 722 pts in DMO A, 268 pts in DMO B, and 1,374 pts in DMO C. We compared these pts with 477,246 dialysis pts in traditional FFS Medicare. More pts in DMOs B and C survived at 1 and 2 yrs compared to FFS.



Fewer pts in DMO C were hospitalized at 1 and 2 yrs compared to FFS with the gap increasing over time. Hospitalizations for DMOs A and B were not significantly different from FFS. Across DMOs, fewer pts were transplanted than in FFS. However, transplantation is not overseen by the DMO, unlike the wait-listing process. DMO A had significantly more pts (11%) wait-listed; DMO C did not have significantly more pts wait-listed; DMO B had significantly fewer pts wait-listed.

While the impact of DM on pt outcomes differed by DMO, the Demonstration provides evidence that DM may improve survival, hospitalization and transplant wait-listing.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1532**

**Validation of an Algorithm for Categorizing the Severity of Emergency Department (ED) Visits in the Medicare Dialysis Population** J. M. Messana,[1] S. Hunter,[1] Robert A. Wolfe,[2] T. H. Shearon,[1] V. B. Ashby,[1] John R. C. Wheeler,[1] John Kalbfleisch,[1] Jeffrey Pearson,[2] Claudia Dahlerus,[2] Richard Hirth,[1] Rajiv Saran.[1] *[1]Univ of Michigan KECC; [2]Arbor Research.*

Differentiation between emergent and non-emergent ED visits may contribute to design of efficient paradigms for utilization of medical services by dialysis patients. The New York University (NYU) algorithm uses primary ICD-9 diagnosis codes to assign severity probabilities to ED visits. Using Medicare claims data, we examined ED visits by Medicare dialysis patients from 1/1/07 to 6/30/08 (1,030,598 visits; 257,581 patients). ED visits are common among the dialysis population (avg 3 ED visits/yr). 92% of all ED visits were categorized as emergent (60%), non-emergent (30%), or intermediate (2%) based on the severity probabilities of the most emergent diagnosis of each visit (Ballard, Medical Care, 2010).

We used logistic regression to examine the relationship between this modified NYU categorization of ED visits and subsequent hospitalization ($\leq$ 1 day) and death ($\leq$ 30 days). Covariates included ED severity group, age, race, sex, ethnicity, ESRD cause, BMI, years on ESRD, and diabetes status. For each group, Table 1 shows the percent of visits followed by a hospitalization or death, and the adjusted odds of subsequent hospitalization or death, compared to non-emergent visits. Emergent and intermediate ED visits were significantly more likely than non-emergent visits to be followed by hospitalization $\leq$ 1 day and by death $\leq$ 30 days.

Table 1

| | Hospitalization <= 1 day of ED visit | | Death <= 30 days of ED visit | |
|---|---|---|---|---|
| ED Visit Severity | % | Adjusted OR | % | Adjusted OR |
| Non-emergent | 29.1 | 1.00 (ref) | 3.8 | 1.00 (ref) |
| Intermediate | 54.1 | 2.50* | 7.0 | 1.38* |
| Emergent | 69.2 | 4.83* | 10.4 | 2.32* |

* p<0.0001

The modified NYU ED severity algorithm is a valid tool for categorization of ED visit severity in this population. Having established a relationship between the severity algorithm and primary outcomes, future research based on this methodology could explore variation in appropriateness of ED utilization by region, facility and patient groups and the impacts of ED utilization on costs of care.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1533**

**Immunogenecity of Single Dose of 2009 Influenza A (H1N1) Monovalent MF59-Adjuvanted Vaccine in Dialysis Patients** Jungmin Son, Soo Bong Lee, Il Young Kim, Harin Rhee, Jung Sub Kim, Sang Heon Song, Eun Young Seong, Ihm Soo Kwak. *Internal Medicine, Pusan National University School of Medicine, Busan, Republic of Korea.*

**Backgrounds :** Governments and public health officials prepared vaccination campaigns against the 2009 influenza A (H1N1) pandemic strain. In a recent study, single dose of monovalent 2009 influenza A (H1N1) MF59-adjuvanted vaccines were highly immunogenic in healthy adults (seroprotection 92%, seroconversion 88%). But the immunogenicity of these vaccines in hemodialysis (HD) and peritoneal dialysis (PD) patients has not been evaluated.

**Methods :** Eighty-two patients (48 HD, 34 PD) were enrolled into the study. Subjects were received single dose of vaccine containing 3.75 μg hemagglutinin of MF59-adjuvanted vaccine. Serum samples were collected immediately before vaccination and 28 days later. Antibody responses were measured by hemagglutination-inhibition assay.

**Results :** Following the single dose of vaccine, seroprotection was observed in 24 of 82 patients (29.3%; 95% CI, 19.2%-39.3%) and seroconversion in 20 of 82 (29.4%; 95% CI, 14.9%-33.9%). Geometric mean fold increase (MFI) was 5.3 (95% CI, 2.9-7.8). Seroprotection rate, seroconversion rate, MFI showed no significant difference between HD and PD group (29.2% vs. 29.4%; 20.8% vs. 26.5%; 5.8 vs. 4.7, respectively). Although both seroprotection rate and seroconversion rate declined when stratified by age (41.7% and 41.7% in age 18-39; 28.6% and 21.4% in age 40-59; 25.0% and 17.9% in age over 60), there was no significant difference between HD and PD group. Sex, dialysis duration, existence of diabetes mellitus, comorbidity, dialysis duration, previous seasonal vaccination, immunosuppressive agent use were not associated with immunogenicity.

**Conclusions :** In dialysis patients, single dose of 2009 influenza A (H1N1) monovalent MF59-adjuvanted vaccine is insufficient to meet the vaccine licensure criteria except geometric mean fold increase. Because the immune system in dialysis patients is severly depressed and antibody response is weaker than that of the normal population, governments and public health officials should consider higher or multiple doses of vaccination.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1534**

**Pandemic (H1N1) 2009 H1N1 Vaccination in Hemodialysis Patients** Philip A. Clayton, Martin P. Gallagher, Julia M. Liang, Roger N. Wyndham, Meg J. Jardine. *Renal Department, Concord Repatriation General Hospital, Sydney, Australia.*

**Aim**: The mortality of pH1N1 infection in hemodialysis patients is around 10 times higher than in the general population, but the efficacy of pandemic (H1N1) 2009 (pH1N1) vaccine in this group is unknown. We assessed the serological response of maintenance hemodialysis patients to a single exposure to pH1N1 vaccine during a period of low influenza activity.

**Methods**: Maintenance hemodialysis patients were vaccinated in two phases. In November 2009 vaccination was offered with 15μg of intramuscular monovalent, non-adjuvanted, split-virus pH1N1 vaccine (Panvax®H1N1, CSL Biotherapies, Melbourne Australia). In March 2010 vaccination was offered with seasonal influenza vaccination containing pH1N1 vaccine. pH1N1-specific hemagglutination inhibition (HAI) titers were measured at baseline and at day 21. Endpoints were derived from FDA criteria and were a) seropositivity (titer ≥40) and b) seroconversion (prevaccination titer of <10 with postvaccination titer of ≥40, or a four-fold or higher increase in titer). Results were compared with FDA licensing criteria specifying seropositivity rates of 70% and 60% and seroconversion rates of 40% and 30% respectively, for people aged 18-64 and 65 and older, as measured by the lower limit of the 95% CI.

**Results**: Vaccination was performed using pH1N1 or the seasonal influenza vaccine containing pH1N1 in 38 and 21 participants respectively. Participants were elderly (median 75 years), predominantly male (66%) and Caucasian (76%). Diabetes was present in 47%. The baseline seroprotection rate was 20% (95% CI:11-33%). At day 21, seroprotection was demonstrated in 64% (95% CI:51-76%) and seroconversion in 68% (95% CI:54-79%) of participants. For participants aged 65 and over seroprotection was 56% (95% CI:40-71%) and seroconversion 60% (95% CI:44-75%).

**Conclusions**: Hemodialysis patients have poorer immune responses to pandemic (H1N1) 2009 vaccination than healthy volunteers following a single exposure to pH1N1 vaccine. These results suggest standard dosing in hemodialysis patients may not meet FDA licensing criteria.

**General Population Diabetes Mellitus and the Incidence of Renal Replacement Therapy in the UK: An Ecological Study of 192 Health Areas** Clare I. Castledine,[1] Julie A. Gilg,[1] David Ansell,[1] Charles Tomson,[2] Fergus J. Caskey.[2,3] *[1]UK Renal Registry, Bristol, United Kingdom; [2]Richard Bright Renal Unit, Southmead Hospital, Bristol, United Kingdom; [3]Clinical Science North Bristol, University of Bristol, United Kingdom.*

**Introduction:**Healthcare is administered via 192 health areas in the UK. The UK Renal Registry (UKRR) collects data electronically on all RRT patients and has reported variation in the incidence rate of RRT between these areas which is only partly explained by the age, ethnicity and socio-economic deprivation profile of each area. The introduction of the Quality Outcomes Framework (QOF), a pay-for-performance scheme for primary care physicians, provides data on the prevalence of known and controlled diabetes for the first time.

**Methods:** The incidence of RRT in each health area for 2007-2008 was obtained from the UKRR database. The prevalence of diabetes mellitus in 2007-2008 and the percentage of these patients achieving HbA1c <7.5% was obtained for each health area from QOF database.

**Results:** There are 192 health areas, median (IQR) population 255,900 (184,000-390,000), with an average of 6642 incident patients per year. Median diabetes prevalence was 3.96%.Each 1% point rise in diabetes prevalence was associated with an 18% higher incidence of RRT (incidence rate ratio (IRR) 1.18(95% CI 1.14-1.22, p<0.0001)). After adjustment for age/gender IRR was 1.23(1.19-1.27, p<0.0001). After adjustment for area level ethnicity and deprivation IRR was 1.22(1.17-1.28, p<0.0001) and after adjustment for life expectancy and cancer mortality IRR was 1.24(1.19-1.30, p<0.0001). Each 1% point

rise in diabetes prevalence was associated with a 32% higher rate of RRT caused by diabetes ($RRT^{DM}$) ($IRR^{DM}$1.32, 1.22-1.43, p<0.0001). After adjustment for age/gender $IRR^{DM}$ was 1.46(1.35-1.58, p<0.0001) and after adjustment for area-level ethnicity/deprivation $IRR^{DM}$ was 1.45(1.32-1.60, p<0.0001). After adjustment for life expectancy/cancer mortality $IRR^{DM}$ was 1.48(1.34-1.63, p<0.0001).

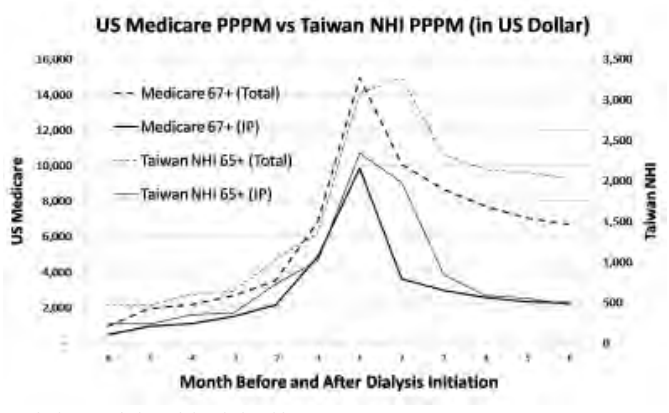
**Conclusions:** In the UK, every 1% point increase in prevalence of diabetes in the general population is independently associated with a 24% higher incidence of RRT and a 48% higher incidence of $RRT^{DM}$.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1536

**A Comparison of Cost Distribution during the Transition to ESRD in the US and Taiwan** Lih-Wen Mau,[1] Xinyue Wang,[1] James P. Ebben,[1] David T. Gilbertson,[1] Herng-Chia Chiu,[2] Allan J. Collins.[1] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Institute of Healthcare Administration, Kaohsiung Medical University, Kaohsiung, Taiwan.*

The burden of ESRD in the US and in Taiwan is among the heaviest in the world, This study aimed to compare the distribution of costs during the 6 months before and after dialysis initiation for older incident ESRD patients in the US and Taiwan. Identified from USRDS ESRD data, patients who initiated dialysis in 2007, were aged ≥ 67 years at initiation, and had Medicare as primary payer for 2 years before initiation were included (n=32,444). A cohort of Taiwanese incident patients from the 1% random sample of the National Health Insurance (NHI) population in Taiwan, aged ≥ 65 years, who initiated dialysis between 2000 and 2008 (n=324) was established for comparison. Taiwan's NHI program uses the same billing format as US Medicare claims. Total costs of Medicare Part A and Part B and of Taiwanese NHI outpatient and inpatient services were calculated by per-patient-per-month (PPPM). PPPM hospitalization costs were also calculated. In the month of dialysis initiation, 75% of the US Medicare and 81% of the Taiwan NHI incident patients were hospitalized; PPPM inpatient costs were highest in the month of dialysis initiation in both study cohorts. However, total PPPM transition cost reached its peak in the first dialysis month for Medicare patients and in the second month for Taiwan NHI patients. The time difference between the peaks in total cost might be due to 48% of Taiwanese patients being continuously hospitalized in the second month after dialysis initiation. Further study is needed to compare differences in use of nephrology care and other health system factors that might explain why the dialysis initiation period seems to be longer for Taiwanese than for US incident ESRD patients.



Disclosure of Financial Relationships: nothing to disclose

## F-PO1537

**Epidemiology and Outcome of Chronic Hemodialysis Patients Requiring Hospital Admissions** Chew Ming Wong,[1] Sridhar Ramanaidu,[1] Soo Kun Lim,[1] Li Ping Tan,[1] Kok Peng Ng,[1] Tee Chau Keng,[1] Wai Yew Kong,[1] Yip-Boon Chong,[1] Si-Yen Tan.[2] *[1]Division of Nephrology, University Malaya Medical Centre, Kuala Lumpur, Malaysia; [2]Nephrology Clinic, Prince Court Medical Centre, Kuala Lumpur, Malaysia.*

Hospital admission among end stage renal disease (ESRD) patients has major implications on healthcare cost and survival of this increasingly prevalent patient population group. Effective identification of the common reasons for admission may help guide strategies targeted at reducing the high rate of morbidity in these patients. We report here an observational study of all admissions involving ESRD patients in University Malaya Medical Centre (UMMC) from 1 January 2009 to 31 Dec 2009. ESRD patients are patients who have undergone maintenance hemodialysis for at least three months.

There were 294 admissions involving 195 patients, 48% were females with mean age 59.6 (range 18-85); 65.6% were diabetics and 19.7% of patients were using non-cuffed dialysis catheter at the time of hospitalization. The reasons for admission were sepsis (29.9%), elective admissions for cataract operations and coronary angiograms (15%), cardiovascular disease (12.2%) and fluid overload (11.6%). Risk factors associated with sepsis related hospitalization were anemia (p=0.026) and hypoalbuminemia (p=0.041). The commonest cause of sepsis was dialysis catheter related sepsis (32.9%) followed by orthopedic related infections (29.5%) and pneumonia (23.8%). The commonest organism grown was methicillin sensitive Staphylococcus aureus. The median length of hospital stay (LOS) was 5 days (IQR 3-8). Sepsis was the strongest predictor for LOS (p=<0.001). The mortality rate was 10.2% and most patients died of septic shock.

In conclusion, although diabetes was the most common cause of ESRD at 54%, there was a higher proportion of diabetic ESRD patients requiring admission. Mortality rate was high with catheter related sepsis being the most common reason for admission. Our findings suggest earlier creation of permanent vascular access can be further optimized to reduce morbidity and in patients dependent on catheters, improvement in catheter care together with use of cuffed catheters may reduce risk of infections.

## F-PO1538

**Pregnancy Related Polyhydramnios in Chronic Dialysis Patients: A Treatable Pathology, a Hemodialysis Adequacy Tool and an Outcome Predictor** Claudio Luders, Silvia Titan, Lilian P. F. Carmo, Igor Marques, Joao Egidio Romao, Jr. *Nephrology, University of Sao Paulo School of Medicine, Sao Paulo, SP, Brazil.*

Polyhydramnios (PH) is one of the most frequent complication in chronic hemodialysis (HD) pregnant women. Increased fetal urine production secondary to urea osmotic diuresis is probably the etiology of the excess of amniotic fluid. Increasing HD dose may act reducing maternal serum urea and consequently the fetal osmotic diuresis. In a previous report, a non-expected association beetween PH and a better fetal outcome was shown. In this study, we wish to further explore the association between amniotic fluid volume and fetal outcome. In the past 10 years we have followed 44 pregnant women that required HD. Of those, twenty developed PH, amniotic fluid index (AFI) > 25cm or excess of amniotic fluid, AFI > 18 cm. Sixteen patients were treated with half an hour increase in HD time. After treatment, all patients normalized the AFI within 30 days. The AFI and serum urea level before and after the change in HD dose were 24.9 ± 6.2 *vs* 16.6 ± 2.3 cm (p<0.001) and 95.9 ± 26 *vs* 66.8 ± 17 mg/dL (p<0.0001), respectively. The gestational age and fetal weight of the patients with excess of amniotic fluid were significantly higher than the remaining 24 patients (35.2 ± 2.4 *vs* 32.1 ± 3.6 weeks, p=0.002 and 2031 ± 478 *vs* 1349 ± 641g, p=0.0003, respectively). In the multivariate linear regression model, we observed that PH was positively related to birth weight, even after adjusting to predialysis serum urea, standard Kt/V and to the presence of preeclampsia (β=417, 95% CI 98 to 737, p=0.01). At univariate logistic regression analysis, the presence of PH was positively related to the fetal outcome (p=0.04). We speculate that the presence of PH is probably a marker of an adequate placental blood flow in pregnant women on dialysis. This hypothesis is corroborated by the presence of a normal umbilical doppler velocimetry in all patient with elevated AFI. We conclude that PH is a treatable pathology, it can be used as an HD adequacy tool and is related to a better fetal outcome.

## F-PO1539

**Impact of Telemedicine in Remote Dialysis Units in Northern Quebec** Murray L. Vasilevsky,[1] Claude Sicotte,[2] Khalil Moqadem,[2] Johanne Desrochers,[1] Madeleine St-Gelais.[1] *[1]Nephrology, McGill University Health Centre, Montreal, QC, Canada; [2]Department of Health Administration, University of Montreal, Montreal, QC, Canada.*

This study was designed to assess the impact of telemedicine on the quality of care of prevalent hemodialysis patients receiving treatment in remote settings. Subjects consisted of First Nation Cree patients dialyzed in two remote satellite units (Unit A and Unit B) in the James Bay region of Northern Quebec. All Cree patients older than 18 and dialyzed for a minimum period of 9 months prior to and after introduction of telemedicine were included. Data extracted retrospectively from monthly lab tests and chart review were collected and compared in periods prior to and after introduction of telemedicine and subjected to ANOVA with repeated measures. 28 patients were included in the analysis.

| | Unit A | | Unit B | |
|---|---|---|---|---|
| | Pre | Post | Pre | Post |
| SBP,mm Hg | 155.7 (15.9) | 155.3 (15.7) | 149.6 (19.1) | 151.2 (15.4) |
| DBP, mm Hg | 82.6 (7.8) | 80.3 (9.8) | 78.4 (9.2) | 78.1 (9.2) |
| Hb g/l | 118.1 (7.6) | 110.0 (10.3) | 115.6 (8.5) | 117.2 (9.2) |
| Albumin g/l | 39.2 (3.0) | 39.4 (2.5) | 38.8 (2.8) | 37.9 (2.6) |
| Glucose mM/l | 7.3 (1.5) | 7.4 (1.7) | 8.4 (2.0) | 8.9 (2.1) |
| HbA1C % | 10 (1) | 10 (1) | 10 (1) | 10 (1) |
| KT/V | 1.4 (0.2) | 1.5 (0.2)* | 1.55 (0.1) | 1.6 (0.2)* |
| P mM/l | 1.9 (0.4) | 1.8 (0.5) | 1.7 (0.3) | 1.9 (0.5) |
| PTH pM/l | 44.5 (42.3) | 73.8 (80.1) | 21.4 (21.4) | 31.3 (21.9) |
| Rx changes/mo | 2.5 (1.4) | 1.8 (1.5) | 5.0 (5.8) | 2.7 (2.2) |
| Transfers/month | 1.3 (0.5) | 1.5 (1.1) | 0.7 (1.0) | 1.1 (1.7) |

mean (SD), * p=.034

Pre-dialysis systolic and diastolic BP, serum Hb, serum albumin, phosphate, PTH, glucose and glycosylated hemoglobin were unchanged. There was a statistically but not clinically significant increase in KT/V in each unit (1.5 vs 1.4 and 1.6 vs 1.5, post vs pre, Unit A and Unit B, respectively, p=.034). The number of prescription medication changes and number of transfers to the University center were unchanged. Although no changes in outcome could be demonstrated, telemedicine provides better security and support for patients and staff and may have contributed to maintenance of K/DOQI targets.

**F-PO1540**

**What Are the Risks Associated with Temporary Haemodialysis Away from Centre?** Richard W. Corbett, Virginia Louise Prout, Deborah Haynes, Claire Edwards, Andrew H. Frankel. *Imperial College Healthcare NHS Trust, London, United Kingdom.*

Temporary haemodialysis away from the patient's 'home' centre is increasing in frequency but there is little data on the effect this change to the patient's dialysis regime has on their health.

Methods: Travel data was collected prospectively over six months on 1179 patients receiving maintenance haemodialysis across our dialysis centres. Biochemical parameters, erythropoietin usage, dialysis access information, positive microbiological investigations, hepatitis serology and antibiotic starts were recorded for twelve weeks prior to and following dialysis away from centre.

Results: 172 individuals, travelled on 200 occasions. 85 trips were made within the UK, while 115 trips were made overseas. 123 had a cuffed central venous catheter [CVC], 48 arterio-venous fistula [AVF] and 1 an arterio-venous graft [AVG].

The blood stream infection [BSI] rate for travellers with CVC was 0.33 vs 0.83/1000 access days (a.d.) [$p<0.05$] in the twelve weeks pre and post travel. The comparable BSI rate for AVF and AVG was identical with a single BSI in this group pre and post travel. Exit site infections were comparable at 0.18 vs 0.30/1000 a.d. [NS]. Parenteral antibiotic starts 1.43 vs 2.32/1000 a.d. and oral antibiotic starts 0.42 vs 1.79/1000 a.d. were both significantly elevated post travel [$p<0.05$] and were mainly instituted for either chest or urinary sepsis.

There was no evidence of hepatitis B or C seroconversion. Haemoglobin levels dropped on return (pre: 12.2 ±0.9 post: 11.9 ±1.3 g/dl, $p<0.05$) but had returned to baseline 8 weeks later. Erythropoietin requirements and phosphate levels were all increased on return to centre.

Conclusion: Travel and dialysis away from a patient's usual haemodialysis unit is associated with anaemia and an increased erythropoietin requirement. The concomitant evidence of an increased risk of bacterial infection, particularly if the patient is dialysing by means of a CVC, may contribute through erythropoietin resistance, as may inadequate dialysis while away from centre. This study provides evidence for the widespread perception that haemodialysis away from centre is associated with increased morbidity.

Disclosure of Financial Relationships: nothing to disclose

**Factors Influencing Regional Differences in the Outcome of Dialysis in Japan** Satoshi Ogata, Shinichi Nishi, Kunitoshi Iseki, Yoshiharu Tsubakihara. *Committee of Renal Data Registry, the Japanese Society for Dialysis Therapy, Tokyo, Japan.*

Background: There are regional differences in the outcome of dialysis, but few studies have investigated the causes.

Methods: We stratified 109 factors by gender and 47 prefectures, including the past history and laboratory data, economic and weather conditions, and institutional and nutritional factors, and we investigated factors associated with regional differences in the incidence rate, the survival of incident dialysis patients in 2004-06 (n=102,011), and the number of dialysis specialists using the database of the Japanese Society for Dialysis Therapy (JRDR-09105) by univariate analysis.

Results: A history of leg amputation ($r=0.427$, $p=0.003$), a history of acute myocardial infarction ($r=0.410$, $p=0.004$), the duration between the first visit to hospital and first dialysis ($r=-0.375$, $p=0.009$), intake of fish and shellfish ($r=-0.418$, $p=0.003$), intake of meat ($r=0.597$, $p<0.0001$), the duration of the snow season ($r=-0.477$, $p=0.0007$), and the amount of personal savings ($r=-0.439$, $p=0.020$) were associated with the incidence of starting dialysis. The number of night dialysis institutions ($r=0.484$, $p=0.0006$), blood albumin level ($r=0.316$, $p=0.030$), Kt/V ($r=0.496$, $p=0.0004$), and dialysis time ($r=0.513$, $p=0.0004$) were correlated with the 1-year survival rate. The number of dialysis specialist was associated with the incidence of starting dialysis ($r=0.513$, $p=0.0002$), Kt/V ($r=0.278$, $p=0.05$), the dialysis time ($r=0.290$, $p=0.048$), blood creatinine after dialysis ($r=-0.298$, $p=0.042$), and 1-year survival ($r=0.297$, $p=0.043$).

Conclusions: Many factors, including the number of specialists, were associated with the incidence of starting dialysis and with survival.

**F-PO1542**

**Quality of End of Life Care: Results from the Pan-Thames Audit Group** Stephen Paul McAdoo,[1] Emma M. Salisbury,[1] Edwina A. Brown,[1] Alistair Chesser,[2] Ken Farrington.[3] *[1]Imperial College Kidney and Transplant Institute, London; [2]Royal London Hospital, London; [3]Lister Hospital, Stevenage, United Kingdom.*

BACKGROUND: Advance discussion and planning of end of life (EoL) care results in patients receiving care in line with their wishes and improved quality of life. The Department of Health document "End of Life Care in Advanced Kidney Disease: a framework for implementation" suggests strategies to achieve high quality end of life (EoL) care for renal patients. To monitor the implementation of these, audit tools are needed to measure quality of EoL management, but currently there is no accepted method of doing this.

AIMS: (1) to develop a proforma to collect information about EoL care; (2) to use the proforma prospectively to collect information about current standards of EoL care; (3) to determine what factors affect quality of EoL care.

DESIGN: We developed a proforma to collect data on EoL care. This was used to prospectively collect data for all deaths in the ESRD population over an 8 week period from 10 centres in London and SE England.

RESULTS: 138 deaths were recorded. Mean age 68 years. 86% on dialysis, remainder transplant or conservative care. 68% of deaths occurred in hospital, remainder at home or hospice. 87% home deaths were sudden. Chosen place of death was known for 22%. Data on inpatient deaths showed that EoL discussion was documented in 30%; dialysis was discontinued in 50%; management was changed to palliative care in 41%; "good quality deat" as judged by form completer was achieved in 51%. Effect of "unexpected" death (37% inpatient deaths) or being non-caucasian (36% total deaths) on EoL care are shown in the Table 1.

Table 1

| | Expected | Unexpected | Caucasian | Non-caucasian |
|---|---|---|---|---|
| Changed to Palliative Care(%) | 67 | 13 | 45 | 32 |
| Dialysis Discontinued(%) | 58 | 18 | 52 | 36 |
| Good Quality Death(%) | 56 | 32 | 51 | 52 |

CONCLUSION: A one-paged proforma completed at the time of death is a useful audit tool for EoL care. Many aspects of EoL care for patients on dialysis are poor. Death being "unexpected" and patient being non-caucasian can result in poorer EoL management. Physicians need to improve their recognition of the EoL phase and to be aware of cultural issues that may affect EoL care.

**Outcomes in Dialysis and Renal Transplant Patients Admitted Due to Respiratory Diagnoses: Impact of the H1N1 Virus** Odiri Jane Eneje, Neill D. Duncan, Tom Cairns, David Taube, Darren S. Parsons. *Imperial College Kidney and Transplant Institute, Imperial College Healthcare NHS Trust, London, United Kingdom.*

**Background**

Respiratory admissions are a major cause of morbidty/mortality in patients on renal replacement therapy. During the winter of 2009 there was concern of the impact of the H1N1 virus epidemic in haemodialysis (HD) and transplant (TX) patients.

**Methods**

We have retrospectively analysed the data (clinical records, radiology, microbiology) for all cases (HD/TX) admitted with a primary respiratory diagnosis from August 2009 to March 2010 to look at primary cause and the impact of the H1N1 virus. We were additionally interested in the requirements for high dependency respiratory care. All patients with flu like symptoms were screened for H1N1 by PCR.

**Results**

There were a total of 1540 non-elective admissions during this time period (45% TX). A total of 246 primary respiratory admissions were identified (HD 179 and TX 67). The majority had no prior respiratory co-morbidity (65.9%). Primary diagnosis included pneumonia (86, 35%), pulmonary oedema (56, 22.8%), combination septic pulmonary oedema (51, 20.7%), pneumonitis (18, 7.3%), exacerbation of COPD/asthma (8, 3.3%) and pulmonary emboli (7, 2.8%). Pulmonary oedema secondary to poor patient compliance was a major cause of admission in HD (41, 16.6%).

Positive microbiology was found in 46 (18.7%): Candida (12), Pseudomonas aeruginosa (4), Streptococcus pneumoniae (2), Klebsiella pneumoniae (2) and Haemophilus influenzae (1). There were 8 cases of admission related to H1N1 infection.

For cases of pneumonitis, pathogens were identified in 8/18 cases these included Cytomegalovirus (3), H1N1 (2), Pneumocystis (2) and Respiratory Syncitial Virus (1).

Of the acute admissions 104 (42.3%) patients required renal high dependence unit care. Of these 16 required non invasive ventilation and 4 (TX 2, HD 2) were admitted to the intensive care unit for ventilation.

Our overall mortality was 11/246 (4.5%): TX (3, 4.5%) HD (8, 4.5%).

**Conclusion:**

Overall there was little impact of the H1N1 virus on respiratory admissions. Our overall mortality from respiratory diagnosis was 4.5% although this was mainly from standard infections.

**Surrogate Dialysis: Insured and Uninsured Patients Outcomes in 5 Privates Clinics in Jalisco, Mexico** Karina Renoirte,[1] Guillermo G. Garcia,[1] Laura Cortes Sanabria,[2] Bertha Alicia De la Torre.[1] *[1]Nephrology, Hospital Civil de Gudalajara, Guadalajara, Jalisco, Mexico; [2]Nephrology, CMNO, Guadalajara, Jalisco, Mexico.*

INTRODUCTION/AIMS: End-stage renal disease represents a serious public health problem in Mexico. We reported lower dialysis acceptance rates in the uninsured (UP) than in the insured population (IP) (99 pmp vs 166 pmp). To correct these disparities in 2006 the State Ministry of Health (SMH) implemented the first hemodialysis program in Jalisco that provides surrogate dialysis for the poor free of charge. In 2008 the Federal Guvernment surrogated some of its patients to private hemodialysis clinics. We evaluate the clinical outcomes of UP and IP patients at 5 private hemodialysis clinics in Jalisco.

METHODS: Clinical and laboratory data was collected from March 2007 thru April 2010. Age, gender, etiology, date of first treatment, vascular access, weekly dialysis hours, EPO use, hemoglobin (HB), calcium phosphorus product (CAxPO4), Kt/V were registered. Student's T-test and were utilized. Survival curves were constructed with the Kaplan-Meier method and compared with the log-rank test.

RESULTS: 72 UP patients and 217 IP started dialysis. UP patients were younger (41±21ys vs 48±19ys, p=0.06), and had less DM (33% vs 46%, p=0.009) than the IP ones. Female gender (47% UP and 40% IP) was similar in both groups. A cross-sectional analysis revealed a greater utilization of AV fistulas among UP patients (23.6% vs 19.3% p=< 0.0001). HB (10.1 ±2.2 g/dL vs 9.94 ±1.94, p 0.510 g/dL), and EPO use was similar (85.8% UP vs 85.2% IP, p=0.660). CaxPO4 (44.61 ±18.6 vs 45.37 ±18.4). Average Kt/V was better for UP group (1.21± 0.72 UP and 0.96± 0.23 IP p= < 0.0001). Survival at 12 and 24 months was 87.5% and 83.3 % among UP and 90 and 78% among IP. It was not statistically significant.

CONCLUSIONS: SMH has open a great opportunity for poor chronic renal failure patients to have access to dialysis treatment. A greater utilization of av fistulas and therefore a better dose of dialysis was observed in these patients compared with the insured patients. The results are encouraging, although a longer follow-up will be needed to assess the full impact of this program in Mexico.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1545

**Effects of Icodextrin on Mortality and Technique Failure in Patients Undergoing Peritoneal Dialysis** Eawha Kang,[1] Sang Choel Lee,[2] Seung Hyeok Han,[3] Dae-Suk Han.[3] *[1]Department of Internal Medicine, NHIC Medical Center, Ilsan Hospital, Goyangshi, Gyeonggi-do, Korea; [2]Department of Internal Medicine, Kwandong University College of Medicine, Goyanshi, Gyeonggi-do, Korea; [3]Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea.*

**Background**: Many studies have suggested clinical benefits of icodextrin in peritoneal dialysis (PD) patients. However, whether icodextrin can improve patient survival is currently unknown. Therefore, this study aimed to investigate the effects of icodextrin on mortality and technique failure in PD patients.

**Methods**: Study subjects were 2,163 patients from 54 centers in Korea who initiated PD from Jul 2003 to Dec 2006. Outcome data were retrieved retrospectively from the Baxter Korea database. A total of 790 patients were identified as icodextrin group who were maintained on this solution for more than 6 months. We compared all-cause mortality and technique failure between patients with and without icodextrin by using propensity score analysis.

**Results**: Propensity score matching yielded 776 matched pairs of patients. There were no significant differences in age, gender, diabetes, cardiovascular comorbidity, socioeconomic status, biocompatible solution use, or center experience between the two groups. All-cause deaths occurred in 91 (11.7%) patients in icodextrin group compared with 168 (21.6%) in non-icodextrin group (hazard ratio [HR], 0.37; 95% confidence interval [CI], 0.29 to 0.48; P<0.001). In addition, icodextrin use was significantly associated with a reduced risk of technique failure (HR, 0.44; 95% CI, 0.30 to 0.65; P<0.001). Icodextrin group had fewer technique failures due to non-compliance compared with non-icodextrin group whereas peritonitis- or ultrafiltration failure-related technique failure was not different between the two groups.

**Conclusion**: This study suggests that icodextrin solution may improve patient and technique survival in PD patients. To confirm these results, a large randomized prospective study is warranted.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1546

**Facility Influenza Vaccination (IV) Practice: Associations with Mortality and Hospitalizations in the US Dialysis Population** J. M. Messana,[1] K. A. Wisniewski,[1] T. H. Shearon,[1] V. B. Ashby,[1] Sandra E. Callard,[1] Rajiv Saran,[1] Bruce M. Robinson.[2] *[1]Kidney Epidemiology and Cost Center, University of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Despite public health and regulatory efforts to increase IV in the US dialysis population, IV rates have only increased to 64% over the last decade. A prior study using 1997-99 data (Gilbertson, 2003) showed that patients who received IV had lower mortality and hospitalization in the following year.

Using the national CMS ESRD database for 2007-08, we examined the relationship between facility IV rates and subsequent mortality and hospitalization. Facilities were grouped into quintiles by percentage of patients vaccinated from 9/07-12/07. Poisson regression models, adjusted for demographic factors, were used to determine the relative risk (RR) of mortality and hospital admission in 2008 among the quintiles.

The median facility IV rate was 67%. Facility IV rate was inversely associated with RR of mortality and hospitalization (Table 1). Facilities vaccinating <52% of patients (lowest quintile) had a 22% higher risk of both mortality and hospitalization compared to facilities vaccinating >77% of patients (highest quintile). On average, facilities with a 10% higher IV rate had 4% and 3.5% lower mortality and hospitalization, respectively (p<0.0001).

Although IV rates continue to rise, the quality gap remains, as evidenced by only 2/3 of this patient population receiving IV during the vaccination period. Our analysis demonstrates that mortality and hospitalization rates continue to be lower in dialysis facilities with higher IV rates.

Table 1. RR of Mortality and Hospital Admission for Facilities by Percent of Patients Vaccinated against Influenza, 2007-2008

| Percent of Patients Vaccinated (Quintiles) | RR of Mortality | RR of Hospital Admission |
|---|---|---|
| 0 – 52 | 1.15* | 1.11* |
| 53 – 63 | 1.04* | 1.05* |
| 64 – 70 (Ref) | 1.00 | 1.00 |
| 71 – 76 | 0.97* | 0.96* |
| 77 – 100 | 0.94* | 0.91* |

## F-PO1547

**Dialysis Facility Practices Aimed at Target Weight Achievement and Patient Outcomes in DOPPS** Rajiv Saran,[1] Douglas S. Fuller,[2] Ananda Sen,[1] Stefan H. Jacobson,[3] Raymond C. Vanholder,[4] Tadashi Tomo,[5] Francesca Tentori.[2] *[1]Univ of MI, Ann Arbor, MI; [2]Arbor Res Collab for Hlth, Ann Arbor, MI; [3]Danderyd Hosp, Stockholm, Sweden; [4]UZ Gent, Gent, Belgium; [5]Oita Univ Hosp, Oita, Japan.*

Optimum intradialytic fluid management (IDFM) is critical in dialysis, but current practice guidelines in this area are not fully developed. We sought to link patient outcomes with strategies utilized by dialysis facilities in 12 countries toward achieving target weight (TW).

Medical Directors of DOPPS III facilities (2005-2008, n=240) reported the typical frequency of TW assessment and rated importance of 7 IDFM practices used to assess TW at their unit: physical exam, on-line volume monitoring, chest X-ray, orthostatic BP, intradialytic hypotension, Hb, and symptoms. Adjusted regressions were used to predict patient-level TW achievement and mortality.

Wide variation was noted across countries for the 7 IDFM practices. TW achievement was improved among patients in facilities indicating higher frequency of TW assessment and higher importance of chest X-ray to assess TW (Figure, upper half). Patients in facilities that rated physical examination to have low importance in assessing TW showed significantly higher hazard of mortality (Figure, lower half) compared to patients in facilities rating it to be very important. Patients in facilities that rated chest X-rays to be very important in determining TW also tended to have a lower HR of mortality.

Higher frequency of TW assessment at dialysis facilities and greater emphasis toward physical examination in determining volume status was associated with improved TW achievement and lower mortality in hemodialysis patients. Additional results regarding on-line volume monitoring suggest that reliance on technology alone may not be the best solution in this area compared with clinical assessment. However, this requires further study.

## F-PO1548

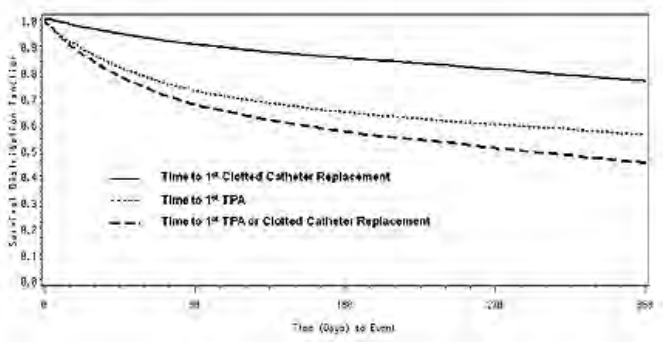
**Central Venous Catheter Dysfunction in Incident Hemodialysis Patients** Eduardo K. Lacson, Weiling Wang, J. Michael Lazarus, Raymond M. Hakim. *Fresenius Medical Care, North America, Waltham, MA.*

**Introduction:** Flow obstruction is a common complication of hemodialysis (HD) catheters. We tracked clotting-related catheter replacement and use of recombinant tissue plasminogen activator (TPA) in a national cohort of incident HD patients.

**Methods:** Among 25,003 incident HD patients admitted in Fresenius Medical Care North America facilities (within 15 days of first dialysis) between January 1 and December 31, 2007, 14,836 patients (59.3%) exclusively used a catheter. These catheter patients were followed for up to one year of catheter use or censored at discharge or upon transition to fistula/graft.. Use of TPA and clotting (non-infection) related catheter replacement(s) were tracked.

**Results**: Mean age was 63.6 ± 15.8 years, 54.0% male, 66.4% white and 29.1% black, with 54.4% having diabetes. Mean follow-up time was 199 ± 129 days. A total of 18,809 TPA administrations and 3,039 non-infection-related catheter replacements occurred during

the study period. Separately, TPA was used by 4,829 patients (32.5%) at a median time of 41 days for the 1st episode while 2,169 catheters present on admission (14.6%) were 1st replaced due to dysfunction at a median time of 75 days. Combined, >50% of patients experienced either intervention, at a median time of 107 days (Figure 1).



**Conclusions**: Flow-related catheter dysfunction requiring TPA or catheter replacement is very common within the first year of HD. This presents a significant cost when bundling starts, and in addition to catheter-related infection, may impact patient outcomes (e.g. hospitalization, quality of life, etc.) and increase utilization of healthcare resources.

## F-PO1549

**Multi-Center Experience of 137 Consecutive HeRO Implants** Shawn Michael Gage,[1] David W. Butterly,[2] Jeffrey Harold Lawson,[1] John R. Ross,[3] Howard E. Katzman,[4] Jason D. Woolard.[5] *[1]Surgery, Duke University Medical Center, Durham, NC; [2]Nephrology, Duke University Medical Center, Durham, NC; [3]Surgery, Bamberg County Hospital, Bamberg, SC; [4]Surgery, University of Miami, Miami, FL; [5]Surgery, Baylor University Medical Center, Dallas, TX.*

**Purpose:** To report a multi-center experience with the novel Hemodialysis Reliable Outflow (HeRO) vascular access device.

**Methods:** Four centers have conducted a retrospective review of patients receiving the HeRO device from implant to last available follow-up. The HeRO is an implantable, completely subcutaneous, hybrid "graft-catheter" device approved for catheter-dependent patients with limited venous outflow. The focus of this evaluation is on HeRO patency and intervention rates, as well as access-related bacteremia. We intend to follow this cohort and update the study data accordingly.

**Results:** Currently, data is available on 137 patients at four institutions with an accumulated 1,346.8 HeRO months. At 6 months, HeRO primary patency is 61.5% (64/104) and secondary patency is 89.4% (93/104). At 12 months, HeRO primary patency is 54.8% (23/42) and secondary patency is 83.3% (35/42). To-date, interventions have been required in 40.1% of patients (55/137) resulting in an intervention rate of 1.8/year. Access-related infections have been reported in 6 patients.

**Conclusions:** To date the HeRO vascular access device has performed comparably to standard AVGs when weighed against the peer review literature. Furthermore, in our experience its performance has proven superior to TDCs in terms of patency, intervention, and infection rates when compared to the peer reviewed literature. The HeRO device has shown great promise as an alternative to catheter dependence as a means for hemodialysis access. Preliminary results are good; however, data from additional prospective randomized trials could make this device a permanent fixture in the vascular access algorithm.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1550

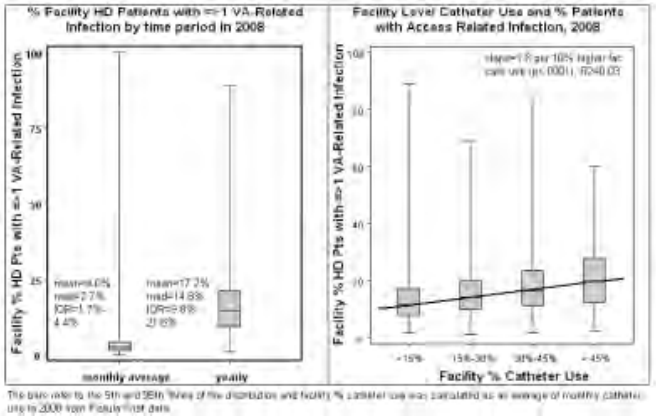
**Hemodialysis (HD) Vascular Access (VA)-Related Infection Rates in US Medicare Patients: Large Variability Not Explained by Facility Catheter Use** N. A. Lueth,[2] J. M. Messana,[2] V. B. Ashby,[2] Sandra E. Callard,[2] Rajiv Saran,[2] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health; [2]Univ. of Michigan Kidney Epidemiology and Cost Center.*

HD VA-related infections are strongly associated with mortality, hospitalization, and high treatment costs. Clinical trials have demonstrated variability in access-related infection rates among facilities, but comprehensive facility-level national comparisons are currently lacking. We examined facility-level rates of HD VA-related infection using Medicare claims data and its relationship with facility catheter use.

Facility-level monthly rates of VA-related overall infection were calculated among all Medicare patients receiving HD in 2008 (monthly mean n=251,544). Infection events were defined by ICD-9 code 996.62 (n=56,636). Facilities with >10 HD patients were included (n=4,972). Because claims with overlapping or proximate dates made it difficult to determine if 2 or more claims linked to more than 1 infection, these analyses only counted 1 infection per month per patient.

Large variability in monthly rates of VA-related infection was seen across facilities (Figure). On average during a month, the median facility % HD patients with ≥1 VA-related infection was 2.7%. The median facility % HD patients with ≥1 access-related infection in 2008 was 14.6%. Greater facility % catheter use was strongly associated with higher rates of VA-related infection (Figure), but explained only a small fraction of the total variability in VA-related infection across dialysis units ($R^2$=3%, p<.0001).

In summary, highly variable rates of VA-related infection are seen across US dialysis units much of which is not explained by catheter use. These results point to large opportunities for improving infection-control among HD patients, and the need to understand the practices explaining these highly variable VA-related infection rates.



Disclosure of Financial Relationships: nothing to disclose

## F-PO1551

**Location of Biofilm on Tunneled-Cuffed Hemodialysis Catheters in Patients with Catheter-Related Bacteremia** Venkataraman Ramanathan,[1] Sarah Riosa,[2] Atef Al Sharif,[2] Adrian Paul Abreo,[1] Saima Aslam,[2] Rabih Darouiche.[2] *[1]Division of Nephrology, MEDVAMC, Baylor College of Medicine; [2]Infectious Diseases, MEDVAMC, Baylor College of Medicine, Houston, TX.*

**Background:** Biofilm on hemodialysis (HD) catheter surface is difficult to eradicate and is associated with bacteremia. Location of biofilm on tunneled HD catheter surface and origin of bacteremia are unknown.

**Methods:** We identified HD patients who had bacteremia and whose tunneled catheter was removed to treat infection. Patients who had exit site or tunnel infection were excluded. Catheter segment immediately distal to cuff and double-barreled distal tip were defined as "extravascular" and "intravascular" segments respectively. Outer and luminal surfaces of both catheter segments were analyzed and compared using Paired Student's t-test.

**Results:** Seventeen HD patients were identified. Peripheral blood culture grew gram(+) organism in 76% of patients. When examined by confocal laser scanning microscope, biofilm was thicker on outer surface when compared to luminal surface for both extravascular (18.3*vs*14.8 μm, p<0.0001) and intravascular segments (15.3*vs*11.6 μm, p<0.0001). Extravascular segments had thicker biofilm when compared to intravascular segments on outer (18.3*vs*15.3 μm, p<0.001) and luminal surface (14.8*vs*11.6 μm, p<0.001). All patients were on antibiotics at time of catheter removal. Catheter culture was positive in 10 patients. Cultures of blood and extravascular outer surface yielded the same strain of organisms in all 10 patients. Microbiologic yield from extravascular luminal was 20% and from intravascular outer and luminal surfaces was 40% and 0%, respectively. DNA fingerprinting with pulsed-field gel electrophoresis confirmed that the organism retrieved from extravascular outer catheter surface was identical to that from peripheral blood culture in the majority of patients (90%).

**Conclusions:** Biofilm is thickest on outer surface of extravascular segment of an infected HD tunneled catheter and cultures from this segment have the highest microbiologic yield and correlation with peripheral blood cultures. Exit site may be the primary source of infection and this catheter segment should be routinely cultured.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1552

**Relationship of EPO Dose to Vascular Access, Serum Albumin and TSAT** B. Horowitz,[1,2] O. Myers,[1] S. Paine,[1,2] P. Zager.[1,2] *[1]UNM, Abq, NM; [2]DCI, Abq, NM.*

The expanded bundle poses a challenge to the financial stability of dialysis facilities. Reducing the amount of EPO administered will help control costs. We postulated that vascular access type (VA), iron saturation (TSAT) and serum albumin (SA) were associated with differences in EPO dose. We conducted a cross sectional study of 6887 DCI hemodialysis patients with fistulas (55%), grafts (24%) and catheters (21%). All patients had Hgb levels from 10 to 12 g/dl. The relationships of VA, TSAT and SA to EPO dose were assessed using an analysis of covariance, adjusting for age, race, sex and diabetes (Table).

Relative Effect Based on Log Transformed EPO

| Comparison | Estimates (95% CI) |
|---|---|
| Catheter vs Graft | 0.88 (0.82, 0.94) |
| Catheter vs AVF | 0.78 (0.74, 0.83) |
| Graft vs AVF | 0.89 (0.84, 0.94) |
| TSAT <20 vs TSAT 20-29 | 0.71 (0.68, 0.75) |
| TSAT <20 vs TSAT 30+ | 0.58 (0.55, 0.61) |
| TSAT 20-29 vs TSAT 30+ | 0.81 (0.77, 0.86) |
| SA <3.5 vs SA 3.5-3.9 | 0.68 (0.64, 0.72) |
| SA <3.5 vs SA 4.0+ | 0.55 (0.51, 0.58) |
| SA 3.5-3.9 vs SA 4.0+ | 0.80 (0.77, 0.85) |

Median SA (3.6 to 3.8 g/dl) and TSAT (22 to 24%) were similar in patients with fistulas (AVF), grafts and catheters. EPO cost was estimated using the average wholesale price (AWP) of $9.58/1000 U. EPO doses were lower in patients dialyzed via AVF vs. graft or catheter. Adjusted mean weekly EPO doses were 4620 U less in patients with AVF vs. catheters, cost differential of $44/patient/week. TSAT ≥ 30% and SA ≥ 4.0 g/dl were each associated with lower EPO doses vs. lower levels of these variables. EPO doses were 8656 U lower in patients with TSAT ≥30% vs. TSAT < 20% and 11,380 U lower in patients with SA ≥4.0 vs.< 3.5 g/dl, cost differentials of $83 and $109 respectively. EPO dose was inversely related to SA and TSAT, regardless of the type of VA. Adjusted mean EPO dose in patients with AVF, SA ≥ 4.0 g/dl and TSAT ≥ 30% was 10,228 U vs. 29,415 U in patients with catheters, SA <3.5 and TSAT <20%. Increasing AVF use, increasing SA and TSAT may reduce costs and improve both financial performance and patient outcomes under the expanded bundle.

Disclosure of Financial Relationships: nothing to disclose

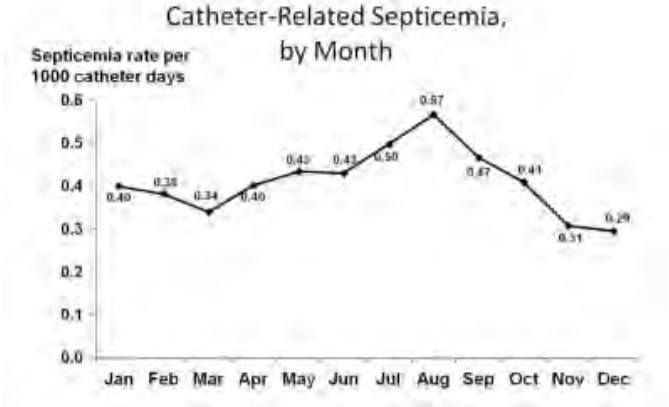
## F-PO1553

**Catheter (CVC) Related Septicemia: Associations with Seasons from the Dialysis Outcomes and Practice Patterns Study (DOPPS)** Charmaine E. Lok,[1] Jyothi R. Thumma,[2] Brenda W. Gillespie,[3] Richard J. Fluck,[4] Mark R. Marshall,[5] Hideki Kawanishi,[6] Bruce M. Robinson,[2,3] Ronald L. Pisoni.[2] *[1]Univ. Hlth. Network-Toronto Gen. Hosp., ON, Canada; [2]Arbor Research, Ann Arbor, MI; [3]Univ. of Michigan, Ann Arbor, MI; [4]Derby City Gen. Hosp., United Kingdom; [5]Middlemore Hosp., Auckland, New Zealand; [6]Tsuchiya Gen. Hosp., Japan.*

While CVC-related sepsis (CRS) contributes to adverse health outcomes in hemodialysis (HD) patients (pts), unexplored risk factors remain, such as season of year and CVC dressing protocols.

8,412 HD pts in 12 countries from DOPPS I and II (1996-2004) were analyzed. CRS was defined as septicemia during or within 15 days after HD CVC use. Catheter time at risk (n=1,754,293 days) and CRS were assigned to 1 of 4 seasons in each country. CRS rates by season and the association of facility vascular access (VA) dressing protocols with hazard ratio (HR) of CRS were determined by Poisson and Cox regression, respectively.

Overall CRS rate was 1.2/month or 0.41/1000 CVC days. In North America, CRS was 0.47/CVC 1000 days. CRS varied by month (Figure) with an adjusted RR for "summer" of 1.42 (95% CI 1.09-1.87) compared to "winter" (Table).



Rate of Catheter-Related Septicemia, by Season

| | Fall | Spring | Summer | Winter |
|---|---|---|---|---|
| septicemia rate /1000 catheter days | 0.34 | 0.38 | 0.49 | 0.34 |
| *Relative rate (RR) of septicemia:* | | | | |
| *Poisson model:* | RR (95% CI) | RR (95% CI) | RR (95% CI) | RR (95% CI) |
| Unadjusted | 0.99 (0.73-1.34) | 1.12 (0.84-1.49) | 1.44 (1.09-1.89)* | 1 (Ref.) |
| Adjusted** | 0.99 (0.73-1.33) | 1.12 (0.84-1.49) | 1.42 (1.09-1.87)* | 1 (Ref.) |

* p-value <0.01
** adjusted for age, gender, race, 13 summary comorbidities, phase and region

CRS was lower with use of betadyne [ adjusted HR=0.81, 95% CI (0.65,0.996)], or chlorhexidine [HR=0.81 (0.59,1.11)] vs. alcohol, with attenuated HRs (0.87-1.06) for combined cleansing agents. VA infection rates varied by personnel type who typically inspects CVC site /changes dressings: nephrologist [HR=0.64 (0.45,0.92)], technician [HR=1.47, 95% CI (0.98,2.2)] compared with nurse.

The higher CRS rate in summer may be due to higher heat, humidity, and perspiration, potentially facilitating bacterial growth and compromising protective measures. Extra vigilance by staff may reduce CRS in this high risk season. Betadyne and chlorhexidine may be more effective than other cleansing agents.

**Comparison of Native Arterio-Venous (A-V) Fistula Needling Using the Button-Hole Versus the Rotation Technique. Evidence for Excess Blood Stream Infections with the Button Hole Method** Rebecca Backenroth, Ruthy Israeli, Dvora Rubinger. *Nephrology, Hadassah University Medical Center, Jerusalem, Israel.*

Native A-V fistulas are considered the preferred access for chronic hemodialysis. However, it is not established which needling technique is optimal. We prospectively compared 2 needling techniques, the rope-ladder or rotation (ROT) and the button-hole (BH) methods, evaluated staff opinions, and reviewed infection rates. The study was done in an ambulatory hemodialysis unit with approximately 70 chronic patients. Blood Stream Infections (BSI) were considered access related only when there was no other plausible cause for infection.

**Results:** In multiple random assessments of 23 BH and 21 ROT patients, mean age 63 and 62 yrs respectively, anxiety level before cannulation, pain, difficulty and complications of cannulation such as bleeding around the needles did not differ between the groups. On termination of dialysis, clotting tended to occur earlier in BH, but this, also, was not statistically significant. Analysis of BSI was performed retrospectively and then prospectively. Interim results are presented in table 1:

table 1

| Group | # of patients | patient months | Unexplained bacteremias |
|---|---|---|---|
| BH, retro | 23 | 1358 | 11* |
| ROT, retro | 21 | 1047 | 1* |
| BH, pros | 41 | 360 | 3** |
| ROT pros | 33 | 234 | 0** |

retro-retrospective; * $X^2$ p<0.05; pros-prospective; **pNS

The fistulas looked and functioned normally in all cases of BSI except 1 where an abscess developed at a BH site. The BSI bacteria were relatively sensitive skin organisms; Staph. aureus was associated with more severe and protracted BSI, and the abscess. Questionnaires revealed that 75% of 16 nurses felt more confident in using the BH method.

**In conclusion**, the BH and ROT cannulation techniques were similar in effectiveness, but BH was preferred by the nurses. Retrospective review of unexplained bacteremias revealed a statistically significant excess of BH associated BSI, with a rate of 1 bacteremia per 123 patient months. Prospective data indicated a similar BH related bacteremia rate, despite enhanced disinfection protocols. Due to these findings, we have suspended BH cannulation when ROT is an option.

**Transvenous Cardiac Device Wires and Vascular Access in Hemodialysis Patients** David A. Drew, Klemens B. Meyer, Daniel E. Weiner. *Tufts Medical Center, Boston, MA.*

Cardiovascular disease is the leading cause of mortality in dialysis patients. Increasingly, cardiac devices such as implantable cardiac defibrillators (ICDs) and pacemakers are being placed for both prevention of sudden cardiac death and for non-lethal arrhythmias; these most often use transvenous pacer wires through the subclavian vein. As these wires may predispose to central vein stenoses, we explored the association between the presence of cardiac devices and vascular access outcomes.

We retrospectively analyzed data from 590 patients who received chronic hemodialysis at DCI Boston since 1995. Cardiac device status, vascular access history and central vein patency were ascertained from review of the DCI and Tufts Medical Center electronic medical record, with radiographs reviewed when available. We recorded the venous access history for each patient, both prior to and after device insertion. The presence of central stenoses was determined by reviewing venogram and duplex results for each patient if available. If imaging was unavailable, stenoses were assumed absent.

From 590 patients, we identified 43 with transvenous cardiac devices; 34 (79%) had imaging and 21 (49%) had documented central vein stenosis. Of these 21, 10 (48%) were catheter dependent after device insertion. In comparison, among 547 patients without devices, 297 (54%) had imaging and 94 (17%) had an identified central stenosis.

In conclusion, hemodialysis patients with cardiac devices have a higher rate of central vein stenoses. This may be related to the physical presence of transvenous pacing wires and has implications for patients' future vascular access options. Careful risk:benefit assessment and consideration of possible alternatives, including use of epicardial leads, should be undertaken prior to transvenous wire insertion in hemodialysis patients as well as late stage CKD patients.

## F-PO1556

**Bacterial Biofilm in Non-Infected Tunneled Hemodialysis Catheters** Venkataraman Ramanathan,[1] Sarah Riosa,[2] Atef Al Sharif,[2] Adrian Paul Abreo,[1] Saima Aslam,[2] George M. Nassar,[3] Rabih Darouiche.[2] *[1]Division of Nephrology, MEDVAMC, Baylor College of Medicine, Houston, TX; [2]Infectious Diseases, MEDVAMC, Baylor College of Medicine; [3]The Kidney Institute of Houston, .*

**Background:** Biofilm forms on the surface of tunneled hemodialysis (HD) catheter and is often associated with bacteremia. Knowledge about biofilm thickness and location is important, especially in the subset of patients without clinical evidence of infection, to plan preventive anti-biofilm strategies.

**Methods:** We identified patients in whom tunneled HD catheter was removed for non-infective etiologies and who did not have current clinical evidence of infection. The sterile

catheter segment immediately distal to cuff and the double-barreled distal tip were defined as "extravascular" and "intravascular" segments respectively. Outer and luminal surfaces of both catheter segments were analyzed separately. Paired Student's t-test was used.

**Results:** We examined 22 catheters with a confocal laser scanning microscope. Median duration of catheter was 101 days. Biofilm was seen in 17 of them (77%). As shown in the table, biofilm was significantly thicker on the outer surface compared to luminal surface for both extravascular and intravascular segments. Overall, extravascular segments had thicker biofilm compared to intravascular segments on both outer and luminal surfaces.

Biofilm thickness

| | Outer surface | Luminal surface | p-value |
|---|---|---|---|
| Extravascular | 3.1μ | 2.4μ | <0.001 |
| Intravascular | 2.4μ | 1.5μ | <0.0001 |
| p-value | =0.001 | =0.001 | |

Despite absence of clinical infection, 3 catheters grew an organism (14%). All the three patients had significant growth from outer surface of extravascular segment. One patient had growth from outer surface of both extra and intravascular segments. S. epidermidis was the commonest organism (3/3) and one patient had S. aureus (1/3).

**Conclusions:** Biofilm is present on the surface of tunneled HD catheter even in the absence of clinical infection. Outer surface of extravascular catheter segment has the thickest biofilm and harbors bacteria in few patients. It is possible that exit site may be the primary port of entry for bacteria.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1557

**Permanent Dialysis with a Catheter: Fact and Fiction OR One Size Does Not Fit All** Kotagal Shashi Kant, Heather Duncan, Mahmoud T. El-Khatib. *Nephrology, Univ of Cincinnati, Cincinnati, OH.*

**Introduction:** The disadvantages of long term catheter use for hemodialysis vascular access are well known. Mortality, infection as well as other morbidities are all increased by catheter use. Both the KDOQI guidelines and Fistula First Initiative reflect this. However, the increasing co-morbidities of incident and increasing vintage of prevalent patients means that there are a group of patients who now dialyse with permanent catheters. Catheter prevalence in dialysis facilities is likely to be viewed as a marker of negative quality. Despite the well known negatives associated with long term catheters, there are patients who are well served by continuing to use catheters when other modalities are not possible..

**Methods:** All records for HD patients at a single outpatient unit were reviewed and three groups of patients were identified who dialyzed with a single type of access (Catheter, Graft or Fistula) for at least 90% of a 24 month period. Treatment parameters, demographics, labs and prcedures done to maintain the access were analyzed in an effort to identify differences among the three groups.

**Results:** Proportions of males, diabetic and black race were equivalent among C, G and F groups. Time since ESRD diagnosis did not differ. Average Kt/V was higher in G, but was >1.6 in C and F groups. Mean epo dose/kg did not vary, but Alb was lower in C.

Comparison of Several Measures by Access Type

| Group | Alb | Kt/V | HD missed d/t hosp | proc/month | proc cost/yr |
|---|---|---|---|---|---|
| C | 3.64* | 1.61* | .10 | 0.15 | $84 * |
| G | 3.83 | 1.82 | .08 | 0.16 | $7500 |
| F | 3.92 | 1.68† | .08 | 0.04† | $1500† |

*C diff from G, ** C diff from F, † F diff from G

Median # HD treatments missed due to hospitalization were similar in C, G and F. Med # Procedures, defined as activase, cath change, angioplasty, declot, stent or revision were significantly lower in F, but similar for G and C. Using estimates for cost of each of these procedures, the average cost per year for maintenance of an access was substantially higher in G.

**Conclusion:** In this selected group of pts we demonstrated that there were no additional costs or hospitalization associated with dialysis catheter use.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1558

**Risk Factors for Central Vein Stenosis Following Tunneled Dialysis Catheter Insertion** Darren Green,[1] Ganepola Arachhige Chandrkumara Wijesekara,[1] Philip A. Kalra,[1] Babatunde Adeniyi Campbell.[2] *[1]Dept. of Renal Medicine, Salford Royal Hospital, Salford, United Kingdom; [2]Manchester Institute of Nephrology and Transplantation, United Kingdom.*

Using central venous catheters for maintenance haemodialysis is associated with a risk of central vein stenosis and long term compromise of vascular access.

The aim of this study was to evaluate whether pathologies which are known to cause vascular or endothelial injury are associated with risk of central vein stenosis following tunneled dialysis catheter insertion, and whether drugs which improve vascular outcome in other settings reduce the stenosis event rate.

Information was collected from a prospective database of all tunneled dialysis lines inserted at a nephrology unit over 2 years. Medical history and blood results from the time of insertion were recorded. Radiological evidence of ipsilateral stenosis of the subclavian, brachiocephalic or internal jugular vein over the following three year period was noted.

178 Permcath catheters were inserted in 134 patients. There were 38 cases of central vein stenosis. There was correlation between the number of tunneled lines and development of stenosis (mean number of catheters, stenosis vs. no stenosis = 1.66 vs. 1.20, p<0.001). The impact of duration of dialysis via tunneled catheter did not reach statistical significance (weeks dialyzing via catheter = 62.2 vs. 47.3, p=0.053). There was no difference in number of preceding temporary dialysis lines. Patients who developed stenosis suffered more episodes of bacteremia during the catheter life (0.84 vs. 0.35, p=0.004). Age, gender, diabetes mellitus, anti-platelet drugs and statins did not link to developing stenosis. More patients who developed stenosis were taking statins, but this did not reach statistical significance (73.68% vs. 55.91%, p=0.070). Mortality at three years was the same in both groups (52.63% vs. 47.91%, p=0.386).

Recurrent line insertion and infection are significant risk factors for developing central vein stenosis, suggesting an important role of chronic inflammation in its pathophysiology. The higher rate of statin use among patients with stenosis may indicate a causative role of hypercholesterolemia.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1559

**Conventional Short Dwell Alteplase (TPA) Is Less Effective Than Overnight Long Dwell TPA in the Treatment of Hemodialysis Catheter Dysfunction (CD)** Subash Regmi, Muneeb S. Malik, Jesse M. Goldman. *Nephrology, Temple University Hospital, Philadelphia, PA.*

Thrombotic dysfunction of hemodialysis (HD) catheters is common. Though tissue plaminogen activator (TPA) is the most commonly used thrombolytic agent to treat dysfunctional HD catheters it is not FDA approved for this indication. Optimal TPA dwell time is unknown to reestablish HD catheter function. **Methods:** We conducted a review of HD pts receiving intracatheter TPA for CD in our inpatient HD unit: 10/01/08 - 12/31/09. We included pts receiving TPA for AKI & CKD-5D. We included tunnelled and non-tunnelled catheters. 409 TPA administrations were identified using our pharmacy database. Review of records identified 48 pts and 68 TPA administrations that fulfilled eligibility criteria. Mean age: 54.13 yrs. Sex: 24 males and 24 females. Catheter type: 47 tunnelled and 21 non-tunnelled. Catheter location: 46 IJ; 22 femoral. Short Dwell (SD): 40 and Long Dwell (LD): 28. Average SD time: 35 minutes; LD time: 2587.5 min. (1.8 days) Range (905-4375 min). Hemoglobin = 9.5 g/dl (SD), 9.9 g/dl (LD). Eligibility Criteria: 1) Documented CD defined as blood flow ($Q_b$) <300 ml/min or $Q_b$ ≤300 ml/min with arterial pressure (AP) ≤ -250 mmHg. 2) Documented HD session post TPA administration. Exclusion Criteria: 1) TPA administered due to heparin contraindication 2) No clear documentation to support CD. SD: TPA instillation in one or both HD catheter ports with dwell time of ≤ 60 min. LD: TPA instillation in one or both HD catheter ports & dwelled > 60 min (1-3 days). Defined Success: Ability to complete one HD session with improvement $Q_b$≥300 ml/min with AP ≥ -250 mmHg.

Short Dwell success: 25%

Long Dwell success: 61%.

Success Reestablishing Adequate Flow

| Dwell Time | Yes | No | Total |
|---|---|---|---|
| Short | 10 | 30 | 40 |
| Long | 17 | 11 | 28 |
| Total | 28 | 41 | 68 |

Fisher's exact = 0.005 1-sided Fisher's exact = 0.003

Conclusions:

Long TPA dwell is more effective in reestablishing adequate blood flow compared with short dwell in HD catheters. Short dwell is still somewhat effective & may be valuable according to clinical circumstances. A prospective, randomized trial is needed to corroborate these results. It is unknown if TPA is superior to Tenecteplase.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1560

**Impact of Hemodialysis Catheter Dysfunction on Utilization of Medical Services** Robert I. Griffiths,[1] Britt B. Newsome,[2] Geoffrey A. Block,[2] Grace Leung,[3] Mark D. Danese.[1] *[1]Outcomes Insights, Inc., Westlake Village, CA; [2]Denver Nephrologists, P.C., Denver, CO; [3]Genentech, Inc., South San Francisco, CA.*

**Purpose:** To evaluate the impact on medical services of catheter dysfunction, defined by National Kidney Foundation Kidney Disease Outcomes Quality Initiative guidelines as failure to attain an extracorporeal blood flow rate (BFR) above 300 mL/min. **Methods:** We conducted a retrospective cohort study using data from DaVita, Inc. merged with the United States Renal Data System. DaVita data contained records for each dialysis session, including date of service, access type, planned and actual BFR, and length of dialysis session. Records for missed dialysis sessions contained the date and reason for missing the session, including "access problems." Patients were included if they had ≥ 8 consecutive weeks of catheter dialysis between 08/2004 and 12/2006. They were followed from first to last catheter dialysis session. Catheter dysfunction was defined as actual BFR < 300mL/min despite a planned BFR ≥ 300mL/min. Two approaches, multivariate repeated measures and case-crossover, were used to analyze associations between catheter dysfunction and patterns of medical services. **Results:** Of 44,470 patients in the merged data set, 9,707 (22%) met the study criteria. The average age was 62, 53% were female, and 40% were black. The median length of catheter dialysis was 190 days. There were 1,075,701 catheter dialysis sessions, 70,361 (6.5%) met the definition of catheter dysfunction, and 6,331 (65.2%) patients had ≥ 1 session with catheter dysfunction. In multivariate repeated measures analysis, catheter dysfunction was associated with increased odds of a missed session due to access problems (OR 2.50; P < 0.001), receiving an access-related procedure (OR 2.10; P < 0.001), either missed session due to access problems or access-related procedure (OR 2.21; P < 0.001), and all-cause hospitalization (OR 1.10; P = 0.001). It was not associated with length of dialysis. Case-crossover results were similar. **Conclusion:** Catheter dysfunction is associated with increased use of medical services and disruptions in dialysis treatment.

Disclosure of Financial Relationships: Research Funding: Outcomes Insights has received research funding from Genentech and Amgen.

**F-PO1561**

**Burden of Catheter Dysfunction in End-Stage Renal Disease (ESRD)** Robert I. Griffiths,[1] Britt B. Newsome,[2] Geoffrey A. Block,[2] Grace Leung,[3] Mark D. Danese.[1] *[1]Outcomes Insights, Inc., Westlake Village, CA; [2]Denver Nephrologists, P.C., Denver, CO; [3]Genentech, Inc., South San Francisco, CA.*

**Purpose:** To describe the epidemiology of dialysis catheter dysfunction in ESRD.

**Methods:** A retrospective cohort study was conducted using data from DaVita, Inc. and USRDS. Patients were included if they received ≥ 8 weeks of uninterrupted hemodialysis through a catheter between 08/2004 and 12/2006, and either (A) catheter hemodialysis was their first treatment modality following ESRD diagnosis, or (B) catheter hemodialysis immediately followed ≥ 1 month of hemodialysis exclusively through a graft or fistula. They were followed from the beginning to the end of catheter dialysis, death, or end of the observation period, whichever came first. Catheter dysfunction during a dialysis session was defined as actual blood flow rate (BFR) < 300mL/min despite planned BFR ≥ 300 mL/min. Multivariate (MV) Cox regression analysis was performed to identify patient factors associated with catheter dysfunction.

**Results:** There were 3,364 patients in the cohort. The average age was 62, 51% were male, 42% were black, 46% had diabetes and 28% had hypertension reported as the underlying cause of renal failure. The cohort accounted for 268,363 catheter dialysis sessions. The median duration of catheter dialysis was 143 days. There were 19,118 (7.1%) sessions with catheter dysfunction, 64% of patients had ≥ 1 catheter dysfunction session during their catheter treatment history, and approximately 30% had ≥ 1 catheter dysfunction session per month on catheter dialysis. The median time to first session with catheter dysfunction was 95 days. In MV analysis, male gender and black race were associated with lower rates of catheter dysfunction. Patients who had received hemodialysis through a fistula or graft immediately prior to catheter hemodialysis had a higher rate of catheter dysfunction compared to those with catheter hemodialysis as their first modality (Hazard Ratio: 1.13; P=0.04).

**Conclusions:** Catheter dysfunction affects approximately 30% of catheter dialysis patients each month. Patients with prior graft or fistula appear to be at higher risk.

Disclosure of Financial Relationships: Research Funding: Outcomes Insights has received research funding from Genentech and Amgen.

**F-PO1562**

**Comparison of the Palindrome Versus Step Tip Tunneled Hemodialysis Catheter: Prospective Randomized Trial** Hyeonseok Hwang,[1] Seokhui Kang,[1] Byung Ha Chung,[1] Bumsoon Choi,[1] Cheol Whee Park,[1] Chul Woo Yang,[1] Yong-Soo Kim.[1, 2] *[1]Division of Nephrology, Department of Internal Medicine, The Catholic University of Korea, Seoul, Republic of Korea; [2]Interventional Nephrology Clinic, Seoul St. Mary's Hospital, Republic of Korea.*

**Background:** The Palindrome tunneled hemodialysis catheter is recently developed vascular access with unique symmetric tip design. The aim of this study was to compare the function and complications of the Palindrome catheter with those of step-tip tunneld hemodialysis catheter.

**Methods:** In this prospective, randomized trial, 22 patients were assigned to the Palindrome catheter group and 23 patients to step-tip catheter group. Interventional nephrologist placed all catheters using ultrasound and fluoroscopic guidance. At baseline and one month, effective flow rate (QbEff) and recirculation was examined at various pump speeds (Qb), and Kt/V of urea was measured at Qb 300 ml/min. The procedure-related data and catheter-related complications were recorded during entire study period.

**Results:** The baseline characteristics, procedure time and placed catheter length were similar between Palindrome and step-tip group (all $p > 0.05$). There were 5 procedure-related complications including tunnel bleeding (n = 1, step-tip) and exit site bleeding (n = 3, Palindrome; n = 1, step-tp) (all p > 0.05). Adjusted means of QbEff at Qb 200, 300, 400 ml/min was 226, 334, 428 ml/min in Palindrome and was 225, 332, 431 ml/min in step-tip group (all $p > 0.05$). The recirculation at each flow, Kt/V of urea (1.45 vs. 1.35) and late complication rate (5% vs. 17%) was similar between two groups (all $p > 0.05$). While the groups did not differ as catheter survival ($p = 0.189$), re-intervention free survival rate was higher in Palindrome group ($p = 0.021$). Of the patients with catheter dysfunction, dialysis lines were reversed in 8 patients (n = 3, Palindrome; n = 5, step-tp) and recirculation tended to be lower in Palindrome than in step-tip group (0.0 vs. 20.3%; $p = 0.124$).

**Conclusion:** The Palindrome catheter was more useful to reduce catheter re-intervention rate than step-tip catheter and might provide minimal recirculation benefit, despite of arteriovenous reversal state.

Disclosure of Financial Relationships: Research Funding: The study was funded by Novartis Pharma.

**F-PO1563**

**Analysis of Exit Site Infections in Facilities Using Electrolytically-Produced Sodium Hypochlorite** Steven M. Wilson, Amy Burdan, Amy Young. *DaVita Inc., Denver, CO.*

**Introduction:** Sodium hypochlorite solution is an effective topical disinfectant and is used to prophylactically reduce the risk of bacterial contamination and skin infections with central venous catheters (CVCs) for dialysis. KDOQI states the average CVC infections for tunneled cuffed catheters is 3.1 per 1000 days at risk. However, little comparative data has been shown about this preparation vs the use of iodine for skin site preparation with ESRD patients. To identify best practices, we surveyed dialysis clinics to document this infection control procedure. **Methods:** 226 dialysis facility administrators (FAs) with a patient census >20 completed the survey. They were asked about their method of skin preparation and patient outcomes. Infection rates in facilities using an electrolytically-produced sodium hypochlorite (ESH; ExSept Plus or Alcavis 50) were compared to those using conventional iodine based antiseptic protocol. The facility proportion of infections was defined as the number of infections found in the study period divided by the number of individuals at risk and their number of days at risk. **Results:** 80% reported using ESH for exit site disinfection. 17% of facilities applied an antibiotic ointment to the exit site following disinfection. Infection rates from 5/09-10/09 showed no significant differences for any month, although in almost all months the observed percentage of infections was lower in facilities using ESH. These facilities had an observed infection rate±SE of 1.99 (±3.26) infections per 1000 patient days with CVC while conventional facilities had an observed infection rate of 2.10 (±7.09) infections per 1000 patient days with CVC (ns). **Conclusions:** ESH use was much higher than expected. This may show a possible change in practice pattern of using ESH in dialysis treatments where both the use of CVCs and infections is common. While the observed proportion of infections was lower in ESH facilities in 5 of 6 months, this difference was not statistically significant. FAs reported anecdotally the perceived benefits of a reduced procedure time to achieve skin disinfection, less aggressive cleaning of the site, no sensitization, and catheter material compatibility.

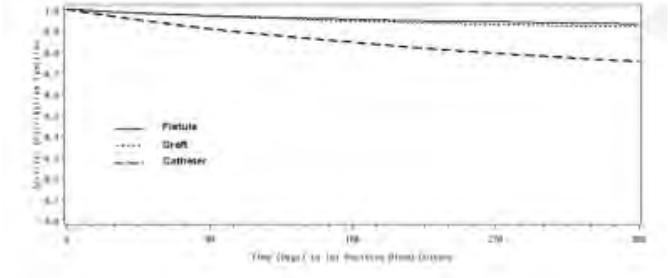
**Hemodialysis Vascular Access Type and Bloodstream Infection Rates** Eduardo K. Lacson, Weiling Wang, J. Michael Lazarus, Raymond M. Hakim. *Fresenius Medical Care, North America, Waltham, MA.*

**Introduction:** We evaluated bloodstream infection (BSI) rates based on positive blood cultures by type of vascular access in a national cohort of incident hemodialysis (HD) patients during their first year.

**Methods:** All HD patients admitted to Fresenius Medical Care North America facilities within 15 days of first-ever dialysis between January 1 and December 31, 2007 with known access type (fistula, graft, or catheter) were included. Use of a catheter was classified under "catheter" despite the presence of another maturing access. Blood culture results from Spectra lab were tracked for up to 1 year or until a change in access type or discharge/death. Age, gender, race, and diagnosis of diabetes were collated on admission.

**Results**: Among 25,003 patients, 78.5% had catheters, 16.6% fistulas, and 4.9% grafts. Mean age was 63.4 ± 15.3 years, 56.1% male, 64.8% white and 30.0% black, with 55.1% DM. Overall, >85% of all blood cultures were captured, with 3,327 (13.3%) patients with at least one positive result during follow-up. The time to 1st BSI by access type, predominantly catheters, is shown in Figure 1.

Figure 1: Kaplan-Meier curves for time to 1st positive blood culture



Median time to presumed catheter-associated BSI was 87 days at a rate of 0.61/1000 catheter-days. The unadjusted hazard ratio for BSI in catheter vs. fistula patients was 3.78 and 3.83 after case-mix adjustment (both p<0.0001). No significant differences existed between fistulas and grafts.

**Conclusions**: Catheter-associated BSI occurs early, within the first 90 days, supporting arteriovenous access placement prior to the need for dialysis or immediate transition towards a permanent access upon HD initiation. The study was limited by incomplete capture of all blood culture results, likely resulting in an underestimate of BSI rates.

Disclosure of Financial Relationships: Employer: I am an employee of Fresenius Medical Care, North America.

**F-PO1565**

**Non Fluoroscopic Insertion of Tunneled Hemodialysis Catheter by Nephrologists** Tee Chau Keng, Wai Yew Kong, Kok Peng Ng, Chew Ming Wong, Yip-Boon Chong, Li Ping Tan, Soo Kun Lim. *Nephrology Unit, University Malaya Medical Center, Malaysia.*

Introduction

Tunneled cuffed catheter (TCC) is the essential lifeline for incident hemodialysis patients without preformed permanent access. Fluoroscopy is mandatory under KDOQI guidelines for TCC insertion but not readily available in many institutions. This invariably results in more usage of non tunneled cuffed catheters (NTCC) which carries unacceptably high risk of infection. We report the role of TCC insertion without fluoroscopy by nephrologists.

Method

We performed a retrospective study on non fluoroscopic TCC insertion by designated nephrologists for incident patients from October 2009 to March 2010. The insertion was via either ultrasound guided cannulation of the deep veins or catheter exchange using the existing NTCC. The procedures were performed using the standard method and guided

by anatomical landmarks, aiming for tip of catheter in the mid right atrium for internal jugular (IJ) catheters or inferior vena cava for femoral catheters. Position of the catheters was verified radiologically post insertion. All patients were discharged to their respective dialysis centers post insertion and followed up by phone calls.

Results

Forty five TCC were inserted in 45 incident patients (24 male and 21 female, mean age 60 years; range 34-89years). Thirty five right IJ, 6 femoral, 3 left IJ, and 1 subclavian TCC were placed. Total length of follow up was 4497 catheter days. The primary patency rates at 30, 60 and 90days were 90.1, 83.3 and 76.9% respectively. The 30, 60 and 90-day secondary patency rates were 95.5, 88.1 and 82.1%. Immediate failure was noted in 2 of the left IJ TCC (4.4%). Catheter dysfunction required intervention was 6.7%. The only complication observed was non life threatening bleeding in 2 patients (4.4%). Infection rates at 30 and 90 days were 4.5 and 18%. Overall infection rate was 0.18 per 100 catheter days. There were 3 deaths but non catheter related.

Conclusion

Non fluoroscopic insertion of TCC, excluding left IJV, in the hands of committed nephrologists can be safe with comparable patency rates. This will invariably reduce the dependency on NTCC in institutions with limited access to fluoroscopy.

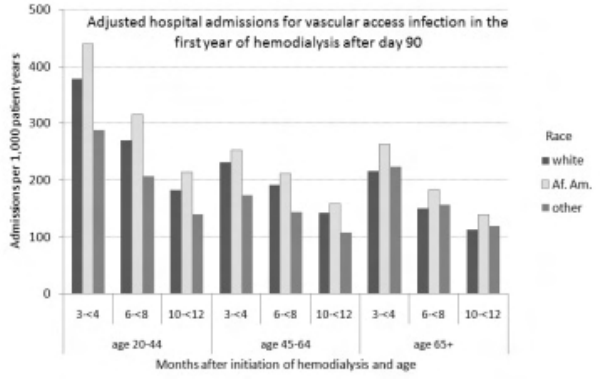
**Racial Disparity in Hospital Admissions for Vascular Access Infection among Incident Hemodialysis Patients** Tricia L. Roberts,[1] Allan J. Collins,[1,2] David T. Gilbertson.[1] *[1]U.S. Renal Data System Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

While mortality in incident HD patients has been lower among African Americans than whites, little is known about predictive factors behind high first-year vascular access (VA) infectious admission rates. We analyzed predictors of hospital admissions for VA infection in the first year of HD following day 90 after initiation in a cohort of 105,313 U.S. incident patients in 2006 and 2007. To allow data availability, included adult Medicare patients survived the first three months of dialysis and had a Medical Evidence Form indicating access type used on first outpatient dialysis. Admission rates for VA infection were computed by age, race, and months from dialysis initiation, and adjusted for gender, primary diagnosis, and initial VA type. We assessed predictors of first admission for VA infection during months 3 to 12 with Cox proportional hazards regression models.



Admissions for VA infection were highest among African Americans compared to whites and other races within each age and interval. Among race and age combinations, African Americans age 20-44 had the highest percentage (67.9%) with only a catheter as the initial access. Compared to whites, African Americans had higher risk of admission for VA infection (HR=1.12; 95% CI 1.07-1.17) and other races had lower risk (HR=0.88; 0.79-0.97). Other factors associated with VA infection were younger age, diabetes, and catheter as initial access type. Age 20-44 African Americans showed significantly higher adjusted risk (P<0.05) than other age and race groups except age 20-44 white. Despite lower overall mortality rates, African Americans had high first-year admissions for VA infection, and catheter use may be a contributing factor. Results suggest further study of differential racial impact of infections on subsequent mortality.

**Effectiveness of a Shower Washing Method without Antiseptics and Histological Findings at Exit-Site of Tunneled Cuffed Venous Catheters** Hiroshi Shibahara,[1] Nami Shibahara,[2] Susumu Takahashi.[3] *[1]Blood Purification Center, Sagamihara Kyodo Hospital, Sagamihara, Kanagawa, Japan; [2]Hashimoto-Minami Internal Medicine Clinic, Sagamihara, Kanagawa, Japan; [3]Nihon University Graduate School, Tokyo, Japan.*

**Background** To prevent tunneled cuffed venous catheter (TCC) from exit-site infections, catheter care is essential. We have reported a new care method designed to prevent infection by normalizing skin conditions at the exit-site, which is directly cleaned using a shower without antiseptic agents. We evaluated the efficacy of this care method and examined histological findings of the skin at the TCC exit-site.

**Methods:** The subjects were 109 hemodialysis patients (male/female, 73/36; mean age, 67.2 ± 12.7 years; diabetes mellitus/non-diabetes mellitus, 48/61; mean catheter days, 57.6 ± 46.7 days), using a TCC, who gave informed consent at Sagamihara Kyodo Hospital and Hashimoto-Minami Internal Medicine Clinic between January 2007 and December 2009. Our method involves washing the TCC exit-site with tap water or physiological saline immediately after TCC insertion. Moisture can be wiped away with non-sterile gauze. No antiseptics are applied. TCC is fixed with an appropriate tape. When bathing at home, the exit-site and surrounding skin can be washed using shower water without a water-proof film covering. Then, moisture is wiped away with a clean laundered towel. Shower washing at the exit-site with tap water is continued until TCC removal. In 10 patients, skin at the TCC exit-site was histologically examined at the time of TCC removal.

**Results:** Exit-site infection occurred in 5 patients (4.6%). Neither tunnel nor catheter-related bloodstream infections were observed during this investigation. Histological examination revealed the surrounding epidermis at the exit-site to show downward growth into the deeper dermis, maintaining the normal skin structure.

**Conclusion**: This washing method is effective in managing TCC exit-sites. The skin at exit-sites retained its normal structure, histologically confirming the efficacy and safety of this catheter care method.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1568

**Hemodialysis Catheters Increase Mortality as Compared to Shunts Especially in Elderly Patients** Gurbey Ocak,[1] Nynke Halbesma,[1] Saskia le Cessie,[1] Ellen K. Hoogeveen,[2] Sandra Van Dijk,[3] Jeroen Kooman,[4] Friedo W. Dekker,[1] Raymond T. Krediet,[5] Elisabeth W. Boeschoten,[6] Marion Verduijn.[1] *[1]Clinical Epidemiology, LUMC, Leiden, Netherlands; [2]Internal Medicine, JBH, Den Bosch, Netherlands; [3]Medical Psychology, LUMC, Leiden, Netherlands; [4]Nephrology, UHM, Maastricht, Netherlands; [5]Nephrology, AMC, Amsterdam, Netherlands; [6]HMI, Naarden, Netherlands.*

**Objectives:** Catheter use has been associated with an increased mortality risk in hemodialysis patients. However, differences in the all-cause and cause-specific mortality risk between catheter use and shunt use in young and elderly hemodialysis patients has not yet been investigated.

**Methods:** 1109 incident hemodialysis patients from 38 centers in the Netherlands between 1997 and 2004 were included in this study. Hazard ratios (HRs) with 95% confidence intervals (95% CIs) were calculated for 2-year all-cause, infection-related, and cardiovascular mortality in elderly patients aged ≥65 years with a catheter as compared to elderly patients and young patients aged <65 with a shunt adjusted for age, sex, primary kidney disease, Davies comorbidity score, angina pectoris, myocardial infarction, heart failure, ischemic stroke, claudication, predialysis care, GFR, and serum albumin levels.

**Results:** Of the 1109 patients, 919 had a shunt and 190 had a catheter. The mortality rate was 76 per 1000 person-years in young patients with a shunt, 129 per 1000 person-years in young patients with a catheter, 222 per 1000 person-years in elderly patients with a shunt, and 427 per 1000 person-years in elderly patients with a catheter. The adjusted HRs in elderly patients with a catheter as compared to elderly patients with a shunt was 1.51 (95% CI 1.10-2.06) for all-cause mortality. The adjusted HRs in elderly patients with a catheter as compared to young patients with a shunt were 3.05 (95% CI 2.04-4.56) for all-cause mortality, 3.17 (95% CI 1.00-10.02) for infection-related mortality, and 2.74 (95% CI 1.54-4.90) for cardiovascular mortality.

**Conclusions:** Especially elderly hemodialysis patients with a catheter have an increased all-cause, infection-related, and cardiovascular mortality risk as compared to young patients with a shunt.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1569

**Pattern of Vascular Access in Hemodialysis Patients: Cross-Sectional Study of Clinical Research Center for End Stage Renal Disease in Korea** Ja-Yong Park,[1,2] Young-Deuk Yoon,[1,2] Ji-Young Choi,[1,2] Se-Hee Yoon,[1,2] Sun-Hee Park,[1,2] Chan-Duck Kim,[1,2] Sung-Ho Kim,[2] Jun-Young Do,[2] Seong Eun Kim,[2] Sang Heon Song,[2] Yeong Hoon Kim,[2] Nam Ho Kim,[2] Yon Su Kim,[2] Shin-Wook Kang,[2] Chul Woo Yang,[2] Yong-Lim Kim.[1,2] *[1]Kyungpook National University School of Medicine; [2]Clinical Research Center for End Stage Renal Disease, Korea.*

**Purpose:** To examine vascular access patterns and contributing factors affecting them in hemodialysis(HD) patients.

**Methods:** From April 2009 to March 2010, we conducted a cross-sectional study to identify vascular access patterns and factors that influence the choice of vascular access according to demographics and co-mobidities using the data from 729 HD patients in CRC for ESRD in Korea.

**Results:** Of the 729 HD patients, 465 patients (63.8%) were being dialyzed with a native arterio-venous fistula(AVF), 137 patients (18.8%) with a graft, 69 patients (9.5%) with a tunneled catheter and 58 (8.0%) patients with a non-tunneled catheter. Of the 614 prevalent patients, the proportions of access pattern are 72.5%, 21.2%, 5.9% and 0.5% respectively. And of the remaining 115 incident patients, the proportions are 17.4%, 6.1%, 28.7% and 47.8% respectively. In the 729 patients, the predictors of native AVF versus other access use are body mass index<25kg/m$^2$(adjusted odds ratio(AOR) 1.483, p=0.049), presence of peripheral vascular disease (AOR 0.263, p<0.001), cerebro-vascular disease (AOR 0.377, p<0.001) and arrhythmia (AOR 0.478, p=0.027). In prevalent patients, the predictors are presence of coronary artery disease (AOR 0.551, p=0.006), peripheral vascular disease (AOR 0.193, p<0.001), cerebro-vascular disease (AOR 0.351, p<0.001), and hypertension (AOR 2.031, p<0.001). In incident patients, there are no predictors influencing the choice of access pattern.

**Conclusions:** In incident HD patients of Korea, there are still a very high proportion of patients starting dialysis with a catheter and no patient-specific factors that influence the

choice of vascular access. Comorbid conditions such as obesity, cardiovascular disease, cerebro-vascular disease and arrhythmia could be possible causes for the high proportion of catheter use in HD patients.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1570

**Relationship between Blood Flow Rate in Tunneled HD Catheter and Dialysis Adequacy** Byung Ha Chung, Seokhui Kang, Hyeonseok Hwang, Bumsoon Choi, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim. *Department of Internal Medicine, Seoul St. Mary's Hospital.*

**Background**: The NKF-DOQI guideline defines central venous catheter (CVC) dysfunction as failure to attain extracorporeal blood flow of 300 ml/min, based on the assumption that a lower blood flow would result in poor dialysis clearance. We observed the relationship between CVC blood flow and dialysis adequacy in Korean hemodialysis patients.

**Methods**: In this prospective interventional study, patients were included when they were on maintenance HD and using a tunneled HD catheter in the right internal jugular vein. Patients underwent dialysis using the FMC 5008 dialysis machine and low flux dialyzer (surface area 1.3 $m^2$).In each patient, urea reduction ratio (URR) and spKT/V were measured at blood flow rate (BFR) of 200, 250 and 300 mL/min.

**Results**: 118 dialysis sessions in 41 patients were analyzed. 30 patients (61.2%) were male. Pre-dialysis BUN, creatinine, hemoglobin, serum protein and albumin levels did not differ among each BFR settings. The mean pre-pump (arterial) pressure during dialysis was significantly lower at BFR of 300 mL/min (-133.0 ± 27.4 mmHg) compared to BFR of 250 mL/min (-99.9 ± 41.0 mmHg) and 200 mL/min (-86.7 ± 12.8 mmHg). The URR and spKT/V at BFR of 200 mL/min (67 ± 6%, 1.36 ± 0.26) was significantly lower than those at BFR of 250 mL/min (71 ± 7%, 1.45 ± 0.24) and 300 mL/min (72 ± 11%, 1.55 ± 0.38) ($P<0.05$, respectively). According to URR, the proportion of inadequate dialysis was significantly higher at BFR of 200 mL/min (13 cases, 34.2%) than at BFR of 250 mL/min (4 cases, 10%) and 300 mL/min (2 cases, 5%) ($P<0.05$). In comparison between the adequate and inadequate dialysis patients, there were significant differences in BFR, sex and body surface area (BSA, $m^2$) and BMI ($kg/m^2$). In multivariate analysis, BFR and BSA were significant predictors for inadequate dialysis. In patients with BSA less than 1.9 $m^2$, adequate dialysis could be attained in more than 90% of patients with BFR of 250 mL/min.

**Conclusion**: Our results suggest that BFR of 250 mL/min may be enough to reach adequate dialysis in Korean hemodialysis patients. The definition of catheter dysfunction needs to be reevaluated.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1571

**Right Atrial Thrombus Associated with Tunneled-Cuffed Hemodialysis Catheters: Usefulness of Transesophageal Echocardiography** Shinji Tanaka, Naobumi Mise, Tokuichiro Sugimoto. *Nephrology, Mitsui Memorial Hospital, Chiyoda-ku, Tokyo, Japan.*

**Purpose:** The aim of this study was to clarify the characteristics of clinically relevant right atrial thrombus (RAT) associated with tunneled-cuffed hemodialysis catheters (TCCs).

**Methods:** This retrospective cohort study comprised 57 consecutive chronic hemodialysis patients (31 male, mean age 72 ± 11 years, mean dialysis vintage 63 ± 95 months) who started to use TCCs between July 1999 and October 2009. All TCCs were inserted via subclavian vein and the catheter tip was located in the right atrium. All patients were followed until the end of 2009 to investigate clinically relevant RAT. Clinically relevant RAT was defined as RAT with refractory fever and/or catheter dysfunction.

**Results:** During the follow-up period of 10 ± 12 catheter-months, clinically relevant RAT (mean size 2.2 ± 0.4 cm) was identified in 5 patients (8.8%), 7.4 ± 7.0 months (range 2-16 months) after TCC insertion. The incidence rate was 0.10 per catheter-year. There was no significant difference in age, dialysis vintage, and diabetic status between patients with and without RAT. RAT was diagnosed by transesophageal echocardiography in 4 patients and enhanced CT in 1, whereas transthoracic echocardiography failed to identify RAT in any of the patients. Bacteremia and septic pulmonary embolism were found in 3 patients. All patients were successfully treated, either by catheter removal in 2 or by catheter salvage with antibiotic and anticoagulant therapy in 3. Four patients died 14 ± 7 months (range 8-25 months) after RAT diagnosis, but no death was attributable to RAT.

**Conclusions:** Clinically relevant RAT was not rare in patients with TCC, and could be formed relatively soon after TCC insertion. Transesophageal echocardiography or enhanced CT is recommended to diagnose RAT.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1572

**A Comparison between Blood Flow Outcomes of Tunneled External Jugular and Internal Jugular Hemodialysis Catheters** Hemender Singh Vats,[1] Micah R. Chan,[1] Henry N. Young,[2] Alexander S. Yevzlin.[1] *[1]Nephrology, University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]Pharmacy, University of Wisconsin School of Pharmacy, Madison, WI.*

**Background**

The right internal jugular (RIJ) vein is the vessel of choice for tunnelled hemodialysis (HD) catheters. The second choice is left internal jugular (LIJ) vein, though use of LIJ potentially jeopardises left arm arteriovenous fistula (AVF) or arteriovenous graft (AVF) placement,given high rates of catheter associated central venous stenosis. The right external jugular (EJ) vein has recently been shown to be a viable alternative to the LIJ, but concerns persist among clinicians about chronic blood flow capacity in EJ catheters. The purpose of this study is to compare the blood flow outcomes in a series of percutaneously placed external jugular (EJ), LIJ and RIJ HD catheters.

**Methods**

Using a prospectively collected database 46 hemodialysis patients referred for tunneled catheter placement were identified over four-year period. We compared the blood flow outcomes of date -matched RIJ, LIJ and EJ catheters . Using ANOVA, the blood flow outcomes of the three tunneled catheter techniques at 30-d and 90-d were compared.

**Results**

The three groups did not differ significantly in demographics or comorbid conditions. The flow data at 30 and 90 days is shown below. Using multiple regression analysis, no covariates (age, gender, race, diabetes) or other identifiable factors were found to be associated with blood flow outcomes at 30-d or 90-d.

Demographics and blood flow (Qb) by tunneled catheter technique

| | Age ( avg, yrs) | Gender (% female) | Race (% African American) | Diabetes Mellitus (%) | Qb at 30 Days | Qb at 90 Days |
|---|---|---|---|---|---|---|
| Right Internal Jugular Vein | 55 | 35.3 | 17.7 | 41.2 | 354.4± 54.48 | 348.5± 56.62 |
| Left Internal Jugular Vein | 60 | 52.9 | 17.6 | 68.8 | 344± 42.14 | 341± 22.42 |
| External Jugular Vein | 52.2 | 43.8 | 31.3 | 58.8 | 380± 55.26 | 365.7± 71.76 |

**Conclusions**

This report demonstrates comparable EJ blood flow outcomes at 30-d and 90-d to both LIJ and RIJ historical data. Further prospective investigation is required to rigorously define the role of EJ CVC placement as another potential long-term access modality.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1573

**Use of Citrate Solution as a Hemodialysis Catheter Lock Does Not Result in Greater tPA Use for Catheter Dysfunction** Abhinai K. Gupta, Andrew I. Chin. *Internal Medicine, Division of Nephrology, University of California at Davis, Sacramento, CA.*

**Purpose:** Hemodialysis (HD) units affiliated with our institution made a switch from the traditional Heparin 5000 units/cc solution (Hep lock) to a Citrate solution (ACD lock) as the standard lock formulation for tunneled catheters (TDC). When TDC dysfunction is noted in the HD unit, our first lines of therapy is the intra-luminal instillation of tissue plasminogen activator (tPA).

**Aim:** We sought to determine whether or not the switch from Hep lock to ACD lock resulted in an increase in TDC dysfunction by comparing the frequency of tPA used before and after this switch.

**Methods:** In this retrospective cohort study, we included only patients who were using a TDC for HD access with Hep lock, at least 2 weeks and up to 3 months before and after the date of switch. Patients were excluded if they were already using ACD locks (for Heparin-Induced Thrombocytopenia). Outcome measures analyzed before and after the switch included: the number of times tPA was used, actual duration of HD treatment, erythropoietin dose, catheter failures requiring exchanges. Statistical testing included comparison of continuous variables by paired T-test, proportions by Chi-test.

**Results:** 67 patients were included in the final analysis.

Comparison before and after switch of TDC locking solution

| | Hep lock | ACD lock | p value |
|---|---|---|---|
| Mean days with TDC | 81 | 83 | |
| Mean HD treatments | 32 | 31 | |
| HD time (min) | 191 | 193 | ns |
| tPA events per 100 HD treatments | 2.4 | 3.8 | ns |
| Erythropoietin (units/HD) | 6916 | 6647 | ns |
| total dose tPA given | 66 | 69 | ns |

Use of tPA did not differ after the switch to ACD lock from Hep lock. The number of catheter failures requiring exchange did not significantly differ in the 2 time periods. No significant adverse effects attributable to either TDC locking solution were noted.

**Conclusion:** We did not find a significantly increased utilization of tPA after switching from Heparin to a Citrate containing TDC lock. Even though the percentage citrate in ACD solution is low (3-4%), tPA use as a surrogate for TDC thrombosis did not change in the 2 time periods. A longer period of observation is needed to confirm the efficacy of ACD for routine TDC use.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1574

**Aboriginal Status and Central Venous Catheter Use in Hemodialysis Patients** Lisa M. Miller, Manish M. Sood, Claudio Rigatto, Joe A. Bueti. *Medicine, Section of Nephrology, University of Manitoba, Winnipeg, MB, Canada.*

Differences in access to health care between different racial groups is described in the literature. In Manitoba, there is a large Aboriginal population that constitutes approximately 30-40% of all hemodialysis (HD) patients. We sought to determine if Aboriginal status is associated with a higher likelihood to commence HD with a central venous catheter(CVC) rather than an arteriovenous fistula (AVF). We conducted a retrospective observational study of patients who started HD between January 1, 2006 and July 1 2009. All data was abstracted by chart review. There were 198 patients included in the study. One hundred sixty seven (84%) started HD with a CVC, 31 (16%) with an AVF, and none with an arteriovenous graft. Sixty-nine (35%) were Aboriginal, 88 (45%) Caucasion, and 38 (20%) other racial

background. Aboriginal patients were more likely to be female (p=0.0079) and have diabetes (p=0.0016) than non-aboriginal people. They were also less likely to live in Winnipeg than non- Aboriginal patients (p< 0.001). However, Aboriginal people were not more likely to start HD with a CVC than non-Aboriginal people. Geographic proximity to Winnipeg was not predictive of starting HD with a CVC. Furthermore, diabetes, hypertension, female gender, coronary artery disease, and peripheral vascular disease were not associated with starting HD with a CVC.

Conclusion: Aboriginal status is not predictive of commencing HD with a CVC.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1575

**Comparison of Macroscopic and Histological Findings at Exit-Site Skin of Tunneled Cuffed Venous Catheters** Nami Shibahara,[1] Hiroshi Shibahara,[2] Susumu Takahashi.[3] *[1]Hashimoto-Minami Internal Medicine Clinic, Sagamihara, Kanagawa, Japan; [2]Blood Purification Center, Sagamihara Kyodo Hospital, Sagamihara, Kanagawa, Japan; [3]Nihon University Graduate School, Tokyo, Japan.*

**Background:** Exit-site infections of tunneled cuffed venous catheter (TCC) are clinically diagnosed based on inflammatory changes of the skin. We compared macroscopic and histological findings of exit-site skin by scoring both to clarify exit-site infections.

**Methods:** Macroscopic and histological examinations at TCC exit-sites upon removal were performed in 15 dialysis patients (male/female, 12/3; mean age, 68.7 ± 15.7; diabetes mellitus/non-diabetes mellitus, 3/12; mean catheter days, 57.5 ± 31.2 days) who gave informed consent at Hashimoto-minami Internal Medicine Clinic and Sagamihara Kyodo Hospital between January 2008 and December 2009. Macroscopic inflammatory changes of exit-site skin were evaluated by the exit-site scoring system for peritoneal dialysis reported by Piraino et al. (Perit Dial Int 2005; 25: 107-131). The exit-site skin was histologically examined, and the degree of erosion or ulcer in the epidermis was scored 1 point, fibrosis, inflammatory cell infiltration, or neutrophil infiltration in the dermis 0-3 points, and subcutaneous abscess or panniculitis 1 point. Histological inflammatory change was scored by adding the points.

**Results:** Scores for macroscopic inflammatory change corresponded approximately to those for histological inflammatory change. In one case, however, the histological inflammatory change score was 2 despite the macroscopic inflammatory change score being 4.

Table 1 Macroscopic and histological inflammatory change scores

| | | Macroscopic inflammatory change scores | | |
|---|---|---|---|---|
| | | 0-2 | 3 | 4 |
| Histological inflammatory change scores | 0-2 | 8 cases | 0 | 1 case |
| | 3 | 2 cases | 0 | 0 |
| | 4 | 0 | 0 | 1 case |
| | 5 | 0 | 2 cases | 1 case |

**Conclusion:** Macroscopically good condition of exit-site skin corresponded to histological findings, showing normal skin structure. Even if exit-site infection was clinically suspected, skin structure might have been well maintained histologically. Further histological investigation is necessary to correctly diagnose exit-site infections of TCC.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1576

**Catheter Reduction Reduces Hospitalization and Mortality** Renee Jg Arnold, David Madigan, John A. Robertson, Abbe Volz. *DaVita Inc., Denver, CO.*

**Introduction:** Use of central venous catheters (CVC) in hemodialysis patients is associated with increased hospitalization and mortality. Published data have shown that an aggressive catheter reduction initiative (CathAway™) can decrease both catheter incidence and duration. We examined the impact of CathAway™ on hospitalization and mortality in the last 15 months of this program.

**Methods:** This was a retrospective analysis of electronic medical records of patients receiving hemodialysis between 1/1/09 and 3/31/10 (n=175,904) at a large dialysis organization. For hospitalization, we employed a Poisson regression with log total treatment time as an offset, and time on catheter as a primary covariate. For mortality, we fitted a Cox proportional hazards model, using access type (arteriovenous fistula or graft versus CVC) as a time-dependent covariate.

**Results:** In the Cox model analysis, CVC was associated with a more than two-fold risk in mortality, even after controlling for demographic and health variables. Total time on CVC relative to total time on dialysis was also a significant positive predictor of hospitalizations after controlling other factors.

| **Mortality** | **Hazard Ratio** | **95% CI** |
|---|---|---|
| Age | 1.03* | 1.03, 1.03 |
| Charlson | 1.04* | 1.03, 1.06 |
| Diabetes | 0.95* | 0.92, 0.99 |
| CVD | 1.04* | 1.01, 1.08 |
| Male | 1.15* | 1.12, 1.18 |
| CVC | 2.31* | 2.27, 2.45 |
| **Hospitalization** | **Poisson Estimate** | **SE** |
| Age | -0.009* | 0.001 |
| Charlson | 0.075* | 0.004 |
| Diabetes | 0.037* | 0.013 |
| CVD | 0.099* | 0.012 |
| Male | -0.141* | 0.010 |
| Catheter Time | 0.001* | 0.000 |

*p<0.01

**Conclusions:** Both having a CVC, and increased time on a CVC, are associated with a marked increase in hospitalizations and mortality. By decreasing both CVC incidence and time with catheter, the DaVita CathAway™ program is associated with significantly decreased morbidity and mortality. Future research will quantify the economic impact of these benefits.

Disclosure of Financial Relationships: Employer: DaVita Inc.

## F-PO1577

**Effectiveness of a Protocol for the Prevention of Hemodialysis Venous Catheters (CVCs) Related Infections** Carlo Guastoni, Cornacchiari Marina, Heidempergher Marco, Antonella Stasi, Nicoletta Bellotti, Corrado Turri, Lucio Bertoncini, Ambrogio Baroli. *Nephrology Unit, Ospedale di Legnano, Legnano, Milan, Italy.*

**INTRODUCTION**

Infections are a major complication of the use of hemodialysis CVCs. Recently Beathard built 5 degrees of efficiency (from really bad to excellent) based on the incidence of bacteremia ( from >7 to <1/1000 catheter day) (Semin Dial 2008; 21:528).

In our study we evaluated the efficacy of CVCs protocol management adopted in our center through a retrospective analysis of all CVCs inserted in 6 years.

**PATIENTS AND METHODS**

From 2003 to 2008 we placed 73 tunneled CVCs (tCVCs) and 75 non tunneled CVCs (ntCVCs) in 148 patients (mean age 67,6 ± 14 years, dialytic age 23,8 ± 33 months, diabetes 21,6 %, cardiovascular diseases 18%, cancer 13,5%) follow-up 48,5 ± 68 days for ntCVCs and 556,5 ± 551,5 days for tCVCs.

The protocol was the following:

-two operators carrying out sterile connection and disconnection

-soap cleansing of CVCs exit site

-sterile gauze cover and tape (if ntCVCs after 10% sodium hypochlorite pack for 10 minutes)

-CVCs protection terminals and blood lines for 5 minutes with gauze soaked in 50% sodium hypochlorite before connection/disconnection.

**RESULTS**

The isolated germ was: Staphyloccus epidermidis in 46,6% of cases, Staphylococcus aureus in 6,6%, Pseudomonas in 10%, Nocardia in 3,3% and not identified in 33,3%. [Table 1]

| | Total CVCs | ntCVCs | tCVCs |
|---|---|---|---|
| Bacteremia (N) | 16 | 4 | 12 |
| Tunnel or exit site infections (N) | 14 | 4 | 10 |
| Total infections (N) | 30 | 8 | 22 |
| Infection rate for 1000 CVCs days | 0,65 | 1,54 | 0,54 |

**CONCLUSIONS**

The implemented protocol resulted in an incidence of infection that matched the "excellent" grade for tCVCs and "good" grade for ntCVCs taking into account all infections (bacteremia + exit site infections + tunnel infections).

The grade was excellent for both CVCs considering bacteremia only.

Our experience confirms the importance of CVCs management in preventing infections incidence in dialyzed patients with CVCs.

## F-PO1578

**Malfunction of Tunneled Cuffed Venous Catheter Due to Poor Catheter-Cuff Connection** Hiroshi Shibahara,[1] Nami Shibahara,[2] Susumu Takahashi.[3] *[1]Blood Purification Center, Sagamihara Kyodo Hospital, Sagamihara, Kanagawa, Japan; [2]Hashimoto-Minami Internal Medicine Clinic, Sagamihara, Kanagawa, Japan; [3]Nihon University Graduate School, Tokyo, Japan.*

**Background:** The cuff of a tunneled cuffed venous catheter (TCC) is firmly fixed to subcutaneous tissues, providing a barrier against infection and preventing unexpected TCC removal. An end-hole type of dual lumen TCC, Soft Cell, is commonly used for dialysis patients. However, we have experienced 15 patients with catheter malfunctions due to a poor connection between the catheter and the cuff since December 2008. We did not experience such malfunctions prior to that date. Therefore, we measured the tensile strength (TS) between the catheter and the cuff of 7 unused Soft Cells.

**Characteristics of 15 patients (18 Soft Cells):** Catheter malfunction with a poor connection between the catheter and the cuff occurred in 15 patients (18 Soft Cells) who had been undergoing dialysis at Sagamihara Kyodo Hospital and Hashimoto-minami Internal Medicine Clinic from December 2008 to December 2009 (male/female, 8/7; mean age, 70.4 ± 10.0 years; diabetes mellitus/non-diabetes mellitus/unknown, 8/6/1; mean catheter days: 40.9 ± 45.1 days). The cuff detached from the catheter in 4 Soft Cells due to slight pulling of the catheter at the time of insertion. The catheter detached from the cuff spontaneously in 8 Soft Cells, and at the time of removal, in 6. All patients were able to undergo dialysis by changing to another TCC or to other forms of vascular access. The cuffs remained under the skin in 14 Soft Cells, which were safely removed surgically.

**Tensile strength of 7 unused Soft Cells:** The TS between the cuff and the catheter of 7 unused Soft Cells was measured using a Universal Testing Machine (IMADA SEISAKUSHO CO., LTD., Aichi, Japan). The average TS was 40.8 ± 22.6 N (range: 19.4 - 80.4N).

**Conclusion:** The TS between the cuff and the catheter of unused Soft Cells varied considerably: the lowest TS was only about one-fourth of the highest TS. This may have been one of the reasons for catheter malfunction in our 15 patients (18 Soft Cells). The causes of malfunction should be promptly investigated and countermeasures taken.

**F-PO1579**

**Inflammatory Markers during Dialysis in Relation to Vascular Access in Hemodialysis Patients** Benaya Rozen-Zvi, Arie Erman, Asher Korzets, Muhammad Khaskiya, Uzi Gafter. *Nephrology and Hypertension, Rabin Medical Center, Petah-Tikva, Israel.*

Background:

Markers of chronic inflammation are associated with increased mortality and morbidity in hemodialysis (HD) patients. Recent studies suggest that non infected catheters are associated with higher inflammatory markers than arteriovenous fistulas (AVF). Therefore, the effect of vascular access on inflammatory markers changes during dialysis was evaluated.

Methods:

Fifty one HD patients were included in our study. Patients were divided into 2 groups, those with tunneled cuffed catheters (n=23) and those with AVF (n=28). Included patients were at least three month on HD treatment and free of infection, malignancy or active bleeding. Blood samples for high sensitivity C-reactive protein (hsCRP) and Interleukin 6 (IL 6) were collected before and after a 4-hour HD session using high flux polysulfone dialyzer. The primary outcome was a change in the inflammatory markers during the dialysis.

Results:

The baseline values were similar in the catheter and the AVF groups for hsCRP (1.27±1.21 mg/dL and 1.37±1.41 mg/dL, respectively, (p=0.8) and IL 6 (5.82±2.54 ng/mL and 5.44±2.87 ng/mL, respectively (p=0.6)). There was no increase in hsCRP values during the HD session and no difference between the change from baseline values in the catheter and AVF groups (-0.016±0.13 mg/dL and -0.01±0.09 mg/dL, respectively (p=0.9)). IL 6 values increased during HD session in the AVF group (5.44±2.87ng/mL to 6.14±2.51 (p=0.02)) and non-significantly decreased in the catheter group (5.82±2.54 ng/mL to 5.3±2.66 ng/mL (P=0.14)). The change from baseline values for IL-6 was significantly greater in the AVF group compared to the catheter group (0.7±1.44 ng/mL and -0.52±1.66 ng/mL, respectively (p=0.008)).

Conclusion:

There is no increase in inflammatory markers in stable HD patients with tunneled cuff catheters, when compared to patients with AV shunts. The slight increase in IL-6 in patients with AV shunts may be explained by the effect of skin puncture, and the clinical significance of this phenomenon needs further investigation.

**Adjunctive Antibiotic Lock Is an Option for Treating Tunneled Catheter Related Infections** Amit J. Joshi, George Dunea, Peter D. Hart. *Division of Nephrology, Stroger Hospital of Cook County, Chicago, IL.*

**Background:** To assess the efficacy of systemic antibiotics and antibiotic catheter locks in treating tunneled hemodialysis catheter related blood stream infections (CRBSI).

**Methods:** We prospectively examined our experience using antibiotic locks along with systemic antibiotics for tunneled CRBSI without clinical signs of tunnel infection. There were 46 episodes of CRBSI during the study period of 2 years. All patients were treated empirically with systemic antibiotics. Once the organism was identified, systemic antibiotics were tailored accordingly and all patients received an antibiotic catheter lock after each dialysis. Clearance of infection was documented by negative surveillance cultures after completion of the antibiotic course.

**Results:** Out of 46 episodes of CRBSI 16(35%) were due to gram positive organisms, 22(48%) to gram negative organisms, and 8(17%) to polymicrobial (≥2 organisms) infections. 19(41%) cases required removal of dialysis catheter. The antibiotic lock protocol was successful in eradicating the infection in 27 of 46 episodes (59%). Clinical cure was similar in both gram positive and gram negative infections (62% and 63% respectively). One patient developed metastatic infection (endocarditis) with MSSA bacteremia. All patients with MRSA and pseudomonas infection required catheter removal.

Table 1

| Organism | No. of catheter infections | Success rate of catheter lock |
|---|---|---|
| **Gram positive** | | |
| Enterococcus | 2 | 2 (100%) |
| MRSA | 2 | 0 (0%) |
| MSSA | 5 | 2 (40%) |
| MRSE | 1 | 0 (0%) |
| MSSE | 3 | 3 (100%) |
| Others | 3 | 3 (100%) |
| **Gram negative** | | |
| Enterobacter | 12 | 8 (66%) |
| Klebsiella | 2 | 2 (100%) |
| Pseudomonas | 2 | 0 (0%) |
| Serratia | 2 | 1 (50%) |
| Others | 4 | 3 (75%) |
| **Polymicrobial** | **8** | **3 (37%)** |

MRSA, methicillin-resistant S.aureus; MSSA, methicillin-sensitive S.aureus; MRSE, methicillin-resistant S.epidermidis; MSSE, methicillin-sensitive S.epidermidis.

**Conclusion:** An antibiotic lock protocol designed to salvage dialysis access was successful in eradicating the infection in 59% of clinically stable patients with CRBSI. Although 41% required catheter removal, it remains an option in patients with no evidence of metastatic or tunnel infection.

**Impact of the Use of the HeRO Vascular Access Device vs. Tunneled Dialysis Catheters on Dialysis Provider Economics in an Era of Bundling** Larry Yost,[1] Lesley Dinwiddie.[2] *[1]The Atticus Group, LLC, Portsmouth, NH; [2]Vascular Access Education & Research, Cary, NC.*

**BACKGROUND:** Hospitalization for catheter-related complications and increased utilization of intravenous medications, as a result of catheter use, negatively impact dialysis provider economics. The HeRO vascular access device is an alternative vascular access option which consists of an ePTFE graft attached to an outflow component, comprised of silicone with nitinol reinforcement, designed to traverse central venous stenoses. Clinical studies have demonstrated a reduction in infectious complications with the HeRO device as compared to catheter-related bacteremia rates reported in the literature. **METHODS:** A quantitative model with multiple input parameters was developed to calculate the potential per annum differences in economic outcomes associated with the use of hemodialysis catheters and the HeRO device for dialysis providers under the proposed Medicare bundled payment system. Baseline assumptions utilized to create the model were obtained from the USRDS 2009 Annual Data Report, the 2008 Annual Report for ESRD CPM Project, and from published results of relevant clinical studies. **RESULTS:** Modeled results indicate the use of the HeRO device vs. dialysis catheters in catheter-dependent patients would result in a per patient, annual economic benefit of $2,226, and a total annual economic benefit of $45,340,620 to dialysis providers. Dialysis providers would generate an estimated incremental revenue of $12,986,444, or $637 per patient, when using the HeRO device, as a result of fewer missed dialysis sessions leading due to hospitalizations for catheter-related bacteremias. Dialysis providers would also realize a projected cost savings of $32,353,993 or $1,587 per patient in association with reductions in medications included in the proposed bundled payment. **CONCLUSION:** Our results suggest that the incorporation of the HeRO device into a vascular access algorithm and its preferential use over a catheter in patients who have exhausted their arteriovenous access options will likely be associated with improved dialysis provider economics under a bundled payment system.

**Factors Influencing Longevity of Dialysis Catheters** Mahmoud T. El-Khatib, Heather Duncan, Kotagal Shashi Kant. *Nephrology, University of Cincinnati, Cincinnati, OH.*

**Introduction:** USRDS data indicate that more than 30% of hemodialysis patients in the US receive treatment through a tunnelled dialysis catheters, and about 70% of incident patients begin treatment with a tunnelled dialysis catheter. The efforts by the "fistula first initiative" and the KDOQI guidelines have failed so far to reduce the use of catheres to less than 10%. Fewer than 50% of dialysis catheters are functional at six months, lost to infection or flow dysfunction. Despite these odds, we found a minority of patients have a single catheter functioning for more than one year and some for more than two years. Data on factors associated with longevity of dialysis catheters are lacking. The aim of this study to evaluate possible factors associated with longevity of these dialysis catheters.

**Methods:** Records from a single outpatient dialysis unit were examined and identified 32 patients who had a single dialysis catheter in place for more than 1 year (Group "L"). The end dates of these catheters were: started using a graft or fistula, pt transferred from clinic or died while catheter was still in use or catheter was replaced for poor function. A comparison group of 37 patients (Group "S") who had catheters for only 4-8 months was also identified; all of these catheters were ended due to dysfunction such as infection or poor flow. Demographics, treatment parameters, lab results and procedures were analyzed by parametric and non-parametric tests.

**Results:** The average duration of the 32 catheters in group "L" was 567 days. The average duration of the 37 catheters in group "S" was 174 days. Among the demographic characteristics of age, time since ESRD diagnosis, race , sex, weight and diabetic status, there were no differences between the patients in each group. In addition, no differences were found in the measures albumin, ferritin, hemoglobin, URR, Kt/V, Platelets or MCV.

**Conclusions:** Many measures were considered in this analysis and were shown not to be factors in the longevity of tunnelled catheters. The possibility of other characteristics like patient hygiene, catheter locks and the type of catheters may play a role in this difference and need to be studied.

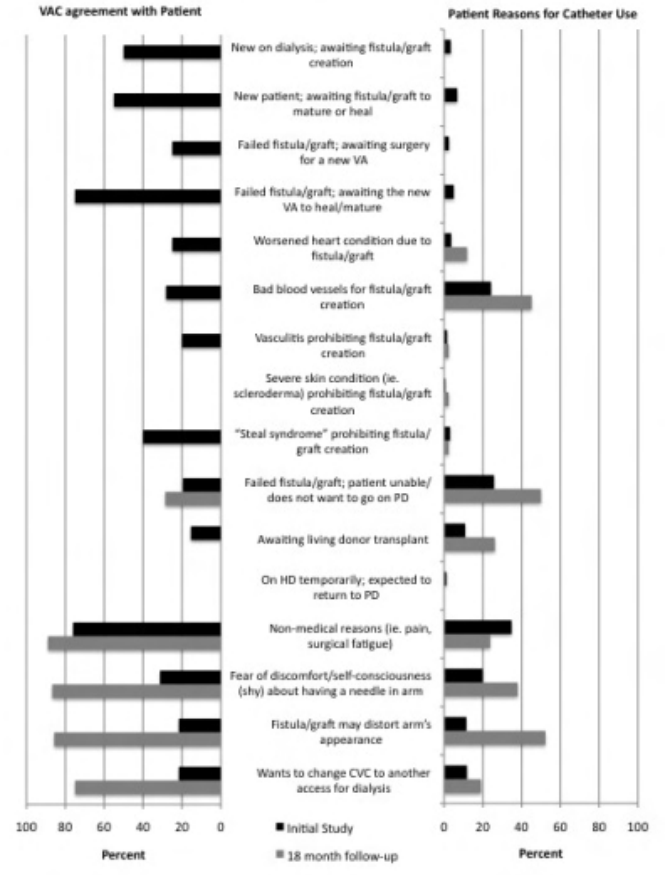
**F-PO1583**

**Discordant Patient Views on Catheter Use May Impact Catheter Prevalence** Maryum F. Chaudhry,[1] Cynthia B. Bhola,[1] Mohammad Z. Joarder,[1] Deborah Lynn Zimmerman,[2] Patricia A. Quinan,[3] David C. Mendelssohn,[3] Charmaine E. Lok.[1] *[1]Toronto General Hospital and the University of Toronto; [2]The Ottawa Hospital; [3]Humber River Regional Hospital.*

Central venous catheter (CVC) use for hemodialysis is associated with increased adverse health outcomes. Our study aimed to discover why patients prefer using CVCs. A multi-center study was conducted in which 322 patients using CVCs and their vascular access coordinators (VAC) were surveyed to determine why patients use CVCs. Patient responses were compared with the VAC to determine their agreement using multi-rater kappa statistics (K). An 18 month follow-up survey was applied to a subgroup of patients still using their CVCs, and their responses were correlated with the VACs' and patients' previous responses.



Predictive associations for specific reasons for CVC use were explored. Patients indicated non medical reasons (eg. surgical fatigue) (35%; K=0.196), previously failed fistulas/grafts (26%; K=0.226), and fear of disfiguration from fistulas/grafts (12%; K=0.164) as the main reasons for CVC use. The VAC was in agreement with the patient 16.5% of the time, in partial agreement 37.0%, and in disagreement 46.5%. Twelve percent of patients wanted to change their CVC, yet the VAC was unaware of this 78% of the time (K=0.140). In the 18 month follow-up, 39.2% of patients at one site were still using CVCs. Major reasons for persistent CVC use were fear of disfiguration from the fistula (52%; K=0.333) and previously failed fistulas/grafts (50%; K=0.286).The significant discordance between the patients' and VACs' views on why the patient is using a CVC suggests a gap in knowledge, understanding or communication between patients and their VAC. Timely education to address this gap and realistic targets are necessary to reduce CVC prevalence.

Figure 1. Patient reasons for prolonged CVC use and VAC agreement.

**F-PO1584**

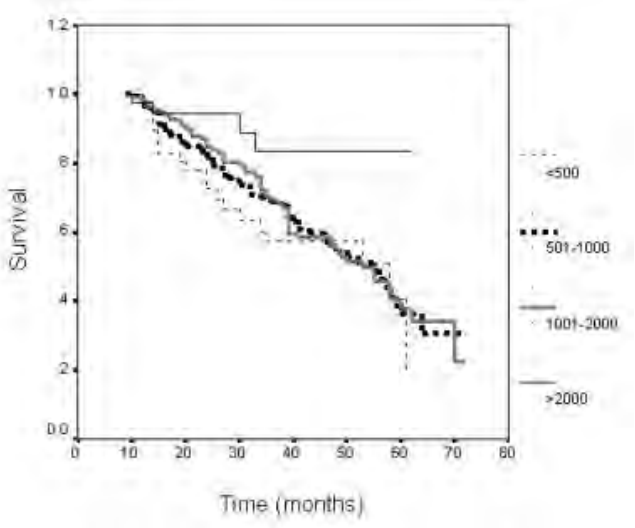
**High Hemodialysis Access Flow Rates Are Not Associated with Increased Mortality** Jesse M. Piceno, Andrew I. Chin. *Internal Medicine, Division of Nephrology, University of California at Davis, Sacramento, CA.*

**Background**: Hemodialysis (HD) arteriovenous shunt flows rates may affect cardiac function. Mortality may be increased in patients with the highest access flow rates.

**Aim**: To determine whether or not high access flow rates, those >2000 cc/min, are associated with greater all-cause mortality.

**Methods**: Retrospective study of thrice weekly HD patients and their first functioning AV shunt. Patients were categorized, based on mean access flow rates measured by ultrasound dilution during the 9-12 month period after insertion of the fistula or graft, into 4 groups: ≤500 cc/min, 501-1000 cc/min, 1001-2000 cc/min, or >2000 cc/min. Unadjusted and adjusted survival models (factors included: age, sex, race, vintage of dialysis, type of access[fistula or graft], weight, and diabetes) were used for analysis up to 5 years after insertion of the access.

**Results**: Unadjusted survival:



Patients with access flow >2000 cc/min (mean flow rate 2754 ± 565 cc/min) had the lowest 5 year mortality on unadjusted analysis compared with all other groups ($p<0.05$). After adjustment for the above mentioned co-factors, the following were associated with increased risk for death: increased age and vintage, Caucasian race, graft use, and shunt flow ≤500 cc/min. High access flow rate >2000 was no longer associated with improved survival after these adjustments. When access flow was analyzed as a continuous factor, higher flows were associated with decreased mortality, but of *very* small effect (HR 0.9996; 0.9993 to 1.0000, p=0.03).

**Conclusion**: In HD patients, an access flow rate of >2000 cc/min, measured at 9-12 months after surgery, was not associated with a higher risk of death. However, the lowest flow, ≤500 cc/min, was associated with a higher risk. Whether or not longer exposure to high shunt flows would eventually contribute to a higher mortality remains to be seen.

**Distal Convoluted Tubule (DCT) Specific Transcripts Identified Using DCT Large Scale Sampling** Nicolas Picard,[1] R. Lance Miller,[2] Johannes Loffing.[1] *[1]Anatomy Institute, University of Zurich, Zurich, Switzerland; [2]NHLBI/NIH, Bethesda, MD.*

The renal distal convoluted tubule (DCT) is important for the renal control of ion homeostasis and blood pressure. Although several DCT-specific ion transporting proteins have been identified, only little is yet known about the molecular mechanisms that regulate DCT function. We hypothesized that gene products that are specifically expressed in the DCT might be of particular importance for the control of DCT cell function. Here, we used Complex Object Parametric Analysis and Sorting (COPAS) to isolate DCTs in large scale for the identification of a DCT transcriptome. A renal tubule suspension was obtained from transgenic mice expressing EGFP specifically in the DCT. The tubules were then separated by COPAS in three fractions (i.e. all tubules, EGFP-positive DCTs and EGFP-negative non-DCT tubules). Real-time PCR and Western blot analysis confirmed the significant enrichment and derichment of known DCT-specific marker molecules in the EGFP-positive and EGFP-negative samples, respectively. Subsequent microarray analysis (Agilent) revealed about 400 genes that are being more than 20-fold enriched in EGFP-positive tubules compared with EGFP-negative tubules. Aside from the known DCT-specific gene-products parvalbumin, NCC and TRPM6, many novel DCT enriched gene products were identified. Among them, Slc16a7 (MCT2) and its accessory protein GP70 (embigin) sticked out. Immunohistochemistry confirmed the significant expression of these two gene products in the DCT. Thus, transcriptomic analysis of COPAS-sorted renal tubules allows the identification of novel DCT-enriched gene products and may provide a pool of novel candidate genes for DCT-specific functions and diseases.

**Generation and Analysis of the Thiazide-Sensitive $Na^+$-$Cl^-$ Cotransporter S707X Knockin Mice as a Model of Gitelman's Syndrome** Sung-Sen Yang,[1] Yu-Juei Hsu,[1] Shinichi Uchida,[2] Sei Sasaki,[2] Shih-Hua P. Lin.[1] *[1]Division of Nephrology, Department of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [2]Department of Nephrology, Okyo Medical and Dental University, Tokyo, Japan.*

Gitelman's syndrome (GS) is characterized by salt losing, hypomagnesemia, hypokalemic metabolic alkalosis, and hypocalciuria. To better model human GS caused by a specific mutation in the thiazide-sensitive $Na^+$-$Cl^-$ cotransporter (NCC), we generated a nonsense Ncc S707X knockin mice corresponding to human S710X, a recurrent mutation with severe phenotypes in Chinese GS patients. Blood pressure, blood and urine electrolytes and biochemistries, mRNA and relevant protein expression in the kidneys were examined. Compared with wild-type or heterozygous littermates, homozygous (Hom) knockin mice

fully recapitulated the phenotype of human GS. The markedly reduced Ncc mRNA and virtually absent NCC protein expression in kidneys of Hom mice was primarily due to nonsense-mediated mRNA decay (NMD) surveillance mechanisms. Expression of epithelial $Na^+$ channel (Enac), $Ca^{2+}$ channels (Trpv5 and Trpv6), and $K^+$ channels (Romk1 and maxi-k) were significantly increased. High $K^+$ intake could not correct hypokalemia but caused a further increase in maxi-k but not Romk1 expression. Renal tissue from a patient with GS also showed the enhanced Trpv5 and Romk1 expression in distal tubules. We suggest that the upregulation of Trpv5 and Trpv6 and of Romk1 and maxi-k may contribute to hypocalciuria and hypokalemia in the Ncc S707X knockin mice and human GS, respectively.

**Angiotensin II Regulates the Thiazide-Sensitive Sodium Chloride Cotransporter through SPAK Independently of Aldosterone** Nils van der Lubbe,[1] Christina Lim,[1] Robert A. Fenton,[1] Marcel Meima,[1] Alexander H. Danser,[1] Robert Zietse,[2] Ewout J. Hoorn.[1] *[1]Erasmus Medical Center, Rotterdam, Netherlands; [2]University of Aarhus, Denmark.*

**Background**

Aldosterone and angiotensin II regulate the sodium chloride cotransporter (NCC), but their independent effects are unknown. Here, we use adrenalectomy followed by the selective infusion of aldosterone or angiotensin II as a model to investigate the independent effects of both hormones.

**Methods**

Adrenalectomy was performed in three experimental groups and one control group of male Sprague-Dawley rats (n=5/group). After surgery, the experimental groups received high-physiological aldosterone, a non-pressor (Ang II-NP) or a pressor (Ang II-P) dose of angiotensin II for eight days via osmotic minipump, while controls received vehicle only. Differential centrifugation was used to obtain plasma membrane and intracellular fractions of whole kidney homogenates.

**Results**

The validity of the model was supported by virtually absent plasma aldosterone concentrations in the control group and the development of hypertension in the Ang II-P group only. Aldosterone, Ang II-NP, and Ang II-P caused significantly more sodium retention than vehicle. Thiazides inhibited the sodium retention induced by Ang II-NP. Compared to controls, aldosterone, Ang II-NP and Ang II-P significantly increased the plasma membrane abundance of NCC (3.0-, 4.5- and 3.5-fold). Aldosterone and Ang II-NP increased phosphorylation of NCC at threonine-53 (4.2- and 4.3-fold). Aldosterone and Ang II-NP increased the intracellular abundance of *Ste20*-related proline alanine-rich kinase (SPAK, 3- and 2-fold). No differences were observed in the intracellular abundance of with-no-lysine kinase 4 (WNK4) and oxidative stress responsive protein 1 (OSR1).

**Conclusion**

This is the first controlled *in vivo* study to show that aldosterone and angiotensin II independently increase the abundance and phosphorylation of NCC. The phosphorylation of NCC was likely mediated by SPAK. These results increase the insight in the hormonal control of renal sodium regulation, which also contributes to the pathophysiology of several forms of hypertension.

## F-PO1588

**Studies on the Relationship between WNK1 and OSR1 Kinases Using Genetic Mouse Models** Jian Xie,[1] Sung-Sen Yang,[2] Shih-Hua P. Lin,[2] Chou-Long Huang.[1] *[1]UT Southwestern Medical Center, Dallas, TX; [2]Tri-Service General Hospital, NDMC, Taipei, Taiwan.*

OSR1 (oxidative stress-responsive kinase-1) and its related SPAK kinase are members of the Ste20 superfamily of MAPK (mitogen-activated protein kinase)-like protein kinase. OSR1 and SPAK, regulate many targets including members of SLC12 family ion transporters that are involved in $Na^+$, $K^+$, and $Cl^-$ transport. Mechanistically, OSR1 and SPAK are phosphorylated and activated by with-no-lysine[K] kinases, WNK1 and WNK4. Activated OSR1 and SPAK, in turn, phosphorylate and activate SLC12 family ion transporters. Mice with homozygous deletion of exons 8-9 of *Osr1*, encoding part of the kinase domain, are embryonic lethal (Yang & Lin, unpublished). Previously, we have reported that deletion of *Wnk1* in mice causes embryonic lethality between E10.5 and E12.5 from cardiovascular (CV) developmental defects. OSR1 is expressed in a wide range of tissues/organs, with high levels in the heart. To test the hypothesis that OSR1 is downstream of WNK1 in embryonic CV development, we compared *Osr1*-knockout embryos with *Wnk1*-knockout embryos. The *Osr1*-knockout embryos are phenotypically identical to wild type littermates up to E9.5, but start to show growth retardation from E10, and die between E10.5 to E13.5 with hemorrhage and pericardial edema. In the yolk sac of *Osr1*-knockout mutant after E10.5, the primitive capillary plexus fails to develop into mature vascular network, leading to defective blood circulation. There is no living *Osr1*-knockout embryo found after E13.5. Thus, OSR1 function is required for CV development in mice. The phenotype of *Osr1* knockout is identical to that of *Wnk1* knockout, except possibly with a slight delay in the onset. This is consistent with the idea that OSR1 is a phosphorylation substrate and downstream effector of WNK1. To further determine OSR1's functions in different organs and its interaction with the WNK1 signaling pathway, a mouse model allowing conditionally expressing constitutive kinase-active mutant form of OSR1 with loxp-cre system is being generated. The effects of constitutive kinase-active OSR1 on various organs and its ability to rescue *Osr1* and *Wnk1* knockout embryos will be investigated.

## F-PO1589

**WNK3 Is a Component of the WNK Signaling Complex and Is Expressed Predominantly along the Distal Convoluted Tubule** Chao-Ling Yang,[1] Kerim Mutig,[3] Sebastian C. Bachmann,[3] David H. Ellison.[1,2] *[1]Nephrology & Hypertension, Oregon Health & Science University, Portland, OR; [2]Renal Section, Portland VA Medical Center, Portland, OR; [3]Anatomy, Charité Universitätsmedizin, Berlin, Germany.*

Mutations of WNK1 and WNK4, members of the WNK kinase family, cause *Familial Hyperkalemic Hypertension* by stimulating NaCl reabsorption and inhibiting K secretion along the distal convoluted tubule (DCT). We have suggested that WNK kinases form a *signaling complex*, together with SPAK and SGK1, in DCT cells, thereby regulating the thiazide-sensitive Na-Cl cotransporter (NCC). While WNK3 regulates NCC *in vitro*, a role for WNK3 *in vivo* has not been clear, because WNK3 was reported to be expressed predominantly by the proximal tubule (PT) and only minimally along the DCT. Those results were obtained using using a commercial antibody, which was not characterized extensively. To determine whether WNK3 plays a substantial role in the distal nephron, we generated a GST-fusion protein encompassing WNK3 residues 2 to 143, to immunize rabbits. Both immunoblots and immunofluorescence indicated that the anti-WNK3 antibody recognizes WNK3, but not WNK1 or WNK4, when WNKs are expressed in Xenopus oocytes or HEK293 cells. The signal was blocked by the immunizing peptide. In kidney, there was modest paracellular WNK3 in PT, thick ascending limb, and connecting tubule, but much stronger cytoplasmic signal sub-apically along the DCT, where it co-localized with NCC. *In situ* hybridization confirmed high level expression by DCT, but not PT. Transient transfection of HEK293 cells with WNK3 increased N-terminal NCC phosphorylation substantially (presumably via SPAK, as WNK3 does not phosphorylate NCC directly; J Clin Invest. 2007; 117:3403). KS-WNK1, a distal nephron-specific isoform of WNK1, inhibited WNK3 kinase activity *in vitro*. In oocytes, KS-WNK1 also inhibited WNK3's ability to stimulate NCC-mediated sodium uptake. In conclusion, WNK3 is highly expressed along the DCT, where it can increase NCC phosphorylation and activity. WNK3 may be a key component of the WNK signaling complex, where it acts in opposition to KS-WNK1 and WNK4.

## F-PO1590

**Similar Effect of All WNK3 Isoforms upon SLC12 Cotransporters** Zesergio Melo,[1] Silvia Cruz,[2] Norma Hilda Vázquez,[1] José Ponce-Coria,[1] Herminia Pasantes,[2] Adriana P. Mercado,[1] Gerardo Gamba.[1] *[1]Molecular Physiology Unit, INNSZ-INCICH-IIB, UNAM, Mexico City; [2]IFC-UNAM, Mexico City.*

With-no-lysine kinase 3 (WNK3) is a member of a subfamily of serine/threonine kinases that has been associated with arterial hypertension. We have previously shown that WNK3-18a and its catalytically inactive form (WNK3-DA) modulate the activity of the SLC12 family members in a mirror image: WNK3 activates NKCC1/2 and NCC while inhibits the KCCs, whereas WNK3-DA does the opposite. In doing so, WNK3 bypasses the tonicity requirements for activation/inactivation of these cotransporters. Thus, WNK3 has been proposed as the cell volume sensitive kinase. Four splice variants are potentially generated from WNK3 gene due to the combination of two exons 18 (18a and 18b) and the presence or absence of exon 22. Exon 18b is unique for central nervous system. Thus, this study was designed to define the effect of all WNK3 variants upon all members of the SLC12 family. By RT-PCR from a fetal brain library exons 18b and 22 were separately amplified and subcloned into the original WNK3-18a or WNK3-DA to obtain all four potential combinations, with and without catalytic activity (18a, 18a+22, 18b, and 18b+22). All subcloned segments were sequenced. The basal activity of the cotransporters and the effect of WNK3 isoforms were assessed by measuring $^{22}Na^+$ or $^{86}Rb^+$ uptake in *Xenopus* oocytes co-injected with each cotransporter and WNK3 or WNK3-DA variants cRNAs. In isotonic conditions the activity of NCC and NKCC1/2 was increased by co-injection with any of the WNK3 isoforms. The positive effect occurred even in hypotonic conditions in which basal activity of NKCC1 is completely prevented. Consistent with these observations, when expressed in hypotonic conditions, all KCCs were active, but in the presence of any of the WNK3 variants the activity was completely reduced. All WNK3 isoforms in their catalytically inactive form produced the opposite effect on the cotransporter. That is, NKCC1/2 and NCC were inhibited, even in hypertonic conditions, while KCCs were activated, even in isotonic conditions. Thus, we conclude that all wild-type and catalytically inactive forms of WNK3 have the same effect on all SLC12.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1591**

**Elevated Thiazide Sensitive Sodium Chloride Co-Transporter Activity in PHAII Mutant Mice** Qingshang Yan,[1] Junhui Zhang,[2] Jesse Rinehart,[1] Richard P. Lifton,[2] Gerhard Malnic,[1] Gerhard H. Giebisch,[1] Tong Wang.[1] *[1]Cellular and Molecular Physiology, Yale University, School of Medicine, New Haven, CT; [2]Internal Medicine, Yale University, School of Medicine, New Haven, CT.*

Mutations in WNK4 cause pseudohypoaldosteronism type II (PHAII), a disease featuring increased renal sodium reabsorption and impaired potassium secretion. PHAII mutant mice exhibited phenotypes of higher blood pressure, hyperkalemia, hypercalciuria and marked hyperplasia of the distal convoluted tubule (DCT). To investigate whether hyperplasia of the DCT is accompanied by increased $Na^+$-$Cl^-$-cotransporter (NCC) activity, we examined the effect of hydrochlorothiazide (HCTZ) on sodium and potassium excretion in wild-type and PHAII mutant mice. GFR was measured by inulin clearance and the absolute (ENa, EK) and fractional (FENa, FEK) $Na^+$ and $K^+$ excretions were measured before and after bolus i.v. of HCTZ (30mg/kg). Experimental data show significantly lower urine volume (0.77 vs. 1.45 nl/min) and $Na^+$ excretion, ENa (0.10 vs. 0.35 microEq/min/100g BW) and FENa (0.16 vs. 0.36%), in mutant mice than that in control, consistent with increased $Na^+$ absorption in PHAII mice. HCTZ produced significant diuretic and natriuretic effect in both WT and mutant mice. The sensitivity was much higher in PHAII mutant mice than that in control. HCTZ produced 5-fold increase of urine volume and 16-fold increase in ENa and FENa in mutant mice but only 2-fold increase in urine volume and 7-fold increase in ENa and EK in WT mice. The baseline $K^+$ excretions was slightly lower in mutant mice than WT. HCTZ produced a similar effect on $K^+$ excretions with 1-fold increase in EK and FEK in both mutant and WT mice. Despite such a high degree of $Na^+$ excretion, the $K^+$ excretion was not enhanced proportionally to $Na^+$ loss in the mutant mice. Given the fact that ROMK channel is inhibited by WNK4 mutation and unchanged in HCTZ-increased $K^+$ excretion, a compensatory mechanism of $K^+$ secretion may occur by calcium and flow-activated MaxiK channel activity. These results indicate that NCC activity is elevated and other $K^+$ secretion mechanisms may be upregulated when ROMK channel is downregulated in PHAII mice.

**WNK4 Inhibits NCC Protein Expression through MAPK ERK1/2 Signaling Pathway** Xiuyan Feng,[1] Yiqian Zhang,[1,2] Bo Zhou,[1] Dexuan Wang,[2] Xuemei Zhang,[3] Dingying Gu,[2] Hui Cai.[1,2] *[1]Medicine/Renal, Emory University School of Medicine, Atlanta, GA; [2]Nephrology, The Second Affiliated Hospital Wenzhou Medical College, Wenzhou, Zhejiang, China; [3]Pharmacology, Fudan University School of Pharmacy, Shanghai, China.*

WNK ((with no lysine (k)) kinase is a subfamily of serine/threonine kinases. Mutations in two members of this kinase family (WNK1 and WNK4) cause pseudohypoaldosteronism type II featuring hypertension, hyperkalemia and metabolic acidosis. WNK1 and WNK4 were shown to stimulate NCC activity through SPAK and OSR1 phosphorylation at T46, T55, and T60 of NCC. Activation of PKC by a phorbol ester inhibits NCC function via activation of ERK1/2 kinase. We have previously shown that WNK4 phosphorylates ERK1/2 in a dose-dependent manner. Knocking down WNK4 expression increases surface NCC expressions in mouse distal convoluted tubular (mDCT) cell. We further examined the effect of knock-down WNK4 on ERK1/2 phosphorylation in mDCT. We found that knock-down WNK4 expression significantly reduced ERK1/2 phosphorylation (0.917 ± 0.17 vs 0.347 ± 0.08, p = 0.006) and knock down ERK1/2 expression increased total NCC expression. To discrete the phosphorylation sites of SPAK/OSR1 from ERK1/2 in WNK4's effect on NCC, we generated serial mutations to these putative SPAK phosphorylation sites on N-terminus of NCC to determine whether WNK4 remains its inhibitory effect on NCC while SPAK phosphorylation sites of NCC are mutated. When Cos-7 cells were transfected with single mutation of NCC T46A, T50A or S91A, WNK4 still inhibits NCC protein expression, whereas Cos-7 cells were trasnfected with single mutation of either NCC T55A or T60A, WNK4 lose its inhibitory effect on NCC protein expression. When Cos-7 cells were transfected with triple mutations of NCC T55A/T60A/S91A, WNK4 retains its inhibitory effect on NCC protein expression. These data suggest that WNK4 inhibits NCC protein expression through a MAPK ERK1/2 signaling pathway and WNK4 down regulates NCC protein expression through ERK1/2-mediated phosphorylation of NCC at the discrete sites other than the SPAK putative sites.

**Treatment of Bartter Syndrome Type IV Caused by R8L Barttin Mutation** Naohiro Nomura, Masato Tajima, Eriko Ohta, Akihito Ohta, Eisei Sohara, Tatemitsu Rai, Sei Sasaki, Shinichi Uchida. *Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan.*

Barttin, a gene product of BSND, is one of four genes responsible for Bartter syndrome. We recently generated barttin knockin mice carrying R8L missense mutation (R8L knockin mice) by gene targeting, and reported the phenotypes in the last ASN meeting. The knockin mice showed Bartter-like phenotypes (hypokalemia, metabolic alkalosis, and decreased NaCl reabsorption in distal tubules) under a low salt diet or a low potassium (K) diet. Plasma membrane localization of both barttin (R8L) and the ClC-K channel were impaired in the knockin mice, and transepithelial chloride transport in the thin ascending limb of Henle's loop as well as thiazide-sensitive chloride clearance, were significantly reduced. Previously, we showed that R8L barttin stably expressed in Madin-Darby Canine Kidney (MDCK) cells was trapped in the endoplasmic reticulum (ER). In this study, we investigated the treatment for R8L mutant barttin in vitro and in vivo. We used curcumin and 17-allylamino-17-demethoxygeldanamycin (17-AAG), which were known to rescue ER-trapped mutant membrane proteins. In R8L mutant barttin stably expressed in MDCK cells, side-specific biotinylation assay revealed that the basolateral expression of R8L mutant barttin was increased after treatment with these agents, whereas the wild-type barttin expression was not altered. In vivo experiment using R8L knockin mice, 17-AAG intraperitoneally administered for a week, and curcumin administered with mouse chow for 9 days, significantly restored the basolateral localization of R8L barttin in the nephron from the thick ascending limb of Henle's loop to cortical collecting ducts. Concomitantly, 17-AAG corrected metabolic alkalosis and hypokalemia, and curcumin restored thiazide-sensitive chloride clearance. These results clearly suggested that the aberrant intracellular localization of R8L barttin is the major cause of this disease, and Batter syndrome type IV caused by R8L mutation could be treated with drugs that release ER-trapped mutant proteins.

**cAMP Stimulates NKCC2 Recycling in the Thick Ascending Limbs (THALs)** Gustavo R. Ares, Pablo A. Ortiz. *Hypertension and Vascular Research Division, Department of Internal Medicine, Henry Ford Hospital, Detroit, MI.*

The apical Na/K/2Cl cotransporter NKCC2 mediates most NaCl reabsorption by the thick ascending limb (TAL). cAMP increases surface NKCC2 by stimulating the rate of exocytosis. We found that NKCC2 is constitutively retrieved from the apical membrane. However, it is not known whether internalized NKCC2 is reinserted into the apical membrane (recycling), and whether cAMP stimulates this step. We hypothesized that cAMP stimulates NKCC2 recycling in the TAL. We measured surface NKCC2 and the rate of NKCC2 recycling in TAL suspensions by surface biotinylation and Western blot. Surface proteins were biotinylated, allowed to internalize for 30 min at 37°C and then biotin was stripped from proteins remaining at the surface. TALs were warmed to 37°C and recycling of NKCC2 to the surface monitored and expressed as % of the internalized pool. We found that internalized NKCC2 recycles back to the plasma membrane in a constitutive manner (7.5 min = 11.4 ± 2.1%, 15 min = 17.2 ± 3.0 %, 30 min = 25.1± 3.3 %, n = 6). Control experiments indicate that the internalized pool does not loose the biotin label nor is degraded (30 min). To stimulate cAMP, we used Forskolin/IBMX. We found that NKCC2 recycling is stimulated (7.5 min = 22.8 ± 3.6 %, 15 min = 44.6 ± 4.8 %, 30 min = 47.3 ± 1.6 %, n = 6, $p<0.05$), by 160% increase at 15 min. Steady-state surface is maintained by NKCC2 arriving from the Golgi and/or a recycling compartment. To study the contribution of the recycling pool in cAMP-stimulated surface NKCC2 we used Brefeldin A, which blocks delivery of membrane proteins from the Golgi but does not block recycling. TALs were treated with vehicle (control) or brefeldin-A for 60 min and then treated with Forskolin/IBMX for 30 min. In control TALs, Forskolin/IBMX stimulated surface NKCC2 by 32 ± 5.5 % ($p<0.05$) and by 21 ± 1.9 % ($p<0.05$) in Brefeldin A-treated TALs. We conclude that NKCC2 undergoes constitutive recycling, and this process is stimulated by cAMP. Our data suggest that recycling of NKCC2 contributes to cAMP-stimulated steady-state surface NKCC2. These are the first data showing recycling of a renal transporter in native TALs.

**VAMP2 but Not VAMP3 Mediates cAMP-Stimulated NKCC2 Trafficking in Thick Ascending Limbs** Paulo S. Caceres,[1,2] Mariela Mendez,[1] Pablo A. Ortiz.[1,2] *[1]Internal Medicine-Hypertension & Vascular Research, Henry Ford Hospital, Detroit, MI; [2]Physiology, Wayne State University, Detroit, MI.*

The apical co-transporter NKCC2 is responsible for most NaCl reabsorption by the Thick Ascending Limb (TAL) of Henle's loop. We found that vasopressin increases steady-state surface NKCC2 by enhancing exocytic insertion via cAMP. The vesicle-associated membrane fusion proteins VAMP2 and VAMP3 are expressed in a sub-apical compartment in TALs. Cleavage of VAMP2 and VAMP3 with tetanus toxin blocks cAMP-stimulated surface NKCC2 and NKCC2-mediated NaCl transport. However, whether VAMP2 or VAMP3 mediates cAMP-stimulated NKCC2 trafficking is unknown. We hypothesized that VAMP2, but not VAMP3, mediates cAMP-stimulated NKCC2 surface expression. To inhibit VAMP2 or VAMP3 in rat TALs, in vivo, we used adenoviruses-mediated gene silencing with a specific VAMP2 or VAMP3 shRNA. Control kidneys were injected with adenoviruses carrying a scrambled RNA sequence (scrambled). We then measured surface NKCC2 expression by surface biotinylation in TAL suspensions in the absence or presence of forskolin/IBMX to increase endogenous cAMP. VAMP2-shRNA decreased VAMP2 expression by 69 ± 5% without affecting VAMP3 ($p<0.05$). Similarly, VAMP3-shRNA decreased VAMP3 expression by 68 ± 8% without affecting VAMP2 ($p<0.05$). Silencing VAMP2 blocked the stimulatory effect of cAMP on surface NKCC2 by 40% (scrambled: 80 ± 9 %, VAMP2-shRNA: 49 ± 4% increase from baseline; $p<0.05$). In contrast, silencing VAMP3 did not affect cAMP-stimulated surface NKCC2 (scrambled: 62 ± 14 %, VAMP3-shRNA: 67 ± 9% increase from baseline). Silencing VAMP2 in the TAL did not affect baseline surface NKCC2 (81 ± 7% of scrambled) or the total pool of NKCC2 (93 ± 9% of scrambled). In contrast, silencing VAMP3 decreased baseline surface NKCC2 by 53 ± 13% ($p<0.05$) and also the total pool of NKCC2 by 59 ± 8% ($p<0.05$). We concluded that VAMP2, but not VAMP3, mediates cAMP-stimulated NKCC2 trafficking in TALs. Our data also suggest that VAMP3 may be involved in constitutive NKCC2 trafficking, biosynthesis and protein processing or turnover.

**Phosphodiesterase 4 (PDE4) Blunts the beta Adrenergic Receptor-Stimulated NKCC2 Trafficking in Rat Thick Ascending Limbs** Mohammed Z. Haque, Pablo A. Ortiz. *Hypertension and Vascular Research, Internal Medicine, Henry Ford Hospital, Detroit, MI.*

The thick ascending limb of the loop of Henle (THAL) reabsorbs ~30% of the filtered NaCl via the apical Na/K/2Cl cotransporter (NKCC2). Acute beta adrenergic receptor stimulation in THALs enhances NaCl reabsorption and increases intracellular cAMP. We found that isoproterenol enhances NKCC2 trafficking to the apical membrane in rat THALs via the cAMP/protein kinase-A pathway. We and others have identified several cAMP-specific phosphodiesterases (PDE) in rat THALs, including PDE1 and PDE4. In other cells PDE4 is primarily responsible for decreasing cAMP generated by beta adrenergic stimulation. We hypothesized that PDE4 decreases beta adrenergic receptor stimulated surface NKCC2 expression in rat THALs. THAL suspensions were obtained from Sprague-Dawley rats and surface NKCC2 expression measured by surface biotinylation and western blot. Data are presented as % of control measured by densitometry. We found that 30 min incubation of THALs with the beta adrenergic receptor agonist, isoproterenol at 0.5 and 1.0 μM increased surface NKCC2 by 14±2 and 29±6% ($p<0.05$) respectively. The effect of 1 μM Isoproterenol was enhanced by nonselective phosphodiesterase inhibition with IBMX (Isoproterenol: 27±6%, IBMX+Isoproterenol: 51±8% of control, $p<0.05$), while IBMX alone had no significant effect (9±5%). To selectively inhibit PDE4 we used 100 μM rolipram, which tended to enhance Isoproterenol-stimulated surface NKCC2 expression from 25±7 to 37±9% of control. However, rolipram (100 μM) alone enhanced surface NKCC2 by 15±3% ($p<0.05$). At a lower concentration (20 μM), rolipram did not affect surface NKCC2 but enhanced the sensitivity to isoproterenol (Control: 100, Isoproterenol 0.2 μM: 100±5, Rolipram 20 μM: 106±6, Rolipram+Isoproterenol: 126±8%; $p<0.05$ *vs* isoproterenol). We concluded that PDE4 decreases beta adrenergic receptor stimulated NKCC2 trafficking in THALs. This may be an important pathway that decreases the stimulatory effect of beta adrenergic agonists on THAL NaCl absorption.

**Regulation of ROMK along Distal Segments by K Diet** James B. Wade,[1] Liang Fang,[1] Richard A. Coleman,[1] Jie Liu,[1] Tong Wang,[2] Paul A. Welling.[1] *[1]Department of Physiology, University of Maryland School of Medicine, Baltimore, MD; [2]Department of Cell and Molecular Physiology, Yale University, New Haven, CT.*

ROMK (Kir1.1) channels are well known to play a central role in renal K secretion, but the specific nephron segments where these channels are regulated in response to changes in dietary K has remained mysterious. Unreliable specificity or low avidity of available antibodies has made addressing this issue especially challenging. Here, we prepared new antibodies to C-terminal sites of ROMK and screened them by Western blot and immunolocation in ROMK null vs WT mice. Of the six rabbits immunized, only two produced antibodies that specifically competed with antigen and were not reactive with ROMK null kidney. Characterization of segmental ROMK expression with nephron-segment antibodies (NCC, calbindin D28 and AQP2) revealed specific ROMK labeling in distal convoluted tubule regions, DCT1 and DCT2; the connecting tubule (CNT); and cortical collecting duct (CCD). ROMK was found diffusely distributed in intracellular compartments and at the apical membrane of each tubular region. Quantification of cytoplasmic labeling indicated that labeling in DCT1 and DCT2 was not significantly increased by high K diet while CNT and CCD labeling were each increased by 25% and 18%, respectively ($P<0.05$). Apical labeling was significantly increased by high K diet in DCT2 (2 fold), CNT (9 fold) and CCD (5 fold) ($P<0.05$) but not in DCT1. Consistent with these large increases in apical ROMK, Western blots of cortical homogenates from mice on high K diet showed a dramatic increase in the abundance of ROMK with mature glycosylation at about 65 kD with no significant change in the immature band of ROMK at about 37 kD. We conclude: 1) caution should be used when employing ROMK antibodies that have not been screened against ROMK null tissue; 2) High K diet causes a large increase in apical expression of ROMK in DCT2, CNT and CCD.

**The Renal IK Channel Complex Contains ROMK2, Beta1 and CFTR Subunits** Qiang Leng,[1] Tatjana Coric,[1,2] Ximing Zhou,[1] Jerry Feng,[1] Divya Chari,[1] Connie Liu,[1] Qingshang Yan.[1] *[1]Cellular & Molecular Physiology, Yale University, New Haven, CT; [2]Department of Pharmacology & Toxicology, The University of Alabama at Birmingham, Birmingham, AL.*

SK (30 pS small conductance $K^+$ channel) and IK (70 pS intermediate conductance $K^+$ channel) are the two major types of $K^+$ channels responsible for $K^+$ recycling and secretion in the thick ascending limb (TAL) of the kidney. IK channels are partially formed by the ATP-dependent potassium channel ROMK. However, their complete molecular identity of has been elusive. The question why ROMK (SK) is ATP-inhibited *in vivo* but loses its ATP-sensitivity in heterologous expression systems has also been a longstanding puzzle in the field of renal physiology. Such ATP-sensitivity is critical for $K^+$ secretion by the cells of TAL and distal nephron segments responsive to aldosterone. Here we constructed a subtraction library to identify the component(s) required for IK formation in addition to ROMK. We determined that a Beta1 subunit is associated with ROMK2 to form an IK channel in *Xenopus laevis* oocytes. Together with CFTR (cystic fibrosis transmembrane conductance regulator), Beta1 subunit also reconstitutes ATP-sensitivity to both IK and SK. These results implicate Beta1 subunit as the missing component in IK channel formation and lead us to propose a multi-subunit IK channel complex involving ROMK2, CFTR, and Beta1 subunits. Overall, our findings not only provide new insights into the formation and regulation of renal $K^+$ channels, but also potential molecular targets for drug delivery to combat renal hypertension, Bartter's syndrome, and other related hereditary diseases.

**WNK4 Inhibits $Ca^{2+}$-Activated Big-Conductance Potassium Channels (BK)** WenHui Wang. *Pharmacology, New York Medical College, Valhalla, NY.*

With–No-Lysine Kinase 4 (WNK4) plays an important role in regulating K transport in the aldosterone-sensitive distal nephron (ASDN). Two types of K channels: ROMK and $Ca^{2+}$ –activated big-conductance K channel (BK), are expressed in the ASDN and involved in K secretion. While WNK4-induced inhibition of ROMK channels is well documented, it is not explored whether WNK4 also regulates BK channels. In the present study we used the perforated whole-cell patch-clamp to examine the effect of WNK4 on BK channels in HEK293T cells transfected with Kcnma1 ( α subunit of BK, mSlo) or Kcnma1 +WNK4. Expression of WNK4 decreased the K currents from 536±28 pA to 247±9 pA. Moreover, coexpression of SGK1 abolished the inhibitory effect of WNK4 on BK channels and expression of WNK4S1169D, in which SGK1 phosphorylation site (Ser 1169) was mutated, failed to inhibit BK channels. This suggests that SGK1 modulates the effect of WNK4 on BK through the phosphorylation of WNK4 at the switch-domain. Also, coexpression of dominant negative dynamin K44A abolished the inhibitory effect of WNK4 on BK channels. Expression of WNK4 stimulated the phosphorylation of ERK and p38 MAPK without changing the total expression of ERK and p-38 MAPK. The stimulatory effect of WNK4 on MAPK activity was attenuated by coexpression of SGK1. The role of ERK and p-38 MAPK in inhibiting BK channels had also been supported by the observation that inhibition of ERK with PD098059 and p-38 MAPK with SB202190 completely abolished the inhibitory effect of WNK4 on BK channels and increased K currents from 247±9 pA to 702±11 pA. We concluded that WNK4 inhibits BK channels by a mechanism stimulating ERK and p38 MAPK.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1600**

**Identification and Functional Characterization of Kir2.6 Mutations Associated with Non-Familial Hypokalemic Periodic Paralysis** Chih-Jen Cheng,[1,2] Shih-Hua P. Lin,[1] Sung-Sen Yang,[1] Yu-Juei Hsu,[1] Chou-Long Huang.[2] *[1]Tri-Service General Hospital, NDMC, Taipei, Taiwan; [2]UT Southwestern Medical Center, Dallas, TX.*

Hypokalemic periodic paralysis (hypoKPP) is characterized by episodic muscle weakness and acute hypokalemia during attacks. It may be familial or non-familial. Familial cases are mostly caused by mutations of voltage-gated Na+ or Ca2+ channels. The non-familial hypoKPP includes thyrotoxic periodic paralysis (TPP) and sporadic periodic paralysis (SPP). Recently, mutations of an inwardly rectifying K+ channel, Kir2.6, are reported in some TPP pts and believed to predispose them to attacks. Kir2.6, is exclusively expressed in skeletal muscle and transcriptionally regulated by thyroid hormone. Whether Kir2.6 mutations are present in other hypoKPP is unknown. Here, we studied a large cohort of Taiwanese pts, with 100 TPP and 60 SPP pts, and 100 unrelated healthy subjects. All pts have severe hypokalemia during attacks (K ~ 2.0 mEq/l). TPP and SPP pts have similar clinical features except that TPP have higher T3 and free T4 and suppressed TSH, and lower serum phosphate. Two TPP pts had the same heterozygous V168M mutation in the 2nd transmembrane segment of Kir2.6. Two SPP pts had different heterozygous mutations- R43C in the N- and A200P in the C-terminal cytoplasmic domain. These 3 mutations were not present in control subjects. Wild type (WT) and mutant Kir2.6 were expressed in HEK cells for functional studies. Western blot of cell lysates showed all 3 mutants express full-length protein and have equal expression as WT. Compared to WT, whole-cell current density for R43C and V168M mutants were reduced by 80% and 40%, respectively. No current was for A200P. Furthmore, V168M and A200P, but not R43C, exerted dominant-negative effects on WT channel. Single channel open probability was reduced in both R43C and V168M . Thus, mutations of Kir2.6 are associated with SPP as well as TPP. The regulation of Kir2.6 by thyroid hormone is not central for mutations of Kir2.6 to cause susceptibility to hypoKPP. Hypofunction of Kir2.6 may depolarize the cell membrane potential rendering Na+ channel inactivated and unavailable for firing when action potential arrives.

**The Kir4.1 Knock Out Mouse Displays Relative Hypokalemia and Increased Urinary $K^+$ Excretion** Daniel A. Gray, Heather L. Connelly, Michael W. Cypress. *Nephrology Unit, University of Rochester, Rochester, NY.*

Mutations in the Kir4.1 potassium channel underlie the SeSAME/EAST syndrome, an autosomal recessive condition characterized by seizures, sensorineural deafness, ataxia and a hypokalemic, hypomagnesemic metabolic alkalosis. To better understand the renal pathophysiology of this syndrome, serum and urine electrolytes have been collected from a generalized Kir4.1 knock out mouse (generated originally by Paulo Kofuji). The knock outs (KO) were smaller than their heterozygous (HET) and wild-type (WT) littermates ($2.12 \pm 0.15$ vs. $2.58 \pm 0.16$ and $2.74 \pm 0.18$ gms respectively). Because the KOs typically die within 2 weeks of age, serum and urine were obtained from 3-5 day old pups. Serum was obtained using a hematocrit tube following decapitation and urine was collected via

bladder aspiration. Serum and urine $K^+$ and $Na^+$ concentrations (in mM) were determined by flame photometry. Serum [$K^+$] was significantly reduced from 6.8 ± 0.5 in WT to 5.1 ± 0.3 in the KO (n=7, p = 0.01). No hemolysis was observed in association with the mild elevation in WT [$K^+$]. WT and HET values did not differ statistically. Although the urine [$K^+$] was similar for all 3 groups, the urine osmolality was significantly lower in the KO (333 ± 4 vs. 403 ± 15 mOsm/kg in WT, p = 0.001). This resulted in a significantly higher transtubular $K^+$ gradient (TTKG) in the KO (13.4 ± 1.0 vs. 8.9 ± 0.7 in WT, p = 0.004). Urinary [$Na^+$] was very low in all groups with a trend toward higher values in the KO (3.6 ± 1.5 vs. 0.7 ± 0.5 in WT, p =0.10). These results suggest that the Kir4.1 knock out displays the $K^+$ wasting phenotype of the SeSAME/EAST syndrome and may provide a useful model for future transport studies.

| | Weight (gms) | Serum [$K^+$] (mM) | Urine [$K^+$] (mM) | Urine [$Na^+$] (mM) | Urine Osm. (mOsm/kg) | TTKG |
|---|---|---|---|---|---|---|

### F-PO1602

**NO Reduces Chloride Absorption in Mouse Cortical Collecting Duct** Vladimir Pech, Seongun M. Hong, Susan M. Wall. *Emory University.*

Nitric oxide regulates blood pressure, in part, by modulating transport of $Na^+$ and $Cl^-$ in the kidney. Therefore, we asked if NO regulates net $Cl^-$ flux ($J_{Cl}$) in the CCD and the transporter(s) that mediate NO-sensitive $Cl^-$ absorption. Thus, $Cl^-$ absorption was measured in CCDs taken from aldosterone treated mice. Reducing NO production by inhibiting nitric oxide synthase (L-NAME, 100 mM) increased $J_{Cl}$ from 35.0 ± 6.4 to 49.6 ± 7.4 pmol/mm/min although transepithelial voltage, $V_T$, was unchanged. Conversely, administration of an NO donor (MAHMA NONOate, 10 µM) reduced $J_{Cl}$ from 45 ± 5 to 28 ± 5 pmol/mm/min and reduced $V_T$ from -26 ± 3 to -15 ± 3 mV. These changes in $J_{Cl}$ and $V_T$ were not time-dependent effects. To determine the transport process that mediates NO-sensitive changes in $J_{Cl}$, we examined the effect of NO on $J_{Cl}$ following either genetic ablation or chemical inhibition of various transporters in the CCD. Application of hydrochlorothiazide (100 mM) to the perfusate had no effect on $J_{Cl}$. Moreover, application of hydrochlorothiazide or bafilomycin (5 nM) to the perfusate did not alter NO-sensitive $J_{Cl}$. Thus, NO modulates $J_{Cl}$ independent of the $Na^+$-dependent $Cl/HCO_3^-$ exchanger or the apical $H^+$-ATPase. In contrast both total and NO-sensitive $J_{Cl}$ were nearly abolished either with application of benzamil (3 µM) to the perfusate or with genetic ablation of pendrin (*Slc26a4*). Following the application of benzamil to the lumen, $J_{Cl}$ and $V_T$ were extremely low at baseline and unchanged with NO donor application. In contrast, in CCDs from pendrin null mice, while $J_{Cl}$ was extremely low in the presence or absence of NO, $V_T$ was substantial under basal conditions and markedly reduced with NO application. Thus, NO-sensitive changes in $J_{Cl}$ cannot be explained fully by changes in paracellular $Cl^-$ transport. Instead, total and NO-sensitive $Cl^-$ absorption observed in the CCD of aldosterone-treated mice depends on the presence of the $Cl^-/HCO_3^-$ exchanger, pendrin. We conclude that NO reduces Cl- absorption in the CCD of aldosterone-treated mice through a mechanism that is pendrin dependent. How benzamil reduces total and NO-sensitive $J_{Cl}$ is unexplained, but may occur, at least in part, by modulating the driving force for pendrin-dependent $Cl^-$ transport.

### F-PO1603

**Pendrin Confers Partial Resistance to the Diuretic Effect of Loop and Thiazide Diuretics in Mice** Hassane Amlal, Sharon L. Barone, Jie Xu, Manoocher Soleimani. *Internal Medicine, University of Cincinnati, Cincinnati, OH.*

Loop diuretics and thiazides are the most commonly used drugs for the treatment of fluid overload in patients with congestive heart failure. It is known that NCC in the distal nephron is activated and partially blocks the diuretic effect of loop diuretics such as furosemide. However, whether pendrin (SLC26A4), which is expressed in the distal nephron, plays any role in enhanced salt absorption in response to loop diuretics or thiazides remains unknown. To address this question, mice with genetic deletion of pendrin (PDS KO) and their wild-type littermates (WT) were treated with furosemide (FURO) or hydrochlorothiazide (HCTZ). Accordingly, mice were placed in metabolic cages with free access to food and water for 3 days. After acclimation, mice were injected subcutaneously with commonly used doses of FURO or HCTZ. Food and water intake, urine volume and chloride excretion were measured for 24 hrs.

The results indicate that PDS KO demonstrated a more robust diuresis to furosemide Vs. WT mice, with urine volume increasing from 2.37 to 4.57 ml/24h, P<0.005 in WT and from 3.08 to 7.62 ml/24h, P<0.002 in PDS KO. The furosemide-induced diuresis was 2-fold higher in PDS KO relative to WT (4.54 ml/24 hrs in KO vs. 2.20 in WT, P<0.02). There was a decrease in food intake in both groups (from 4.5 to 1.32 gm/24h, P<0.0001 in WT and from 5.0 to 1.52 gm/24h, P<0.001 in PDS KO). Despite the reduction in chloride intake subsequent to reduced food intake, PDS KO exhibited a significantly higher chloreuresis as compared to WT mice (0.612 vs. 0.306 mEq/24h, P<0.006). With regards to HCTZ, baseline food intake, urine volume and chloride excretion were similar between WT and PDS KO mice. However, 24h HCTZ caused a significant chloreuresis (0.35 vs. 0.17 mEq/24h, P<0.006) and diuresis (2.86 vs. 1.47 ml/24h, P<0.01) in PDS KO vs. WT mice. Unlike FURO, HCTZ did not significantly alter food intake. We conclude that PDS deletion makes mice susceptible to severe volume depletion in response to furosemide and HCTZ. This clearly suggests that PDS plays an important compensatory role by partially blunting fluid loss of loop and thiazide diuretics in mice kidney.

### F-PO1604

**Pendrin Regulation by pH and Protein Kinases A and C** Anie Azroyan,[1] Gilles Crambert,[1] Kamel Laghmani,[1] Alain Doucet,[1] Aurelie Edwards.[2] *[1]UMRS 872, ERL 7226, Centre de Recherche des Cordeliers, Paris, France; [2]Chemical and Biological Engineering, Tufts University, Medford, MA.*

Pendrin is expressed in the kidney in type-B intercalated cells of the collecting duct where it contributes to the reabsorption of NaCl and the secretion of bicarbonate, thereby participating in the regulation of blood pressure and acid/base homeostasis. Despite its importance, the intrinsic properties and regulation of pendrin are poorly documented. In this study, we investigated the regulation of pendrin activity by its glycosylation status, extracellular and intracellular pH, and protein kinases A (PKA) and C (PKC) in cultured kidney epithelial cells stably transfected with pendrin cDNA. Pendrin activity was determined by monitoring intracellular pH changes induced by variations in transmembrane anion gradients. Using structural analysis and in situ directed mutagenesis we identified asparagines at position N167 and N172 as pendrin glycosylation sites. Mutation of those sites did not alter its cell surface expression and activity. We also showed, by combining transport measurements and a mathematical model, that pendrin activity is stimulated at both low intracellular and low extracellular pH, suggesting the presence of a proton regulatory site. Finally we found that pendrin activity is significantly increased by the addition of 8Br-AMPc and decreased by phorbol esther (an activator of PKC) treatment. Preliminary measurements of pendrin cell surface expression suggest that the stimulation of PKC, but not that of PKA, reduces pendrin trafficking to the plasma membrane.

**CLIC1 Potentiates Acute Toxic Injury** John C. Edwards,[1] Barbara Ulmasov.[2] *[1]UNC Kidney Center, University of North Carolina, Chapel Hill, NC; [2]Internal Medicine, St. Louis University, St. Louis, MO.*

CLIC1 is a member of the family of "chloride intracellular channels" that is highly expressed in several epithelia including renal proximal tubule and pancreatic duct. CLIC1 has also been implicated as a plasma membrane chloride conductance supporting superoxide production by macrophages. If CLIC1 supports superoxide production, it may contribute to tissue injury during toxic or ischemic insults. The purpose of this study was to determine whether CLIC1 plays a role in acute toxic injury in organs where it is abundantly expressed, using a mouse model in which the gene for CLIC1 has been disrupted. WT and matched Clic1-/- mice were subjected to folic acid (FA) induced acute kidney injury (AKI) or cerulein (CER) induced acute pancreatic injury (API). To induce AKI, mice were given 250 mg/kg injection of FA. Plasma BUN on day 2 was taken to assess severity of AKI. Results: WT day 2 BUN 397 ± 32, n=17; KO day 2 BUN 261 ± 38, n=21; P=0.013. For API, mice were given 6 hourly injections of cerulein (50 µg/kg) and then sacrificed 9 hours after the first injection. The pancreas was removed, weighed, and processed for RNA and TBAR assay (reflecting oxidative injury). Results: Pancreatic weight (mg): WT control 138 ± 10, n=9; WT CER 241 ± 15, n=10; KO control 138 ± 6, n=9; KO CER 185 ± 16, n=10. The difference in extent of edema between CER-treated WT and KO is significant (P<0.01). TBAR values (pmole/mg protein): WT control 126 ± 19, n=9; WT CER 182 ± 17, n=10; KO control 146 ± 12, n=9; KO CER 123 ± 9, n=10. The differences between TBAR levels in WT control vs. WT CER, and between WT CER vs KO CER are significant (P<0.02 and 0.01, respectively) while the difference between WT and KO controls is not significant. In the WT mice, the mRNA level for CLIC1 increased 10.1 fold following cerulein treatment (95% confidence interval 7.9 - 12.9). We conclude that CLIC1 plays a role in acute toxic injury in both kidney and pancreas: CLIC1 mRNA increases following injury in wild type mice, absence of CLIC1 results in attenuated injury of both kidney and pancreas and in pancreas, this correlates with lower level of a marker of lipid peroxidation.

**Altered Ion Currents of ClC-5 by Dent's Disease-Causing Mutations** Teddy Grand,[1,2,3] Jacques Teulon,[1,2,3] Stéphane Lourdel.[1,2,3] *[1]UMR_S 872 Equipe 3, UPMC Université Paris 06, Paris, France; [2]UMR_S 872 Equipe 3, INSERM, Paris, France; [3]ERL 7226, CNRS, Paris, France.*

The $Cl^-/H^+$ antiporter ClC-5, has been linked to Dent's disease, an X-linked renal disease associated with low molecular weight proteinuria, hypercalciuria and nephrolithiasis. CLC-5 is expressed on early endosomes of proximal tubule cells, where it is thought to play a critical role in endosomal function. The impact of Dent's disease-causing mutations on CLC-5 function has not been yet fully investigated. Here, we thought to investigate the functional consequences of three published mutations (E267A, S270G and S270R) in *X. laevis* oocytes and in HEK293 cells. The ClC-5 mutants were synthesized from human wild-type (WT) ClC-5 extracellularly HA tagged subcloned into pTLN expression vector (kindly provided by T. J. Jentsch, FMP/MDC, Berlin, Germany) for expression in *X. laevis* oocytes or into the peGFP expression vector for expression in HEK293 cells. We evaluated electrical activity, subcellular targeting and protein expression of WT and mutant ClC-5 by two-electrode voltage-clamp, immunocytochemistry, chemiluminescence and western blot analysis. The E267A and S270G mutants showed a significant reduction of currents by 50% ($p$<0.001, n=19) and 20% ($p$<0.001, n=24) by comparison to those of WT ClC-5. Currents

recorded with the S270R mutant were not significantly different from non-injected (NI) oocytes ($p<0.001$, n=6). We found no significant difference between these mutants and WT ClC-5 in terms of subcellular targeting and protein expression levels. All mutants trafficked normally to the cell surface and to early endosomes and displayed complex N-glycosylation. In conclusion, this study shows that these three mutants ClC-5 display a reduced electrical activity without alteration of protein expression and subcellular distribution.

**CFTR from Divergent Species Responds Differently to Channel Inhibitors** Maximallian Stahl,[1,2] Klaus Stahl,[1,2] Marie B. Brubacher,[1,2] John N. Forrest.[1,2] *[1]Nephrology Division, Yale Univ School of Medicine, New Haven, CT; [2]Mt. Desert Island Biological Lab, Salisbury Cove, ME.*

Comparison of diverse species is a powerful tool to study the structure of channel proteins. Ion permeation in ion channels is influenced by charged amino acid side chains around the entrance of the channel pore. These residues attract oppositely charged ions thus increasing their local concentration, while repelling ions of like charge. Site directed mutagenesis has identified positively charged residues in anion channels. We investigated the response of human, killifish, pig, and shark cystic fibrosis transmembrane conductance regulator (hCFTR, kfCFTR, pCFTR, sCFTR) to inhibitors of the channel: CFTRinh-172, glibenclamide, and GlyH-101. From mutagenesis studies each inhibitor is thought to bind to specific positively charged amino acids in CFTR. Using perfusions and primary cultures of the shark rectal gland, and expression studies of each species protein in cRNA microinjected Xenopus laevis oocytes, we observed fundamental differences in the sensitivity to inhibition by these channel blockers. In perfusion studies, stimulation with forskolin and IBMX increased chloride secretion 15-30 fold. However, endogenous sCFTR was insensitive to inhibition by CFTRinh-172 (no inhibitory effect). This was confirmed in cultured rectal gland epithelial cells (2.5 ± 0.15 % maximum inhibition). In oocyte expression studies shark CFTR was again insensitive to CFTRinh-172 (maximum inhibition 8 ± 1.4%), pCFTR was insensitive to glibenclamide (maximum inhibition 12.8 ± 4.2%), whereas all species were sensitive to GlyH-101. The amino acid residues considered responsible for inhibitor binding by previous site directed mutagenesis are entirely conserved in the CFTR isoforms studied. These experiments demonstrate profound differences in the sensitivity of different CFTR proteins to inhibition by CFTR blockers that cannot be explained by the targeted amino acids. Rather, the potency of CFTRinh-172, glibenclamide and Gly-H101 on the CFTR chloride channel is likely dictated by the local environment and the three dimensional structure of residues that form the vestibule and the chloride pore.

**TGFβ1-Dependent Downregulation of CFTR Is Mediated by DAB2 in Human Epithelial Cells** Agnieszka Swiatecka-Urban.[1] *[1]Nephrology, Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]; [3].*

TGFß1 plays a fundamental role in the pathogenesis of acute and chronic kidney disease and is an important genetic modifier in cystic fibrosis. TGFβ1 inhibits CFTR expression and function by mechanisms that are incompletely understood. Recent work has demonstrated that the multifunctional adaptor protein and an endocytic adaptor, Disabled-2 (Dab2) is integral to TGFβ1 signaling. Our previously published work demonstrated that Dab2 interacts with CFTR. Thus, we hypothesized that Dab2 mediates the TGFβ1-dependent downregulation of CFTR in epithelial cells. The primary differentiated human bronchial epithelial (HBE) cells endogenously expressing wild type (WT)-CFTR and polarized human airway epithelial cells (CFBE41o-) stably expressing WT-CFTR were used as a model of human epithelial cells. Our studies demonstrate that TGFβ1 treatment induced transcriptional responses, including Smad2 phosphorylation and the nuclear translocation of phosphorylated Smad2 in the HBE and CFBE41o- cells. Treatment with TGFβ1 significantly decreased CFTR expression in cell lysates and in the apical plasma membrane in a concentration and time-dependent manner, and the treatment with TGFβ receptor I inhibitors prior to stimulation with TGFβ1 prevented Smad2 phosphorylation. Endogenous Dab2 co-immunoprecipitated with members of the TGFβ1 signaling cascade. Silencing Dab2 expression reduced Smad2 phosphorylation at baseline and after TGFβ1 treatment. Moreover, silencing Dab2 increased CFTR abundance in cell lysates and in the plasma membrane and increased the CFTR mediated chloride secretion. Taken together, our data demonstrate that in human airway epithelial cells, including primary differentiated human bronchial epithelial cells, TGFβ1 downregulates CFTR expression by a mechanism that involves Dab2 mediated signal transduction through the canonical TGFß1 signaling cascade. We anticipate further studies will increase our understanding of the ion transport regulation by TGFß1 and will elucidate the effects of high-producing TGFß1 genotype on the function of ion channels.

**F-PO1609**

**ATP Inhibits NaCl Absorption Via Basolateral P2X Receptors in Mouse Medullary Thick Ascending Limb (mTAL)** Rita D. Marques,[1] Helle A. Praetorius,[1] Markus Bleich,[2] Jens G. Leipziger.[1] *[1]Physiology and Biophysics, Aarhus University, Aarhus, Denmark; [2]Institut of Physiology, Christian Albrechts University Kiel, Kiel, Germany.*

Extracellular nucleotides regulate epithelial transport via luminal and basolateral P2 receptors. Renal epithelia express multiple P2 receptors, which mediate significant inhibition of solute absorption. Recently, we identified several P2 receptors in the medullary thick ascending limb (mTAL) including luminal and basolateral P2Y2 receptors. In addition we found evidence for a basolateral P2X receptor. It has recently been suggested that extracellular nucleotides influence ion transport in this segment. Objective: Investigate if extracellular ATP influences NaCl absorption in mTAL. Methods: We used isolated, perfused mouse mTAL to electrically measure $Na^+$ absorption. By microelectrodes we determined the transepithelial voltage (Vte) and the transepithelial resistance (Rte) and via these the transepithelial $Na^+$ absorption (equivalent short circuit current, Isc). Results: Non-stimulated mTALs show the following transport characteristics: Vte: +9.03±0.44 mV, (lumen-positive), Rte: 8±1.1 Ω $cm^2$, Isc: 1404±21.4 μA/$cm^2$ (n=16). As expected, luminal furosemide (100 μM) completely blocked transport. Basolateral ATP (100 μM) acutely (within 1 minute) and reversibly reduced the absorptive Isc. After 2 minutes a maximal reduction was measured and amounted to 19.6±2.8% (n=8). In the presence of ATP transport inhibition was sustained. Suramin inhibited the ATP effect. Basolateral UTP, a P2Y2/P2Y4 receptor agonist was without effect as was adenosine. Conclusion: These data define that basolateral ATP exerts a significant inhibition of $Na^+$ absorption in mouse mTAL and point to a P2X receptor-mediated mechanism. Intriguingly, these data add yet another example of P2 receptor mediated inhibition of tubular transport in intact renal epithelium.

**A Comparison of P2 Receptor mRNA Expression Levels in the Renal Cortical Collecting Duct in Response to Altered Dietary Sodium and in DOCA-Induced Hypertension** Scott S. P. Wildman,[1] Clare M. Turner,[2] Joanne Marks,[3] Claire M. Peppiatt-Wildman,[1] Robert J. Unwin.[3] *[1]Royal Veterinary College, London, United Kingdom; [2]Hammersmith Hospital, London, United Kingdom; [3]UCL Medical School, London, United Kingdom.*

ENaC control Na reabsorption along the CD and help determine systemic blood pressure. Activation of P2 receptor (P2R) subtypes ($P2X_{4\text{ and/or }4/6}$ and $P2Y_{2\text{ and/or }4}$) expressed in CCD can alter ENaC activity[1]. It is known that changes in ENaC activity, following dietary Na restriction, affects the expression levels of some P2Rs[1]. We have proposed that P2R may locally regulate ENaC activity in the CCD and could be involved in the pathogenesis of hypertension.

We have investigated P2R mRNA levels in CCDs from adult Sprague-Dawley rats maintained on 'low' (0.01%), 'normal' (0.5%) or 'high' (4%) Na diets (for 10 days), and in DOCA-salt hypertensive rats (unilateral nephrectomy, 1% NaCl drinking water and DOCA treatment for 5 weeks; SBP = 189±12 $mmHg^{-1}$).

Kidneys were microdissected and CCDs isolated (~15mm). RNA was extracted and reverse transcribed, and the cDNA transcripts used for real time-PCR. A ratio was calculated of the P2R gene of interest ($P2X_{1\text{-}7}$ or $P2Y_{1,\,2,\,4\text{ and }6}$) to a house-keeping gene (HPRT).

We could not detect significant levels (i.e.>0.5 arbitrary units;AU) of $P2X_{2,3,5,7}$ and $P2Y_1$ mRNA under any experimental condition. Significant amounts of mRNA were detected for $P2X_4$ and $P2Y_{2\text{ and }6}$ in CCDs from rats on a 'normal' Na intake. CCDs from rats on a 'low' Na diet showed a significant increase in abundance of $P2X_4$ and $P2Y_6$ mRNA (2-fold); CCDs from rats maintained on a 'high' Na diet showed a significant decrease in abundance of $P2Y_2$ mRNA (to less than 0.5 AU); CCD $P2X_{1\text{ and }6}$ and $P2Y_4$ mRNA levels were not significant on a 'normal' Na diet, but were increased on a 'low' Na diet. There were no differences in mRNA expression between 'normal' Na diet and DOCA-salt hypertensive rats.

P2R mRNA expression levels change in the rat CCD in response to changes in dietary Na but not in DOCA-salt hypertensive rats.From these data it is unlikely that altered CCD P2R function plays a role in the DOCA model of hypertension.

**F-PO1611**

**Decreased $P2X_7$ Receptor mRNA Expression in the CCD of the $P2X_4^{-/-}$ Mouse: A Clue to the Identity of the P2X Luminal Sodium Sensor?** Siobhan N. George,[1] Teresa M. Kennedy-Lydon,[1] Holly B. Callaghan,[1] Eilidh Craigie,[2] David G. Shirley,[2] Frederick W. K. Tam,[3] Claire M. Peppiatt-Wildman,[1] Robert J. Unwin,[2] Scott S. P. Wildman.[1] *[1]Royal Veterinary College, London, United Kingdom; [2]UCL Medical School, London, United Kingdom; [3]Hammersmith Hospital, London, United Kingdom.*

$Na^+$ reabsorption in the CD is controlled by ENaC. It determines the final amount of reabsorbed $Na^+$ and therefore arterial blood pressure. ENaC activity is inhibited by the activation of an apical $P2X_4$ receptor complex when luminal $Na^+$ is high (145 mM), and potentiated when $Na^+$ is lowered (to 50 mM). Consequently we have proposed that $P2X_4$ complexes are luminal $Na^+$ sensors responsible for locally regulating ENaC activity and therefore blood pressure [1]. Currently we are investigating whether $P2X_4$ receptors are significant regulators of ENaC using a $P2X_4^{-/-}$ mouse. We have compared P2X receptor mRNA levels in the CCD of wildtype and $P2X_4^{-/-}$ mice, using real time-PCR.

Kidneys from terminally anaesthetised mice (C57 wildtype and $P2X_4^{-/-}$) were microdissected and CCDs isolated (~15 mm). RNA was extracted and reverse transcribed and the mRNA transcripts used for real time-PCR. A ratio of mRNA expression was calculated of the P2 receptor gene of interest ($P2X_{1-7}$) to a house-keeping gene (β-actin).

We failed to detect significant levels (<20 arbitary units) of $P2X_{1,2}$ and $_3$ mRNA in wildtype and $P2X_4^{-/-}$ mice. In contrast, significant amounts of mRNA were detected for $P2X_{4,5,6}$ and $_7$ receptor subunits in CCD of wildtype mice. CCDs from $P2X_4^{-/-}$ mice showed a significant decrease in abundance of $P2X_4$ and $_7$ mRNA levels.

In conclusion, the $P2X_4^{-/-}$ mouse CCD does not express $P2X_4$ mRNA - thus validating this mouse model for determining the significance of the $P2X_4$ receptor subunit in regulating ENaC activity. In addition, levels of $P2X_7$ mRNA are also significantly decreased in the $P2X_4^{-/-}$ mouse. Interestingly, a functional $P2X_{4/7}$ heteromeric assembly exists [2], and consequently the possibility exists that the $P2X_{4/7}$ receptor is the sodium sensor in the CCD responsible for the local regulation of ENaC.

**P2Y Receptor Activation Induces Chloride Secretion through Calcium-Activated Chloride Channels in Kidney Inner Medullary Collecting Duct Cells** Madhumitha Rajagopal, Alan C. Pao. *Division of Nephrology, Department of Medicine, Stanford University, Stanford, CA.*

Dysregulation of natriuretic pathways can cause renal salt retention, extracellular fluid volume expansion, and hypertension. Recent studies have shown that urinary ATP increases when rats are placed on a high salt diet. Patch-clamping studies have shown that ATP acts via $P2Y_2$ receptors to inhibit ENaC channels in the cortical collecting duct. $P2Y_2$ knockout mice have increased ENaC activity and develop hypertension, suggesting that this pathway is important for salt homeostasis and blood pressure regulation. We used the mIMCD-K2 cell line as a model system for inner medullary collecting duct epithelium to study other ion transport pathways that might be regulated by P2Y receptors. With an Ussing chamber setup, we observed that ATP acts from both the apical and the basal side of cell sheets to increase chloride ($Cl^-$) secretion. Basal addition of ATP caused a transient increase in short-circuit current ($I_{sc}$), whereas apical addition caused first a transient and then a sustained increase. Both responses were completely inhibited by pre-treatment with $10^{-3}$M FFA, a calcium ($Ca^{2+}$)-activated $Cl^-$ channel blocker. Using specific $P2Y_1$ and $P2Y_2$ receptor agonists, we found that both $P2Y_1$ and $P2Y_2$ receptors at the basal surface mediated the transient $I_{sc}$ increase, and $P2Y_2$ receptors on the apical surface mediated the transient and sustained increases in $I_{sc}$. Furthermore, pre-treatment with a $P2Y_1$ antagonist abolished the effect of the $P2Y_1$ agonist on $I_{sc}$ from the basal side but not of the $P2Y_2$ agonist on $I_{sc}$ from either side. ATP-mediated transient and sustained increases in $I_{sc}$ were also blocked by pre-treatment with phospholipase C (PLC) inhibitor (U73122) and $Ca^{2+}$ chelator (BAPTA-AM), suggesting that ATP signals through PLC and intracellular $Ca^{2+}$ to activate $Ca^{2+}$-activated $Cl^-$ channels. These studies identify two P2Y receptor signaling pathways in inner medullary collecting duct cells that can respond to increases in urinary ATP by stimulating $Cl^-$ secretion. These signaling pathways could represent another mechanism by which urinary ATP can enhance NaCl excretion under conditions of high dietary salt intake.

## F-PO1613

**The Utility and Accuracy of Four Equations in Predicting Sodium Levels in Dysnatremic Patients** Ramy Magdy Hanna,[1,2] James Wilson.[1,2] *[1]Department of Medicine-Division of Nephrology, Olive view-UCLA Medical Center, Sylmar, CA; [2]David Geffen School of Medicine, University of California Los Angeles (UCLA), Westwood, CA.*

**Introduction:** The Ardogue Madias equation (AM), the Barsoum Levine (BL) equation, the Electrolyte free water clearance based equation (EFWC), and the Nguyen Kurtz (NK) equation are four derived equations based on the empirically derived Edelman equation for predicting Na2 from a known Na1 and fluid/electrolyte input and output.

**Methods:** Our study includes 25 mostly hyponatremic patients and 29 data points. We calculated Na2 based on 5 increasingly precise sets of rules. Sets A-D included all 25 patients and 29 data points. Set E contained 9 patients and 13 data points, and was rigorous to the point of accounting for every ion of sodium/potassium and every ml of fluid intake and output to calculate Na2. All of our data and analysis was reviewed by a statistician.

**Results:** Bland Altmann analysis showed no highly significant trends. Pearson correlation was highly significant (**p<0.00001)* for all 4 equations in sets A-D. In set E,correlations were significant for the NK and EFWC based equations (**P=0.028, and 0.048 respectively).* We note that the correlation observed for a control equation (where Na1=Na2) was also highly significant (**p<0.00001)*. We compared the root mean squared error (RMSE) for all four equations and across the board found it to be between 5.5 and 6.5 meq/L of Na for all sets and 6-7 for both iterations of the control equation Na1=Na2. The average delta Na seen was less than the RMSE (2.55 sets A-D, and 3.23 for set E). Increasingly rigorous analysis did not positively affect accuracy. Up to 20meq/L variability between the predicted and actual Na was noted.

**Conclusion:** Like similar studies in hypernatremic patients (Lindner et.al.), our analysis shows highly significant pearson correlations. We show that the control equation Na2=Na1 is also highly correlated. The lack of correlation seen for the AM and BL equation in set E was due to small sample size. The high variability and RMSE shows that none of these equations are effective for predicting Na2 from Na1 for the range of delta sodium seen in our cohort.

## F-PO1614

**Responses to Tolvaptan in Regard to Serum Sodium (SNa) and Serum Arginine Vasopressin (AVP) Levels in Patients with Hyponatremia** Rick P. Vaghasiya, Meghana R. Gaiki, Maria V. Devita, Michael F. Michelis. *Division of Nephrology, Lenox Hill Hospital, NY, NY.*

Hyponatremia is the most common electrolyte disorder in hospitalized patients. With the development of agents that increase solute-free water clearance, management of dilutional hyponatremia has been facilitated. The nonselective, intravenous, vasopressin receptor antagonist conivaptan has been used for treating euvolemic and hypervolemic hyponatremia. More recently, tolvaptan, an oral, selective vasopressin V2 receptor blocking agent has also been introduced for this indication. We report experience with tolvaptan at our institution regarding changes in SNa, urine osmolalities and AVP levels pre and post drug administration.

Patients with euvolemic and hypervolemic hyponatremia were selected. Indications for tolvaptan included SNa level ≤ 125 meq/L or symptomatic patients with less marked hyponatremia. Each patient received an initial oral dose of 15 mg tolvaptan. An additional 15 mg dose was given 24 hours after the initial dose if the patient failed to achieve an adequate response. Five patients are reported.

The mean SNa increase was 7.4 meq/L (range 2-11 meq/L) in the first 24 hours post initial tolvaptan dose. Two patients required 1 dose, 2 patients received 2 doses and 1 patient required 3 doses to achieve a SNa level > 130 meq/L. Urine osmolalities decreased a mean of 243 mOsm/kg H2O. In patients that required repeated dosing, the urine osmolalities continued to be suppressed. The mean AVP level pre tolvaptan was 7.6 pg/mL. For 4 patients, AVP levels 24 hours post tolvaptan administration changed by 0, -1, +1.5, and +26.7 pg/mL, respectively. AVP level post treatment was not available for 1 patient. The patient with an initial decrease in AVP, had an increase of 6.7 pg/mL after a second dose of tolvaptan. There were no significant drops in blood pressure associated with tolvaptan administration. Two patients experienced an 8 meq/L increase in SNa level within 12 hours post tolvaptan dose, both of which responded to D5W infusion.

These data indicate that the use of the oral V2 receptor blocking agent, tolvaptan, can successfully treat significant dilutional hyponatremia in hospitalized patients.

## F-PO1615

**RLY5016: A Novel, Non-Absorbed, Therapeutic Polymer for Serum Potassium Control** I.-Zu Huang,[1] Thomas M. Blok,[2] Michael Burdick,[1] Jamie Cope,[1] Sherin Halfon,[1] Kathleen H. Mellinger,[3] Craig K. Park,[1] James T. Vanderlugt,[2] David A. Bushinsky,[4] Detlef Albrecht.[1] *[1]Relypsa, Santa Clara, CA; [2]Jasper Clinic, Kalamazoo, MI; [3]Battelle, Richland, WA; [4]U. Rochester, NY.*

RLY5016 is a novel, high-capacity, non-absorbed, cation exchange polymer being developed for serum potassium (K) control. RLY5016 is administered as a calcium salt and consists of smooth, free-flowing, low-swelling spherical beads (~100um). In two Phase 1 studies, dose-response and different dosing regimens of RLY5016 were evaluated.

In study RLY5016-101, following single-dose and baseline (BL) periods, 31 healthy volunteers (HVs) received 1g, 5g, 10g, or 20g three times a day (TID) of RLY5016 (3, 15, 30, or 60g/d) or placebo orally for 8 days in a double-blind, randomized, parallel-group design. A dose-dependent increase in mean daily fecal K excretion and a corresponding decrease in urinary K excretion compared to BL were observed (Figure). RLY5016 isolated from feces demonstrated that the in vivo K binding capacity of RLY5016 exceeded 1mEq/g. RLY5016 was well tolerated in all dose groups and adverse events (AEs) were mild to moderate in severity.

In study RLY5016-102, 12 HVs received 30g/d RLY5016 orally for 18 days total in a crossover design administered as 10g TID, 15g twice a day (BID), or 30g once a day (QD). No significant differences were observed between the dose regimens in mean daily fecal or urinary K excretion. AEs were mild to moderate in severity, and were reported for 1, 5, and 7 subjects in the TID, BID, and QD periods, respectively.

RLY5016 resulted in a significant dose-dependent increase in mean daily fecal K excretion and decrease in urinary K excretion indicating appreciable intestinal K binding, was effective when administered in several dosing regimens, and was well tolerated.

Figure: Dose-Dependent Effect of RLY5016 on Mean Daily Fecal and Urinary K Excretion

**RLY5016: A New, Effective, Non-Absorbed, Therapeutic Polymer To Control Serum Potassium** Jamie Cope,[1] Vic Ciaravino,[1] Xunxiang Du,[1] Marcus M. Fischer,[1] Lawrence Lee,[1] Jonathan A. Mills,[1] Murray J. Pettitt,[2] Megan Leah Strawford,[2] Jerry Buysse.[1] *[1]Relypsa, Santa Clara, CA; [2]Prairie Swine, Saskatoon, Canada.*

Sodium polystyrene sulfonate (Na-PSS; e.g. Kayexalate, Kionex) has been used for the treatment of hyperkalemia for half a century. Recently the efficacy and safety of Na-PSS, which is commonly co-administered with large amounts of sorbitol as a cathartic, has been called into question. There is a clear clinical need for a safe and effective polymer for reducing total body potassium (K) that does not require sorbitol co-administration.

RLY5016 is a novel cation-exchange polymer that is being developed for long term control of serum K in patients at risk for hyperkalemia. The polymer is free flowing and low swelling and has excellent GI tolerability without added sorbitol.

RLY5016 is safe and non-absorbed when dosed in rats and dogs. The polymer was well tolerated and safe at doses of 15g/kg/d when administered for 4 weeks in rats and 3.75g/kg/d when administered for 9 months in dogs. In dogs, 99.9% of the administered 13C-RLY5016 dose was recovered in the feces, <0.1% was detected in the urine and 0.002% in the plasma.

Administration of RLY5016 to rats and pigs with normal renal function increased the fecal excretion of potassium with a concomitant reduction in urinary potassium excretion. RLY5016 isolated from pig feces showed that the in vivo binding was 0.8 mEq K per g polymer in these animals.

In rats with compromised potassium homeostasis, induced by partial nephrectomy and the administration of adriamycin, trimethoprim and quinapril (NADR+TQ), hyperkalemia developed rapidly. Administration of RLY5016 in NADR+TQ rats maintained potassium in the normal range.

RLY5016 increased potassium excretion in the feces and thereby controlled hyperkalemia in animals with renal insufficiency.

The Effect of RLY5016 on Serum K Levels in Hyperkalemic NADR+TQ Rats

**RLY5016: A Novel, Effective, Non-Absorbed, Oral Polymer for the Control of Serum Potassium in Heart Failure and Chronic Kidney Disease** David A. Bushinsky,[1] I.-Zu Huang,[2] Stefan D. Anker,[3] Faiez Zannad,[4] Bertram Pitt.[5] *[1]U. Rochester, Rochester, NY; [2]Relypsa, Santa Clara, CA; [3]Charite, Berlin, Germany; [4]CHU, Nancy, France; [5]U. Michigan, Ann Arbor, MI.*

Both heart failure (HF) and chronic kidney disease (CKD) often coexist. Despite the increased mortality risk among these patients, effective therapies such as inhibitors of the renin-angiotensin-aldosterone system (RAAS) are underutilized due to the high prevalence of life threatening hyperkalemia (HK). In this study (RLY5016-202), 104 chronic HF patients with a serum $K^+$ ($S_K$) of 4.3-5.1 mEq/L clinically indicated to receive spironolactone (SPI) were evaluated. Patients with: 1) CKD (eGFR< 60mL/min) on one or more HF therapies (ACEIs, ARBs, BBs) and/or 2) documented history of HK within last 6 months leading to discontinuation of an AA, ACEI, ARB, or BB, were given SPI 25 mg/d and randomized to either 30 g/d of the oral $K^+$ binding polymer RLY5016 (55 pts) or placebo (PL, 49 pts) for 4 wks. The primary endpoint was a change from baseline (BL) $S_K$ at the end of the double-blind treatment. Secondary endpoints were proportion of patients with HK ($K^+$ >5.5 mEq/L), and whose SPI dose could be increased to 50 mg/d. Baseline characteristics were similar between treatment groups. Starting mean $S_K$ was 4.69 ± 0.06 mEq/L on RLY5016 and 4.65 ± 0.07 mEq/L on PL. RLY5016 significantly decreased mean $S_K$ from BL compared to PL (-0.22 mEq/L vs +0.23 mEq/L, p<0.001), reduced the incidence of HK compared to PL (7% vs 25%, p=0.015), and increased the number of patients whose SPI dose could be increased (91% vs. 74%, p=0.019). Among CKD patients (n=28), there was also a significant decrease in mean $S_K$ change from BL with RLY5016 vs PL (-0.14 mEq/L vs +0.38 mEq/L, p=0.031) and a lower incidence of HK (7% RLY5016 vs 39% PL, p=0.017). RLY5016 was well tolerated. Study withdrawal due to an adverse event (AE) was 7% on RLY5016 vs 6% on PL and there were no drug-related serious AEs. The oral $K^+$ binding polymer RLY5016 effectively controls $K^+$ in patients with HF and CKD given SPI and may allow increased use of RAAS inhibitors in these patients.

**Renal Transplant Recipients with Hyperkalemia and Acidosis: The Thiazide Test** Antje Fürstenberg, Nikhil Johri, Robert J. Unwin, Stephen B. Walsh. *Department of Nephrology and Physiology, Royal Free Hospital, University College London Partners Renal Centre, London, United Kingdom.*

Calcineurin inhibitors (CNIs) are known to provoke hyperkalaemia in many patients: the mechanisms for this are unclear. The precise syndrome that occurs is of hyperkalemia, hypertension, mild metabolic acidosis and hypercalciuria.

This is the same phenotype as pseudohypoaldosteronism type 2 (PHA2, Gordon's syndrome), caused by mutations of WNK kinase 1 or 4, which disinhibit expression of the Na-Cl cotransporter (NCC) in the distal convoluted tubule. We hypothesised that NCC activity is increased in CNI induced hyperkalemia, and that we could use a thiazide test to demonstrate NCC overactivity in the same way that it detects NCC underactivity in Gitelman's syndrome.

The subjects were: 6 patients with CNI induced hyperkalaemia and acidosis (CNI) and 3 healthy controls (CTL). All gave written consent. Baseline blood and urine samples were taken for Na, K, Cl, Mg, Ca and creatinine measurements. 10mg of bendrofluazide was given and bed rest observed for 4 hours, water intake encouraged and urine samples repeated at 30-minute intervals.

The change in FE from baseline to the maximal FE achieved (termed the ΔFE) was used, as previously described for the thiazide test.

Results:

$FE_{Cl}$: The $\Delta FE_{Cl}$ was higher in the CNI group than the CTL group (6.03 ± 4 vs. 2.2 ± 1 p=0.03)

$FE_{Na}$: The $\Delta FE_{Na}$ was also higher in the CNI group (6.1 ± 1 vs. 1.8 ± 0.3 p=0.01)

$FE_{K}$: The $\Delta FE_{K}$ was higher in the CNI group, compared to the CTL group (13.3 ± 2 vs. 5.8 ± 0.4 p=0.03)

$FE_{Mg}$: The $\Delta FE_{Mg}$ was higher in the CNI group than the CTL group (11.1 ± 3 vs. 2.9 ± 1, p=0.01)

$FE_{Ca}$: The $\Delta FE_{Ca}$ was also higher in the CNI group than the CTL group (4.2 ± 0.5 vs. 0.2 ± 0.3, p=0.002)

The results are compatible with an increased expression of NCC in the CNI group, with supramaximal $\Delta FE_{Cl}$, $\Delta FE_{Na}$, $\Delta FE_{K}$ and $\Delta FE_{Mg}$. The $\Delta FE_{Ca}$ was also significantly raised in the CNI group; the hypocalciuria seen with thiazides may relate to volume contraction, and so may not occur acutely. These data point toward a specific mechanism for CNI induced hyperkalaemia and support thiazides as a specific treatment for this phenomenon.

**Large-Scale Profiling of Protein Half Lives and Translation Rates in Renal Collecting Duct Cells** Dane H. Slentz, Ming-Jiun Yu, Trairak Pisitkun, Jason D. Hoffert, Mark A. Knepper. *NHLBI, NIH.*

In a given cell type, steady-state protein abundance is determined by a balance between rates of protein production and degradation. Long-term exposure of collecting duct principal cells to vasopressin causes an increase in abundance of the water channel

protein aquaporin-2, a process critical to regulation of water excretion. However, whether the abundances of other proteins undergo parallel changes is unknown and mechanisms of abundance changes are unexplored. We carried out large-scale measurements of protein half-lives ($t_{½}$) and relative translation rates for natively expressed proteins in cultured renal mpkCCD(clone 11) cells (±dDAVP, 1 nM) using metabolic labeling with stable isotopes (SILAC) coupled with protein mass spectrometry (LC-MS/MS). A mass-balance model, assuming first-order kinetics of degradation, allowed calculation of $t_{½}$ and the relative translation rate for each identified protein. Initial experiments (n=3) have provided $t_{½}$ measurements for over 1,000 proteins, a small fraction of which (<1%) was found to change significantly in response to vasopressin, including a 66% decrease in the $t_{½}$ for the adhesion protein B-CAM, whose stability is believed to be regulated by SUMOylation via UBC9. The $t_{½}$ of aquaporin-2 was not significantly changed (mean 12.6 hr). Translation-rate measurements show that among all proteins quantified (>500), 55 changed significantly at least 1.5-fold. Among these were two additional proteins involved in cell adhesion and epithelial polarity, viz. afadin and β-catenin-like protein-1. Aquaporin-2 showed the largest increase in translation rate in response to dDAVP (>16-fold). Many of the proteins showing changes in abundance in response to vasopressin did not have corresponding changes in mRNA levels (Affymetrix arrays). Further studies are underway to define the mechanism of mRNA-independent changes in translation rates in response to vasopressin.

## F-PO1620

**Mice Lacking TRPV4 Show Abnormal Thirst Regulation in Absence of Renal Defects** Sylvie Janas,[1] Sara Terryn,[1] Olivier R. M. Schakman,[2] Johannes Loffing,[3] Philippe Gailly,[2] Olivier Devuyst.[1] *[1]Nephrology, UCL; [2]Cellular Physiology, UCL; [3]Anatomy, University of Zürich.*

TRPV4 is a polymodal cation channel of the transient receptor potential (TRP) family. It is expressed in hypothalamic neurons including the subfornical organ, median preoptic area, and the organum vasculosum of the lamina terminalis, where it could play a role in osmotic sensing. TRPV4 has also been evidenced in the thick ascending limb (TAL) of the rat nephron, where its role remains unclear. To further analyze the role of TRPV4 in osmoregulation, we investigated its distribution pattern and the functional consequences of its disruption in mouse. Using qPCR on microdissected segments and immunohistochemistry, we found that TRPV4 is abundantly expressed in the proximal tubules (apical and basolateral), late distal convoluted tubules and throughout the connecting tubules and collecting ducts (basolateral), including principal and intercalated cells. By contrast, TRPV4 was undetectable in glomeruli and TAL, and weakly abundant in early DCT. Metabolic studies in 12 weeks old TRPV4 knock-out (KO) and wild-type (WT) mice revealed that disruption of TRPV4 does not influence renal function and urinary concentration at baseline. The KO mice did not exhibit anomalies in activity, rearing, food and water intake. Moreover, both WT and KO mice showed a similar renal NaCl and water excretion in response to furosemide injection, acute water loading (100 µl/g BW i.p.), overnight water deprivation, and chronic dietary NaCl restriction (17 days, 0.01% NaCl). However, acute administration of hypertonic saline solution (0.5 M NaCl) resulted in a significantly lower water intake in the TRPV4 KO vs WT mice, suggesting a central defect in osmoregulation. These results demonstrate that TRPV4 is widely expressed in the mouse kidney, but not in the TAL. Disruption of TRPV4 is not reflected by significant alterations in the renal handling of NaCl and water. However, TRPV4 KO mice show a decreased thirst response to hypertonic NaCl, which substantiates the major role of TRPV4 in the central regulation of osmolality.

## F-PO1621

**Membrane Topology of Mouse Urea Transporter B Defined Using Epitope Tags** Bryce MacIver, John Mathai, Mark L. Zeidel.

Urea fluxes via urea transporters (UTs) help regulate urine osmolality. Hydropathy analysis of many mammalian and bacterial UT sequences show a common motif of a highly hydrophobic region of 5 transmembrane helical passes. UT-B comprises 2 such regions (here called TM1 and TM2) linked by a hydrophilic domain. To assess the validity of the predicted topology map we placed hemagglutinin (HA) tags at various positions in the protein predicted to be intracellular or extracellular loops (fig. 1). We expressed these tagged proteins in *Xenopus* oocytes and assayed for UT function by isotope uptake. We then examined the accessibility of the HA tag to its antibody in whole oocytes. Intracellular tags only become accessible when the oocyte is permeabilized by detergent. All tagged positions in fig. 1 show urea uptake 5-15 times that of control except TM1-1, which appears to be non-functional and TM2-1, which shows ~2 fold increase. To date, antibody localization of TM1-2 and G1 tags corroborate their predicted position, while G2 tag differs in that it appears accessible with detergent permeabilization.

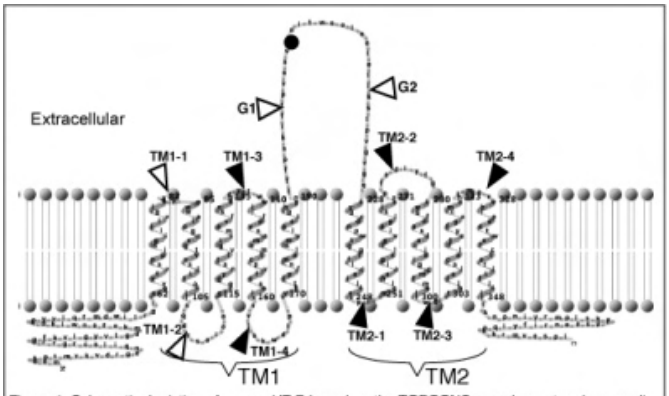

Figure 1. Schematic depiction of mouse UT-B based on the TOPCONS membrane topology prediction algorithm (Bernsel, A. *et al.* Nucleic Acids Research, 2009) and drawn with TMRPres2D (Ioannis, C. *et al.* Bioinformatics, 2004). The topology prediction shows two regions labeled TM1 and TM2 that each comprise 5 transmembrane passes. Open triangles depict positions of HA tag insertions that have been tested for both functionality and location with respect to the membrane while closed triangles are HA tagged insertions tested for function only at this time. The closed circle represents a likely glycosylation site.

Recently a crystal structure of a bacterial UT (dvUT) was reported (Levine *et al*., Nature, 2009). This structure supports the predicted topology showing two hemi-cylindrical domains similar to TM1 and TM2 in fig.1, but adding an additional helix to the 5 transmembrane spans from the topology prediction. However, this additional helix, termed the pore helix, does not span the membrane, instead each pore helix lies at a 50° angle to create a selectivity filter suitable for urea. Interestingly, the G2 tag falls within a region equivalent to a pore helix region of dvUT, yet is functional, but requires detergent for antibody access. In conclusion, our topology mapping corroborates closely with the dvUT structure.

**Dietary Protein Affects Urea Transport across Bladder Epithelium in Rats** David A. Spector, Jie Deng, Kerry J. Stewart. *Divs of Renal Medicine and Cardiology, Johns Hopkins Univ Sch of Med, Baltimore, MD.*

Mammalian bladder epithelia (urothelia) is generally considered impermeable to urinary constituents, but high levels of urea and creatinine and presence of UTB and other transporters in bladder tissue suggest that net urothelial transport (Tx) may occur. We developed an in-vivo rat model to study water and solute Tx across urothelia. To determine the effects of dietary protein on urea Tx we collected 24 hour urines from four groups of rats (n=12) provided with diets differing in protein concentrations (40%, 18%, 6%, 2%- protein deficient ), instilled 0.3 ml urine via urethral catheter into bladders (isolated by ureteral ligation) of anesthetized 225 gm rats, and measured urine volume and concentrations of urea and other solutes (as "controls") in Instilled and Retrieved (after 60 min dwell) urine. Net change (= Tx) of volume and solutes across urothelium were calculated as**:** Retrieved minus Instilled, and differences within and between groups were compared.**Results**: After one hour bladder dwell, there was a mean 2% increase in retrieved urine volume ($p < .0001$) which did not differ between dietary groups. As dietary protein decreased there was a stepwise fall of Instilled UN concentration as well as net urea Tx - reflected by a decrease in change of urine urea concentration (table) and quantity (mg,not shown).

| Dietary Protein | 40% | 18% | 6 % | 2% |
|---|---|---|---|---|
| Instilled UN concentration,mg/dl | 5157* | 2937* | 549 | 247 |
| UN concentration change,mg/dl | -583* | -270 | -141 | -87 |
| percent change | - 11.1 | -11.5 | -25.5* | -23.2* |

* $p < .0001$ vs other diets

In contrast, percent of instilled urea transported was greater in the two low dietary protein groups than in the higher dietary protein groups ($p < .0001$). Regression analysis (not shown) showed a strong direct relationship between initial urine urea concentration and resultant urea Tx. Urine creatinine and K concentrations also fell following one hour bladder dwell, but there were no differences in transport between dietary groups. **Conclusions**: Urea and other solutes are transported across rat urothelia, with magnitude of urea Tx mediated, in part, by dietary protein concentration and consequent urine urea nitrogen concentration.

## F-PO1623

**Urea Is Important for the Urinary Concentration Capacity of the Isolated Blood Perfused Rabbit Kidney** Paul S. Steels,[1] Jerry Toelsie,[2] Yves Cuypers,[1] Robbert Bipat.[2] *[1]University Hasselt, Belgium; [2]Anton de Kom University, Suriname.*

It is generally accepted that urea plays a critical role in the urine-concentrating mechanism in mammals, but herbivores have a different handling of urea than carnivores and omnivores (Bankir in The Kidney 5th ed. Brenner p. 595). Gunther and Rabinowitz ( KI, 1980,17,205) have reported that urea did not enhance the concentrating ability in calm, unanesthetized, vasopressin-treated rabbits. In this study we used the isolated blood perfused rabbit kidney (Cuypers et al Pfluegers Arch,2000,440,634) to test whether its urinary concentrating activity is indeed independent of urea. Left kidneys of female rabbits

were perfused with 25 ml autologous, heparinized blood at a pressure of 100 mm Hg and at 38°C . The urea concentration was changed via a continuous infusion of 0.1 ml/min in the venous line, to compensate for the urine excretion. [Arg8]-vasopressin (30 IU/l) was added to the perfusion fluid in all experiments. A recovery period of 25 minutes was followed by 4 thirty-minute periods of perfusion during which urine was collected and blood samples were taken . In high urea series (n=8) and low urea series (n=7) the following values were measured from P1 to P4.

| Perfusion period | Pur (mmol/l) | U/Pur | FEur (%) | UF (µL/min.gkw) | Uosm (mOsm/kg) | TCH2O (µL/min.gkw) | TCH2O /UF |
|---|---|---|---|---|---|---|---|
| P1 | 15 | 9 | 18 | 6 | 660 | 6.6 | 1.2 |
| P4 | 18 | 12 | 27 | 5 | 609 | 5.1 | 1.0 |
| P1 | 3.2 | 19 | 43 | 8 | 616 | 8.6 | 1.1 |
| P4 | 1.4 | 12 | 61 | 9 | 387 | 5.0 | 0.6 |

From these results (Uosm and $T_{[sup]C[/sup]H2O}$ /UF) we conclude that urea plays an important role in the urine concentrating mechanism of the rabbit in contrast to the findings of Gunther and Rabinowitz, who applied an osmotic diuresis with mannitol. The high U/P values for urea and the high FEur in the low urea compared to the high urea series, suggest that urea might be actively secreted, although this issue is controversial when studied in isolated rabbit tubular segments (Kawamura, Kokko, JCI,1976,58,604; Knepper,AJP,1983,244,F622).

## F-PO1624

**SPAK-Dependent Activation of Thiazide-Sensitive $Na^+$-$Cl^-$-Cotransporter by Vasopressin** Turgay Saritas,[1] Kerim Mutig,[1] David H. Ellison,[2] Eric J. Delpire,[3] Alexander Paliege,[1] Shinichi Uchida,[4] Sebastian C. Bachmann.[1] *[1]Department of Anatomy, Charite University Berlin, Berlin, Germany; [2]Division of Nephrology & Hypertension, Oregon Health & Science University, Portland, OR; [3]Department of Anesthesiology, Vanderbilt University School of Medicine, Nashville, TN; [4]Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan.*

The $Na^+$-$Cl^-$ cotransporter (NCC) of distal convoluted tubule (DCT) effectively contributes to the fine regulation of urine electrolyte composition. Acute activation of NCC by angiotensin II involves luminal trafficking as well as phosphorylation by WNK/SPAK kinases. Vasopressin (AVP) activates NCC by binding to type 2 receptors (V2R), but the kinases involved have not been elucidated. We propose a significant role for SPAK in the AVP-induced activation of NCC.

SPAK-knockout (SPAK-/-, Behav. Brain Res. 2010; 208:377-82.) and wild-type mice (WT) and AVP-deficient Brattleboro rats (DI) were treated with the V2R agonist, dDAVP, or vehicle for 30 min. Kidneys were studied by immunohistochemistry and Western blot.

SPAK and phospho-SPAK were co-expressed with NCC in DCT. dDAVP treatment increased NCC phosphorylation at S71 in WT mice (+87%, $p<0.05$) but less so in SPAK-/- mice (+45%, $p<0.05$). Phosphorylation of NCC at T53 was also significantly increased in WT (+153%, $p<0.05$) whereas SPAK-/- mice showed no change. In DI rats, dDAVP produced increases of SPAK and NCC phosphorylation in 11ß-hydroxysteroid dehydrogenase 2-negative DCT1 (pS373-SPAK: +52%; pS71-NCC: +42%; pT53-NCC: +147%; $p<0.05$) but not in DCT2 of DI rats.

We conclude that V2R stimulation enhances NCC activity via phosphorylation events that depend on SPAK, although other kinases are also involved. Activation of NCC by V2R occurs predominantly along the aldosterone-insensitive DCT1, suggesting that NCC activation by aldosterone is mechanistically distinct.

## F-PO1625

**Renomedullary Blood Flow and Blood Volume Are Increased during Vasopressin Escape** Fredrik Palm,[1,2] Per Liss,[2] Angelica Fasching,[2] Lars-Ove Magnusson,[2] Petter Quick,[3] Anders Persson,[3] Joseph G. Verbalis.[4] *[1]Nephrology & Hypertension, Georgetown University; [2]Uppsala University, Sweden; [3]CMIV, Linköping University & Hospital, Sweden; [4]Endocrinology & Metabolism, Georgetown University.*

Hyponatremia is a common electrolyte disorder usually caused by inappropriate vasopressin (AVP) levels relative to serum osmolality. The degree of the hyponatremia is limited by "escape" from AVP-induced antidiuresis, characterized by increased urine volume and decreased urine osmolality independently of circulating AVP. The mechanisms mediating escape are not fully understood, but we have hypothesized that increased renomedullary blood flow (BF) contributes to this process. We therefore investigated intrarenal BF and blood volume distribution in rats with and without escape.

Sprague-Dawley rats (n=10) were infused with DDAVP (5 ng/h) to produce maximal antidiuresis. Half were fed a liquid diet (AIN-76) to produce escape; half were fed a solid diet to prevent escape. After 5 days, all rats were anesthetized with Inactin and high resolution images (voxel size 97x97x600 µm) of renal BF were acquired using a Siemens Definition Dual Source CT. Iopromide (0.15 ml/rat) was rapidly injected iv and the contrast over the kidney area was collected during 30s. Data were evaluated by analyzing local renal contrast density utilizing the Siemens Syngo body perfusion tool and correlated to the aorta.

Cortical and medullary BF were 709±41 and 251±50 ml/100ml/min respectively in non-escaped rats. Cortical BF in escaped rats was similar (588±81 ml/100ml/min), but medullary BF was increased compared to non-escaped rats (666±105 ml/100ml/min). Blood volumes were similar in the two groups in cortex (42±1 vs. 49±6 ml/100ml), but elevated in the medulla of escaped rats (70±3 vs 18±3 ml/100ml).

Our results demonstrate that escape is accompanied by markedly elevated renomedullary BF and volume. Elevated BF to the renal medulla results in reduced interstitial osmolality, and may also contribute to the down-regulation of aquarporin-2 water channels known to accompany escape. These results therefore provide a potential mechanistic explanation for the reduced ability to concentrate urine during AVP escape.

Disclosure of Financial Relationships: Honoraria: AstraZeneca.

## F-PO1626

**Characterizing the Roles of eNOS, nNOS, and Angiotensin II in Renal Escape from Antidiuresis** Saad Hussain, Lisa Nicole Linde, Joseph G. Verbalis. *Medicine, Georgetown University, Washington, DC.*

Down-regulation of renal vasopressin (AVP) V2 receptors (V2R) and aquaporin-2 (AQP2) water channels plays a critical role in escape from AVP-induced antidiuresis, but the signaling underlying V2R and AQP2 down-regulation is not known. Previous studies have implicated endothelial and neuronal nitric oxide synthase (eNOS & nNOS), angiotensin II (AngII), and prostaglandins (PG) as molecules involved in modulating V2R activity, and thus possible mediators of escape. We studied the role of these molecules in escape by creating a mouse model of escape and comparing mice with selected gene deletions to C57Bl/6 wild type (WT) mice. For each experiment, 15 mice were divided into 3 groups of n=5: 1) single gene knockout (KO) mice (eNOS, nNOS, or Ang II receptor 1a [atr1a]; Jackson Labs, ME) fed a gel diet and infused with dDAVP; 2) WT mice fed a gel diet and infused with dDAVP; and 3) WT mice fed a solid diet and infused with dDAVP. All experiments were repeated to yield a combined n=10 for each group. Antidiuresis was induced in all groups via dDAVP administration (0.0435 ng/ul/hr/g body weight); groups 1 & 2 were water loaded via the gel diet with high water content, whereas group 3 was not water loaded. Urine volume, osmolality, [Na+] and [K+] as well as ad lib water intake, food intake and weight were measured daily. Escape from antidiuresis was observed over the course of 5 days in groups 1&2; group 3 did not escape antidiuresis. The eNOS KO mice exhibited a near normal pattern of escape from antidiuresis, although the mean urine volume was significantly lower than WT on days 3 & 4. Both the nNOS and atr1a KO mice showed a significantly delayed time course of escape, but they ultimately escaped to the same absolute levels as WT by day 5. Our data demonstrate that each of these signaling molecules likely plays a role in escape from antidiuresis, since no KO mice strain exhibited the same pattern of escape as WT mice. However, each of the KO strains eventually escaped antidiuresis. Consequently, we conclude that eNOS, nNOS, and AngII all participate in the escape mechanism, but none appear to be independently responsible for the phenomenon of renal escape from antidiuresis.

## F-PO1627

**INSIGHT: Investigation of the Neurocognitive Impact of Sodium Improvement in Geriatric Hyponatremia: Efficacy and Safety of Tolvaptan** Joseph G. Verbalis,[1] Howard S. Ellison,[2] Kianoosh Kaveh,[3] Mary Hobart,[4] John Ouyang,[4] Holly B. Krasa,[4] Frank S. Czerwiec.[4] *[1]Georgetown U., Washington, DC; [2]Rockdale Med. Res. Assoc., Conyers, GA; [3]Coastal Neph. Assoc., Port Charlotte, FL; [4]Otsuka PR&C, Rockville, MD.*

INSIGHT tested tolvaptan effects on neurocognitive function, gait and bone metabolism in elderly patients with sub-clinical hyponatremia.

Fifty-seven subjects ≥50 yrs old with asymptomatic (normal Mini-Mental State Exam), chronic hyponatremia (124-134 mEq/L) were randomized to double-blind treatment (1:1 T=tolvaptan:P=placebo) titrated 15 to 60 mg/d to achieve a target serum [$Na^+$] of 138 mEq/L over 21 d. Mean age was 71yrs in both groups; in each group 30% were taking psycholeptic, and 30% psychoanaleptic drugs.

Serum [$Na^+$] rose from 129 to 136 for T and 130 to 132 for P; +5.15 mEq/L ($p<0.01$), and fell after withdrawal (129 T, 132 P). No overly rapid correction was seen. Cognitive speed, the composite primary endpoint, improved by 0.39 in T and by 0.20 in P (z-score) for an estimated treatment effect of +0.23 ($p=0.08$) at therapy day 21, then fell by -0.17 and -0.05 after withdrawal. The effect was driven by each component (Reaction time +0.20, $p=0.21$; Psychomotor Speed +0.27, $p=0.02$; Processing Speed +0.26, $p=0.21$). Overall Neurocognitive Composite favored T nominally, but not statistically (+0.12, $p=0.16$). The Romberg test improved ($p=0.02$); Postural Sway and the Get-Up-and-Go were divergent, the former favoring P; the later T. Nominally greater serum osteocalcin increases and urine N-telopeptide decreases were seen in T. Correlations with serum [$Na^+$] were significant for Psychomotor Speed; $r=0.319$, $p=0.025$. Thirst, pollakiuria and weight decrease were commonly reported; few (2 T, 1 P) subjects had serious adverse events.

Normal appearing elderly hyponatremic subjects demonstrated improvements in some neurocognitive and gait tests as well as markers of bone metabolism after treatment with tolvaptan. INSIGHT therefore shows that correction of asymptomatic hyponatremia can be safely achieved in elderly adults, supports published data that this can lead to improved neurological functional, and suggests potential reversal of hyponatremia-induced bone loss.

**F-PO1628**

**Dynamic Changes in Vesicle Movement on the Onset of Hypertonic Challenge** Udo Hasler,[1] Paula Nunes,[1] Richard Bouley,[2] Isabelle Roth,[1] Eric Feraille,[1] Dennis Brown.[2] *[1]Department of Cellular Physiology and Metabolism, University of Geneva, Geneva, Switzerland; [2]Program in Membrane Biology/ Nephrology Division, Harvard University, Boston, MA.*

Cell volume is restored within minutes of hypertonic stimulation via a regulatory volume increase (RVI) mechanism during which the challenged cell undergoes cytoskeletal remodeling and changes in channel/transporter activity. The aim of this study was to investigate changes in vesicle trafficking dynamics that may occur during RVI. We monitored movement of vesicle sub-populations by spinning-disk confocal microscopy performed on live LLC-PK1 cells loaded with FITC-dextran or expressing various fluorescent-tagged proteins (Rab5, 7, 10, 11, ssGFP, AQP2 and V2R). Analysis of movies using ImageJ software of cells exposed to isotonic (290 mOsmol/kg) and then NaCl-hypertonic (500 mOsmol/kg) medium revealed an immediate and dramatic reduction of movement of all vesicle sub-populations upon hypertonic exposure. Movement partly resumed thereafter with different half-maximal recovery times between subpopulations, ranging from 5 min to more than 30 min. In cells loaded with dextran, some vesicles entirely recovered while others remained immobilized during the entire period of analysis (30 min). The effects of hypertonicity was reiterated in two other renal epithelial cell lines (mpkCCDcl4 and mCCDcl1) and in medium in which NaCl was replaced by glucose or mannitol. Confocal microscopy, Western blot and phalloidin fluorescence analysis revealed that hypertonicity induces important effects on actin filament rearrangement that were partly mimicked by jasplakinolide, an actin polymerization agent. Like hypertonicity, jasplakinolide abolished movement of a subset of dextran-loaded vesicles that, unlike hypertonicity, did not recover over time. Recovery of movement of vesicles temporally immobilized by hypertonicity was not affected by jasplakinolide, defining actin remodeling as a factor governing changes in vesicle dynamics by hypertonicity. These observations reveal that hypertonicity 'stalls' vesicle trafficking/sorting events, possibly reflecting cell damage, a situation that must be corrected in order to ensure cell survival.

**Broad Range Neutral Amino Acid Transporter ($B^0AT1$) Requires Association with Collectrin for Surface Expression in Kidney Cells** Marta Torrente,[1] Lisa Arps,[2] Simone M. R. Camargo,[1] Francois Verrey.[1] *[1]Institute of Physiology and ZIHP, University of Zurich, Zurich, Switzerland; [2]Division of Infectious Diseases, University Hospital Zurich, Zurich, Switzerland.*

The broad range neutral amino acid transporter ($B^0AT1$) is expressed in the brush border of the renal proximal tubules and small intestine and was shown to be crucial for the luminal amino acid uptake and thus for the regulation of amino acid homeostasis. Loss-of-function mutations of $B^0AT1$ result in Hartnup syndrome, an autosomal-recessive inherited disorder characterized by aminoaciduria and, in some cases, pellagra-like rashes, cerebellar ataxia, and psychosis. Recent data indicate that $B^0AT1$ requires the presence of an accessory protein called collectrin for its expression in kidney proximal tubule whereas in small intestine an analogous role is played by angiotensin converting enzyme 2 (ACE2), a protein also expressed in proximal tubules. The mechanism of interaction between collectrin and $B^0AT1$, the stability and the functional role of that interaction, and the reason why collectrin is preferred to ACE2 in kidney cells remain unclear. To address these questions, we utilized Madin-Darby canine kidney (MDCK) cells as expression system. In a first series of experiments, we observed that the constitutive expression of $B^0AT1$ was toxic for the cells. Therefore, using lentiviral transduction and a KRAB repressor system we produced cells that inducibly express either $B^0AT1$ or collectrin or both. Expression of $B^0AT1$ and collectrin was verified at the mRNA and protein levels using RT-PCR and western blot. Immunofluorescence experiments showed that collectrin expressed alone is substantially localised at the luminal cell surface whereas $B^0AT1$ expressed alone remains intracellular. When $B^0AT1$ and collectrin are coexpressed, the quantity of both gene products is decreased but $B^0AT1$ localizes at the apical surface, as does collectrin. In conclusion, we generated cell lines expressing inducible $B^0AT1$ and collectrin in which the surface expression of $B^0AT1$ depends on collectrin coexpression, as in kidney proximal tubule, and thus represent a very good model for testing the role and the mechanism of $B^0AT1$-collectrin interaction.

**Uremic Toxins Inhibit Transport by Multidrug Resistance Protein 4 and Breast Cancer Resistance Protein** Henricus A. M. Mutsaers,[1,2,3] Lauke Ringens,[1,2] Jeroen Van den Heuvel,[1,2] Lambertus V. Heuvel,[1,4] Joost G. Hoenderop,[1,3] Rosalinde Masereeuw.[1,2] *[1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Dept. of Pharmacology & Toxicology; [3]Dept. of Physiology; [4]Dept. of Pediatrics.*

During chronic kidney disease (CKD), there is a progressive accumulation of toxic solutes due to inadequate renal clearance. These uremic toxins can cause a multitude of pathologies, including renal fibrosis, anemia and cardio-vascular disease. The current dialysis strategies are not completely adept to remove uremic toxins, indicating that active transport is required for complete clearance. Therefore, we investigated whether uremic toxins can influence transport activities of two important efflux pumps, *viz.* multidrug resistance protein 4 (MRP4) and breast cancer resistance protein (BCRP). The interaction of several uremic toxins with [$^3$H]methotrexate ([$^3$H]MTX) and [$^3$H]estrone sulfate ([$^3$H]E1S) uptake was studied in membrane vesicles isolated from MRP4- or BCRP-overexpressing human embryonic kidney (HEK293) cells, respectively. Our results show that hippuric acid, indoxyl sulfate and kynurenic acid inhibit MRP4-mediated [$^3$H]MTX uptake (calculated $IC_{50}$ values: 906 μM, 2 mM, 8 μM, respectively) and BCRP-mediated [$^3$H]E1S uptake ($IC_{50}$ values: 1.9 mM, 719 μM and 38 μM, respectively), whereas indole-3-acetic acid and phenylacetic acid only impede [$^3$H]MTX uptake by MRP4 ($IC_{50}$ values: 1.8 mM and 5.8 mM, respectively). In contrast, p-cresol, p-toluenesulfonic acid, putrescine, oxalate and quinolinic acid did not alter transport mediated by MRP4 or BCRP. Furthermore, our results indicate that the tested uremic toxins mostly act as non-competitive inhibitors for MRP4 and BCRP-mediated uptake. Moreover, the $IC_{50}$ values are lower than the maximal concentration of these toxins measured in the plasma of end-stage CKD patients. In conclusion, this study shows that several uremic toxins inhibit active transport by MRP4 (5 out of 10 tested toxins) and BCRP (3/10) at clinically relevant concentrations. Indicating, that uremic toxins hamper kidney function leading to further progression of CKD. Novel strategies should focus on preserving transport activity enabling adequate renal clearance.

**Inhibitory Effect of Cadmium on Sp1 Binding to *SGLT1* Promoter Is Independent from PKC Activation** Niloofar Tabatabai,[1] Ivan Kamyshko,[2] Rajendra Kishore Kothinti.[2] *[1]Medicine, Medical College of Wisconsin, Milwaukee, WI; [2]Chemistry and Biochemistry, University of Wisconsin-Milwaukee, Milwaukee, WI.*

Cadmium (Cd) exposure causes glucosuria. Glucose reabsorption depends on sodium-glucose cotransporters (SGLTs). Transcription of human SGLT1 gene is regulated by Sp1, whose binding sequence (GC1) is conserved in mouse and pig. Using cultured primary mouse kidney cells, we showed that Cd inhibits sodium (Na)-dependent uptake of glucose, decreases SGLT1 mRNA levels, and inhibits the binding of Sp1 to GC1. Since Sp1 activity can be modulated by phosphorylation, and Cd activates Protein Kinase C (PKC), we examined the role of PKC in inhibition of Sp1 activity by Cd. LLC-$PK_1$ cells were treated either with $CdCl_2$; a PKC agonist, phorbol 12-myristate 13-acetate (PMA); or a specific PKC inhibitor, GF109203X. Glucose uptake was measured using a fluorescent substrate, 2-NBDG. DNA binding activity of nuclear Sp1 was examined by Electrophoretic Mobility Shift Assay (EMSA). To examine PKC activity, expression of c-Fos, which is known to be induced by PKC, was determined by Western blot. To examine mRNA levels of SGLT1, RT and TaqMan real time PCR were performed. Results showed that exposure of cells for 24 hr to 2.5-15 μM Cd decreased Na-dependent uptake of glucose by 22-91%. Compared to controls, SGLT1 mRNA decreased by 70% and c-Fos protein increased by 8 fold in cells exposed to 20 μM Cd for 24 and 2 hours, respectively. Similarly, exposure to 160 nM PMA decreased SGLT1 mRNA by 70% and up-regulated c-Fos expression by 9.5 fold after 6 and 2 hours, respectively. EMSA showed that Cd treatment reduced binding of nuclear Sp1 to GC1 by 40%; however, PMA had no effect on Sp1 activity. GF109203X did not restore Sp1 activity and had no effect on SGLT1 mRNA levels in Cd-treated cells; however, it blocked the inhibitory effect of PMA on SGLT1 mRNA expression. Our results showed that Cd activated PKC, and that both Cd and PMA reduced SGLT1 mRNA levels; only Cd reduced Sp1 binding to GC1, while blockade of PKC activity only protected against the effects of PMA. We conclude that PKC does not play a role in Cd-mediated inhibition of Sp1 binding to *SGLT1* promoter.

***Drosophila* Prestin Provides an *In Vivo* Model for Oxalate Kidney Stone Formation** Taku Hirata,[1,2] Pablo Cabrero,[3] Julian A. T. Dow,[3] Michael F. Romero.[1,2] *[1]Physiology & Biomedical Engineering, Mayo Clinic College of Medicine, Rochester, MN; [2]O'Brien Urology Center, Mayo Clinic College of Medicine, Rochester, MN; [3]Biomedical and Life Sciences, University of Glasgow, Glasgow, United Kingdom.*

Kidney stones are major causes of emergency room admissions worldwide. While most stones are of calcium oxalate, our understanding of the convergence of genetic, environmental and metabolic factors that trigger formation, and the dynamics of nucleation and formation, are still patchy. The solute carrier 26 (Slc26) transporters are anion transporters with diverse substrate specificity including $Cl^-$ and oxalate ($ox^{2-}$) exchange. Slc26a6 knockout mice show nephrolithiasis (Ca-oxalate kidney stones). Slc26a6 is expressed in kidney and gut epithelia, playing a central role in secretion and absorption of anions such as chloride, $ox^{2-}$, sulfate ($SO_4^{2-}$), bicarbonate ($HCO_3^-$), The Slc26a6 protein mediates electrogenic $Cl^-/ox^{2-}$, $Cl^-/nHCO_3^-$, $Cl^-/SO_4^{2-}$ exchange. Recently, chicken and zebrafish prestin were shown to mediate electrogenic $Cl^-/ox^{2-}$. We have cloned and localized the *Drosophila melanogaster* Slc26a5 (dPrestin). This dPrestin mRNA is heavily expressed in the gut (adult and larva) and Malpighian tubules ("kidney"). Flies or dissected Malpighian tubules fed oxalate show Ca-oxalate crystal accumulation within hours. *In vivo* dPrestin knockdown reduces crystal formation. Kinetically, dPrestin is similar to mammalian Slc26a6. These results indicate that this system is a *Drosophila* model of kidney stones formation, allowing us study the factors regulating and competing with $ox^{2-}$ transport *in vivo* to understand the genetic influences of kidney stones. Such regulatory genes would be gene candidates for human nephrolithiasis.

**Mechanism of Phosphoenolpyruvate Carboxykinase (PEPCK) mRNA Stabilization during Acidosis** Sachin S. Hajarnis, Lynn Taylor, Norman P. Curthoys. *Biochemistry and Molecular Biology, Colorado State Univ, Fort Collins, CO.*

Onset of metabolic acidosis triggers an essential renal response that includes a pronounced increase in catabolism of plasma glutamine, increased reabsorption and net production of bicarbonate, and increased synthesis and excretion of ammonium ions. A rapid and pronounced increase in PEPCK is a paradigm for this response. This response is effectively modeled in a clonal line of porcine LLC-$PK_1$-$F^+$ cells that exhibit 5-fold increases in PEPCK mRNA and protein when treated for 24 h with acidic medium (pH 6.9, 9 mM $HCO_3^-$). This response is mediated, in part, by a 2-fold increase in the half-life of PEPCK mRNA. HuR is an RNA binding protein that stabilizes mRNAs in response to various stress conditions. siRNA knockdown of HuR decreased basal expression and significantly inhibited the pH-responsive increase in PEPCK protein. Electrophoretic mobility shift assays established that purified recombinant HuR binds with high affinity to multiple sites in the final 92-nucleotides of PEPCK mRNA. Use of deletion and mutated constructs mapped the binding of HuR to a CU-sequence and to two highly conserved AU-rich elements. Segments containing these sites were previously shown to bind recombinant p40-AUF1 and to mediate the rapid turnover of PEPCK mRNA. Selective enrichment of phosphoproteins indicated that treatment with acidic medium results in increased phosphorylation of HuR and AUF1. The pH-responsive stabilization of PEPCK mRNA is reproduced in a chimeric β-globin mRNA that contains the 3'-UTR of PEPCK mRNA. Mutation of a single conserved AU-rich element within the chimeric mRNA resulted in a 2.3-fold increase in half-life and loss of pH-responsive stabilization. Finally, pH-responsive stabilization of the chimeric mRNA is inhibited by SB203580, an inhibitor of p38 MAPK, but not by U0126, an ERK1/2 inhibitor. Therefore, activation of the p38 MAPK pathway may mediate the covalent modification and remodeling of proteins that bind to the pH-response element. This mechanism may stabilize multiple mRNAs and contribute to the pronounced remodeling of the proteome of the renal proximal tubule that occurs during metabolic acidosis.

**The Diuretic Effect of a Small Molecule Inhibitor of CLC-K1 in Rats** Paru P. Kathpalia,[1] Andrew E. Howery,[2] Lise Bankir,[3] Justin Du Bois,[2] Merritt Maduke,[4] Alan C. Pao.[1] *[1]Division of Nephrology, Stanford University School of Medicine, Palo Alto, CA; [2]Department of Chemistry, Stanford University, Palo Alto, CA; [3]INSERM UMRS 872, Paris, France; [4]Department of Molecular and Cellular Physiology, Stanford University School of Medicine, Palo Alto, CA.*

Hyponatremia is the most common electrolyte disorder in the United States and contributes to significant patient morbidity and mortality. Disruption of the renal medullary concentrating gradient by blocking the activity of the chloride channel CLC-Ka (CLC-K1 in rodents) in the thin ascending limb of the loop of Henle represents one strategy to promote aquaresis and treat hyponatremia. We have developed a second-generation small molecule inhibitor, 4,4'-octanamidostilbene-2,2'-disulfonate (OADS), that can specifically inhibit CLC-Ka transport activity. *Xenopus laevis* oocytes expressing CLC-Ka, CLC-Ka-N68D, or CLC-0 were treated with various concentrations of OADS, and chloride currents were measured by two-electrode voltage clamp technique. OADS inhibited CLC-Ka with an apparent affinity of 2 μM and exhibited no measurable effect on the skeletal muscle homolog CLC-0. The affinity of OADS for CLC-Ka decreased by five-fold when an N68D mutation was introduced, suggesting that OADS has substantially less affinity for CLC-Kb. Based upon these findings, we hypothesized that OADS, by specifically blocking CLC-K1 in the kidney, would enhance excretion of water in the whole animal. In conscious rats, intraperitoneal injection of OADS induced a three- to five-fold increase in urine output, with an associated fall in urine osmolality, within the first 4 hours of administration. These findings suggest that OADS may increase water excretion by inhibiting CLC-K1 in the thin ascending limb of Henle's loop and indicate that CLC-Ka/1 may be a new potential drug target for the treatment of hyponatremia.

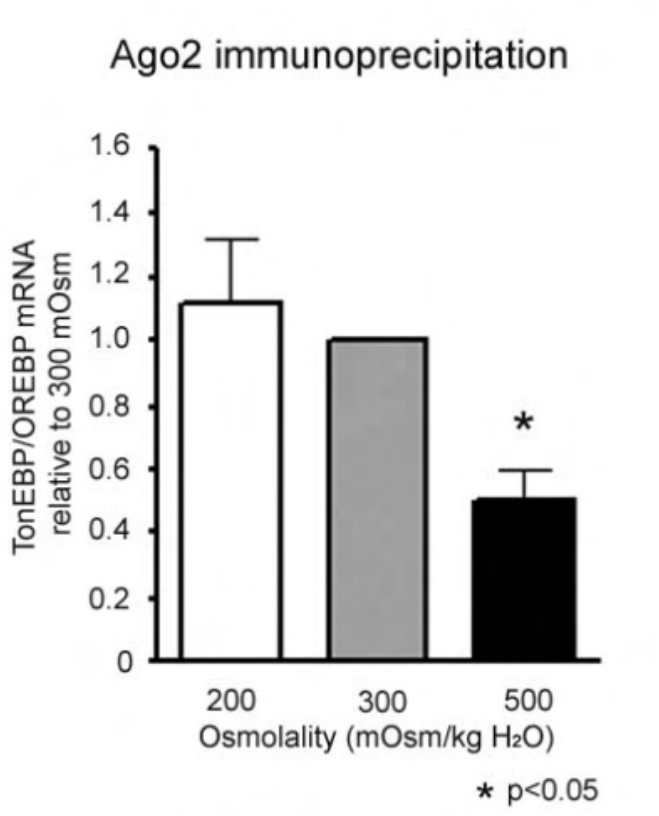
**Regulation of TonEBP/OREBP Expression through Ago2 Mediated microRNAs** Yuichiro Izumi, Morgan Gallazzini, Joan D. Ferraris, Maurice B. Burg. *LKEM/NHLBI, National Institutes of Health, Bethesda, MD.*

The osmoprotective transcription factor, TonEBP/OREBP, is important for cell survival under hypertonic conditions, such as exist in the kidney medulla. Hypertonicity is known to increase TonEBP/OREBP mRNA and protein abundance, reaching a peak after several hours, followed by decrease to a lower steady level. The regulatory mechanism of the acute increase is not completely understood. Since the 3'-UTR of TonEBP/OREBP mRNA contains many predicted microRNA binding sites, we investigated the possible involvement of Argonaute 2 (Ago2) mediated microRNA activity on TonEBP/OREBP expression in HEK293 cells. We found that siRNA-mediated knockdown of Ago2 increases TonEBP/OREBP protein abundance. We measured mRNAs that co-immunoprecipitate with HA-tagged-Ago2 (HA-Ago2) by RT-PCR. TonEBP/OREBP mRNA is enriched in the Ago2 immunoprecipitate. As a control, betaine/GABA (BGT1) mRNA, which has few predicted microRNA sites in its 3'-UTR, is not detected in the Ago2 immunoprecipitate. Acutely (1.5 hours) raising osmolality from 300 to 500 mosmol/kg by increasing NaCl decreases the amount of TonEBP/OREBP mRNA in the Ago2 immunoprecipitate, without any change in the total amount of RNA in the immunoprecipitate.



After 24 hours of high NaCl, TonEBP/OREBP mRNA is no longer lower in the Ago2 immunoprecipitate. We suggest that reduced association of TonEBP/OREBP mRNA with the Ago2 microRNA processing complex contributes to the acute high NaCl-induced increase of TonEBP/OREBP expression, resulting in accelerated adaptation to hypertonicity.

**Cultured Human Glomerular Endothelial Cells Display ACE-Mediated Angiotensin-II-Generating Capacity and Limited Angiotensin-II-Degrading Activity** Juan Carlos Q. Velez,[1,2] Michael G. Janech,[1,2] John M. Arthur,[1,2] John R. Raymond.[1,2] *[1]Department of Medicine, Medical University of South Carolina, Charleston, SC; [2]Medical and Research Services, Ralph H. Johnson VA Medical Center, Charleston, SC.*

The intraglomerular renin-angiotensin system (RAS) is linked to the pathogenesis of progressive glomerular diseases. We previously showed that podocytes and mesangial cells play distinct roles in the metabolism of angiotensin (Ang) peptides. However, little is known about the corresponding role of glomerular endothelial cells (GECs). Thus, we explored the RAS enzymatic profile of human GECs (hGECs) in culture. Identity of hGECs was confirmed by expression of platelet/endothelial cell adhesion molecule by immunoblotting. Cells were grown to confluence and serum-starved overnight. Then, cells were exposed to 1 μM Ang-I or Ang-II for up to 8 hours. Cell media samples were collected at various time points and subjected to MALDI-TOF mass spectrometry for Ang peptide analysis. $_{13}C_{,15}N$-valine labeled peptides were used for quantification. During incubation of Ang-I, Ang-II was the most abundant fragment, with lesser amount of Ang-(1-7) detected. Peak for Ang-(2-10) was near the lower limit of detection. When cells were incubated in the presence of captopril (100 μM), Ang-II formation was almost completely abolished (137.8 ± 6.1 nM vs. 5.5 ± 0.5 nM of Ang-II at 4 hours, without and with captopril, respectively; $p<0.001$), suggesting that Ang-II generation is ACE-mediated. The overall rate of disappearance of Ang-I when exposed to hGECs was similar to that observed under exposure to human podocytes (hPODs). The difference resided on the predominant fragments generated by each cell type, i.e., Ang-II for hGECs, and Ang-(2-10) and Ang-(1-7) for hPODs. On the other hand, hGECs metabolized Ang-II at a significantly slower rate compared to hPODs (0.63 vs. 2.20 pmol Ang-II/μg cell protein/hr, respectively; $p<0.001$). These results indicate that hGECs possess prominent ACE activity and limited Ang-II metabolizing activity, in clear contrast to the RAS enzymatic capacity of hPODs. Injury to specific cell types within the glomeruli may lead to distinct effects on the intrarenal RAS balance.

**Neutrophil Serine Proteases PR3 and Elastase Interact with Glomerular Endothelial Cells Causing PAR-1 Cleavage without Direct PAR Activation**
Samantha Tull,[1] Anne Bevins,[1] Sahithi Josna Panchagnula,[1] Simon C. Satchell,[3] Bahjat Al-Ani,[1] Lorraine Harper,[1] Julie M. Williams,[1] Edward Rainger,[2] Caroline O. S. Savage.[1] *[1]Immunity and Infection; [2]Clinical and Experimental Medicine, University of Birmingham, United Kingdom; [3]University of Bristol, United Kingdom.*

**INTRODUCTION:** Neutrophil proteases, proteinase 3 (PR3) and elastase (HLE) appear to have key roles in the glomerular endothelial cell (GEC) injury/activation that occurs during glomerulonephritis (GN). However, the mechanism by which proteases interact with EC remains unclear. Protease activated receptors (PARs) are activated by specific cleavage and are potential targets of PR3 and HLE. In in-vivo models of GN, both PAR-1 and PAR-2 deficient mice showed reduced crescent formation. **AIM:** To determine if PR3 or HLE, via PARs, caused the alterations in EC phenotype, observed in GN. **METHODS:** EC PAR protein levels were assessed by FACS. Thrombin, trypsin and agonist peptides (ap) for PAR-1 (TFLLR) and PAR-2 (SLIGKV) assessed EC PAR activation. vWF release from viable EC was used as a marker of EC activation. Calcium signalling was detected by fluorimetry and fluorescent microscopy. **RESULTS:** GEC and Human Umbilical Vein ECs (HUVEC) had similar patterns of PAR-1 and PAR-2 expression. PAR-2 mRNA was up-regulated by TNFα while PAR-1 mRNA was largely unaffected. Functional PAR-1&2 were expressed on the EC surface (n=3). Serine proteases caused (time and dose dependent) PAR-1 cleavage, but not receptor activation (n=3). In viable EC, PAR-1-ap induced EC vWF release to the same extent as PR3, after 2hr exposure to either stimuli (n=4). SiRNA knockdown showed that despite the similar effects of PR3 and PAR-1ap on EC vWF release, neither PAR-1 nor PAR-2 activation caused PR3 or HLE-mediated vWF release. GEC calcium signalling indicated that both proteases interacted with and disarmed surface PAR-1, but not PAR-2 receptors. **CONCLUSION:** This study indicates the complex interactions between PAR-1 and proteases. PAR activation and serine protease-induced alterations in EC function may both modulate the inflammation associated with GN; although our data suggests they may act through parallel but independent pathways.

**F-PO1638**

**Proteomic Mapping of Endothelial Cell Surface Proteins in the Kidney and Glomerulus**
Zan Liu,[1] Yutaka Yoshida,[2] Eishin Yaoita,[2] Tadashi Yamamoto,[2] Kota Takahashi.[1] *[1]Regenerative and Transplant Medicine, Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Structural Pathology, Nephrology, Niigata, Japan.*

Endothelial cell (EC) membrane is critically important for their functions, but the characteristics of endothelial cell membrane shave have not well examined in the kidney and glomerulus yet. Our aim was to elucidate protein components of EC membrane proteins of the kidney and glomerulus. In the present study we isolated these membrane fractions and analysed them by mass spectrometry (MS). To isolate rat renal EC membrane specifically, the cationized colloidal silica beads coating method was applied, which is based upon the ionic interaction of cationic colloidal silica with negatively charged EC membranes. Specific labeling of ECs was revealed by light microscopy and transmission electron microscopy. Glomeruli were also isolated for glomerular EC membrane preparation. By homogenization and density ultracentrifugation the membranes with beads were enriched and the enrichment of membranes was confirmed by Western blot analysis using antibody against EC-specific protein caveolin 1. Endothelial membrane proteins from whole kidneys and glomeruli were digested with trypsin and analyzed by MS, respectively. We identified various types of EC proteins and found some difference proteins betweens EC membrane proteins of whole kidneys and glomeruli. We concluded that ECs membranes were isolated from whole kidneys and glomeruli directly, and that mapping of the microvascular EC surface proteome was provided for further understanding of kidney EC membrane pathology and physiology and difference in characteristics of ECs between the kidney and glomerulus.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1639**

**Novel Proteins in Nephrotic Syndrome: Circulating Angiopoietin-Like 4 (Angptl4) Reduces Proteinuria While Inducing Hypertriglyceridemia in Nephrotic Syndrome**
Lionel C. Clement,[1] Camille E. Mace,[1] Maria Carmen Avila-Casado,[2] Elizabeth Soria-Castro,[2] Sumant S. Chugh.[1] *[1]Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Pathology, Instituto Nacional de Cardiologia, Mexico City.*

While investigating a role of podocyte secreted Angptl4 in minimal change disease (MCD) (Clement *et al*, Nature Medicine, in revision), we noted increased circulating Angptl4 levels in human MCD and membranous nephropathy, and in rats with experimental MCD (puromycin nephrosis, PAN). To investigate specific biological effects of circulating Angptl4 in nephrotic syndrome, adipose tissue specific aP2-Angptl4 TG rats were developed. In addition to selective overexpression from the adipose tissue, these rats develop elevated circulating levels of Angptl4 oligomers, but do not develop proteinuria or changes in glomerular morphology. In fact, 18 hours urine albumin excretion was reduced in aP2-Angptl4 TG rats compared to wild type littermates (WT male 367±47 μg/18 hours, TG male 113±12 μg/18 hours;P<0.001). Following induction of PAN, TG rats developed less proteinuria compared to WT littermates (WT 220±30 mg/18 hours, TG 80±25 mg/18 hours, P<0.05). Since Angptl4 is a known inhibitor of lipoprotein lipase (LPL), we assessed plasma triglyceride levels and post-heparin LPL activity. TG rats had higher plasma triglyceride levels and lower LPL activity compared to wild type rats (P<0.05 for both), and these effects were exaggerated following induction of PAN (P<0.01). A longitudinal multiorgan survey in PAN for Angptl4 expression revealed that upregulation of Angptl4 was confined to glomeruli in the early stages (Day 6), but also increased in adipose tissue in later stages (Day 10 onwards) during decline of proteinuria. Using anti-V5 antibodies, we demonstrated binding of Angptl4-V5 secreted by the transgene to glomerular endothelium. Also, recombinant Angptl4 protected cultured glomerular endothelial cells from oxidative injury. In summary, circulating Angptl4 secreted from podocytes and adipose tissue in nephrotic syndrome induces hypertriglyceridemia by binding endothelial LPL, while reducing proteinuria via protective effects on the glomerular endothelium.

**Severe Glomerular Pathology in Mice Lacking Glomerular Endothelium-Enriched Endocytic Regulator *Ehd3* and the Related Gene *Ehd4***
Manju George,[1] Mark Allan Rainey,[1] Mayumi Naramura,[1] Babu J. Padanilam,[2] Kirk W. Foster,[3] Simon C. Satchell,[4] Hamid Band.[1] *[1]Eppley Institute for Research in Cancer and Allied Diseases, UNMC, Omaha, NE; [2]Department of Cellular and Integrative Physiology, College of Medicine, UNMC, Omaha, NE; [3]Department of Pathology and Microbiology, College of Medicine, UNMC, Omaha, NE; [4]Academic Renal Unit, University of Bristol, Bristol, United Kingdom.*

Eps15 Homology Domain-containing protein 3 (EHD3), a member of an endocytic recycling regulator family, is highly expressed in glomerular endothelium, but its physiological role is unknown.

We generated *Ehd3* knockout mice that completely lack EHD3. *Ehd3*$^{-/-}$ mice developed normally, were healthy and did not develop proteinuria. Light and electron microscopy showed unaltered glomeruli, and immunofluorescence analyses revealed normal expression/localization of glomerular proteins. Strikingly, *Ehd3*$^{-/-}$ glomerular endothelial cells showed increased levels of EHD4 (an EHD protein normally present in the peritubular vasculature).

We, therefore, generated *Ehd3* and *Ehd4* double-null mice and confirmed the lack of expression of both genes in the kidney. *Ehd3*$^{-/-}$*; Ehd4*$^{-/-}$ mice were small at wean, developed proteinuria and died between 1-7 months of age. Analyses of H&E, PAS, and Jones silver-stained *Ehd3*$^{-/-}$*; Ehd4*$^{-/-}$ kidney sections revealed glomerulomegaly and changes consistent with ongoing endothelial injury, such as duplication of basement membranes, mesangial cell interposition, and RBC fragmentation. Tubular changes included luminal dilatation and protein re-absorption droplets. Abnormal patterns of synaptopodin, nephrin and desmin expression were seen by immunofluorescence. Ultrastructural studies revealed subendothelial widening, loss of glomerular endothelial fenestrations and segmental podocyte foot process effacement.

Our results suggest that EHD3 and EHD4 are critical for glomerular endothelial health. These significant findings are the first report in which deletion of genes expressed in glomerular endothelium results in glomerular endothelial dysfunction and also induces downstream detrimental changes that affect the integrity of the glomerulus as a whole.

**Factor Responsible for Hematuria in IgA Nephropathy**
Hirotsugu Iwatani,[1] Yasuyuki Nagasawa,[1] Ryohei Yamamoto,[1] Kenichiro Iio,[1] Masayuki Mizui,[1] Arata Horii,[2] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Otolaryngology, Suita Municipal Hospital, Suita, Osaka, Japan.*

**Introduction** Some patients with IgA nephropathy(IgAN) manifest macroscopic hematuria after tonsillectomy(TXL). The aim of our study is to analyze the mechanism of temporal aggravation of hematuria after TXL. **Methods** The subject of our study is 16 IgAN patients who underwent TXL combined with steroid pulse as a treatment and who gave informed consent. Control patients (n=9) were chronic tonsillitis or sleep apnea patients who underwent TXL. A series of urine samples, obtained from pre-TXL until the next morning, were analyzed by dipstick test. Urinary cytokines such as tumor necrosis factor-α, granulocyte-macrophage colony-stimulating factor(GM-CSF), monocyte chemoattractant protein-1, interleukin-6, macrophage inflammatory protein-1β and interferone-γ were analyzed. We also analyzed cell markers (CD25&CD3, CD8&CD5, CD38&CD20, CD16&CD56, CD45RA&CD4, HLA-DR&CD4 and CD11b&CD8) of peripheral blood before TXL, immediately after TLX, one week after TXL, and after steroid pulse, with flow cytometer(FCM). Next, $CD16^+CD56^+$ cells as well as $CD16^-CD56^+$ and $CD56^-$ cells were sorted from the peripheral blood of patients with IgAN using MACS. Equal number of each cell fraction was transplanted to each nude rat via tail vein and the urine was analyzed with dipstick test. **Results** The aggravation or occurrence of hematuria was temporally seen after TXL in patients with IgAN, but not in control. FCM analysis of the peripheral blood of patients with IgAN indicated $CD16^+CD56^+$ cells, which contain natural killer cells and natural killer T cells, tended to increase immediately after TXL and returned to the basal level in one week, unlike in control. Urinary cytokine profiling revealed that GM-CSF, cytokine secreted from natural killer cells, peaked in the second or third urine sample after TXL. When we transplanted $CD16^+CD56^+$ cells to nude rats, the recipients manifested strong and consistent hematuria, unlike $CD16^-CD56^+$ or $CD56^-$ cells. **Conclusions** $CD16^+CD56^+$ cells in the peripheral blood are the hematuria-inducing factor of IgAN.

**F-PO1642**

**Genetically Determined Regulation of the P2X7 Receptor-Inflammasome Pathway in Macrophages of Glomerulonephritis-Susceptible Rat Strains**
Simona Deplano,[1] Frederick W. K. Tam,[1] Robert J. Unwin,[2] Charles D. Pusey,[1] H. Terence Cook,[3] Jacques Behmoaras.[3] *[1]Renal Medicine, Imperial College, London, United Kingdom; [2]Centre for Nephrology, University College London Medical School, London, United Kingdom; [3]CCIR Renal Medicine, Imperial College, London, United Kingdom.*

The P2X7 receptor (P2RX7) is a ligand-gated cation channel that is expressed by a variety of immune cells, including macrophages and lymphocytes. Our previous studies showed that P2X7 receptor antagonists reduce glomerular macrophage infiltration in nephrotoxic nephritis (NTN) in Wistar Kyoto (WKY) rats. We therefore hypothesized that P2RX7-Nlrp3 inflammasome-mediated caspase-1 activation is altered in WKY bone marrow derived macrophages (BMDMs).

We found that P2RX7 mRNA levels were markedly up-regulated in the WKY BMDMs when compared with NTN-resistant Lewis BMDMs. We also observed that the majority of inflammasome genes in WKY rats are up-regulated in both basal and LPS-stimulated macrophages when compared with NTN-resistant Lewis rats. In addition, the expression of IL-18 and IL-33, two cytokines that depend on caspase-1 activation and processing, are markedly increased in LPS-stimulated WKY BMDMs. Interestingly, none of the up-regulated inflammasome genes were controlled by Crgn1 and/or Crgn2, two major NTN QTLs for glomerular crescent formation and proteinuria previously identified in this model.

We then analyzed the secreted IL-1beta levels following BzATP and LL37 (P2X7 agonists) stimulation in LPS-stimulated BMDMs by sandwich ELISA. In both conditions, WKY BMDMs showed increased levels of IL1-beta when compared with Lewis BMDMs, suggesting that P2RX7-mediated IL1-beta secretion is dysregulated in WKY BMDMs, which is likely to be due to up-regulated inflammasome genes. Genetic studies aimed at characterizing the master-regulator controlling the P2X7 receptor-inflammasome pathway are underway, which should help to define this pathway in macrophage-mediated crescentic glomerulonephritis.

**Association of Anti-PLA2R IgG Subclasses with Clinical Remission and Relapse in Primary Membranous Nephropathy**
Fahim Malik,[1] Frank Eitner,[2] Jurgen Floege,[2] David J. Salant,[1] Laurence H. Beck.[1] *[1]Nephrology, Boston University School of Medicine, Boston, MA; [2]Nephrology and Immunology, RWTH Aachen University Hospital, Aachen, Germany.*

Background: Our laboratory has recently shown a direct association between levels of circulating antibodies to the phospholipase A2 receptor (PLA2R) and clinical activity in primary membranous nephropathy (MN). The goal of this study was to examine serial levels of anti-PLA2R IgG subclasses from 3 patients in whom clinical remission was followed by subsequent relapse.

Methods: Serum samples and 24-hr proteinuria data were available at 25-30 time points over the course of 3-7 years from three patients with primary MN. Each patient had entered a clinical remission after immunosuppressive therapy, but had subsequently relapsed. Retrospective semi-quantitative analysis of anti-PLA2R levels was performed by immunoblotting native glomerular PLA2R with serum (1:25) followed by antibodies specific for human IgG1, IgG3 or IgG4. Band intensity was quantitated by densitometry.

Results: All three patients were initially positive for anti-PLA2R, but exhibited differences in the levels of anti-PLA2R IgG subclasses during the course of their disease. Patient 1 had a complete clinical remission that followed the disappearance of anti-PLA2R. Re-emergence of IgG1 and IgG3 anti-PLA2R, followed closely by IgG4 anti-PLA2R, preceded the relapse of nephrotic syndrome by months. Patient 2 similarly showed a decline in proteinuria following the disappearance of anti-PLA2R; however IgG1, IgG3, and IgG4 anti-PLA2R all appeared concurrently or slightly following the relapse of proteinuria. Patient 3 exhibited IgG4 anti-PLA2R that persisted at all time points. In contrast, the IgG1 and IgG3 anti-PLA2R subclasses more closely mirrored the changes in proteinuria.

Conclusion: Measurement of anti-PLA2R IgG subclasses provides useful information for monitoring disease course and relapse. IgG1 or IgG3 anti-PLA2R may be better associated with proteinuria than IgG4 anti-PLA2R, but the temporal relationship between the initial re-appearance of anti-PLA2R and the return of proteinuria is variable.

**MK-2 Inhibition Reduces Albumin-Induced Podocyte Endocytosis and COX-2 Expression**
Adam Guess,[1] Ruma Pengal,[1] Shipra Agrawal,[1] Rainer Benndorf,[1,2] William E. Smoyer.[1,2] *[1]Clinical and Translational Research, Nationwide Children's Hospital, Columbus, OH; [2]Department of Pediatrics, Ohio State University, Columbus, OH.*

Damage to the glomerular filtration barrier results in the passage of serum proteins into the urinary space and increased exposure of podocytes and tubular cells to albumin and IgG, etc. Normally most albumin that passes through the filtration barrier is reabsorbed by the proximal tubules via receptor-mediated endocytosis. However, it has recently been reported that podocytes express the transport receptors FcRn and megalin, and can endocytose albumin and IgG. When exposed to albumin overload, podocytes undergo apoptosis through TGF-β1/p38 MAPK pathways. Additionally, increased COX-2 expression levels enhance susceptibility of podocytes to injury. While COX-2 induction is known to be regulated by p38 MAPK through the transcription factors C/EBP and CREB/ATF, the involvement of MAPKAPK-2 (MK-2), a kinase directly downstream of p38 MAPK, is unclear.

We hypothesized that targeted inhibition of MK-2 in podocytes will decrease albumin-induced cell injury via reduced albumin endocytosis and/or lessened COX-2 expression.

Using conditionally immortalized cultured murine podocytes, we analyzed whether normal serum concentrations of albumin stimulate the p38 MAPK/MK-2 pathway and induce COX-2 expression, and whether the novel MK-2 inhibitor, C23, reduces pathway activation, decreases albumin uptake, or inhibits COX-2 expression.

We found that podocytes endocytosed albumin and that normal serum concentrations of albumin stimulated the p38 MAPK/MK-2 pathway, as measured by both activation of p38 and MK-2, and phosphorylation of MK-2's primary downstream target hspb1 (hsp25). These concentrations of albumin also induced COX-2 mRNA expression. Of greater interest, we found that specific MK-2 inhibition reduced both podocyte albumin uptake and COX-2 mRNA levels.

We conclude that podocyte exposure to serum concentrations of albumin may contribute to cellular injury via stimulation of MK-2 and/or COX-2. Thus targeted MK-2 inhibition may be a promising therapeutic approach to reduce podocyte injury in many glomerular diseases.

**CD28 Superagonist mAb (JJ316) Ameliorates the Induction of Experimental Autoimmune Glomerulonephritis (EAG) in Rats**
Jitendra K. Gautam,[1] Di Wu,[1] Thomas Hünig,[2] Kline Bolton.[1] *[1]University of Virginia HS, Charlottesville, VA; [2]Institute for Virology and Immunobiology, University of Würzburg, Würzburg, Germany.*

We have previously shown that EAG in Wistar Kyoto (WKY) rats can be induced by immunization with a 13 amino acid nephritogenic peptide (P13) homologous to the alpha3(IV)NC1 domain resulting in severe glomerulonephritis, immune cell infiltration and proteinuria. A specific T-cell response results in glomerular basement membrane (GBM) damage with epitope spreading and amplification of the disease. Superagonistic anti CD28 mAb (JJ316) induced upregulation of (CD4+CD25+FoxP3+,Tregs) has been reported to prevent or treat several experimentally induced or genetically predetermined autoimmune diseases.

In the present study we examined the protective capacity of JJ316 in prevention of EAG. Two sets of WKY rats (n=15/set) were immunized with P13 in CFAh37RA at day 0. One of the two sets also received JJ316 (tail vein iv) (1mg/dose) on -6,-3, 0 & +3 days. 24 hr urine protein was followed over a course of 8 weeks as the marker for development of EAG. Post experimental kidneys from all the animals were processed for H&E sections and immunofluorescence staining (IgG and fibrinogen) to score the disease severity. Rats in JJ316 group demonstrated overall protection from EAG development over the course of experiment as monitored by 24 hr urine protein and histology. FACS analysis of JJ316 set had a higher percentage of Tregs at +3 day time point compared to control. Histology group average scores (IgG, fibrinogen and H&E) were also significantly lower in the JJ316 rat set. JJ316 group data sets were statistically closer to the age matched control set.

These findings show that in the EAG model JJ316 acts as a protective agent if given prior to disease initiation. JJ316 is probably acting by up regulating Tregs to ameliorate the autoimmune process. Similar strategies might benefit human autoimmune glomerulonephritis.

**A Novel Transgenic Mouse Indicates a Role for Toll-Like Receptor Signaling in Type 1 Membranoproliferative Glomerulonephritis**
Sambit Kumar Nanda,[1] Susan C. Coventry,[2] Kenneth R. McLeish,[3] Philip Cohen,[1] David W. Powell.[3] *[1]Medical Research Council Protein Phosphorylation Unit, Dundee, Scotland, United Kingdom; [2]Pathology and Pediatrics; [3]Medicine, University of Louisville and VMAC, Louisville, KY.*

Type I Membranoproliferative glomerulonephritis (MPGN) is mediated by subendothelial and mesangial immune complex deposition. The idiopathic form predominates in children, while secondary forms associated with autoimmune diseases, monoclonal gammopathy, and chronic infections occur most commonly in adults. Pathogenesis of MPGN is poorly understood and effective treatment is unproven. Development of an animal model of MPGN would provide an important tool for investigating pathogenesis and treatment. We developed a transgenic mouse that expressed a mutated form of ABIN1 (D485N) lacking the inhibitory function for NF-KB activation. The resulting molecular phenotype of these animals was over-activation of NF-KB. These mice demonstrated enlarged spleens, lymph nodes, and Peyer's Patches; B-cell proliferation leading to enhanced immunoglobulin production; and enhanced cytokine production. Light microscopy of kidney sections from 4 and 6 month old mice showed lobular glomeruli with focal areas of mesangial hypercellularity and matrix expansion, narrowing of the capillary lumens, and diffuse thickening and double contour appearance of basement membranes. The glomerular changes were associated with extensive interstitial cellular infiltration. Electron microscopy showed discrete electron dense deposits in the mesangium and subendothelial space, and immunohistochemistry showed that these deposits contained complement C3. Serum levels of Cystatin C were elevated in the transgenic mice, compared with wild type mice. Crossing ABIN1 (D485N) mice with MyD88 deficient (toll-like receptor (TLR) non-responsive) mice suppressed lymphoproliferation and renal histologic abnormalities. We conclude that chronic TLR

activation produces a model of progressive glomerulonephritis with histologic features of human type 1 MPGN. This model will advance our understanding of the molecular and cellular mechanisms of MPGN.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1647**

**Dysregulated Glomerular Stem/Progenitor Cells Participate in Crescent Formation in Munich Wistar Fromter (MWF) Rats, ACEi Modulates Stem Cell Activation and Preserves the Niche** Paola Rizzo,[1] Marina Morigi,[1] Elena Gagliardini,[1] Cinzia Rota,[1] Giuseppe Remuzzi,[1,2] Ariela Benigni.[1] *[1]Mario Negri Institute for Pharmacological Research, Bergamo, Italy; [2]Ospedali Riuniti, Bergamo, Italy.*

MWF rats develop progressive glomerular injury which culminates in glomerulosclerosis. We previously reported that ACEi renoprotection in this model is associated with more parietal podocytes and better preserved glomerular architecture. Here, we studied the time course of the lesions, their cellular components and the effect of the ACEi. Early lesions were glomerular to capsule adhesion - synechiae - (10-25w) followed by extensive extracapillary crescent formation (25-60w). Glomerulosclerosis developed at later stage starting from 40w. Large majority of cells forming synechiae and crescents were claudin+ WT1- parietal epithelial cells (PECs, 60%) and to a lesser extent claudin- WT1+ podocytes (28%). Both PECs and podocytes were in a proliferating state (BrdU+). We next analyzed the cell composition of the Bowman's capsule in control Wistar rats. Ninety % claudin+ PECs expressed NCAM, a marker of metanephric mesenchime that we describe here for the first time in adulthood, suggesting the stem/progenitor nature of this population. In MWF rats, NCAM+ cells were extensively found in synechiae and crescents. ACEi reduced crescents by at least 40% and fully prevented glomerulosclerosis. ACEi also reduced the proliferation of stem/progenitors and restored the ratio between PECs/parietal podocytes in Bowman's capsule. PECs of MWF rats (50-60w) had a remarkable reduction of cEBPδ -a transcription factor known to maintain stem/progenitor cells in a quiescent state- which was normalized by ACEi. When NCAM+ PECs were isolated and cultured from glomeruli of control rats, cEBPδ was expressed at high levels. Angiotensin II ($10^{-7}$ M) reduced the expression of cEBPδ. Thus, chaotic migration and proliferation of stem/progenitor cells of the rat Bowman's capsule pave the way to crescent formation and subsequent sclerosis. ACEi, by moderating stem/progenitor activation, restores the niche, ameliorates glomerular architecture and prevents renal disease progression.

**Podocyte Dedifferentiation and Autophagy Are Governed by Tissue Transglutaminase That Is Critical to Glomerular Injury in Rapidly Progressive Glomerulonephritis** Cécile Fligny,[1] Marine Milon,[1] Sandra Schordan,[2] Laurent Mesnard,[3] Patrick Bruneval,[4] Pierre-Louis F. Tharaux.[1] *[1]Paris-Cardiovascular Research Center - PARCC, Inserm and Université Paris-Descartes, Paris, France; [2]Institut für Anatomie und Zellbiologie, Ernst-Moritz-Arndt-Universität Greifswald, Greifswald, Germany; [3]UMR 702, Inserm, Paris, France; [4]Service d'Anatomie Pathologique, Hôpital Europeen Georges Pompidou, Assistance Publique-Hôpitaux de Paris, Paris, France.*

We discovered marked early expression of TG2 in podocytes from mice and patients with crescentic rapidly progressive glomerulonephritis (RPGN). Thus, we investigated the role of the TG2 in experimental RPGN, in which immune-mediated endothelial stress leads to podocytes injury. First, outgrowth of podocytes from isolated glomeruli from Podocin-Cre x TG2lox/lox mice revealed that TG2 inactivation specifically in podocytes leads to a strong inhibition of their proliferation. Increased accumulation of LC3 and p62 positive autophagosomes in TG2-deficient podocytes was observed. In the anti-GBM model of RPGN, TG2 invalidation markedly attenuated glomerular injury. Albuminuria to creatinuria ratio was 25-fold lower in TG2 KO mice at day 11 ($0 \pm 0\%$ vs. $21.9 \pm 7.4$, $p<0.001$) that displayed a complete absence of crescent formation ($0 \pm 0\%$ of the glomeruli at day 4 and 30 vs. $25 \pm 6\%$ at day 4 and $45 \pm 6\%$ at day 30, $p<0.001$). Accordingly, TG2 deficiency prevented the development of renal railure with BUN within normal ranges at day 30 ($39.0 \pm 1.6$ mg/dl vs. $76.7 \pm 23.5$ mg/dl, $p<0.001$). TEM analysis of podocytes demonstrated unaffected podocyte ultrastructure in TG2 KO at day 4, compared to TG2 WT mice which already displayed mild to severe foot process effacement.

At last, specific TG2 gene deletion in Podocin-Cre x TG2lox/lox mice also caused significant protection against the development of the RPGN.

We conclude that TG2 in podocytes is critical to RPGN, in part through promotion of proliferation and autophagy. This study suggests that targeting the TG2 pathway would be clinically beneficial for treatment of severe RPGNs.±

**Ubiquitin C-Terminal Hydrolase-L1 (UCH-L1) Activity Induces Polyubiquitin Accumulation in Podocytes and Increases Proteinuria in Rat Membranous Nephropathy** Catherine Meyer-Schwesinger, Tobias N. Meyer, Elion Hoxha, Friedrich Thaiss, Rolf A. Stahl. *Department of Internal Medicine, Nephrology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

UCH-L1 is a key protease in the ubiquitin-proteasome pathway that regulates the intracellular pool of monoubiquitin and is associated with neurodegenerative diseases and cancer. Recently, we described the de novo expression of UCH-L1 in podocytes of patients with membranous nephropathy where UCH-L1 expression correlated with increased ubiquitin content. Here, we investigated the role of UCH-L1 for the ubiquitin homeostasis and proteasomal degradation in a rat model of membranous nephropathy. After disease induction UCH-L1 expression increased in podocytes and coincided with decreased glomerular monoubiquitin content. Following an initial increase of proteasomal activity, the ubiquitin proteasome system (UPS) was impaired. UPS impairment was characterized by decreased proteasomal activity and increased polyubiquitin content in glomerular lysates. Besides an increase of ubiquitin in podocytes, aggregates were observed 1 year after disease induction, as in human membranous nephropathy. Inhibition of UCH-L1 hydrolase function with LDN57444 in membranous nephropathy reduced UPS impairment. Strikingly, proteinuria was also ameliorated by UCH-L1 inhibition. In contrast, inhibition of proteasomal activity with MG132 enhanced UPS impairment resulting in further polyubiquitin accumulation, ubiquitin aggregation in podocytes and increased proteinuria. In additional in vitro experiments, UCH-L1 over-expression resulted in the accumulation of mono- and polyubiquitinated proteins in cultured podocytes. In contrast, stable knock-down of UCH-L1 reduced mono- and polyubiquitinated proteins and significantly increased proteasomal activity, indicating that the observed effects in rat membranous nephropathy also occurred in cultured podocytes. These data show that ubiquitin C-terminal hydrolase L1 activity results in polyubiquitin accumulation, proteasome inhibition and disease aggravation in experimental membranous nephropathy.

**Evaluation of Notch Signaling in Rodent Models of HIV-Associated Nephropathy (HIVAN) and in Human HIVAN Patients** Madhulika Sharma,[1] Pravin C. Singhal,[2] Paul E. Klotman,[3] Shilpa Buch,[4] Gregory B. Vanden Heuvel.[1] *[1]Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS; [2]Medicine, North Shore LIJ Health System, Great Neck, NY; [3]Medicine, Mount Sinai School of Medicine, New York, NY; [4]Pharmacology, University of Nebraska, Omaha, NE.*

Notch signaling has emerged as an important pathogenic pathway in a wide range of glomerular diseases. Human Immunodeficiency Virus Associated Nephropathy (HIVAN) presents with sclerosing glomeruli. To determine the role of the Notch pathway in HIVAN, we evaluated Notch signaling in two rodent models of HIVAN and in human HIVAN patients. Using an HIV transgenic rat model (HIV Tg) that expresses seven of the nine HIV genes, we found increased Notch1, Notch3, and Notch4 activation in the glomeruli associated with increased cell proliferation and podocyte dedifferentiation. Using an HIV transgenic mouse model (Tg26) we found an increase in the intracellular domains of Notch1 and Notch4 in the glomeruli, indicating Notch signaling activation. To determine whether Notch signaling was elevated in the podocytes, we evaluated the expression of Notch signaling members in podocyte cell lines obtained from Tg26 mice or control mice. We observed increased expression of the Notch effector protein Hes1 in the Tg26 podocyte mouse line, compared with the expression in wild type cells. These results demonstrate activation of the Notch pathway in the Tg26 mouse line. Finally, we evaluated Notch signaling in renal biopsy samples from HIVAN patients. We found increased levels of the cleaved Notch1, Notch3, and Notch4 in the glomeruli, compared with the expression in normal kidneys. Taken together, our results suggest that activation of the Notch pathway in podocytes contributes to the pathogenesis of HIVAN.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1651**

**Elevated Circulating Levels of IGFALS Induce Classic Molecular and Morphologic Changes in Human Non-HIV Collapsing Glomerulopathy** Camille E. Mace,[1] Lionel C. Clement,[1] Hilal Arnouk,[1] Elizabeth Soria-Castro,[2] Maria Carmen Avila-Casado,[2] Sumant S. Chugh.[1] *[1]Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Pathology, Instituto Nacional de Cardiologia, Mexico City, Mexico.*

Injection of sera from patients with non-HIV collapsing glomerulopathy into disease susceptible rats induces proteinuria and glomerular collapse (Avila-Casado and colleagues, Kidney International 2004). Incubation of these sera with cultured GECs and M15 cells induces molecular changes associated with collapsing glomerulopathy, including downregulation of nuclear WT1 expression, and changes in key cell-cell and cell-matrix contact proteins. We conducted proteomic analysis using DIGE in 24 cm 2D gel format of six patients and control sera depleted of 12 common proteins. Six replicates of each 2D gel (run in 2 different percentages in the second phase) were conducted and analyzed independently by 2 individuals using DeCyder software. Ten most prominent spots that were increased in the patient sera, and seen in at least two of six patient sera, were excised, digested and identified by MALDI-MS/MS and Q-TOF. In vitro screening using

recombinant proteins showed that one of these proteins, Insulin like Growth Factor Acid Labile Subunit or IGFALS, dramatically reduced the expression of WT1 in M15 cells by confocal imaging, in a manner reminiscent of the effect of patient sera on these cells. To test if IGFALS has similar effects in vivo, we conducted pilot studies in Rrm2b -/-, a strain of mice that develop proteinuria and progressive glomerular collapse. Young Rrm2b -/- mice, prior to any morphological evidence of glomerular collapse or significant albuminuria, were injected with purified recombinant IGFALS, and assessed for development of albuminuria. Preliminary studies show a significant increase in albuminuria at 18 hours after injection. The histology of these mice is currently analyzed. In summary, IGFALS is a key circulating factor in human non-HIV collapsing glomerulopathy.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1652**

**Deletion of Drosha in Podocytes Results in Collapsing Glomerulopathy** Olga Zhdanova,[1,2,3] Shekhar Srivastava,[1,3] Lie Di,[1,3] Duncan B. Johnstone,[5] Lawrence B. Holzman,[5] Laura M. C. Barisoni,[4] Edward Y. Skolnik.[1,2,3] *[1]Skirball Institute for Biomolecular Medicine, New York University Langone Medical Center, New York, NY; [2]Division of Nephrology, Department of Internal Medicine, New York University Langone Medical Center, New York, NY; [3]Departments of Pharmacology, New York University Langone Medical Center, New York, NY; [4]Department of Pathology, New York University Langone Medical Center, New York, NY; [5]Division of Nephrology, Department of Internal Medicine, University of Pennsylvania, Philadelphia, PA.*

MicroRNAs have been shown to play key roles in both the function and differentiation of a number of different cell types. Drosha and Dicer, two RNAase III enzymes, function in a stepwise manner to generate a mature microRNA. Previous studies have demonstrated that podocyte-specific deletion of Dicer results in a collapsing glomerulopathy. Unlike Dicer, Drosha is thought to play a more specific role in miRNA biogenesis. We now show that a podocyte-specific deletion of Drosha results in a similar phenotype to Dicer mutants confirming that the Dicer mutant phenotype is due to the loss of miRNAs. Drosha mutants developed proteinuria at 2 weeks of age and died of renal failure between 4-8 weeks of age. Drosha mutants developed a collapsing glomerulopathy characterized by folding and wrinkling of the glomerular basement membrane, glomerular sclerosis, pseudocrescent formation, and extensive podocyte foot process effacement. Podocytes displayed a dedifferentiated phenotype with progressive downregulation of mature podocyte markers such as nephrin, podocin, WT-1 and synaptopodin, and upregulation of the injury-related marker desmin. Interestingly, cells in the pseudocrescents were nestin and Ki-67 positive suggesting that pseudocrescents in Drosha mutants were composed of proliferating dedifferentiated podocytes. These findings confirm that microRNAs play a critical role in podocyte biology. Identifying changes in specific miRNAs in various podocyte diseases should provide both new insight into disease pathogenesis and novel therapeutic targets.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1653**

**Complement C5b-9 Upregulates the Function of the Ubiquitin Proteasome System (UPS) in Glomerular Epithelial Cells (GEC)** Thomas M. Kitzler, Joan Papillon, Julie Guillemette, Andrey V. Cybulsky. *Medicine, McGill University, Montreal, QC, Canada.*

In experimental membranous nephropathy, complement C5b-9 induces sublethal GEC injury and proteinuria. C5b-9 may also trigger mechanisms that restrict injury or facilitate recovery. The UPS selectively degrades damaged or abnormal proteins. Following ubiquitination, proteins are targeted for breakdown by the 26S proteasome. We propose enhanced UPS function as a mechanism to limit complement-induced GEC injury. UPS function was monitored by the degradation of a transfected UPS reporter, $GFP^u$, which consists of a short degron, CL1, fused to the C-terminus of green fluorescent protein (GFP). By immunoblotting, we demonstrated decreased $GFP^u$ levels in GEC after treatment with antibody and sublytic normal serum (NS), compared with GEC treated with antibody and heat-inactivated serum (HIS). In separate experiments, using C8-deficient serum with or without purified C8, cycloheximide (an inhibitor of protein synthesis), and the proteasome inhibitor, MG132, we confirmed that the decrease of $GFP^u$ was due to C5b-9 assembly and enhanced proteasomal degradation of the reporter. $GFP^u$ mRNA levels (RT-qPCR) were unaffected by complement treatment. By analogy to $GFP^u$, in the presence of cycloheximide, complement accelerated degradation of cyclin A, an endogenous substrate for the proteasome. The c-jun N-terminal kinase (JNK)-directed inhibitor, SP600125, attenuated the effect of complement on $GFP^u$ expression, while inhibitors of the extracellular signal-regulated kinase and p38 were not effective. Complement did not affect the level of ubiquitin mRNA in GEC (RT-qPCR), the ubiquitination of $GFP^u$, nor overall ubiquitination of proteins. Proteasome inhibition with MG132 increased the cytotoxic effect of complement in GEC (lactate dehydrogenase cytotoxicity assay), confirming the functional importance of the proteasome in limiting complement cytotoxicity. Treatment of GEC with doxorubicin also resulted in decreased $GFP^u$, suggesting that an increase in UPS function is not limited to complement-mediated injury. Enhanced UPS function, by accelerating removal of damaged proteins may be a novel mechanism to limit complement-induced injury.

**F-PO1654**

**Glomerular Epithelial Cell (GEC)-Targeted hHO-1 Expression Reduces Proteinuria in Adriamycin Nephrotoxicity** Pu Duann,[1] Elias A. Lianos,[1] Ling-Mei Chiang.[2] *[1]Medicine Dept / Nephrology Div, Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Pediatrics, Chang-Gung Memorial Hospital, Keelung, Taiwan.*

We previously reported that GEC targeted Heme-Oxygenase (HO-1) expression reduces proteinuria in pNeph-human(h) HO1 transgenic mice following glomerular immune injury. Adriamycin (ADR) causes GEC toxicity via increased oxidative stress. This study used our recently developed line of transgenic mice (pNeph-hHO1 on a FVB background), in which hHO-1 was expressed in GEC (Am J Physiol Renal Physiol. 297[5]:F1476. 2009). FVB control and transgenic mice received 11 mg/kg body weight ADR by a single tail vein injection and 20-h urine samples were collected for urine protein (Up) and creatinine (Uc) analysis. Renal morphology was assessed by light and electron microscopy. ADR treatment induced proteinuria in both pNeph-hHO1 transgenic (Tg) mice and their wild-type (Wt) littermates. Up/Uc values prior to and on days 2 and 3 following ADR were: 0.89, 4.40 and 7.12 in Tg, and 1.01, 6.91 and 12.04 in Wt mice. The reduction of proteinuria was found to be statistically significant in pNeph-hHO1 transgenic mice on day 3 (p value= 0.033). In glomeruli of ADR-treated mice there was foot process effacement. This effect was less pronounced in pNeph-hHO1 mice in which integrity of slit diaphragms was preserved. We conclude that GEC targeted HO-1 expression protects against ADR toxicity by preserving integrity of the glomerular capillary permeability barrier to protein.

**F-PO1655**

**The Use of Heparin (H) and Aspirin (ASA) To Improve Pregnancy Outcomes in Patients with Early Preeclampsia (PE)** Michelle L. Lubetzky, Orli Etingin, Terri Edersheim, Phyllis August. *Nephrology and Hypertension, New York Presbyterian-Weill Cornell, New York, NY.*

Introduction: Early onset preeclampsia (PE) has a high recurrence rate, and is associated with significant morbidity. The use of heparin (H), aspirin (ASA) or both to prevent early PE in women with and without thrombophilic disorders is controversial.

Methods: We investigated the hypothesis that anticoagulation (H and ASA) prevents recurrent PE and report a case series of 21 women with a history of early (<34 weeks gestation) PE, treated with H and/or ASA in subsequent pregnancies.

Results: Women were 35.7 ± 1 years old (mean± SD), and mostly Caucasian (19/21). Four had pre-existing chronic hypertension. All had early (<34 weeks) PE in one or more untreated pregnancies prior to the treated pregnancy. 20 of 21 had one or more genetic or acquired thrombophilias; 10 women had 2 or more thrombophilias. Treatment started shortly after conception with H and ASA (n=16), ASA alone (n=4) or H alone (n=2) and continued until shortly before delivery.

Figure 1 shows maternal and fetal outcomes in untreated and treated pregnancies. Only one woman had recurrent PE at 37 wks; a recurrence rate (4.7%) significantly less than recurrence rates (about 25%) for early PE reported in the literature (P=0.016).

| | Most Recent Prior, Untreated Pregnancy(n=21) | Treated Pregnancy (n=21) | P value |
|---|---|---|---|
| Preeclampsia | 21/21 | 1/21 | 0.016 |
| Gestational Age at delivery (weeks) | 29.4±4.8 | 37.7±1.2 | 0.001 |
| Fetal loss | 10/21 (47%) | 0 | 0.001 |
| Birth weight (gm) | 1,386±.4 | 2,98±.49 | 0.0001 |
| Growth Restriction | 55 % | 0 | 0.001 |
| Placental Abruption | 4/21 | 0 | ns |

Conclusions: We observed significantly improved pregnancy outcomes in women with a history of early, severe PE who were treated with heparin and/or aspirin in a subsequent pregnancy. Although almost all women had either acquired or genetic thrombophilias, our data do not permit assessment of the relevance of thrombophilias to the pathogenesis of PE. Randomized controlled trials of anticoagulation in women at high risk for recurrent PE are needed.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1656

**Proteinuria in Preeclampsia Correlates Positively with Serum sFlt-1/PlGF Ratio and Negatively with Serum PlGF** Cilene Carlos Pinheiro,[1,3] Cristiane Bitencourt Dias,[3] Gianfranco Zampieri,[2] Patrícia Rayol,[1] Luiz Gozzani,[1] Viktoria Woronik.[3] *[1]Uti Adulto, Hospital e Maternidade Santa Joana, São Paulo, São Paulo, Brazil; [2]Salomão e Zoppi - Medicina Diagnóstica, São Paulo, São Paulo, Brazil; [3]Nefrologia, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, São Paulo, Brazil.*

Release of anti-vasogenic factors into maternal circulation seems to be involved in preeclampsia **(PE)**. Maternal outcomes are more benign in later **PE** (≥34th wk) than in earlier **PE** (<34th wk). This study evaluated clinical and biochemical status of thirty-five pregnant with **PE** that were enrolled at their hospital admission. Specimens of urine were obtained to measure 8- isoprostane and placental growth factor (PlGF), and plasma to measure PlGF and sFlt-1 (soluble fms like tyrosine kinase 1). Patients were stratified in groups according to gestational duration. Results table 1.

Clinical parameters of pregnant women with severe (< 34 weeks) and mild (≥ 34weeks) preeclampsia

| | <34 gestational weeks n= 20 | ≥34 gestational weeks n=15 | P |
|---|---|---|---|
| Age (years) | 29.0 ± 3.2 | 31.2 ± 3,87 | ns |
| Gestational age (weeks) | 28.9 ± 4.1 | 36.1 ± 1.5 | 0.03 |
| Systolic BP (mmHg) | 170.0 ± 20.2 | 163.3 ± 23.8 | ns |
| Diastolic BP (mmHg) | 107.8 ± 13.2 | 108.7 ± 15.5 | ns |
| Serum sFlt-1 (pg/mL) | 11781 ± 6304 | 7157 ± 5017 | 0.03 |
| Serum PlGF (pg/mL) | 87.23 ± 110.6 | 159.7 ± 154 | 0.05 |
| Serum sFlt-1/PlGF ratio | 474.7 ± 475.1 | 133.4 ± 151.9 | 0.01 |
| Urinary PlGF (pg/mL) | 8.4 ± 6.8 | 42.6 ± 71.7 | 0.03 |
| Isoprostane urinary (pg/mL) | 1128 ± 1557 | 4527 ± 4474 | 0.04 |
| Proteinuria (g/day) | 1.8 ± 2.4 | 0.4 ± 0.5 | 0.02 |
| Creatinine (mg/dL) | 0.7 ± 0.1 | 0.7 ± 0.17 | ns |

Mean ± SD Isoprostane was measured in 12 and 5 patients, respectively; serum sFlt-1 and PLGF were measured in 20 and 13 patients, respectively.

Proteinuria showed positive correlation with serum sFlt-1/PlGF ratio (r=0.58, p=0.0007) and negative correlation with serum PlGF (r=-0.47, p=0.0085). Severe preeclamptic patients showed lower urinary isoprostane; lower serum and urinary PlGF levels; higher serum sFlt-1/PlGF ratio and protein excretion rate.

## F-PO1657

**Hypertension in Pregnancy Is Associated with an Increased Risk for Microalbuminuria Later in Life** Vesna D. Garovic, Stephen T. Turner. *Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Women with a history of hypertension in pregnancy, including preeclampsia, are at increased risk for cardiovascular disease (CVD) and end-stage renal disease (ESRD) later in life. As microalbuminuria has been associated with both CVD and progression of renal disease, this study aimed to assess whether a history of hypertension in pregnancy is associated with microalbuminuria later in life. We studied 3031 women, median age 54 years, who participated in the Family Blood Pressure Program (FBPP). The percentage with microalbuminuria, defined as a urine albumin/creatinine ratio ≥ 25 mg/g differed significantly among nulliparous women (n=39, 11%); women with a history of normotensive pregnancies (n=249, 13%), and women with a history of at least one hypertensive pregnancy (n=90, 19%) (*P*=0.002). Multiple logistic regression models were used to compare odds ratios (OR) for microalbuminuria among the groups, after controlling for effects of race, age, education, family history of CVD, diabetes, smoking, current hypertension, body mass index (BMI), and family relationships. There was no significant difference in OR between nulliparous women and those with a history of normotensive pregnancies (*P*=<INS cite=mailto:vdg01 dateTime=2010-06-17T20:58><INS cite=mailto:Stephen> </INS></INS>0.39). In contrast, women with hypertensive pregnancies, when compared to those with normotensive pregnancies, had a significantly greater OR of 1.4 for microalbuminuria later in life (*P* =0.02). In conclusion, a history of hypertension in pregnancy is associated with an estimated 40% greater odds for microalbuminuria later in life, independent of traditional CVD risk factors and BMI. Microalbuminuria may serve as an intermediate biomarker for the increased risks of CVD and ESRD later in life among women with a history of hypertension in pregnancy.

## F-PO1658

**Hypertension in Pregnancy Is Associated with Decreased Ankle Brachial Indices Later in Life** Iasmina Craici, Steven Wagner, Stephen T. Turner, Vesna D. Garovic. *Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

**Background:** Decreased ankle brachial indices (ABI) have been associated with both cardiovascular disease (CVD) and atherosclerosis. Women with a history of hypertensive pregnancy have also been shown to have an increased risk of future cardiovascular disease and stroke. The aim of this study was to assess if hypertension in pregnancy is associated with changes in ABI later in life, which may be a marker of increased risk for CVD in women with a history of hypertensive pregnancy disorders.

**Methods:** We studied 1698 women who participated in the Genetic Epidemiology Network of Arteriopathy (GENOA) study. Subjects were categorized as nulliparous, i.e., those with no history of pregnancy lasting more than 6 months, (n=145), women with a history of normotensive pregnancies (n=1272), and women with a history of at least one hypertensive pregnancy (n=281). We fit multiple linear regression models to compare mean ABI among the groups. All models included race, age, education, family history of CVD, diabetes, smoking, current hypertension, and dyslipidemia, as adjustment variables and were fit with generalized estimating equations to account for the sibling relationships in the data. As ABI levels may be influenced by body mass index (BMI), the analyses were performed both with and without BMI in the model.

**Results:** There was no significant difference in ABI between nulliparous women and those with a history of normotensive pregnancies either with BMI included (p=0.932) or removed (p=0.960) from the model. In contrast, women with hypertensive pregnancies, compared to those with normotensive pregnancies, had lower ABIs, both when BMI was added (p=0.012) or removed (p=0.047) from the multiple regression model.

**Conclusion:** A history of hypertension in pregnancy is associated with lower ABI levels later in life, independent of traditional CVD risk factors and BMI. A decreased ABI may be reflective of atherosclerotic burden and serve as a marker for increased CVD risk in women with a history of hypertensive pregnancy disorders.

## F-PO1659

**Meta-Analysis of Pregnancy Outcomes in Patients with Positive Anti-Phospholipid Antibodies and Biopsy Proven Lupus Nephritis** Andrew Smyth, Suzanne Norby, Vesna D. Garovic. *Division of Nephrology & Hypertension, Mayo Clinic, Rochester, MN.*

Introduction

We reported previously that lupus nephritis (LN) was associated with hypertension in pregnancy and premature births. We aimed to review the associations between pregnancy outcomes and biopsy proven lupus nephritis and positive anti-phospolipid antibodies (APA).

Methods

We searched databases from January 1980 to April 2009, reviewed bibliographies and specialty journals. Random-effects methods were used to evaluate complication rates and associations. APA were considered positive in the presence of anti-cardiolipin antibodies and/or, lupus anticoagulant, and/or anti-phospholipid syndrome. Lupus nephritis biopsies were classified using the WHO Classification System.

Results

Twenty-eight papers including 1416 patients and 2225 pregnancies were included. APA were positive in 619 pregnancies and were associated with hypertension (p=0.029), premature birth (p=0.004) and induced abortion rate (p=0.016). No statistically significant associations were observed between histological subclass grouped into proliferative (Class III and IV, n=245) and non-proliferative (Class II and V, n=86) and pregnancy outcomes, including live birth vs. unsuccessful pregnancy (p=0.3853), and maternal complications (p=0.5789).

Conclusion

APA were associated with hypertension, premature birth and increased rate of induced abortion, thereby emphasizing the importance of screening for these antibodies in SLE pregnancies. Stratification of pregnancy outcomes by biopsy classification yielded no significant associations. However, a limited amount of data was available for this analysis, and histological pattern might not have influenced the pregnancy outcomes due to the fact that most of these biopsies were performed years prior to the pregnancies that were analyzed.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1660**

**Vasculature Structure and Function in Women with and without a History of Pregnancy Induced Hypertension** Catherine M. Brown,[1,2] Alice V. Stanton,[2] John J. Walshe.[1] *[1]Department of Nephrology, Beaumont Hospital, Dublin 9, Ireland; [2]Molecular and Cellular Therapeutics, Royal College of Surgeons in Ireland, Dublin, Ireland.*

**Objective:** Studies have linked a history of gestational hypertension (GH) or preeclampsia (PET) with an increased risk of death from ischaemic heart disease and cerebrovascular events. The aim of this study was to test if such women demonstrate abnormal large vessel structure and/or function at 2 years post partum.

**Methods:** A cross sectional observational study of 114 women with a history of PET (n=40), a history of GH (n=33) and a history of normal BP throughout pregnancy (n=41). Levels of established cardiovascular risk factors (age, body mass index, smoking habit, systolic BP, fasting cholesterol and glucose) were recorded. The assessments of vascular structure and function included; ultrasonic measurement of common carotid intima-media thickness (IMT) (a measure of early atherosclerosis), carotid-to-femoral pulse wave velocity (PWV) (a measure of large artery stiffness), and brachial flow-mediated dilatation (FMD) (a measure of large artery endothelial function).

**Results:**

Results: mean values (± SD) for the three groups

| | Control (n=41) | PET(n=40) | GH (n=33) | ANOVA p-value |
|---|---|---|---|---|
| Common Carotid IMT (mm) | 0.46 ± 0.1 | 0.50 ± 0.1 | 0.50 ± 0.1 | p= 0.001 |
| Carotid to-Femoral | 8.2 ± 0.6 | 8.6 ± 0.7 | 8.7 ± 0.8 | p= 0.002 |
| Brachial FMD (%) | 23 ± 12 | 14 ± 8.8 | 20 ± 11 | p= 0.001 |

After adjustment for established cardiovascular risk factors, common carotid IMT remained significantly greater in both groups of women with a history of pregnancy induced hypertension (p=0.04), whilst brachial FMD remained significantly blunted in women with a history of PET (p=0.003).

**Conclusions:** Women with a history of PIH demonstrate clear abnormalities in vascular structure and function. These differences are independent of established risk factors for cardiovascular events. The greater atherosclerosis and endothelial dysfunction exhibited by these women could contribute to the excess cardiovascular morbidity and mortality experienced by these women in later life.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1661**

**Levels of Systolic BP before 20 Weeks Gestation Are a Predictor of Subsequent Gestational Hypertension** Catherine M. Brown, John J. Walshe. *Department of Nephrology, Beaumont Hospital, Dublin 9, Ireland.*

**Background:**

Blood pressure in women who develop either preeclampsia (PET) or gestational hypertension (GH) is by definition ≤ 140/90 mmHg in the first 20 weeks of pregnancy. Preeclampsia differs from GH in that it is associated with proteinuria (≥ 300mg in a 24hr urine collection). We reviewed early pregnancy data on a group of women to assess differences in their blood pressure at their first booking visit.

**Methods and results:** A retrospective review of data from the bookings visits of women who developed no blood pressure complications, controls (n= 65), women who later developed PET (n=67) and women who later developed GH (n= 66). The following were recorded at their booking visits, the average of 2 blood pressure readings, their weight and age as well as pregnancy outcomes ( weeks gestation at delivery, baby weight, apgar scores, type of delivery and serum urate and total urine protein (TUP) where available).

**Results:**

Results: mean values (± SD)

| | Control (n= 65) | PET (n= 67) | GH (n=66) | ANOVA p value |
|---|---|---|---|---|
| Age at booking (yrs) | 29 ± 4.6 | 31 ± 5.4 | 30 ± 5.2 | p= 0.3 |
| Booking systolic BP mmHg | 114 ± 11 | 119 ± 11 | 123 ± 11 | p<0.001 |
| Booking diastolic BP mmHg | 69 ± 7 | 70 ± 12 | 74 ± 11 | p= 0.01 |
| Booking weight (kg) | 75 ± 12 | 77 ± 13 | 84 ± 1 | p= 0.001 |
| Baby weight (kg) | 3.6 ± 0.4 | 3.0 ± 0.9 | 3.4 ± 0.5 | p< 0.001 |
| Weeks gestation at delivery | 39 ± 1 | 38 ± 3 | 39 ± 2 | p= 0.03 |

Women who developed either PET or GH had significantly higher systolic BP (SBP) at their booking visit. After adjustment for weight and age, booking SBP remained significantly higher for the GH group compared to controls (p= 0.003).

**Conclusions:**

In women who developed gestational hypertension, systolic and diastolic BP at their booking visit was significantly higher when compared to both the PET group and the control group. After adjustment for weight and age, this difference in systolic BP remained significant in the GH group compared to controls. Women who develop GH in pregnancy need regular BP monitoring post partum and follow up screening for cardiovascular risks.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1662**

**Plasma Hemopexin Activity and Preeclampsia: sFlt1 Counteracts Hemopexin Activity and Expression In Vitro** Winston W. Bakker, Judith Muis, Theo Borghuis, Harry Van Goor, Marijke M. Faas. *Pathology, University Medical Center, Groningen, Netherlands.*

**Background:** The soluble VEGF receptor, denoted as s-Flt1, is increased in preeclampsia, causing endothelial dysfunction. Active plasma hemopexin, (Hx) controls vascular responsiveness for angiotensin II by shedding endothelial angiotensin II receptors (AT-1). Hx activity is increased in pregnancy but inhibited in preeclampsia. The question emerged whether Hx activity can be counteracted by sFlt-1, leading to persisting angiotensin II sensitivity in preeclampsia.

**Methods:** We incubated purified active Hx with sflt-1followed by evaluating Hx activity using a standard amidolytic assay. Control incubations were done with sFlt1 supplemented with its ligand VEGF-A. Expression of Hx on endothelial cells was evaluated after overnight incubation with either sFlt alone or sFlt1+ VEGF, using flow cytometry.

**Results**: sFlt-1 showed a dose dependent inhibition of Hx activity [ Hx activity, in arbitrary units: 0.80 ±0.10; Hx+sFl-t1,( 2.5 ng/ml): 0.71±0.20; Hx+sFlt-1 (5.0 ng/ml): 0.51±0.10;Hx+sFlt-1(10.0 ng/ml) 0.49±0.13.(P< 0.05; each +sFlt-1 value vs Hx alone)] Supplementation of VEGF (10ng/ml) + 5.0 ng sFlt-1 to Hx resulted in a significant increase of Hx activity[0.62±0.5 vs 0.51±0.10, P< 0.05] and addition of the same amount of VEGF with 10.0 ng/ml sFlt-1 to Hx resulted in 0.71±0.2 vs 0.49±13.0 (P<0.01). VEGF alone was negative in this test system.

In cultured endothelial cells dose dependent inhibition of Hx expression occurred after incubation with sFlt-1 (2.5 ng/ml): 30%± 10% (P<0.05); 5.0 ng/ml: 42%±6% (p< 0.01); 10.0 ng/ml: 46% ± 10% (p<0.05);(P-values: sFlt-1+ Hx vs Hx expression alone). As VEGF per sé appeared to affect Hx expression, no VEGF/sFlt-1 interactions could be studied using this assay.

**Conclusion**: The activity of plasma Hx as well as its expression on endothelial cells are inhibited by sFlt-1 in vitro. Potential counteraction of plasma Hx activity and /or Hx release from endothelial cells by sFlt-1 in vivo may contribute to a contracted vascular bed and hypertension in patients with preeclampsia.

**Hypertension in Pediatric Renal Replacement Therapy Patients in Europe, Results from the ESPN/ERA-EDTA Registry** Karlijn J. Van Stralen,[1] Marijn A. M. Kramer,[1] Kitty J. Jager,[1] Franz S. Schaefer,[3] Enrico E. Verrina,[2] Jaap Willem Groothoff.[1] *[1]Academic Medical Center, Amsterdam, Netherlands; [2]G Gaslini Hospital, Genoa, Italy; [3]University of Heidelberg Children's Hospital, Heidelberg, Germany.*

**Objectives**

Determine the prevalence of hypertension (HT) and the distribution of blood pressure (BP) in the European paediatric renal replacement therapy population, for both renal allograft recipients and dialysis patients, and to identify potential determinants associated with hypertension.

**Methods**

Data were derived from the ESPN/ERA-EDTA registry from 2734 children, providing over 10,000 measuements, aged younger than 18 from 1999 to 2009, from 15 European countries. HT was defined as either SBP or DBP ≥95$^{th}$ percentile for age, height and gender. Information on use of antihypertensive medication was available for 54.2% of the patients. Percentages were weighted according to the number of blood pressure measurements available. Linear mixed model analyses were used to determine effect of parameters on HT.

**Results**

HT was present in 40% of haemodialysis, 40% of peritoneal dialysis and 29% of transplant patients. Of those on antihypertensives, 49% had uncontrolled HT (BP ≥90$^{th}$ percentile), while 16% of those not on medication had HT. Having HT was associated with younger age, treatment with haemodialysis and not having CAKUT. There was not difference between males and females. Patients who were hypertensive at start of RRT became less hypertensive in the subsequent years.

**Conclusions**

In this large European cohort fewer patients suffered from HT compared to US studies. Despite the awareness of the possible consequences of HT in the paediatric European RRT population, it is still inadequately treated.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1664**

**Predictors of Hypertension in Children and Adolescents: Role of Perinatal Events** Tetyana L. Vasylyeva, Candace A. Myers, Michael Okogbo. *Department of Pediatrics, Texas Tech University Health Sciences Center, Amarillo, TX.*

**Purpose:** Pre-maturity and low birth weight (LBW) cause hypertension (HTN), ischemic heart disease, and obesity in young adults. The objective of our study was to identify preventable risk factors for the development of HTN in 8-21 years-olds and to assess pediatricians' awareness of the problem.

**Methods:** A retrospective chart review was conducted of 128 children and adolescents born in 1992-2002, at gestational ages (GA) ≤ 37 weeks. Eligible cases had at least five blood pressure recordings during childhood. Familial, neonatal, and postnatal data were collected.

**Results:** Nine percent of the subjects were born at a GA under 28 weeks, 10%: 28-39 weeks, 45%: 31-34 weeks, and 36%: 35-37 weeks. Seven percent of the children born at a GA less than 30 weeks developed HTN *vs.*17% who were born after 30 weeks. We found that 9% of the babies ≤ 1500 g developed HTN compared to 18% of those over 1500 g. Thirteen percent of the babies were small for GA and of these, only 4% developed HTN later in childhood. Of the 7% born large for GA, 20% developed HTN. HTN was noted in 15% of the children born appropriate for GA. The development of HTN was more common in males (56%) than females (12.5%) and a higher prevalence was observed in Hispanics compared to Whites and African-Americans. Among breastfeed babies 25% developed HTN *vs.* 11% of formula-fed babies. Other factors that influenced the development of HTN were maternal age, HTN, and diabetes. In this cohort, the risk of developing HTN by age 18 or 21 was 27% or 33%, respectively (interval regression analysis). The odds ratio of developing HTN was 11.5 if pre-term children became obese and 0.84 if the baby developed respiratory distress syndrome. HTN was diagnosed by the primary care pediatricians in only 32% of the HTN children in our study.

**Conclusion:** Fetal programming of diseases must be considered for the treatment and prevention of HTN among premature/LBW patients. Environmental factors may play a critical role. In our ongoing study we will try to identify preventable risk factors for HTN in patients born preterm/LBW as well as increase pediatricians' awareness of the problem.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1665

**Predictors of Response to Antihypertensive Medication in Children with Primary Hypertension** Hanan K. Tawadrous,[1] Sreevidya Kusuma,[1] Anita Pandey,[2] Svetlana Ten,[2] Amrit Bhangoo,[2] Anil K. Mongia.[1] *[1]Pediatric Nephrology, SUNY Downstate Medical Center, Brooklyn, NY; [2]Pediatric Endocrinology, SUNY Downstate Medical Center, Brooklyn, NY.*

**Background:** Improvement of blood pressure in children is important to prevent target organ damage. Medications along with life style modification are recommended in case of severe HTN. However some patients might be resistant to antihypertensive medication.

This study was done to identify factor that predict response to blood pressure medication in pediatric population with primary HTN.

**Objective:** We studied changes in blood pressure, and cardiovascular disease (CVD) risk factors to determine whether LSM and antihypertensive medications produced improvement in blood pressure and cardiovascular risk factors.

**Design/Methods:** This study included 87 children with new-onset HTN referred from July 2002 to October 2009. The patients after routine work up were advised life style modification and medication were added as per the standard guidelines. Patients with improvement in blood pressure to less than 95% were referred to as responders and rest as non responders.We used paired t-test to evaluate the changes in each group in respect to BP, BMI, Cholesterol, LDL, TG, HDL, and microalbumin compared to the baseline.

**Results:** Mean follow up period was 2.1 years. 58 (66.6%) were boys.73 patients (83.9%) were of AA origin.55 (63%) were overweight. Of 87 patients, 33(37.9%) had stage I hypertension and 38(43.7%) had stage II hypertension. Of these 44 patients were prescribed pharmacologic treatment in addition to lifestyle modification. At baseline pts with or without response to medication did not differ significantly with respect to age, sex ,Race, BMI LDL(P=0.79) ,Cholesterol(P=0.71), TG(P=0.30), HDL(0.39), microalbumin (P=0.24). However at follow up patients with poor response to antihypertensive medication had statistically higher TG(137 vs77mg/dL$p<0,05$), lower HDL(35vs 46mg/dl;p=0.006) and higher free T3(177vs117;p=0.01)

**Conclusion:** Patients with poor response to antihypertensive medication have an unfavorable metabolic profile at follow up. Lifestyle modification might not have been aggressively followed in such patients.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1666

**A Slight Increase in Salt Reduces Endothelial Ecto-Phosphatase (CD 39) In Vitro** Winston W. Bakker,[1] Titia Lely,[2] Theo Borghuis,[1] Harry Van Goor,[1] Marijke M. Faas.[1] *[1]Pathology and Medical Biology, University Medical Center, Groningen, Netherlands; [2]Obstetics and Gynecology, University Medical Center, Groningen, Netherlands.*

**Background**. High dietary sodium intake is associated with cardiovascular and renal risk. Endothelial ectonucleoside triphosphate diphosphohyrolase-1(ENTPD-1) i.e. CD 39, is an important endothelial ecto enzyme, protecting the vessel wall from microthrombus formation and proinflammatory stimuli. The question emerged whether endothelial injury caused by sodium may involve CD39 impairment, leading to increased vessel wall sensitivity.

**Methods**. Confluent human endothelial cells were co-cultured with human peripheral blood mononuclear cells (PBMC; $0.5x10^6$ cells /well) using medium (RPMI 1640) with a standard amount of NaCl (154.0 mMol/L)(low salt, LS), or with "high" NaCl (155.54 mMol/L)(HS), or LS medium supplemented with an $O_2^-$ scavenger superoxide dismutase (SOD,592.0 U/ml) ( LS+SOD), or HS medium supplemented with 592.0 U/ml SOD (HS+SOD). After 16 hrs, cytospins of endothelial cells were immunostained for CD39. Expression was semi-quantitatively scored using an arbitrary scale. In another set of experiments PBMC alone were incubated for 16 hrs at 37°C in LS or HS medium and washed and labelled with dichlorofluorescein diacetate for detection of $O_2^-$ release by flow cytometry.

**Results**. Endothelial cells cultured in high salt medium showed a significant decrease of CD39 expression as compared with cells cultured in LS medium with or without SOD, showing normal CD39 expression. PBMC in high salt medium showed significantly enhanced $O_2^-$ production. as compared with low salt medium. (365.3±73.0 vs 164.8 ± 24.7 in arbitrary units, n=4; $P< 0.01$). No significant CD39 impairment was seen in endothelial mono-cultures in HS versus LS medium. Preliminary data in PBMC from volunteers on high salt versus low salt intake (with approximately 1% difference in plasma NaCl) showed also reduced CD39 expression.

**Conclusion**. A minor increase in sodium affects endothelial CD39 expression in vitro. This form of endothelial injury is mediated through toxic oxygen products produced by PBMC. Further investigation into the role of endothelial CD39 and sodium status is warranted.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1667

**Evaluation of Interactions of Dapagliflozin and Bumetanide** Christopher S. Wilcox,[1] Xiaoni Liu,[2] Sreeneeranj Kasichayanula,[2] Anh Bui,[2] David W. Boulton,[2] Bruce R. Leslie,[2] Steven C. Griffen.[2] *[1]Georgetown University School of Medicine, Washington, DC; [2]Bristol-Myers Squibb, Princeton, NJ.*

Dapagliflozin (DAPA) is a competitive, reversible, selective inhibitor of sodium glucose cotransporter 2 (SGLT2), which mediates most proximal tubule glucose and $Na^+$ reabsorption. DAPA is an investigational diabetes drug whose glucosuric MOA results in diuresis. This study assessed potential pharmacokinetic (PK) and pharmacodynamic interactions of DAPA with a loop diuretic, bumetanide.

METHODS: 42 healthy volunteers (HV) were randomized to 1mg bumetanide, 10mg DAPA, or DAPA plus bumetanide qd for 7 days. On Day 8, all subjects received DAPA plus bumetanide qd for 7 more days. Samples were collected for PK analyses on Days 7 and 14 and for PD analysis daily from Days -1 to 14.

Neither drug meaningfully affected the PK of the other. Adverse events were consistent with the profiles of the individual drugs, with one subject treated for hypokalemia 1 day after completing treatment, and another with orthostatic hypotension and syncope in a subject receiving both drugs together. DAPA, but not bumetanide, increased glucose excretion and urinary osmolality. Urine volumes increased transiently with DAPA, bumetanide, or the combination, and return to baseline was longer (9 days vs. 2 days) when the two drugs were initiated simultaneously vs. singly. Urinary $Na^+$ increased by 22mEq (35%) with DAPA alone, although this response is complicated by the lack of $Na^+$ balance at baseline. However, DAPA added after 7 days of bumetanide increased urinary $Na^+$ by 64mEq [78%; difference 42mEq, 95% CI (23, 61)]. Bumetanide added after 7 days of DAPA resulted in a greater increase (101mEq) in urinary $Na^+$ than when given alone [75mEq; difference 27mEq; 95% CI (8, 46)]. Effects on urinary $Na^+$ were transient (about 2-3 days) for all treatments.

Treatment with DAPA, bumetanide or the combination was safe in this study in HV. Dapagliflozin produces glucosuria and osmotic diuresis as well as a natriuretic effect that was additive with a loop diuretic. DAPA appears to have a low potential to produce serum electrolyte disturbances and does not have clinically significant PK interactions with the loop diuretic, bumetanide.

Disclosure of Financial Relationships: Consultancy: A consultancy agreement with Bristol-Myers Squibb.

## F-PO1668

**Dietary Intake of Amino Acids Influences Blood Pressure in Patients at High Cardiovascular Risk** Katherine R. Tuttle,[1,2] Joan E. Milton,[1] Diane P. Packard,[1] Robert Short.[1] *[1]Providence Medical Research Center, Providence Sacred Heart Medical Center & Children's Hospital, Spokane, WA; [2]Nephrology Division, Department of Medicine, University of Washington School of Medicine, Seattle, WA.*

Diets augmented with plant proteins appear to lower blood pressure (BP), while greater intake of animal proteins may do the opposite. The purpose of this study was to determine if individual amino acids that vary by food source influence BP in patients at high cardiovascular risk defined by a prior myocardial infarction. Participants in a clinical trial of low-fat vs. Mediterranean-style diets (n=92) were randomized to interventions that provided ≥13 individual and group sessions over 2 years. Nutrient intake was serially assessed at baseline, 3 months, and then every 6 months by 3-day food diaries and laboratory studies. Baseline BP was 125±19/73±10 mm Hg (mean±standard devation, SD) in hypertensive participants (n=44) and 114±11/71±9 mm Hg in non-hypertensive participants (n=48), p=0.002. Diuretics were used more commonly in hypertensive than non-hypertensive participants, 23% (10/44) vs. 2% (1/48), p=0.003. Usage of other anti-hypertensive agents, age (59±9 yr), body mass index (29±6 kg/m$^2$) estimated glomerular filtration rate (62±20 ml/min/1.73m$^2$), and urinary albumin/creatinine (14±36 mg/g), sodium (155±76 mmol/day), and potassium (72±28 mmol/day) did not differ by hypertension status. The independent amino acid variables (quartiles of intake) were analyzed by generalized estimating equation models with covariates for the dependent variables of time-varying systolic and diastolic BP (SD units). Intake of methionine ($\beta$=0.24, $p<0.001$; $\beta$=0.20, p=0.006) and alanine ($\beta$=0.15, p=0.005; $\beta$=0.20, p=0.004) were associated with higher systolic and diastolic BP (data shown respectively). Threonine had a reverse effect ($\beta$=-0.17, p=0.008; $\beta$=-0.16, p=0.053). Conclusions: Greater intake of methionine and alanine, amino acids enriched in animal proteins, had consistently positive relationships to higher BP. In contrast, intake of threonine, an amino common in plant proteins, was associated with lower BP.

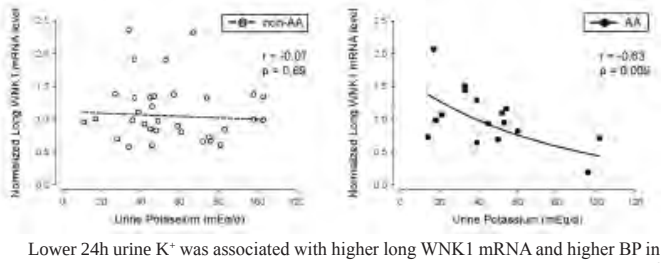
**Dietary Potassium Deficiency Is Associated with Long WNK1 in African Americans** Susan Hedayati,[1,2] Masoud Afshar,[2] Beverley Adams-Huet,[2] Jian Xie,[2] Orson W. Moe,[2] Chou-Long Huang.[2] *[1]Nephrology, Dallas VA Medical Center; [2]Nephrology and Clinical Sciences, University of Texas Southwestern Medical Center, Dallas, TX.*

Mechanisms that mediate salt-sensitive hypertension are poorly understood. African Americans (AA) have higher salt-sensitivity and may be more affected by dietary $K^+$ deficiency. Dietary $K^+$ restriction in rats increased whole-kidney WNK1 mRNA levels. Upregulation of WNK1 in humans causes hypertension in type 2 pseudohypoaldosteronism.

We sought to investigate whether lower dietary $K^+$ as measured by 24h urine $K^+$ ($U_{K+}V$) is associated with increased human peripheral long WNK1 mRNA expression (using white blood cells as surrogate tissue), and with higher blood pressure (BP), and whether this association was more pronounced in AA. Of the 52 normal subjects with BP <140/90 enrolled, 17 were AA and 35 non-African American (non-AA). Mean age was greater in AA vs. non-AA, 41 ±9 vs. 32 ±11 years, p =0.001. Systolic BP was 111 ±12 in AA and 104 ±12 in non-AA (p =0.05). Diastolic BP was 68 ±7 in AA and 63 ±9 in non-AA, p =0.07. $U_{K+}V$ was not different between AA (47 ±26 meq/d) and non-AA (55 ±24 meq/d), p =0.3. There was a weak and statistically non-significant negative correlation between $U_{K+}V$ and WNK1 in the overall sample (r =-0.25, p =0.07). However, when the analysis was stratified by race, the magnitude of this association was substantially stronger in AA and statistically significant, r =-0.63, p =0.009. There was no correlation in non-AA, r =-0.07, p =0.7. Similarly, there was a negative correlation between $U_{K+}V$ and systolic BP in AA, r =-0.61, p =0.009, but not in non-AA.



Lower 24h urine $K^+$ was associated with higher long WNK1 mRNA and higher BP in AA but not in non-AA. We postulate that WNK1 may play a role in the pathogenesis of salt-sensitivity of blood pressure related to dietary $K^+$ deficiency in African Americans.

**The Effect of Sodium Intake on Blood Pressure and Kidney Function: Data from Korea National Health and Nutrition Examination Survey (KNHANES)** Seong-Woo Lee,[1] Ho Seok Koo,[1] Ho Jun Chin,[1,2] Ki Young Na,[1,2] Kwon Wook Joo,[1] Yon Su Kim,[1] Dong Wan Chae,[1,2] Curie Ahn,[1] Jin Suk Han,[1] Suhnggwon Kim.[1] *[1]Internal Medicine, Division of Nephrology, Seoul National University College of Medicine, Seoul, Korea; [2]Internal Medicine, Seoul National Bundang Hospital, Seongnam, Korea.*

Background: There have been controversies on the effect of sodium intake on blood pressure and kidney function. Method: Data from the 3rd and 4th KNHANES were used. A total of 13,051 who were aged ≥ 20 years, and not missing data of serum creatinine and sodium intake were included for the analysis. Sodium intake was calculated by using 24 hours' recall method. All values of blood pressure or kidney function were adjusted by age, sex and systolic blood pressure (SBP) and/or diastolic blood pressure (DBP) by using ANCOVA. Result: SBP was not associated with sodium intake (p=0.057). However, DBP revealed substantial association with sodium intake: 75.19 (0.15) mmHg in 1Q of Na, 76.02 (0.13) mmHg in 2Q of Na, 76.08 (0.13) mmHg in 3Q of Na and 75.96 (0.13) mmHg in 4Q of Na (p <0.001). In post-hoc analysis, only 2Q of Na significantly increased DBP compared to 1Q of Na (p=0.001), while no changes were observed in the comparison of the other two adjacent quartiles. In participants with hypertension (HTN), DBP was not affected by the increase of sodium intake. However higher amount of sodium intake increased DBP in participants without HTN. Sodium intake was also related to estimated glomerular filtration rate (eGFR): 80.61 (0.30) ml/min/1.73m$^2$ in 1Q of Na, 80.25 (0.26) ml/min/1.73m$^2$ in 2Q of Na, 79.47 (0.25) ml/min/1.73m$^2$ in 3Q of Na and 79.59 (0.25) ml/min/1.73m$^2$ in 4Q of Na (p=0.008). In post-hoc analysis, however, we could not find statistically significant change in comparison of the two adjacent quartiles. Conclusion: Higher amount of sodium intake increased DBP, but not linearly. Sodium intake was not associated with SBP. The increasing effect of sodium intake on DBP could be found in participants without HTN, but not in participants with HTN. Although sodium intake was associated with eGFR, dose dependent change was not found in this study. Prospective study needs to be followed to confirm our result.

**F-PO1671**

**Urinary Albumin Excretion and Ambulatory Blood Pressure in a Hypertensive Population** Julian Segura, Manuel Gorostidi, Alejandro De la Sierra, Juan J. De la Cruz, Jose R. Banegas, Luis M. Ruilope. *on Behalf of the, Spanish Society of Hypertension ABPM Registry Investigators.*

**Objective**: The value of ambulatory blood pressure monitoring (ABPM) as the gold standard to investigate the role of blood pressure (BP) in renal disease is now-a-days considered.

**Methods**: We analyzed data from a subsample of 2,551 hypertensive patients from the Spanish Society of Hypertension ABPM Registry in whom quantitative data of urinary albumin excretion was available. Albuminuria was assessed by the albumin/creatinine ratio (ACR) and values were categorized as follows: normoalbuminuria was considered when ACR <10 mg/g in men or <15 mg/g in women, high-normal albuminuria when ACR 10-20 mg/g in men or 15-30 mg/g in women, microalbuminuria when 21-200 mg/g in men or 31-300 mg/g in women, and macroalbuminuria when ACR values were above this thresholds.

**Results**: Mean age was 59 years and 53.5% of patients were men. The distribution of different categories of ACR was: normoalbuminuria 67.4%, high-normal albuminuria 13.1%, microalbuminuria 15.9%, and macroalbuminuria 3.6%. There was an increase in systolic BP levels in all ABPM periods (24-h, daytime, and nighttime) from normo- to macroalbuminuria (p for trend <0.001) despite the use of more antihypertensive drugs (from 1.39 to 2.42 per day). The most pronounced increase in systolic BP was observed during nighttime (119.9, 122.8, 125.3, and 137.3 mmHg respectively in normal, high-normal, micro-, and macroalbuminuria). There was also a progressive increase in the prevalence of the non-dipper pattern, from 50.1% in normoalbuminurics to 72.5% in patients with macroalbuminuria.

**Conclusions**: ABPM characterizes the different stages of albumin excretion in urine and could help to the surveillance of BP control and its influence on albuminuria.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1672**

**Urinary Albumin Excretion within the Normal Range Is Associated with Severity of Coronary Artery Disease** Juan F. Navarro,[1,2] Carmen Mora,[2] Mercedes Muros,[3] Ana Gorgoso,[4] Horacio Perez,[4] Haridian Herrera,[2] Beatriz Meneses.[2] *[1]Nephrology Service, University Hospital Ntra. Sra. Candelaria (HUNSC); [2]Research Unit, HUNSC; [3]Clinical Biochemistry, HUNSC; [4]Cardiology Service, HUNSC, Santa Cruz de Tenerife, Spain.*

Increased urinary albumin excretion (UAE) is associated with a higher risk of coronary artery disease (CAD). However, data about the relationship between normal UAE and CAD are scarce. The aim of this study was to analyze in patients underwent coronary angiography (CA) the relationship between normoalbuminuria and the severity of coronary lesions. Three-hundred and forty seven consecutive patients under elective CA were included. Increased UAE was observed in 101 subjects, whereas 246 patients (146 males, 100 females; mean age 64±12 years) showed normal renal function and normal UAE (albumin/creatinine ratio (A/C) < 30 mg/g). Coronary lesions were observed in 132 normoalbuminuric patients (78 males, 54 females; mean age 64±11 years), whereas CA was normal in the remaining 114 subjects. Prevalence of diabetes, arterial hypertension and dyslipidemia among these subjects were 34%, 61% and 47%, respectively. The mean number of coronary lesions was 2.9. The mean percent occlusion of the left coronary artery (LCA), left anterior descending artery (LDA) and right coronary artery (RCA) were 68%, 70% y 66%, respectively. Patients with coronary lesions showed a higher A/C ratio than subjects with normal coronariography (12.9 vs 8.2 mg/g, p<0.0001). There were no differences regarding the number of coronary lesions when patients were stratified according to UAE. However, subjects in the highest tertile showed a significantly higher severity of coronary occlusion at all locations: LCA (p<0.05), LDA (p<0.001) and RCA (p<0.0001). Multiple regression analysis showed an independent association between A/C and severity of coronary lesions: RCD (r=0.24, p=0.01), LDA (r=0.21, p<0.05), with a trend regarding LCA (r=0.12, p=0.1). In conclusion, UAE within the normal range is independently associated with severity of coronary artery occlusion. Therefore, UAE, even within the normal range, may be a useful clinical tool in the risk stratification of coronary artery lesions.

**F-PO1673**

**Is There a Relationship between Microalbuminuria and Hypertension in Children?** Mohammed Faizan,[1,2] Atena Asiaii,[1] Siraj Amanullah,[1,2] Sharon W. Su.[1,2] *[1]The Warren Alpert Medical School of Brown University; [2]Department of Pediatrics, Hasbro Children's Hospital, Providence, RI.*

Recently published NHANES data has confirmed the association between microalbuminuria (MA) and hypertension (HTN) in the adult US population. We have previously looked at the relationship between MA and HTN in children as determined by 24 hour ambulatory blood pressure monitoring (ABPM) in a retrospective cohort, but failed to find an association likely due to small sample size. (PAS 2008, *abstract*). **Objective:** To determine an association between MA and HTN as assessed by 24 hour ABPM. **Methods:** Retrospective cohort study from July 1997 to April 2010, on non-diabetic patients between the ages of 0-21 years. All patients had a diagnostic study with 24 hour ABPM in an urban pediatric nephrology clinic. HTN was defined as the 95th percentile of systolic and/or diastolic BP for age, gender and height. MA was defined as an elevated urine microalbumin to creatinine ratio of 19 mg/gm (laboratory definition) on a single random urine sample. **Results:** 229 pts were included. Mean age was 13.7 yrs. 150 (65.5%) were males. 74 pts

(32.3%) met the criteria for HTN. Mean BP in the HTN group was 135/77 vs. 118/65 in the normotensive group. MA was seen in 49 (21.4%) pts. **Microalbuminuria was found to be significantly associated with HTN (OR = 2.2, 95% CI:1.17-4.27).** No statistically significant association was found between hypertension and the following variables*: age, sex, BMI, serum creatinine, glucose, sodium, potassium, family history of hypertension, diabetes, hyperlipidemia, and cardiovascular or renal disease.* **Conclusion:** Viazzi et al have recently reported that microalbuminuria is a predictor of chronic renal insufficiency in non-diabetic hypertensive adults. This relationship is not defined currently in children. Our study shows an association between microalbuminuria and hypertension in children, as determined by 24 hour ABPM. With the explosive rise in the incidence of obesity and metabolic syndrome in children, it is especially relevant to further explore this relationship prospectively, using microalbuminuria as an important screening tool for future risk of morbidity and mortality.

## F-PO1674

**Control of Hypertension and Other Risk Factors in the Cardiovascular Outcomes in Renal Atherosclerotic Lesions (CORAL) Clinical Trial** Katherine R. Tuttle, Richard A. Dart, Barbara A. Greco, Kenneth A. Jamerson, Alexander M. M. Shepherd, Lance D. Dworkin, William L. Henrich, Donald Cutlip, Timothy P. Murphy, Christopher J. Cooper. *CORAL Trial Study Group, NHLBI, Bethesda, MD.*

The CORAL trial has enrolled patients with atherosclerotic renal artery stenosis (RAS) complicated by hypertension and/or chronic kidney disease (CKD). At entry, participants were randomized to receive stent revascularization or not. All participants receive optimal medical therapy for risk factors. The blood pressure (BP) goal is <140/90, or <130/80, mm Hg in the setting of CKD or diabetes. Renin angiotensin system inhibition is first-line therapy with add-on drugs to achieve BP goals. The LDL cholesterol (LDL-C) goal is <70 mg/dl. Among those with diabetes, the HbA1c goal is <7%. The purpose of this study is to evaluate risk factor control among CORAL participants over time. Age at entry was 69±9 (mean±SD) years with 465/931 (50%) men. Diabetes was present in 297/887 (34%). CKD was common 432/751 (58%), and the estimated glomerular filtration rate was 51±16 ml/min/1.73m$^2$. Bilateral RAS or arterial stenosis in a solitary kidney was identified in 149/931 (16%), while prevalent cardiovascular disease (CVD) occurred in 611/890 (69%).

| BP (mm Hg) | Baseline | 1 year | 2 year | p value |
|---|---|---|---|---|
| <140/90 goal | 248/311 (79%) | 200/213 (94%) | 115/123 (93%) | <0.001 |
| Mean±SD | 151±23/79±14 | 134±20/74±13 | 134±19/74±13 | <0.001 |
| <130/80 goal | 345/574 (60%) | 274/348 (79%) | 131/163 (80%) | <0.001 |
| Mean±SD | 149±23/78±12 | 136±19/73±12 | 134±21/71±12 | 0.001 |
| LDL-C (mg/dl) | | | | |
| <70 goal | 202/699 (29%) | 171/465 (37%) | 106/259 (41%) | 0.013 |
| Mean±SD | 90±33 | 85±33 | 82±39 | 0.100 |
| HbA1c (diabetic) | | | | |
| <7% goal | 168/232 (73%) | 100/163 (61%) | 53/85 (62%) | 0.009 |
| Mean±SD | 6.8±1.4 | 7.2±1.7 | 6.9±1.1 | 0.043 |

**Conclusions:** CORAL participants are at high-risk for CKD and CVD complications. Control of risk factors is approaching goal or improving overall. Whether renal artery stenting adds further benefit on BP, CKD and/or CVD endpoints will be determined as main study outcomes.

Disclosure of Financial Relationships: Consultancy: Fibrogen Inc., Eli Lilly and Co.Research Funding: NIH/NHLBI.

## F-PO1675

**The Effect of Renal Artery Stenting on Left Ventricular Mass: Interim Analysis of the RASCAD Trial** Carmelita Marcantoni,[1] Luca Zanoli,[2] Stefania Rastelli,[2] Giovanni Tripepi,[3] Massimo Matalone,[1] Domenico Di Landro,[1] Corrado Tamburino,[4] Carmine Zoccali,[3] Pietro Castellino.[2] *[1]Nephrology, Cannizzaro Hospital, Catania, Italy; [2]Int Medicine, University of Catania, Catania, Italy; [3]CNR_IBIM, Reggio Calabria, Italy; [4]Cardiology, University of Catania, Catania, Italy.*

The effect of renal revascularization on left ventricular mass (LVM) is not known.

The Stenting of Renal Artery Stenosis in Coronary Artery Disease (RASCAD) study is a RCT designed to evaluate the effect of renal artery stenting+medical therapy (C) vs medical therapy alone (P) on LVM progression (primary endpoint) and CV morbidity and mortality in patients (pts) affected by coronary artery disease (CAD) and renal artery stenosis (RAS).

**Methods**

Pts with RAS>50%≤80% were randomly assigned to undergo C or P therapy. Clinical and echocardiographic studies were performed at baseline and every year. LVM was indexed to BSA (LVMI, g/m2).The interim analysis of enrolled pts who have at least 1yr echocardiographic control is reported.

**Results**

During a 2-year enrolment time, 84 pts were randomized: 43 in C arm and 41 in P arm. At baseline, clinical characteristics were not different between two groups (Male 54% in C vs 65% in P; age 69±8 yrs in C vs 69±9 in P; eGFR 68±24 ml/min in C vs 60±20 in P; LVMI 124±31 g/m2 in C vs 117±27 in P; SBP 133±20 mmHg in C vs 131±16 in P; DBP 73±11mmHg in C vs 74±12 in P). Echocardiographic data at 1yr were available in 38C vs 35P and showed a significant regression of LVM, associated with a better blood pressure control in both groups. However, there were not significant differences between two treatment arms (ΔLVMI -4.9% in C vs -4.1% in P, p=NS; ΔSBP-3.1% in C vs -4.2% in P, p=NS; ΔDBP -2.3% in C vs -6%in P, p=NS) . ΔGFR was also not different between two groups (-1.8ml/minin C vs +1.7ml/min in P, p=NS). The number of major cardiovascular events was similar in the two treatment groups (14 in C vs 19 in P, p=NS).

**Conclusions**

The interim analysis of the RASCAD study showed that the stenting of RAS did not add any advantage to the medical therapy on regression of left ventricular mass in pts affected by CAD. Further, stenting of RAS did not affect CV morbidity and mortality.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1676

**Systolic Blood Pressure and Incident Peripheral Artery Disease in a Community Study** Jennifer A. DeGraauw,[1] Jessica B. Kendrick,[1] Dirk Sander,[2] Michel B. Chonchol.[1] *[1]University of Colorado Denver Health Sciences Center, Denver, CO; [2]Technical University of Munich, Munich, Germany.*

Purpose: Systolic blood pressure (SBP) levels that affects risk for incident peripheral arterial disease (PAD) in the elderly with and without chronic kidney disease (CKD) has been poorly studied.

Methods: Using a community population-based cohort of elderly participants, we evaluated 3354 participants enrolled in Intervention Project on Cerebrovascular Diseases and Dementia over a six year follow-up period. SBP was evaluated in four strata (<120, 120-129, 130-139, and ≥ 140 mmHg). Incident PAD was defined as a new onset of ankle brachial index (ABI) <0.9 assessed at the end of the follow-up period. Chronic kidney disease (CKD) was defined as a Creatinine Clearance (Ccr) < 60 mL/min/1.73 m2 estimated by the Cockroft-Gault equation. The relationship between incident PAD according to SBP level at baseline were tested with Cox proportional regression models. All analyses were adjusted for cardiovascular risk factors.

Results: In those participants with no PAD at baseline (n=2684) their mean (SD) age, SBP, ABI and Ccr were 69±7 years, 139±18 mmHg, 1.08±0.10 and 78±21 mL/min/1.73m2, respectively. During the course of the follow-up period 581 (21%) of patients with no PAD at baseline developed an ABI < 0.9. In this group of patients SBP was directly associated with incident PAD. In fully adjusted models every 10 mmHg increase in SBP had an 8% increase in the risk of developing PAD (HR: 1.08; 95% CI 1.05 to 1.11; p=0.006). SBP at baseline above the reference group (120-129 mmHg) was associated with a higher risk of incident PAD in the 2194 participants with normal kidney function: (adjusted HR and 95% CI) 0.91(0.82, 1.01), 1.0 (REF), 1.29 (1.18,1.41), and 1.51 (1.22, 1.87) for SBP <120, 120-129, 130-139, and ≥ 140 mmHg, respectively after adjusting for confounders. However, there was not a statistical significant relationship between SBP and incident PAD found in the 490 participants with CKD.

Conclusion: Higher SBP levels appear to be an independent risk factor for the development of incident PAD in the elderly with normal kidney function but not in those with underlying kidney disease.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1677

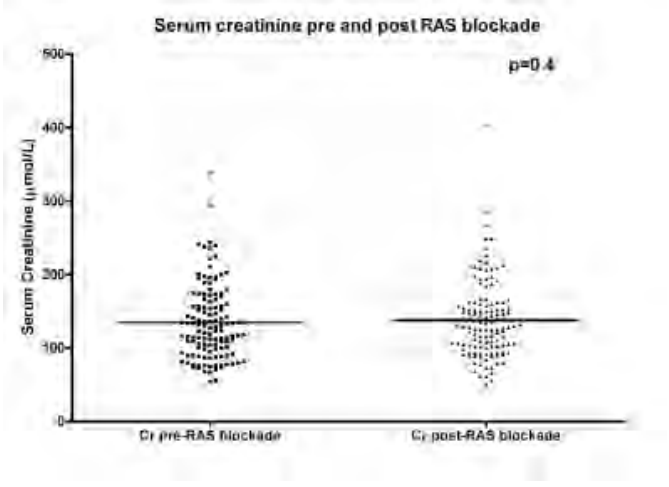
**Renin Angiotensin Blockade Is Safe in Atheromatous Renal Artery Stenosis (ARAS)** Marie Fisk, Jennifer M. Cross. *University College London Partners Kidney Centre, Royal Free Hospital, London, United Kingdom.*

The use of renin angiotensin system (RAS) blockade has historically been contraindicated in the presence of ARAS despite its role in this form of hypertension. HOPE, LIFE and ALLHAT, however, all demonstrate improved survival with RAS blockade in cohorts predicted to have 20-30% occult ARAS.

Aim : To assess whether RAS blockade results in deterioration of renal function in ARAS

Methods : Single centre cohort study of patients with magnetic resonance angiography defined ARAS identified in 2008 and 2009. Degree of stenosis, blood pressure (BP), current medication and plasma creatinine (Cr) were recorded at baseline and 6 monthly intervals. RAS blockade was preferentially prescribed aiming for a BP of 140/80 mmHg. Cr was measured two weeks after drug introduction. Subjects already on RAS blockade were continued and pre drug creatinine sought retrospectively.

Results: 143 patients were identified with a mean study follow up period of 11 months. At baseline 47% had >70% ARAS, 13% bilateral disease and 26% had undergone revasularisation. 64% required > 3 antihypertensive agents. RAS blockade had been commenced in 55% of subjects prior and 28% during the study period. Change in Cr after introduction of treatment (Figure 1), median Cr pre and post-RAS blockade; 129µmols/L and 130µmols/L respectively. At baseline clinic attendance, median Cr =149[SD ±68.33] µmols/L, 6month follow up =157[SD ±68.33]µmols/L. Mean BP at baseline was 142[SD±20.5]/74[SD±13.1]mmHg.



Conclusions: No significant deterioration in renal function was observed following introduction of RAS blockade in this ARAS cohort. Although 6.3% were referred with a label of intolerance to RAS blockade, all were successfully established on treatment. RAS blockade, in combination with other antihypertensive agents, achieved effective blood pressure control with stable renal function over medium term follow up.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1678**

**Effects of Renal Nerve Ablation on Renal Perfusion and Components of the RAAS** Christian Ott,[1] Axel Schmid,[2] Ulrike Raff,[1] Rolf Janka,[2] Michael Uder,[2] Roland E. Schmieder.[1] *[1]Nephrology and Hypertension, University Hospital Erlangen, Erlangen, Germany; [2]Radiological Institute, University Hospital Erlangen, Erlangen, Germany.*

**Purpose of the study:** Renal nerve ablation emerged as new therapeutic approach for treatment resistant hypertension. Measurement of the renal and sympathetic activity revealed a decrease in sympathetic drive to the kidney and small resistance vessels after renal nerve ablation. The precise mechanism how renal nerve ablation exerts its BP-lowering effects are not yet fully understood.

**Methods:** In a pilot study 8 patients (55.4±13 years) with treatment resistant hypertension were included and following assessments were done before (day-1), after (day+1) and again after 3 months of renal nerve ablation. Renal plasma flow (RPF) was measured by magnetic resonance imaging with arterial spin labeling. After 30 min. of complete rest in supine position blood and urine samples were collected for the determination of the individual components of the RAAS.

**Results (median (interquartile range)):** Compared to day-1, there was no change in RPF both day+1 (265 (242-267) vs. 255 (236-89) ml/min/100g, p=0.811) and 3 months (p=0.392) after renal nerve ablation. Plasma renin activity and serum angiotensin II levels did not differ between day-1 and day+1 as well as after 3 months of renal nerve ablation. In contrast, there was a significant acute decrease of aldosterone (day-1: 161 (140-265) vs. day+1: 110 (101-168) pg/ml, p=0.012) and in accordance increased urinary sodium/potassium ratio (day-1: 2.41 (1.17-3.44) versus day+1: 6.02 (4.83-7.92), p=0.028). After 3 months these changes were no longer evident. Urinary angiotensinogen levels, considered as parameter of local renal RAS activity, tended to be reduced at day+1 (p=0.116) and was significantly decreased after 3 months (6.06 (3.02-13.8) vs. 16.6 (8.50-37.0) ng/ml, p=0.046) compared to day-1 levels.

**Conclusion:** Our data indicate that a decrease of aldosterone with the consequence of a greater urinary sodium excretion occurs after the procedure. However, whether this will lead to a long term reduction of total body sodium content needs to be established. Renal perfusion did not appear to be significantly changed.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1679**

**Intradialytic Hypertension Is Associated with Sympathetic Overactivity and with Enhanced Baroreceptor Function** Dvora Rubinger, Rebecca Backenroth, Dan Sapoznikov. *Nephrology and Hypertension Services, Hadassah University Medical Center, Jerusalem, Israel.*

The mechanisms of intradialytic hypertension (HD-Ht) are not well defined. To assess the role of autonomic function during intradialyic hypertensive episodes (Hy), continuous beat to-beat blood pressure and heart rate recordings were performed in non-diabetic patients, 38 with (hypertensive, Ht) and 30 patients without HD-Ht episodes (normotensives, Nt). HD-Ht was defined as an increase in systolic blood pressure of at least 25 mmHg during or immediately after hemodialysis (HD). Systolic (SBP) and mean (MBP) blood pressure, the variability of SBP and interbeat intervals (IBI) in the low frequency (LF) range (LF SBP, LF IBI) and the baroreceptor index LFα were monitored along a whole HD session.

SBP and MBP, similar in Nt and Ht at the beginning (B), were significantly higher in Ht than in Nt at HD end (E). LF indices, representative of sympathetic nervous system activation, were improved after HD in Nt, but not in Ht. SBP, IBI, LF SBP, LF IBI and LFα (median and interquartile range) at HD beginning (B-HD), at the initiation (B-Hy) and during hypertensive episodes (Hy), and at the end (E-HD) of HD are shown in Table1:

Table 1

| Period | SBP (mmHg) | IBI (msec) | LF SBP ($mmHg^2$/Hz) | LF IBI ($msec^2$/Hz) | LFα (msec/mmHg) |
|---|---|---|---|---|---|
| B-HD | 132 (30) | 816 (154) | 80 (33) | 1118 (1515) | 3.40 (2.21) |
| B-Hy | 141 (26) | 842 (144) | 83 (51) | 1367 (1772) | 3.79 (3.55) |
| Hy | 158 (22) | 825 (162) | 76 (40) | 1222 (2002) | 3.55 (2.42) |
| E-HD | 145 (39) | 865 (150) | 71 (44) | 1009 (1546) | 3.57 (2.85) |
| p B-HD vs.B-Hy | 0.006 | 0.013 | NS | 0.010 | 0.024 |
| p B-HD vs.Hy | 0.001 | NS | NS | 0.006 | 0.056 |
| p B-HD vs.E-HD | 0.001 | NS | NS | NS | NS |

These results show that in Ht: 1. HD fails to normalize blood pressure. 2. Initiation of intradialytic hypertensive episodes is associated with increased IBI, LF IBI and LFα. 3. LF IBI and LF α remain significantly increased during Hy. These data point to sympathetic overactivity and enhancement of baroreflex as possible mechanisms of intradialytic hypertension episodes. The causes of sympathetic overactivation remain to be determined.

Disclosure of Financial Relationships: nothing to disclose

**Evaluation of Chronologic Plasma Metanephrine Levels Prior to Diagnosis of Pheochromocytoma** Sylvia C. Yoon, Kevin C. Abbott, Stephen W. Olson. *Nephrology, Walter Reed Army Medical Center, Washington, DC.*

**Introduction**:

Pheochromocytoma is a rare disease with significant morbidity and mortality. Elevated plasma metanephrines are highly sensitive and specific for diagnosis. There is no current knowledge about the progression of plasma metanephrine levels prior to diagnosis. We hypothesize that plasma metanephrines become elevated and continue to rise prior to the diagnosis of pheochromocytoma.

**Methods**:

Thirty-three subjects with biopsy proven pheochromocytoma were identified using military databases. The Department of Defense Serum Repository (DoDSR) identified an age, sex, race, and age of serum matched healthy control for each study subject. Three chronologic serum samples for each subject prior to diagnosis were sent from the DoDSR to Quest diagnostics for measurement of plasma metanephrine levels. Fisher's exact test, T-test, and ROC curve were used for data analysis.

**Results**:

A greater percent of disease subjects had an elevated plasma metanephrine level (>205 pg/mL) prior to diagnosis compared to healthy controls (88% vs. 12%; p=<0.0001). Repeat analysis for subgroups less than 2 years (96% vs. 0%, p<0.0001), 2-8 years (95% vs. 5%, p<0.0001), and greater than 8 years prior to diagnosis (39% vs. 12%, p=0.05) remained significant. An elevated plasma metanephrine level was 95% sensitive and 95% specific for future pheochromocytoma up to 8 years prior to diagnosis. ROC curve demonstrated 100% specificity for plasma metanephrine levels greater than 277 pcg/mL (area under curve = 0.88). Disease subjects had a larger percent of subjects with a greater than 20% average rise in plasma metanephrines per year compared to controls (67% vs. 7%; p<0.0001). A greater than 40% rise in plasma metanephrines per year was 100% specific (50% vs. 0%; p<0.0001).

**Conclusions**:

Elevated and rising plasma metanephrine levels are associated with future pheochromocytoma many years prior to diagnosis. This novel data could provide a future diagnostic and prognostic tool for high risk populations identified by increasingly robust genetic analysis capabilities. A more prompt diagnosis could prevent irreversible outcomes such as end organ damage, metastasis, and peri-operative death.

**Suppression of Plasma Renin Concentration and Angiotensin II after Inhibition of Systemic Nitric Oxide Synthesis in Healthy Subjects. A Dose-Response Study** Thomas Larsen, Frank H. Christensen, Jesper N. Bech, Erling B. Pedersen. *Departments of Medical Research and Medicine, Holstebro Hospital, Holstebro, Denmark.*

**Purpose**

The relationship between NO and renin has never been investigated in a dose-response study in humans. We wanted to test the hypothesis that systemic NO inhibition causes a dose-dependent suppression of the plasma renin concentration (PRC).

**Methods**

The effect of L-NMMA, an inhibitor of nitric oxide synthase, was investigated in a randomized, placebo-controlled, blinded, cross-over, dose-response study in healthy males (n=12; mean age 20). On four different occasions, subjects received either saline vehicle or one of three different doses of L-NMMA (Bachem) after an overnight fast. L-NMMA was administered as a 3 mg/kg bolus over 3 min, followed by infusion at 2 mg/kg/hr for 60 min, a 4.5 mg/kg bolus + 3 mg/kg/hr infusion, and a 6 mg/kg bolus + 4 mg/kg/hr infusion. Blood samples were obtained at baseline after three hours of supine rest, after 60 min of L-NMMA infusion, and 60 min after cessation of the infusion. PRC and angII were measured using RIAs. Data were analyzed using a general linear model with repeated measures.

**Results**

Mean baseline PRC and angII were 11±4 pg/ml and 9±4 pg/ml, respectively (means±SD), with no difference in baseline values between groups. PRC decreased significantly from baseline during administration of all three L-NMMA doses (dose 1: -20%; dose 2: -30%;

dose 3: -41%), but not during infusion of saline vehicle (9%). Likewise, L-NMMA induced a suppression of angII (dose 1: -15%; dose 2: -22%; dose 3: -33%), whereas saline vehicle did not (4%). Mean arterial pressure (MAP) increased dose-dependently.

**Conclusion**

Systemic inhibition of NO synthesis caused a significant dose-dependent suppression of both PRC and angII in healthy males, which is in good agreement with the role of NO as a stimulator of renin secretion. Thus, the increase in MAP during NO inhibition was *not* mediated by the renin-angiotensin-system. The novel finding that PRC and angII gradually decreased with increasing L-NMMA dose, suggests that basal renin secretion is highly dependent on NO in healthy subjects.

**Shift Work Predicts Disparate Hypertension Risk in African Americans** Sung Ja Lieu, Gary C. Curhan, John P. Forman. *Nephrology, Brigham and Women's Hospital, Boston, MA.*

Background: In the US, the age-adjusted prevalence of hypertension in the non-Hispanic black population is 50% higher than that of the non-Hispanic white population, particularly among black women, and this disparity persists even after controlling for standard hypertension risk factors. Alteration of circadian rhythm, such as with rotating night-shift work or short sleep duration, has been associated with blood pressure elevations in some studies; notably, the adverse physiologic responses to sleep alterations are more pronounced in blacks compared to whites, and thus circadian disruption may be a novel risk factor for hypertension among blacks.

Methods: We prospectively examined the association between rotating night-shift work and the risk of hypertension in 100,484 white and 1,896 black women who participated in the Nurses' Health Study II from 1989-2005. Data on shift work was collected from nurses at baseline and then updated every two years from 1989-2001. Those with hypertension in 1989 were excluded. Associations between rotating night-shift work and incident hypertension were analyzed using Cox proportional hazards regression controlling for age, BMI, physical activity, alcohol intake, DASH score, family history of hypertension, hours of sleep, oral contraceptive use and menopausal status.

Results: Through 2005, we identified 603 incident cases of hypertension in blacks and 19,572 cases in whites. After adjusting for potential confounders, the relative risk for incident hypertension in the blacks was 1.51 (95% confidence interval, 1.11-2.07) and 0.98 (95% confidence interval, 0.93-1.03) in whites. The P value for interaction between shift work and race was 0.001.

Conclusion: Rotating night-shift work is independently associated with hypertension risk in blacks but not in whites. Disruption of circadian rhythms may be a novel risk factor for the development of hypertension in blacks.

Disclosure of Financial Relationships: nothing to disclose

**Intradialytic Hypertension Is Associated with Endothelial Cell Dysfunction: Preliminary Results of the Mechanisms and Treatment of Intradialytic Hypertension (MATCH) Study** Jula K. Inrig, Peter N. Van Buren, Bohyun Catherine Kim, Robert D. Toto. *UT Southwestern.*

**Purpose:** Intradialytic hypertension (HTN) is associated with higher hospitalization rates and all-cause mortality, yet the mechanism is uncertain. We hypothesized that intradialytic HTN is associated with endothelial cell dysfunction (ECD), a novel marker of adverse cardiovascular outcomes.

**Methods:** We performed a prospective case-control study including 25 HD patients (pts) without (controls) and 25 HD patients with intradialytic HTN (defined as a systolic BP decrease ≥10 mmHg vs increase ≥10 mmHg during 4/6 consecutive HD sessions). Endothelial cell function was assessed by ultrasonographic measurement of brachial artery flow mediated vasodilation (FMD) and flow cytometric analysis of endothelial progenitor cells (EPCs) from peripheral blood. Wilcoxan rank sum test was used to compare BP, FMD, and EPCs ($ALDH_{br}$+, CD34+/CD133+ cells).

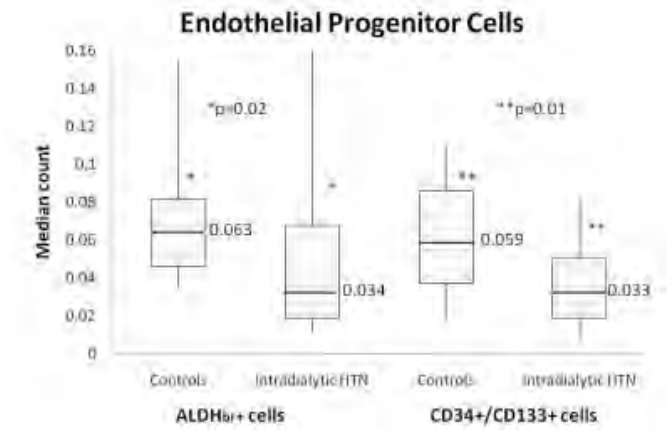
**Results:** Baseline characteristics were similar between groups (Table).

Baseline Characteristics

| | Controls (n=25) | Intradialytic HTN (n=25) |
|---|---|---|
| Age, yrs | 53 | 54 |
| Hispanic | 56% | 64% |
| Black | 40% | 36% |
| Male | 80% | 80% |
| Diabetes mellitus | 80% | 84% |
| Heart failure | 12% | 12% |
| CAD, CVA, or PVD | 36% | 32% |
| PreHD Systolic BP mmHg (2-week average) | 156* | 143* |
| PostHD Systolic BP mmHg (2-week average) | 127* | 159* |

*p<0.01 for between group comparison of pre and postHD SBP

Endothelial cell function was impaired in pts with intradialytic HTN as measured by decreased median $ALDH_{br}$+ cells and decreased median CD34+/133+ cells (Figure). Also, there was a trend toward lower endothelial-dependent brachial artery FMD in pts with intradialytic HTN as compared to controls (2.5±1% vs 3.6±3%, p=0.1).



**Conclusion:** Intradialytic HTN is associated with endothelial cell dysfunction. We speculate that ECD may partially explain the higher hospitalization rates and all-cause mortality observed in these pts.

Disclosure of Financial Relationships: Research Funding: Genzyme.

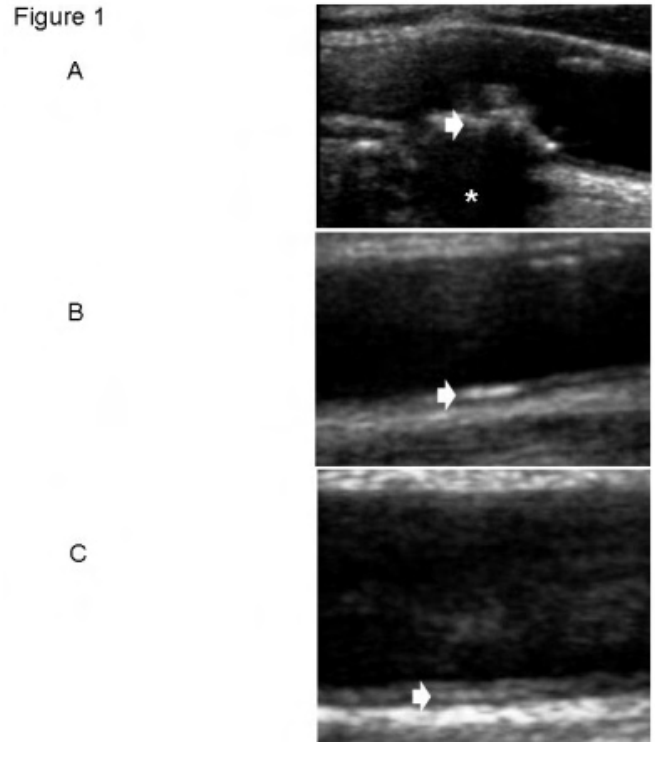
## F-PO1684

**Large Arteries Calcification in Dialysis Patients Is Located in the Intima and Related to Atherosclerosis** Blai Coll,[1] Angels Betriu,[2] M. Vittoria Arcidiacono,[3] Jose M. Valdivielso,[3] Elvira Fernandez.[1] *[1]UDETMA, Hospital Universitari Arnau de Vilanova, Lleida, Spain; [2]UDETMA, Hospital Universitari Arnau de Vilanova, Lleida, Spain; [3]Nephrology Experimental Laboratory, IRB Lleida, Lleida, Spain.*

**Background:** Vascular calcification (VC) has a significant impact in cardiovascular diseases of patients in dialysis. However, VC is assessed with X-ray-based techniques, which do not inform about the calcium localization (intima, media, atherosclerosis-related). The aim of the present work is to study VC using arterial ultrasound to report the exact location of calcium and to study its related factors.

**Design and methods:** observational, cross-sectional, case-control study. Patients under dialysis and age-and-sex matched subjects with normal kidney function were included in the study. Demographic data and laboratory values were collated. Carotid, femoral and brachial ultrasounds were performed to assess VC and atherosclerosis burden using an standardized protocol.

**Results:** 232 patients in dialysis and 208 controls were included in the study. Cardiovascular risk factors were predominantly found in controls, although the burden of atherosclerosis was higher in the dialysis group. VC was significantly more prevalent in the group of dialysis than controls, and in both groups the most prevalent pattern of VC was the linear calcification, located in the intima of the artery wall.



Among the variables significantly and positively related with the linear calcification were age and dialysis. Conversely, the absence of atherosclerosis, low levels of C-reactive protein and phosphorus were significantly protective for the development of linear calcification.

**Conclusions:** vascular calcification in large, conduit arteries is more prevalent in patients in dialysis than controls and is predominantly located in a linear fashion in the intima of the arteries.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1685

**Seasonal and Circadian Variability in Systolic Blood Pressure in Chronic Hemodialysis Patients** Frank Van der Sande,[2] Len A. Usvyat,[1] Jeroen Kooman,[2] Stephan Thijssen,[1] Nathan W. Levin,[1] Peter Kotanko.[1] *[1]Renal Research Institute, NY, NY; [2]Maastricht University Medical Centre, Maastricht, Netherlands.*

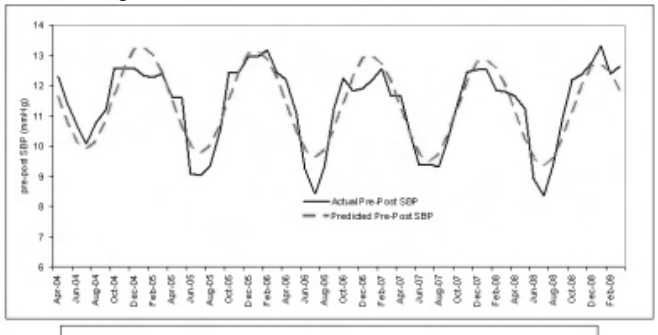
In the hemodialysis (HD) population, systolic blood pressure (SBP) follows circannual and circadian rhythms. The aim of the present study was to assess seasonal and circadian variations in SBP and intradialytic change in SBP across diverse climatic US regions.

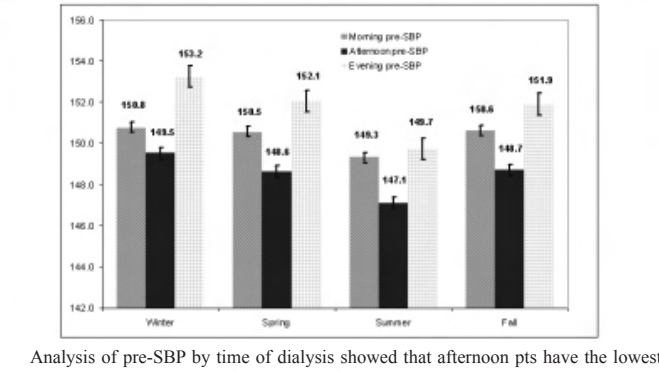
We reviewed records of HD patients (pts) treated in RRI clinics b/n Apr 1, 2004 and Mar 31, 2009. Seasons were defined on calendar basis. Intradialytic change in SBP (ΔSBP) = pre-SBP – post-SBP.

Cosinor analysis was conducted to test for seasonality in pre-SBP and ΔSBP. RRI clinics were grouped in distinct major climate groups: continental, mediterranean, and subtropical. Consideration was given to the dialysis shift (morning, afternoon, evening).

10,303 pts were studied (55% male, 49% black, avg age [stdev]: 60.5 [15.5] yrs). Across all climatic zones, pre-SBP was highest in winter (mean [95% CI]): continental (150.4 [0.15]), mediterranean (146.3 [1.08]), subtropical (152.0 [0.72]). Pre-SBP was consistently lowest in summer: continental (148.4 [0.15]), mediterranean (143.2 [1.04]), subtropical (151.0 [0.74]).

Cosinor analysis demonstrated a seasonal component of pre-SBP and ΔSBP. The drop in ΔSBP was largest in winter and smallest in summer.





Analysis of pre-SBP by time of dialysis showed that afternoon pts have the lowest pre-SBP across seasons & evening pts have highest pre-SBP.

This study demonstrates a significant seasonal influence on pre-SBP and ΔSBP in chronic HD pts with the largest intradialytic SBP drop in winter and the smallest in summer. Evening pts have highest pre-SBP while afternoon pts have lowest pre-SBP. Taken together, evening pts in the winter experience the highest drop in SBP during txt while afternoon summer pts experience the smallest intradialytic drop in SBP.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1686

**Effects of Aliskiren on Blood Pressure and the Predictive Biomarkers for Cardiovascular Disease in Hemodialysis-Dependent Chronic Kidney Disease Patients with Hypertension** Shiho Hanawa, Yoshiyuki Morishita, Junko Chinda, Eiji Kusano. *Nephrology, Jichi Medical University, Shimotsuke, Tochigi, Japan.*

The renin-angiotensin-aldosterone system (RAS) plays pivotal roles in the pathogenesis of hypertension and inflammation both are major risk factors for cardiovascular disease (CVD) in hemodialysis-dependent chronic kidney diseases (HDD-CKD) patients. In this study, we assessed the efficacy of a direct renin inhibitor, aliskiren, on blood pressure (BP) and CVD predictive biomarkers, such as brain natriuretic peptide (BNP), high-sensitivity C-reactive protein (hs-CRP), and diacron-reactive oxygen metabolite (d-ROM) in hypertensive HDD-CKD patients. Thirty hypertensive HDD-CKD patients were assigned to receive aliskiren (150mg) orally once daily with their existing antihypertensives. After 8 weeks, aliskiren treatments reduced systolic blood pressure (SBP) from 169.0±20.1 mmHg to 153.7±19.6 mmHg ($p< 0.001$) and diastolic blood pressure (DBP) from 78.1±12.0 mmHg to 73.0±13.6 mmHg ($p=0.048$), respectively. RAS was suppressed by 8 weeks aliskiren treatment as follows: PRA (from 3.6±4.0ng/ml/hr to 1.0 ±1.5ng/ml/hr ($p=0.004$)), angiotensin I (from 1704.0±2580.9 pg/ml to 233.7±181.0 pg/ml ($p=0.009$)), angiotensin II (from 70.2±121.5 pg/ml to12.4±11.5pg/ml ($p=0.022$)) and aldosterone (from 107.9±148.0 pg/ml to 73.1±34.6pg/ml (N.S)). The biomarkers for CVD were inhibited by 8 weeks aliskiren treatment as follows: BNP (from 362.5±262.1pg/ml to 300.0±232.0pg/ml ($p=0.043$)), hs-CRP (from 6.2±8.1 mg/l to 3.5±3.7 mg/l ($p=0.022$)) and d-ROM (from367.0±89.8 U.CARR to 328.3±70.9 U.CARR ($p=0.022$)). These effects of antihypertensives, blockade of RAS and inhibition of biomarkers for CVD by aliskiren were detected in HDD-CKD patients regardless of the combination with ACEIs and/or ARBs. Furthermore, the inhibition levels of biomarkers for CVD by aliskiren were independent of the decreased levels of SBP and DBP. These results suggested that aliskiren was effective for BP control and may have cardiovascular protective effects independent of its blood-lowering effect in hypertensive HDD-CKD patients.

### F-PO1687

**Serum Uric Acid Is Associated with Hypertension in Pediatric Dialysis Patients** Douglas M. Silverstein,[1] Poyyapakkam Srivaths,[2] Asha Moudgil,[1] Stuart Goldstein,[3] Daniel I. Feig.[2] *[1]Pediatric Nephrology, Children's National Medical Center, Washington, DC; [2]Pediatric Nephrology, Baylor College of Medicine, Houston, TX; [3]Pediatric Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

**Background:** Elevated serum uric acid (UA) is associated with hypertension (HTN). The role of such an association in children on chronic dialysis and after renal transplant (TX) is not known.

**Methods:** We assessed the association of serum UA with blood pressure (BP) in 46 children receiving maintenance hemodialysis (HD), 17 receiving peritoneal dialysis (PD) and 34 patients with a stable renal TX.

**Results:** UA levels were similar in HD (6.8±0.2) and PD (6.5±0.3 mg/dl) patients, and the levels in both groups were significantly higher compared to TX recipients (5.2±0.2, mg/dL; $p<0.0001$). A negative relationship was observed between UA and dialysis vintage ($r= -0.35$, $p=0.005$) in all dialysis patients and weekly Kt/V in PD patients ($r= -0.52$, $p=0.03$). In TX patients, UA levels were inversely related to GFR ($r= -0.54$, $p=0.0007$) and positively associated with time since TX ($r=0.40$, $p=0.02$). Systolic BP (SBP) percentile was significantly higher in HD compared to TX patients (88.6±2.4 versus 72.4±3.3, $p=0.0004$). Pre-treatment SBP percentile was associated with a high UA level (>6 mg/dl) in HD patients only (91.9±2.3 versus 79.3±5.8, $p=0.01$). SBP and DBP percentiles were 10 and 15% lower, respectively, in PD patients with UA level ≤6.0 mg/dl compared to what those with UA level >6 (p=ns).

**Conclusions:** 1) UA levels are higher in dialysis versus TX patients; 2) UA levels increase with dialysis vintage and time since TX, perhaps related to decreasing residual renal function in dialysis and decreasing GFR in TX patients; 3) UA levels are associated with high BP in HD but not in PD or TX patients.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1688

**The Effect of L-Carnitine Supplementation on the Arterial Stiffness of Patients on Hemodialysis** Botond Csiky,[1,2] Istvan Wittmann.[2] *[1]FMC Dialysis Center, Pecs, Hungary; [2]Nephrological Center and 2nd Dept. of Medicine, University of Pecs, Pecs, Hungary.*

Hypothesis and objectives

The most common cause of morbidity and mortality in patients on chronic hemodialysis is cardiovascular disease. According to data from clinical studies, structural and functional alterations of the large arteries are contributing to the high cardiovascular mortality of these patients. A well accepted way for examining the stiffness of the large arteries is measuring the augmentation index (AIx).

L-carnitine supplementation in hemodialysis patients has beneficial effects on lipid alterations and is improving cardiac function. There is no data on the effect of L-carnitine supplementation on the arterial stiffness.

The aim of the present study was to evaluate the effect of L-carnitine supplementation on the AIx of hemodialysis patients.

Patients and methods

Stable chronic hemodialysis patients (n=22, age=59±13 years, male/female: 14/8) were supplemented with L-carnitine. 11 patients were normotensive, 11 patients were treated hypertensives. The patients medical and dialysis treatment was unchanged during the study period. Renal replacement therapy: hemodiafiltration 3x4 hours weekly using polysulphone membranes. L-carnitine supplementation: 1000 mg iv, after each dialysis treatmet for 9 weeks. Blood pressure measurements were performed with calibrated automatic devices. AIx was measured by applanation tonometry (SphygmoCor, AtCor Inc) prior to the respective dialysis treatment, before L-carnitine supplementation was started and at the end of the 9th week of supplementation.

Results

Predialysis blood pressure measured at the beginning of the carnitine supplementation period and at its end was unchanged (129.3±18.9/76.4±10.9 vs 127.7±12.7/75.2±10.4 mmHg). The AIx was significantly lower at the end of the L-carnitine supplementation period than before it (30.24±14.18% vs 35.86±10.49%; p<0.05).

Conclusions:

L-carnitine supplementation is decreasing the stiffness of the large arteries in chronic hemodialysis patients. Besides its effect on lipid homeostasis and cardiac function, L-carnitine supplementation may decrease the cardiovascular morbidity and mortality of these patients by improving their vascular stiffness.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1689**

**Serum Osteoprotegerin Level and Vascular Stiffness in Hemodialysis Patients** Jung Eun Lee, Sung Jin Moon, Jwa-Kyung Kim, Hye Rim An, Yong Kyu Lee, Sung-Kyu Ha, Hyeong Cheon Park. *Internal Medicine, Yonsei University College of Medicine, Seoul, Korea.*

Vascular calcification and increased vascular stiffness is a frequent finding in uremic patients. Osteoprotegerin (OPG), a soluble decoy receptor of the osteoclast activator, acts as an important regulatory molecule in vascular calcification. Increased OPG levels have been associated with stiffening of the large vessel walls, that may contribute to high cardiovascular mortality observed in hemodialysis (HD) patients. This study was carried out in order to evaluate the risk factors of vascular stiffness and the link between OPG and vascular stiffness in HD patients. We enrolled 97 HD patients. Baseline demographic and biochemical parameters, including calcium phosphate metabolism, were collected prior to a midweek dialysis at the time of arterial stiffness measurements. Arterial stiffness was measured by pulse wave velocity (PWV) using an automated device (VP-2000, Colin Co. Ltd., Japan). Vascular calcification score (VCS) was evaluated using plain radiographs of pelvis and hands (score up to 8) as done by Adragao et.al.(Nephrol Dial Transplant, 2004). Serum OPG level was measured by ELISA kits (R&D systems). We divided two groups according to median value of heart-femoral PWV (1178 cm/s). Higher PWV group was older (59.0±10.8 vs. 54.0±13.2 years, p=0.042), and had more male (67.3 vs. 43.8 %, =0.019) and more DM patients (77.6 vs. 43.8 %, p=0.001), higher DM duration (118.1±124.7 vs. 59.7±107.5 months, p=0.017), lower cholesterol (128±27 vs. 142±37 mg/dL, p=0.033), lower HDL-cholesterol (36±8 vs. 42±14 mg/dL, p=0.011) and more severe VCS patients (41.7 vs. 12.8%, p=0.020). Pulse wave velocity positively correlated with age (r=0.319, p=0.001), DM duration (r=0.329, p=0.001), serum OPG level (r=0.300, p=0.003), and VCS (r=0.343, p=0.001). Multiple linear regression analysis revealed that DM (β=223.9, p=0.007), serum OPG (β=0.081, p=0.012), and moderate-severe VCS (β=155.5, p=0.050) were independently associated with PWV. In onclusion, our data show that increased serum OPG level as well as DM status and severe VCS closely associated with increased vascular stiffness in HD patients.

**F-PO1690**

**Evaluating the Utility of Ambulatory Blood Pressure Monitoring in Kidney Transplant Recipients** Kevin C. Wen, Sita Gourishankar. *Department of Medicine, University of Alberta, Edmonton, AB, Canada.*

PURPOSE

Hypertension is a major risk factor for graft failure and cardiovascular disease in kidney transplant recipients(KTX). We aim to assess whether 24 hr ambulatory blood pressure monitoring(ABPM) is superior to clinic blood pressure measurement(CBP) in a cohort of KTX.

METHODS

We performed 24 hr ABPM(Spacelabs) in 244 prevalent KTX, transplanted between 1972 and 2007. CBP values were obtained at the visit closest to day of ABPM. Pearson correlations and linear regression were used to compare CBP and ABPM.

RESULTS

The average clinic SBP was 137.09±19.38mmHg, and DBP was 79.89±10.51mmHg. The ABPM average SBP was 131.34±15.35mmHg and DBP was 75.37±8.8mmHg; daytime ABPM average SBP was 133.54±14.97mmHg and DBP 77.36±9.09mmHg. The correlations between CBP, 24 hr ABPM and daytime ABPM are poor and the range of differences are substantial(Figure 1). CBP measurements overestimate both 24 hr and daytime ABPM by linear regression analysis(p<0.001). 37(15%) patients had increased night-time mean arterial pressure(MAP) and met criteria for "non-dipping". Graft function was not found to be associated with night-time decline in MAP.

CONCLUSION

In this largest study to date in KTX blood pressure monitoring, we found that CBP frequently overestimates ABPM, highlighting the prevalence of white-coat hypertension. The improved accuracy of ABPM will decrease overprescribing of BP medications to avoid hypotension, drug interactions, and non-adherence. In contrast, identifying the nocturnal "non-dippers", not evident by CBP, facilitates appropriate management, as under-treatment of hypertension could lead to accelerated graft dysfunction, cardiovascular disease and mortality. Finally, graft function is not associated with night-time decline in MAP as suggested by previous studies. These data suggest the improved accuracy of 24 hr ABPM is beneficial for BP monitoring in KTX.

| Clinic BP (mmHg) | | ABPM (mmHg) | Correlation | Difference (mmHg) |
|---|---|---|---|---|
| SBP | 137.09±19.38 | Day 133.54±14.97 | 0.555(p<0.001) | -3.56±16.67 (-56 to 57) |
| | | 24 Hour 131.34 ±15.35 | 0.535(p<0.001) | -5.75±17.11 (-64 to 54) |
| DBP | 79.99±10.51 | Day 77.36±9.09 | 0.504(p<0.001) | -2.53±9.24 (-37 to 31) |
| | | 24 Hour 75.37±8.8 | 0.481(p<0.001) | -4.62±9.98 (-37 to 40) |

**F-PO1691**

**Suppression of the Nitric Oxide Pathway in Metastatic Renal Cell Patients Receiving VEGF-Targeted Therapy** Emily S. Robinson,[1] Eliyahu V. Khankin,[2] Mallika D. Dhawan,[1] Miranda Jo Rogers,[3] Toni K. Choueiri,[3] S. Ananth Karumanchi,[2] Benjamin D. Humphreys.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Beth Israel Deaconness Medical Center, Boston, MA; [3]Dana Farber Cancer Institute, Boston, MA.*

**Background**: Hypertension (HTN) and albuminuria are common side effects of vascular endothelial growth factor (VEGF) targeted therapy. The mechanism of HTN in humans receiving these drugs is unknown. We hypothesized that it is caused by suppression of VEGF-mediated vasodilation via the nitric oxide (NO) and prostacyclin pathways.

**Methods**: Urine was collected from 80 patients with metastatic renal cell carcinoma (mRCC) from 2002-2009, 40 at baseline and 40 on VEGF inhibitors. Urinary albumin:creatinine ratio (ACR), nitric oxide (NO) and its downstream effector, cyclic GMP (cGMP), and biomarkers along the prostaglandin pathway: prostaglandin E2 (PGE2), 6-keto PGF 1α, and cyclic AMP (cAMP) were measured and normalized to creatinine. T-tests and Wilcoxon rank sum tests were used to compare linear data.

**Results**: The mean age in both groups was 61.8 years and 76% were male. cGMP/Cr was suppressed in patients on VEGF inhibitors (0.28 pmol/ug vs. 0.39 pmol/ug; p=0.01). There was a trend toward suppression of NO/Cr (0.46 umol/mg vs. 0.62 umol/mg; p=0.09). Both comparisons were strengthened when patients on bevacizumab (a VEGF ligand inhibitor) were excluded and only small molecule tyrosine kinase inhibitors (sunitinib and sorafenib) were analyzed (for cGMP/Cr, p=0.003; for NO/Cr, p=0.01). PGE2, 6-keto PGF1α, and cAMP did not differ between the groups. In patients on VEGF inhibitors, systolic blood pressure rose from 126.7mmHg at baseline to 138.6mmHg on the medications (p=0.0009). The ACR was higher in patients on VEGF inhibitors than those not on VEGF inhibitors (median 18.4mg/g vs. 4.6mg/g; p=0.009).

**Conclusions**: The NO pathway is suppressed in mRCC patients on VEGF targeted therapy suggesting that inhibition of VEGF-mediated eNOS activation may be the primary cause of HTN. These findings support the need for prospective studies exploring these mechanisms and their possible utility as biomarkers of efficacy and toxicity in patients on VEGF inhibitors.

**F-PO1692**

**Page Kidney: A Forty-Year Single Centre Experience** Andrew Smyth,[1] Bjorg Thorsteinsdottir,[1] Guilherme Oliveira,[2] Garvan Kane,[3] Vesna D. Garovic.[1] *[1]Division of Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [2]Division of Cardiology, MD Anderson, Houston, TX; [3]Division of Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

**Introduction**

Initial clinical description of Page Kidney (PK), a form of renin mediated hypertension, included athletes who became hypertensive after flank trauma causing renal subcapsular hematoma. Subsequently several non-traumatic etiologies were identified. In this study, we review and contrast presenting features, clinical findings, and treatment outcomes among patients with renal subcapsular hematoma leading to hypertension.

**Methods**

We reviewed demographic and clinical data for patients at our institution from 1960-2000 with hypertension attributable to renal hematoma confirmed either by diagnostic imaging or post-operative surgical pathology.

**Results**

Twenty-seven patients with PK and a mean age of 40.8±15.6 years were included. Etiologies included iatrogenic (n=10), spontaneous hemorrhage (n=9) and trauma (n=8). Trauma patients were younger(p=0.017) and hematuria occurred more commonly in spontaneous and iatrogenic cases(p=0.004). GFR at presentation was similar in all groups, as was systolic (SBP) and diastolic (DBP) blood pressures (Table). Surgical treatment was employed in 70.4%(n=19), 42.1%(n=8) of spontaneous, 36.8%(n=7) iatrogenic and 21.1%(n=4) trauma(p=0.231). Post-treatment GFR and DBP were similar in all groups, but SBP was lower in trauma patients (Table).

| Parameter / Etiology | Iatrogenic | Spontaneous | Trauma | p-Value |
|---|---|---|---|---|
| MDRD GFR at presentation (mL/min/1.73.m2) | 31.5 | 37.4 | 63.2 | 0.089 |
| SBP at presentation (mmHg) | 173.2 | 175.2 | 161.8 | 0.277 |
| DBP at presentation (mmHg) | 100.8 | 102.7 | 103.1 | 0.949 |
| MDRD GFR after intervention (mL/min/1.73m2) | 32.8 | 43 | 59.7 | 0.213 |
| SBP after intervention (mmHg) | 160.4 | 167.6 | 134 | 0.049* |
| DBP after intervention (mmHg) | 95.2 | 95 | 87.6 | 0.488 |

**Conclusion**

Among patients with hypertension and subcapsular hematoma, we did not observe significant differences in presenting features, pathological findings, and treatment modalities based on etiology, but those with trauma etiology had improved SBP control after intervention.

**The Clinical Features of Renal Infarction: Single Center, Retrospective Study** Dong-Won Lee, Dong Jun Park, Hyun-Jung Kim, Hyeon Jeong Lee, Jong Woo Seo, Se-Ho Chang. *Internal Medicine, Gyeongsang National University Hospital, Jinju, Republic of Korea.*

Since acute renal infarction is not a common disease that has nonspecific manifestations and laboratory findings, it is often diagnosed late or even missed. Although there are some reports for clinical characteristics of renal infarction, large scale of studies including many patients is rare. To evaluate clinical features and laboratory findings of the patients with renal infarction, we retrospectively reviewed the medical records of ones who were diagnosed as renal infarction from January, 1995 to April, 2010. We enrolled total 80 patients diagnosed as renal infarction by computer tomography and/or ultrasonography. Male to female ratio was 52:28 and the mean age was 58.6±17.2 years old. Underlying diseases were as follows: cardiovascular disease (61.3%), trauma (6.3%), malignancy associated (5%), post-transplantation of kidney (1.3%), iatrogenic (1.3%), intraabdominal mass associated (2.5%), Buerger's disease (1.3%), diabetes or hypertension (11.3%), no underlying disease (10%). The site of renal infarction was right (40.5%), left (36.7%), both (22.8%) and its magnitude was less than 25% (57.7%), 25% ~ 50% (24.4%), more than 50% (17.9%). Initial symptoms were abdominal pain (90%), anorexia (12.5%), nausea (27.5%), vomiting (23.8%), oliguria (1.3%). Initial signs included abdominal tenderness (76.3%), costovertebral angle tenderness (50.0%), fever (10%), and hypertension (32.5%). Initial abnormal laboratory values showed increased WBC (70.0%) and elevation of AST (66.3%), ALT (48.8%), CK (35.3%), LDH (100%), azotemia (serum creatinine ≥1.4 mg/dL, 21.8%). Proteinuria (68.1%) and hematuria (66.7%) was also manifested in renal infarction. The magnitude of renal infarction is positively correlated with presence of azotemia (≥1.4 mg/dL of serum creatinine level, $P < 0.05$). Maximal creatinine level was positively correlated with the magnitude of renal infarction ($P < 0.05$). Because acute renal infarction is usually associated with underlying diseases or conditions, we should intensify our efforts to find underlying disease. In the case of unknown etiology of renal infarction, treatment of plan remains to be determined.

**Beneficial Effects of ARB Olmesartan on Ambulatory Blood Pressure Profile and Renal Function in Hypertensive Patients with CKD** Mai Yanagi,[1] Yoshiyuki Toya,[1] Tetsuya Fujikawa,[2] Hiroyuki Kobori,[3] Satoshi Umemura.[1] *[1]Department of Medical Science and Cardiorenal Medicine, Yokohama City University School of Medicine, Yokohama, Japan; [2]Department of Public Health, Yokohama City University School of Medicine, Yokohama, Japan; [3]Department of Medical and Physiology, Molecular Core in Hypertension and Renal COE, Tulane University Health Sciences Center, New Orleans, LA.*

Objective: In patients with CKD, employing therapeutic strategy to lower blood pressure (BP) and reduce proteinuria is important for a slower progression to kidney failure and a prevention of cardiovascular disease. We examined whether an angiotensin II type I receptor blocker olmesartan would improve ambulatory BP profile in hypertensive patients with CKD. Methods: 46 hypertensive patients with CKD were randomly assigned to the olmesartan treatment group (n=23) or the control treatment group (n=23). At baseline and 4 months after the treatment, 24-h ambulatory BP monitoring and measurements of biochemical parameters were performed. We analyzed the after-treatment/ baseline ratio (A/B ratio) of the ambulatory BP values and renal function parameters in the olmesartan group and the control group respectively, and made a comparison between both groups. Results: There were no significant differences in baseline parameters. The A/B ratio of 24-h ambulatory systolic BP values in the olmesartan group was significantly lower than that in the control group.(0.93±0.08 versus 0.99±0.08; $P$=0.021) There was no significant difference in the A/B ratio of daytime systolic BP values between both groups. However, the A/B ratio of nighttime systolic BP values in the olmesartan group was significantly lower than that in the control group (0.91±0.10 versus 1.00±0.08; $P$=0.006). Furthermore, treatment with olmesartan resulted in a significant decreases in the A/B ratios of proteinuria and urinary type IV collagen excretions. (0.72±0.41 versus 1.45±1.48; $P$=0.036 and 0.87±0.42 versus 1.48±0.87; $P$=0.007) Conclusion: Olmsartan improves diurnal BP profile by preferential lowering of nighttime BP, which is accompanied by effective reduction of proteinuria in hypertensive patients with CKD.

## F-PO1695

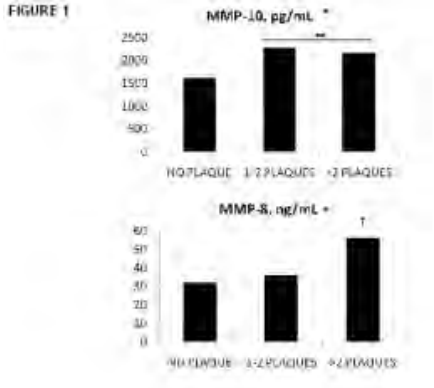
**Serum Matrix Metalloproteinase 10 Is Associated with the Severity of Atherosclerosis in Patients with Chronic Kidney Disease** Blai Coll,[1] Jose A. Rodriguez,[2] Javier Diez,[2] Angels Betriu,[1] Jose M. Valdivielso,[1] Elvira Fernandez,[1] José A. Paramo.[2] *[1]UDETMA, Hospital Arnau de Vilanova, Lleida, Spain; [2]CIMA, University of Navarra, Pamplona, Spain.*

BACKGROUND: Cardiovascular disease is the leading cause of mortality in chronic kidney disease. Matrix metalloproteinases play a major role in atherosclerosis. We hypothesized that alterations in metalloproteinases 8, 10 and their tissue inhibitor 1 can be associated with the severity of atherosclerosis in kidney disease patients.

DESIGN AND METHODS: This is a cross sectional, observational study performed in 111 patients stages I to V, 217 patients on dialysis and 50 healthy controls. The severity of atherosclerosis was estimated with the Atherosclerosis Score, combining the results of ankle-brachial index and carotid ultrasound. Serum levels of metalloproteinases 8, 10 and tissue inhibitor 1 were measured by ELISA.

RESULTS: Metalloproteinases 8,10 and tissue inhibitor 1 levels were significantly ($p<0.001$) increased in patients than controls, being higher in patients on dialysis than in earlier stages of the disease ($p<0.01$). The severity of atherosclerosis score was also more prevalent in the dialysis group (84.7% ), in whom serum metalloproteinases 8, 10 and tissue inhibitor 1 were also significantly ($p<0.05$) higher.

FIGURE 1



After multivariate analysis, metalloproteinase 10, dialysis, C-reactive protein, age and male gender were associated with increased risk of atherosclerosis.

CONCLUSION: Chronic kidney disease patients exhibit elevated levels of circulating metalloproteinase 10, which was independently associated with the severity of atherosclerosis and may represent a new biomarker of atherosclerotic disease.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1696

**Soluble TWEAK as a Novel Biomarker of Atherosclerotic Burden in Subjects with Chronic Kidney Disease** Blai Coll,[1] Jesus Egido,[2] Angels Betriu,[1] M. Vittoria Arcidiacono,[1] Jose M. Valdivielso,[1] Elvira Fernandez.[1] *[1]UDETMA, Hospital Arnau de Vilanova, Lleida, Spain; [2]Vascular Research Laboratory, Fundación Jiménez Diaz, Madrid, Spain.*

BACKGROUND:

Chronic kidney disease (CKD) patients present higher rates of atherosclerosis than subjects with normal kidney function.

Soluble TNF-like weak inducer of apoptosis (sTWEAK) has been inversely related to endothelial function in CKD patients. However, there is no data on the relationship between sTWEAK and atherosclerostic burden in CKD.

DESIGN AND METHODS:

Case-control, cross sectional, observational study. Study population consisted in: 195 patients in dialysis; 58 at CKD stages I-III, 86 at IV-V and 86 controls. Control was defined as normal kidney function, no diabetes and without atherosclerosis. Carotid atherosclerosis was assessed measuring carotid intima-media thickness and identifying carotid plaques. Ankle-brachial index was used to diagnose peripheral atherosclerosis. Plasma sTWEAK concentrations were determined in samples after overnight fasting.

RESULTS:

CKD patients were significantly older than controls (66(13) vs. 54(8), $p<0.001$), and with lower values of body mass index, total, HDL and LDL cholesterol (all $p<0.001$). 126 (37.2%) CKD patients were male and most of them were receiving lowering blood pressure drugs (72.3%) and statins (45%). According to previous reports, sTWEAK levels were significantly reduced in CKD patients compared to controls (315.05 (79) pg/mL vs 401.12 (110); $p<0.05$). Interestingly, patients with more severe atherosclerosis presented a higher reduction in sTWEAK concentrations (311 (79) vs 367 (104); $p<0.001$). In the multiple

linear regression analyses, the variables influencing sTWEAK levels were severity of atherosclerosis (B coefficient -24, p=0.03), previous cardiovascular disease (B coefficient 23, p=0.02) and chronic kidney disease (B coefficients ranging from -93 to -63, p<0.001).

CONCLUSION

A significantly reduction in sTWEAK plasma levels were observed in CKD patients with more severe atherosclerosis. Our results could indicate that sTWEAK is a novel biomarker of atherosclerotic burden in CKD patients

**F-PO1697**

**Non-Dipper Status and Left Ventricular Hypertrophy (LVH) May Be the Risk Factors for the Development of Chronic Kidney Disease (CKD) in Non-Diabetic Hypertensive Patients** Hye Rim An, Jung-Hwa Ryu, Mina Yu, Seung-Jung Kim, Kyu Bok Choi, Dong-Ryeol Ryu. *Division of Nephrology, Department of Internal Medicine, School of Medicine, Ewha Womans University, Seoul, Korea.*

**Purpose:** In this study, we hypothesized that non-dipper status would be associated with the development of CKD in patients treated with antihypertensive medications.

**Methods:** This study included 102 non-diabetic hypertensive patients with estimated glomerular filtration rate(eGFR)≥60ml/min/1.73m$^2$. Baseline demographic and laboratory data were collected and 24-hr ambulatory blood pressure monitoring(ABPM) and echocardiogram were performed at the beginning of the study, and the levels of serum creatinine were followed up. Non-dippers were defined if their nocturnal systolic BP did not decrease by ≥10% compared to the average daytime BP, and CKD was defined as a sustained decrease in eGFR of <60 ml/min/1.73m$^2$.

**Results:** The average duration of follow-up was 51.7±12.5 months. When participants (mean age 56.0±10.4 years, 39 men, initial eGFR 81.4±16.1ml/min/1.73m$^2$) were divided into two groups as dippers (n=60) and non-dippers(n=42), there were no significant differences in age, duration of hypertension, mean fulltime BP by 24-hr ABPM, urine albumin/creatinine(A/C) ratio, and eGFR between two groups. During the follow-up period, an eGFR < 60ml/min/1.73m$^2$ occurred in 11 patients, and the incidence of CKD was higher in non-dippers compared to dippers [8(7.8%) vs. 3(2.9%) patients, p<0.05]. When comparisons were made between patients who developed CKD and not, patients with CKD had higher baseline urine A/C ratio (52.3±58.6 vs. 17.8±29.3mg/g, p<0.05), higher prevalence of LVH [3(27.3%) vs. 5(5.5%) patients, p<0.05) and lower serum HDL-cholesterol (41.7±8.3 vs. 50.4±12.4mg/dl, p<0.05). In a multiple logistic regression analysis, non-dipper status (OR 6.91), the presence of LVH (OR 35.4), and initial eGFR (OR 0.85) were independent risk factors for the development of CKD.

**Conclusion:** These findings suggest that non-dipper status and LVH may be the therapeutic targets for the prevention of the development of CKD in non-diabetic hypertensive patients.

**F-PO1698**

**Ambulatory Blood Pressure Monitoring: Role in Patients with Chronic Kidney Disease and Hypertension** Erdal Sarac. *Internal Medicine, St Elizabeth Hospital, Youngstown, OH.*

Hypertension is present 80-90% patients with CKD with increased risk of cardiovascular events in this population**.** Most CKD patients require multiple BP medications and only 11% of patients reach target BP goal of < 130/80 mmHg. We performed a retrospective study to evaluate the benefits of 24 hour Ambulatory Blood Pressure Monitor (ABPM) in this population.

A retrospective chart review was undertaken of non dialysis (stage 3-5) CKD patients (n=102) with hypertension who underwent 24 ABPM study. The patients were seen at an outpatient CKD clinic and had both office BP measurement and subsequent 24 hour ABPM study. Demographics, past medical history, labs, and number of BP medications were included. Statistical analysis was undertaken using SPSS 17 with *t* test and *chi square*. Office BP was assessed by staff twice with appropriate manual BP cuff in one visit and classified as hypertensive or normotensive with cut off BP of 140/90 mm Hg. 24 hour ABPM was performed, using Welch Allyn 6100*: a)* Average day time, night time and 24h BPs were recorded b) classified as hypertensive ( true HTN, masked HTN) if 24h average BP>135/85 *c)* classified as normotensive (white coat HTN, normotensive) if 24h average BP <135/85 *d)* dippers and non-dippers as per definition.

The results revealed that Office BP misdiagnosed BP in 42% cases and could not identify white coat HTN and masked HTN. As much as 51% of hypertensive patients with Office BP measurement turned out to have white coat HTN (WCH)**.** In addition, 24% normotensive patients with Office BP measurement turned out to have masked HTN with a prevalence of 8%. Non-dipper status prevalence was 58%, concordant with literature and Correlated with advance age (p<0.05).

In summary, office BP measurement in patients with CKD is not sufficient. Combining office BP and ABPM can avoid misclassification of HTN, therefore can avoid under treatment of masked HTN or overtreatment of WCH. Therefore, we recommend use of 24 hour ABPM study in hypertensive CKD patients to achieve target BP and improve cardiovascular risk in this patient population.

**Modifiable Risk Factors for Incident Hypertension Are Attenuated in Older Women** Lisa J. Cohen, Gary C. Curhan, John P. Forman. *Nephrology, Brigham and Women's Hospital, Boston, MA.*

PURPOSE OF STUDY: Because the pathobiology of hypertension changes with advancing age, we investigated whether diet and lifestyle factors that strongly influence the risk of new-onset hypertension in younger and middle aged women would have similarly robust associations in an older population.

METHODS: We used the Nurses' Health Study I to perform a prospective cohort study in 87,001 women without a baseline history of hypertension**.** Person-time and new cases of hypertension were measured during 24 years of follow-up, and stratified into three age groups (under 50 years, 50-60 years, over 60 years). Cox proportional hazard regression models were used to calculate hazard ratios (HR) and 95% confidence intervals (CI) for six modifiable lifestyle factors. Attributable fractions were calculated to estimate the percent of hypertension that could hypothetically be avoided had all women in a given age group adhered to various combinations of healthy lifestyle factors. We tested appropriate interaction terms to determine whether the HR for individual risk factors and the attributable fractions varied significantly by age group.

RESULTS: During 1,184,602 total person-years of follow-up, 37,348 incident cases of hypertension occurred. We found significant age-related decreases in the associations between BMI, heavy (>30 g/week) alcohol intake, and analgesic use with incident hypertension. For instance, compared to a women with a BMI<25, a woman under age 50 with a BMI>30 had a 5.35-fold greater risk of developing hypertension. For women between age 50 and 60, the HR was 3.17. In women over 60, the HR was 2.14. We also found that attributable fractions for a combination of healthy lifestyle factors became significantly weaker in the older age groups. For example, had all cohort participants had both a normal BMI (<25) and a high degree of physical activity, then 65% of hypertension could hypothetically have been prevented among women <50 years old, but this fraction decreased to 52% for women aged 50-60 years, and to 42% for women older than 60 years.

CONCLUSION: The association between classic risk factors for incident hypertension may be attenuated in older women.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1700**

**Resistant Hypertension: A CKD Clinic Intervention Program To Improve Patient Care** Aashish K. Pandey, Susan P. Steigerwalt, Susan M. Szpunar, Joel Topf, Keith A. Bellovich, Robert Provenzano. *Nephrology and Hypertension, St. John Hospital and Medical Center, Detroit, MI.*

Twenty percent of patients treated in a CKD clinic can be labeled as having resistant hypertension (RH) yet are often overlooked. RH is defined as blood pressure that remains above goal in spite of the concurrent use of three antihypertensive agents of different classes. Having to manage multiple co-morbid conditions in this clinic setting leads to incomplete evaluations for the causes of RH. Checklist reminder systems improve adherence to treatment guidelines. We investigated whether a checklist reminder system and educational interventions improve the rate of completing a thorough evaluation of CKD patients for the causes of resistant hypertension.

After analysis of our database of clinic visits for CKD stages 2-4 from January 2007-December 2009, 130 patients were identified with RH by the above criteria, who had three or more office visits within 18 months, which served as our baseline cohort. The interventions consisted of : a checklist reminder to the provider placed on each patient chart; BPTru™ cuffs were utilized for measuring seated and standing blood pressure for each patient visit; and patient teaching materials on home blood pressure monitoring, physical activity and diet were readily made available in the clinic.The Epworth sleepiness scale was attached to each new patient chart.

A preliminary result 3 months subsequent to these interventions has identified 31 RH patients out of a total of 133 patients (23.3%).

A comparison between baseline data and post intervention are as follows:

Charateristics

| | baseline(n=130) | post intervention (n=31) |
|---|---|---|
| Standing Clinic BP | 8.5% | 80.6% |
| Home BP utilized | 8.8% | 93.5% |
| Meds increased at visit | 23.6% | 64.5% |
| OSA considered | 7.9% | 77.4% |
| Blood aldosterone/renin | 4.6% | 44.8% |
| 24 hour urine Na | 1.5% | 41.9% |
| other secondary evaluation | 35% | 40 % |

As this is an interim analysis, statistical testing will not be performed until the end of the intervention. Our preliminary results show dramatic improvement in these strategies to improve the evaluation and management of resistant hypertension by staff education and provider checklist reminder systems.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1701**

**Decreased eGFR without Evidence of Kidney Damage in Women with a History of Gestational Hypertension (GH)** Catherine M. Brown, John J. Walshe. *Department of Nephrology, Beaumont Hospital, Dublin 9, Ireland.*

**Study Objective:** Preeclampsia has been limked to an increased risk of subsequent ESRD.[1] Our aim was to assess renal function in a group of women 2 years post partum with a previous history of gestational hypertension (GH) in pregnancy and women with uncomplicated pregnancies (controls).

**Methods:** A cross sectional observational study; women with a previous history of GH (n=33) and a group of women with a history of normal BP throughout pregnancy (n=41). Gestational hypertension was defined as a systolic BP of at least 140 mmHg and/or a diastolic BP of at least 90 mmHg on two occasions at least 6 hours apart after the 20th week of gestation, without proteinuria (< 0.3 gm in a 24 hour urine collection). At 2 years post partum, levels of serum creatinine (umol/l), eGFR (using IDMS-traceable MDRD study equation), urinalysis, total cholesterol, BMI and age were recorded. Applanation tonometry was used to record central blood pressure.

**Results:**

Mean values (± SD)

| | Control (n=41) | GH (n=33) | ANOVA p-value |
|---|---|---|---|
| Age (years) | 33 ± 3.7 | 33 ± 4.2 | p= 0.8 |
| BMI (kg/m²) | 24 ± 3.4 | 30 ± 7.2 | p<0.001 |
| Central Systolic BP mm Hg | 109 ± 8.1 | 123 ± 16 | p< 0.001 |
| Central Diastolic BP mm Hg | 71 ± 6.2 | 80 ± 9 | p< 0.001 |
| Creatinine (umol/l) | 67 ± 11 | 74 ± 10 | p = 0.009 |
| eGFR (MDRD) | 92 ± 17 | 82 ± 12 | p= 0.008 |
| Total cholesterol ( mmol/l) | 4.5 ± 0.7 | 5.2 ± 0.8 | p= <0.001 |

Urinalysis was negative in all cases. After adjustment for age, BMI and central systolic BP, differences in serum creatinine remained significant between the GH and control group (p= 0.03) as did eGFR between the two groups (p=0.04).

**Conclusions:** Women with a history of GH have a higher serum creatinine and a lower eGFR compared to controls. Although they have no obvious kidney damage, this group of women with a history of GH, may be at increased risk of future kidney disease and require ongoing monitoring. Long term studies of women with gestational hypertension are warranted.

### Gene Polymorphisms Contributing to Hypertension in IgA Nephropathy

Maki Shinzawa,[1] Ryohei Yamamoto,[1] Yasuyuki Nagasawa,[1] Tatsuya Shoji,[2] Noriyuki Okada,[2] Atsushi Yamauchi,[3] Yoshiharu Tsubakihara,[2] Enyu Imai,[1] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Department of Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Department of Nephrology and Hypertension, Osaka General medical Center, Osaka, Japan; [3]Department of Nephrology, Osaka Rosai Hospital, Sakai, Osaka, Japan.*

**Background:** Hypertension (HT), which is one of the major risk factors for chronic kidney disease, has been reported to be affected by multiple genetic and environmental factors. The aim of the present study was to identify genetic factors associated with HT in patients with IgA nephropathy (IgAN), the most common glomerulonephritis in the world, with its onset mainly in younger population.

**Design and setting:** Multicenter cross-sectional study.

**Patients:** 240 patients aged 15-50 years with urinary protein ≥0.25g/day among 1132 patients diagnosed as IgAN by renal biopsy in three major nephrology centers in Osaka, Japan between 1990 and 2005.

**Outcome:** HT defined as ≥140 and/or 90mmHg of systolic and diastolic blood pressure or use of antihypertensives at renal biopsy.

**Independent variables:** 28 polymorphisms with the frequency of minor genotype ≥10% among 100 candidate polymorphisms and clinical characteristics at diagnosis: age, gender, BMI, eGFR, urinary protein, total cholesterol, and uric acid.

**Statistics:** We assessed associations between HT and polymorphisms using $\chi^2$test in dominant and recessive models. We identified polymorphisms associated with HT even after adjustment for clinically relevant factors in multivariate logistic regression models.

**Results:** Baseline characteristics: age 33(24-43) years (median (interquartile range)), male 40.4%, systolic and diastolic blood pressure 122±17/76±14mmHg (mean±SD), HT 36.3%, eGFR 79±27mL/min/1.73m², and urinary protein 0.7(0.4-1.3)g/day. Among 28 polymorphisms, *CD14* (-159CC vs. CT/TT P=0.028) and *ACE* (DD vs. DI/II P=0.034) were significantly associated with HT. Multivariate logistic regression models revealed that *CD14* -159CC (Odds Ratio 3.55[95%CI 1.66-7.61]) and *ACE* DD (4.22[1.72-10.3]) were independently associated with HT.

**Conclusion:** *CD14* C159T and *ACE* I/D contributes to HT in IgAN patients.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1703

### Transvenous Biopsies of Kidneys beyond Renal Artery Stenosis Demonstrate Fibrosis Correlated to Reduced Single Kidney Blood Flow but Not Urinary or Blood TGF-beta Levels

Monika L. Gloviczki,[1] Mira T. Keddis,[1] Michael A. Mckusick,[2] Sanjay Misra,[2] Joseph P. Grande,[3] Vesna D. Garovic,[1] Lilach O. Lerman,[1] Stephen C. Textor.[1] *[1]Nephrology and Hypertension, Mayo Clinic; [2]Radiology, Mayo Clinic; [3]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.*

**Background and Methods:** The relationship between post-stenotic kidney fibrosis and blood flow in human atherosclerotic renal artery stenosis (ARAS) is poorly understood. We examined tissue from transvenous kidney biopsies for percent fibrosis (trichrome sections) and immunohistochemical staining for transforming growth factor beta (TGF-beta) in 9 subjects with measured single kidney blood flow (contrast transit on multi-detector CT) and GFR (iothalamate). Renal vein renin, oxygen, and TGF-beta levels were obtained. Biopsies were compared with age, gender and statin matched nephrectomy specimens from patients with total vascular occlusion.

| | Moderate ARAS with biopsy N=9 kidneys | Severe ARAS with nephrectomy N=9 kidneys | |
|---|---|---|---|
| Age (years) | 64.2±3.3 | 62.2±2.9 | NS |
| Creatinine (mg/dL) | 1.1±0.1 | 1.8±0.2 | p<.01 |
| ACE/ARB Rx | 9 | 7 | NS |
| Statin Rx | 3 | 2 | NS |
| Kidney size (long axe in cm) | 10.3±0.5 | 8.9±0.3 | p<.05 |
| Single kidney GFR (mL/min/kidney) | 29.3±6.6 | | |
| GFR/1.73 (mL/1.73m2) | 67.5±8.5 | 42.5±4.9 | p<.05 |

**Results:** The degree of tissue fibrosis in biopsy samples ranged from 4 to 26%. The semi-quantitative TGF-beta staining score was 2.3 (0=0%, 1 <25%, 2 =25-50%, 3 >50%) and despite higher GFR overlapped the range in kidneys with total occlusion. Kidney was smaller in nephrectomy samples. Percentage of renal blood flow in post-stenotic kidney (RBF) was inversely related to the trichrome estimate of fibrosis (R=.84, p=.0093) and the TGF-beta score (R=.77, p=.038). Urinary and venous measurements of TGF-beta did not correlate with blood flow, TGF-beta staining or kidney function in these studies, nor did they differ from patients with essential hypertension.

**Conclusion:** These data demonstrate parenchymal tissue fibrosis and TGF-beta immunostaining in ARAS biopsies are related to reduced blood flow, are manifest before total occlusion, and are not reflected in peripheral blood or urinary levels of TGF beta.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1704

### Seasonal Variation in Endothelial Function and Migration of CD 34+ Cells May Be Due to Changes in Vitamin D Levels

Rajesh Mohandas, Mark S. Segal. *Department of Medicine, University of Florida, Gainesville, FL.*

Seasonal variation in the incidence of heart disease and stroke has been well documented in several multicenter trials. The exact mechanisms that underlie this are unclear, but changes in temperature, pollution, lipids and other mechanisms have been proposed. Low levels of vitamin D have been associated with increased mortality and cardiovascular events. It has also been shown that there are seasonal variations in serum vitamin D levels, even in people living in warmer weather. However, the effect of vitamin D on endothelial function and angiogenesis is unclear. Recently progenitor cells have been isolated from circulation that might have an important role in maintaining endothelial health. We hypothesized that the seasonal variations in endothelial function are the result of variations in vitamin D levels and its effects on bone marrow derived progenitor cells. **Methods:** We utilized data and specimens that were collected prospectively for a study examining the effects of lowering uric acid on hypertension and endothelial function in African Americans. To better delineate a seasonal effect, data was grouped into those collected end of summer (Aug-Sept) and end of winter (Feb-Mar). Endothelial function was assessed by peripheral arterial plethysmography. CD34+ cells were isolated using immunomagnetic beads coated with antibodies to CD 146. Migration of CD34+ was assessed using a Boyden membrane chamber by migration of CD34+ cells towards recombinant human SDF-1. **Results:** Migration of CD34+ were significantly lower at the end of winter compared to end of summer [(2.3 ± 2.08 n=14) vs. ( 8.2 ± 8.8 n=18) p < 0.05)]. Endothelial function as determined by EndoPAT trended to be improved at the end of summer [2.51 ± 0.68 (n=9)] compared to end of winter [2.14 ± 0.56(n=10) p = 0.22]. Mechanistically, when CD34+ cells were treated with exogenous vitamin D3, they showed enhanced migration towards SDF. **Conclusion :** Seasonal variation in vitamin D levels as well as the direct effects of vitamin D on the migration of CD34+ cells suggests that the seasonal changes in endothelial function, are at least in part, due to the direct effect of vitamin D on CD34+ cells.

### Involvement of Matrix Metalloproteinase-2 in the Development of Aortic Calcification in Uremic Rats

Chiaki Kumata,[1] Masahide Mizobuchi,[1] Hiroaki Ogata,[2] Fumiko Kondo,[1] Fumihiko Koiwa,[3] Eriko Kinugasa,[2] Tadao Akizawa.[1] *[1]Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan; [2]Internal Medicine, Showa University Northern Yokohama Hospital, Yokohama, Japan; [3]Division of Nephrology, Department of Medicine, Showa University Fujigaoka Hospital, Yokohama, Japan.*

Background: Vascular calcification is the most important cause of cardiovascular disease in patients with chronic kidney disease (CKD). Medial layer vascular calcification, which is recognized to be an active process (the transformation of vascular smooth muscle cells into osteoblast-like cells), is common in CKD patients, We have recently reported the possibility of interaction between elastin degradation and medial layer vascular calcification *in vitro* (Calcif Tissue Int 2009). Matrix metalloproteinase-2 (MMP-2), which induces the degradation of elastin, has been implicated in the elastic calcification in arteries of CKD patients. However, the precise mechanisms by which elastin degradation interacts with the development of vascular calcification remain to be studied.

Methods: To clarify the mechanisms by which elastin degradation is involved in the development of medial layer vascular calcification in the uremic milieu, we induced aortic medial layer calcification in 5/6 nephrectomized uremic rats (male Sprague-Dawley rats) fed a diet containing high phosphate (1.2%) and lactate (20%). After 8 to 10 weeks, the rats were euthanized for the measurement of serum chemistries and histological analyses.

Results: The uremic rats showed significant increases in blood pressure, serum creatinine, phosphate, and parathyroid hormone levels compared with those of normal rats. Von Kossa staining showed the medial layer aortic calcification in some of uremic rats. In calcified lesions, a decrease in elastin was observed by elastin staining indicating that elastin degradation could occur in the calcified area. In addition, MMP-2 expression determined by immunohistochemistry was observed in the calcified area.

Conclusions: Elastin degradation induced by MMP-2 might be involved in the development of aortic calcification in uremic rats.

**The Selective P2X$_7$ Receptor Antagonist A438079 Ameliorates Vascular Smooth Muscle Cell Calcification *In Vitro*** John William Booth,[1] Jill T. Norman,[1] David C. Wheeler,[1] Robert J. Unwin,[1] Frederick W. K. Tam.[2] *[1]Centre for Nephrology, UCL Medical School, United Kingdom; [2]Imperial College Kidney and Transplant Institute, Imperial College, United Kingdom.*

**Introduction** Vascular calcification (VC) in chronic kidney disease (CKD) is now recognised to involve an active process in the vessel wall, where vascular smooth muscle cells (VSMCs) adopt an osteoblastic phenotype *in situ.* The P2X$_7$ purinoceptor (P2X$_7$R) is an ATP-sensitive, non-selective cation channel with roles in inflammation and cell death; it is also expressed in osteoblasts, where it contributes to normal bone formation. We hypothesized that P2X$_7$R may have a role in the pathogenesis of VC and tested this using an *in vitro* model.

**Methods** Primary human coronary artery VSMCs (TCS Cellworks) at 50-60% confluence were grown for 7 days in normal medium ($Ca^{2+}$ 1.8mM, $PO_4^{2-}$ 1.0 mM) or calcification medium ($Ca^{2+}$ 2.7mM, $PO_4^{2-}$ 2.0 mM), with or without lipopolysaccharide (LPS) 10µg/ml as an inflammatory stimulus, in the absence or presence of the selective P2X$_7$R antagonist A438079 (1, 3, 10, 20µM; Tocris Bioscience). Calcification was assessed qualitatively by phase contrast microscopy. Calcification at day 7 was quantified colorimetrically by the *o*-cresolphthalein complexone method, corrected for cell protein concentration. Expression of P2X$_7$R and the inflammatory cytokine interleukin (IL)-1β mRNA were measured by quantitative RT-PCR.

**Results** High $Ca^{2+}$ and $PO_4^{2-}$ concentration induced calcification compared with normal medium (0.348 µg calcium/µg protein vs 0.016; $p<0.001$). No significant increase in calcification was seen with LPS. Addition of A438079 (10-20µM) led to a marked reduction in calcification (10µM, 0.085 vs 0.348; $p=0.002$). This effect was sustained in the presence of LPS. Both LPS and calcification media induced expression of IL-1β mRNA. A438079 had no effect on expression of this cytokine. No significant change in P2X$_7$R mRNA expression was seen with high $Ca^{2+}$ and $PO_4^{2-}$ medium or LPS, individually or in combination.

**Conclusion** The P2X$_7$R antagonist A438079 reduces calcification significantly in this *in vitro* model. Hence P2X$_7$R appears to be a promising candidate for investigation as a future treatment target for VC in CKD.

**Early Compromised Phosphate Handling in Renal Failure Leads to Vascular Calcification In Vitro and in the Adenine Rat Model of Chronic Kidney Disease** Navid Shobeiri,[1] David P. Beseau,[1] Kristin M. McCabe,[1] Michael A. Adams,[1] Rachel M. Holden.[2] *[1]Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada; [2]Medicine, Queen's University, Kingston, ON, Canada.*

Vascular calcification (VC) is markedly accelerated in patients with chronic kidney disease (CKD) and is a major risk factor for mortality in this population. Phosphate (P) is considered to be a key signaling molecule involved in the development of VC. We used the adenine rat model of CKD to assess the time course of VC development and an in vitro organ culture approach to determine aortic predisposition to VC. Using pieces of aorta incubated in DMEM (0.9 to 3.8mM P) for 2 or 4 days we determined that in vitro calcification only occurred at phosphate concentrations above 3.4mM. Rats (14 wks old) were given an adenine diet (0.25%) for 3-11 weeks. This intervention generated mild kidney failure at 3 weeks (serum creatinine 142±12µM vs control 50±5 µM) and more severe failure after 5 weeks (creatinine: 232±30 µM). At 5 weeks these CKD animals had significantly elevated serum phosphate over controls (5.3±0.5 vs 2.4±0.2 mM). At 3 weeks, none of the animals had VC whereas at 5 weeks (17%), 7 weeks (57%) and 11 weeks (78%) there was a progressive increase in the incidence of VC. Compared to control aortas (1.1±0.4 Ca; 2.0±0.7 P µg/mg) incubated in pro-calcification media (3.8mM phosphate) for 2 days, aortas taken from CKD animals pre-calcification (i.e. @ 3 weeks of adenine) had significantly increased tissue calcium (Ca) and phosphate content (3.5±0.8 Ca; 6.3±1.3 P µg/mg) and this process rapidly progressed in all aortas by day 4 (17.6 µg/mg in CKD; 15.3 µg/mg in controls). Furthermore, in our in vivo experiments, CKD animals which eventually calcified had early elevation of serum phosphates (6.0±0.4mM) compared to CKD animals that did not calcify (4.4±0.3mM). Using an organ culture approach, our results reveal, that adenine-induced CKD promotes an increased predisposition of the aorta to phosphate-induced calcification in vitro at a very early stage of the disease. This finding supports the concept that animals with established systemic phosphate elevation early in CKD proceed to develop VC.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1708**

**Mouse Aortic Rings Develop Medial Calcification under Elevated Phosphate Conditions That Is Accelerated by Treatment with Elastase** Cecilia M. Giachelli,[1] Wei Ling Lau,[2] Ashwini S. Pai.[1] *[1]Bioengineering, University of Washington, Seattle, WA; [2]Nephrology, University of Washington, Seattle, WA.*

Hyperphosphatemia has emerged as a non-traditional risk factor for vascular calcification and mortality in the chronic kidney disease population. Recently, elastin degradation by matrix metalloproteinases and elastases has been suggested to play an important role in uremic arterial calcification. We studied the vascular wall changes that occur in mouse aortic rings cultured in elevated phosphate (Pi) medium.

Aortas from C57BL/6 mice were harvested, stripped of perivascular fat and cut into 2-3 mm sections. Rings were cultured in DMEM/5% FBS for 9 days with Pi concentrations varying between 1-3 mM. For time-course analysis, rings were cultured in 2.2 mM Pi for 15 days. Calcium content in non-cultured day 0 mouse aorta was 0.93 ± 0.22 mcg calcium normalized to dry weight (mcg/mg). The aortic rings developed medial calcification that was more severe with increasing phosphate concentration (1.6 ± 0.56 mcg/mg at 1 mM Pi, vs 36.81 ± 6.52 mcg/mg at 1.8 mM Pi, vs 104.15 ± 8.56 mcg/mg at 3 mM Pi). Degree of calcification increased with time in 2.2 mM Pi medium (4.48 ± 1.36 mcg/mg at day 3, vs 42.52 ± 12.54 mcg/mg at day 9, vs 97.8 ± 11.06 mcg/mg at day 15). Vascular smooth muscle cells in the medial layer showed loss of SM22-alpha expression with upregulation of Runx2/Cbfa1 by immunohistochemical analyses, indicating a transition to a bone-forming phenotype.

To determine the effect of elastin degradation on calcification, aortic rings from DBA/2J mice were cultured for 9 days in DMEM/5% FBS containing 3.2 mM Pi. A subset of rings was incubated with elastase for 24 hours prior to the 9-day culture. Calcium content from control aortic rings cultured in standard 1 mM Pi medium was 10.41 ± 2.48 mcg/mg. Rings cultured in 3.2 mM Pi developed calcification in the range of 81.22 ± 4.62 mcg/mg. Elastase pretreatment produced more severe calcification (130.55 ± 20.28 mcg/mg).

In conclusion, mouse aortic rings develop medial calcification that is dependent on phosphate dose and duration of exposure. Elastin degradation accelerates this phosphate-induced vascular calcification.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1709**

**Age-Related Increase in the Predisposition to Vascular Calcification in Adenine-Induced Chronic Kidney Disease** Kristin M. McCabe, Navid Shobeiri, Bonnie W. Y. Shum, Kimberly J. Laverty, David P. Beseau, Michael A. Adams, Rachel M. Holden. *Queen's University, Kingston, ON, Canada.*

The development of vascular calcification (VC) in elderly patients generates significantly increased cardiovascular risk. In patients with chronic kidney disease (CKD) the VC process occurs much more rapidly. There remains a significant gap in knowledge regarding the relevant factors contributing to this accelerated development. In the present study we sought to determine whether age, as well as treatment with warfarin, impacted the time course, magnitude and consequences of CKD in an adenine model. Male Sprague Dawley rats were fed a diet containing either 0.25% adenine (CKD) or 0% adenine (control), both diets containing high phosphate (1%) and low vitamin K (0.2 mg/kg). Animals began the diet at either 9 or 14 weeks of age. After 6-7 weeks on the diet, kidney function was assessed by measuring serum creatinine and VC was assessed using the calcium-O-cresophthalein assay. Creatinine levels were significantly elevated in the CKD group (young, 245.7 ± 43 µmol/L; old, 280 ± 77 µmol/L) compared to controls (67 ± 19 µmol/L). Serum phosphate levels were also elevated in CKD animals (1.5x) and linearly correlated with creatinine ($r^2=0.73$, $p<0.0001$). FGF-23 serum levels were elevated by over 10 fold in CKD animals as compared to control animals and this had a positive correlation with serum creatinine ($r^2=0.70$, $p=0.0001$) and serum phosphate ($r^2=0.35$, $p=0.02$). Warfarin treatment did not alter the levels of creatinine, phosphate and FGF-23. Thus, the dietary adenine model was found to produce equivalent CKD-related outcomes (creatinine, phosphate, FGF-23) in the young and old groups. Despite the similar stimulus vascular calcification was only observed in the older group; i.e. the calcium content of the thoracic aorta of older animals (31 ± 26 ng/mg) was more than 200 fold higher than in young animals (0.12 ± 0.02 ng/mg). Taken together, these results indicate that there is an age-related alteration in the microenvironment of the aorta that predisposes this tissue to a greater risk of vascular calcification. *(Funds: KFOC, KM:OGS).*

**F-PO1710**

**Involvement of Parathyroid Hormone Related Protein in Vascular Calcification of Patients with End Stage Renal Disease and Its Possible Mechanism Study** Fang Liu, Ping Fu, Songmin Huang, Rong Gou, Youqun Huang, Wenxing Fan. *Division of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

**Objective**: Vascular calcification is the major risk factor for cardiovascular events of ESRD patients. Parathyroid hormone related protein (PTHrP) is a new multifunctional peptide to be considered not only a uremic toxin, but also a cardiovascular regulator. This study was to investigate the role of PTHrP in vascular calcification and its possible mechanism.

**Methods**: (1) the inferior epigastric arteries were obtained from 23 maintenance hemodialysis ESRD patients and 3 cases as normal control. HE staining, elastic fiber staining, the lizarin bordeaux calcium staining, immunohistochemical staining and real-time

quantitative PCR were performed. (2) human aortic smooth muscle cell line was in vitro cultured, PTHrP-siRNA was transfected by liposomes. The cells were divided into seven groups: control group; PTHrP-siRNA-24h; $10^{-8}$mM human recombinant PTHrP (rh-PTHrP)-24h; PTHrP-siRNA+$10^{-8}$mM rh-PTHrP-24h; PTHrP-siRNA-48h; $10^{-8}$ mM rh-PTHrP-48h; PTHrP-siRNA+$10^{-8}$ mM rh-PTHrP-48h. Western Blot and real-time quantitative PCR were used to detect the protein and mRNA expressions of BMP-2/ Cbfa1.

**Results**: (1) Compared with the normal control group, arterial vascular walls were thickened, medial elastic fibers decreased significantly, calcium salt staining increased, and the expressions of PTHrP, BMP-2/Cbfa1 detected by immunohistochemistry significantly increased, and the expressions of PTHrP, PTH1R, BMP-2/Cbfa1 mRNA detected by real-time quantitative PCR were significantly in ESRD patients. Correlation analysis showed that the calcification score was closely related with the expression of PTHrP and BMP-2/ Cbfa1. (2) Western Blot and real-time quantitative PCR show that rh-PTHrP can stimulate the expressions BMP-2/Cbfa1 in non-time-dependent manner; PTHrP-siRNA could partly reduce the expression of BMP-2/ Cbfa1 induced by rh-PTHrP.

**Conclusions**: The expressions of PTHrP, BMP-2/Cbfa1 increased in calcificational arterial vessels of ESRD patients; PTHrP might be involved in the development of vascular calcification by inducing the activation of BMP-2/ Cbfa1 pathway.

## F-PO1711

**Pulse Pressure, Arterial Stiffness and Malnutrition in Chronic Kidney Disease** Catarina Santos,[1] Ricardo Vizinho,[2] José Diogo Barata.[2] *[1]Nephrology Department, Hospital Amato Lusitano, Castelo Branco, Portugal; [2]Nephrology Department, Hospital Santa Cruz, Carnaxide, Portugal.*

Pulse pressure (PP) is of clinical interest for cardiovascular risk stratification and correlates strongly with arterial stiffness, inflamation and malnutrition. In chronic kidney disease (CKD) the accuracy of peripheral PP (pPP) may be misleading because of vascular stiffening and its prognostic value decreased in this setting. We aimed to evaluate peripheral and central PP in CKD patients and determine its association with arterial stiffness, inflamation and malnutrition. In 40 patients with CKD stages 4 and 5 not on dialysis we determined C- reactive protein (CRP) and albumin and measured pPP and central pulse pressure (cPP), augmentation index (Aix), reflected wave time transit (RWTT), left ventricular ejection time (LVET) and RWTT/LEVT ratio. The central hemodynamic parameters were obtained by radial tonometry (Sphygmocor®) and the statistical analysis was performed using SPSS. Thirty patients were male, average age 62.2 ± 15 years and 10 patients (25%) had type 2 diabetes. The average pPP was 60.8 ± 18.3 mm Hg and cPP 48.2 ± 16.7 mm Hg (p=0.000). pPP and cPP were higher in diabetics (p=0.009 and p=0.05, respectively). Average albumin was 3.6 ± 0.4 g/dL and CRP 0.5 ± 0.4 mg/dL. pPP correlated positively with central systolic arterial pressure (r=0.578; p=0.000) and cPP (r=0.881; p=0.000), inversely with RWTT/LEVT ratio (r=-0.324; p=0.047) but not with Aix (r=0.207; p=0.200), CRP (r=0.324; p=0.123) or albumin (r=-0.173; p=0.418). cPP correlated positively with Aix (r=0.446; p=0.005), CRP (r=0.438; p=0.041) but inversely with RWTT/LEVT ratio (r=-0.433; p=0.007) and albumin (r=-0.378; p=0.043). By logistic regression analysis, predictors of Aix included cPP (β= 0.29; p=0.015), RWTT/LVET ratio (β= -0.56; p=0.000), diastolic arterial pressure (β=0.22; p=0.03) and albumin (β=-0.29; p=0.015). Peripheral PP, however, was not associated with Aix (β= 0.182; p=0.222). We conclude that in CKD pPP is higher than cPP but the two variables correlate positively. However, cPP, rather than pPP, and albumin are better predictors of arterial stiffness in this setting.

## F-PO1712

**Transplantation of Metanephros Suppresses the Vascular Calcification in Rats with Adenine-Induced Renal Failure** Shinya Yokote,[1,2] Takashi Yokoo,[1,2] Kei Matsumoto,[1,2] Ichiro Ohkido,[1] Tetsuya Kawamura,[1] Tatsuo Hosoya.[1] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [2]Internal Medicine, Project Laboratory for Kidney Regeneration, Institute of DNA Medicine, Tokyo, Japan.*

*Background.* It has been shown transplanted metanephros may undergo complete nephrogenesis in the host animal, forming a functional kidney. However, metabolic function of transplanted metanephros, in particular for secondary hyperparathyroidism and vascular calcification in chronic renal failure (CRF), remains unknown. To determine this, we studied the therapeutic effect of metanephros transplantation on vascular calcification in rat with CRF.

*Methods.* CRF was induced in 11-week-old male Wistar rats by feeding 0.75% adenine containing diet for 4 weeks, followed by normal diet for another 2 weeks . Time course changes of serum levels of inorganic phosphorus(P), calcium(Ca), parathyroid hormone , 1-α25dihydroxyvitamin D3(1-25$(OH)_2D_3$) were measured. Whole metanephroi from embryonic day 15 rats were transplanted into the omentum and the epidermidic area (Tx groups) at 4weeks. At the end of study, vascular calcification was evaluated by Von Kossa-stained sections, CT scan, and Ca and P content in aorta. Maximal parathyroid gland area was also measured.

*Results.* Aortic calcification and enlarged parathyroid glands were observed in adenine-fed rats, whereas, Tx group (n=12) had significantly reduced vascular Ca and P compared with control CRF group (n=11). Histopathologic examination of the thoracic aorta media (von Kossa staining) also showed Tx suppressed the vascular calcification compared with the control CRF group. RT-PCR showed 1α hydroxylase mRNA was significantly increased in the metanephroi of Tx group compared with native kidney of control CRF group. However, there are no significant differences between these two groups on serum 1-25$(OH)_2D_3$ level and Ca×P product, suggesting its anti-calcification effect can be independent of 1-25$(OH)_2D_3$ activation.

*Conclusions.* These data showed transplantation of metanephroi can contribute to suppress the vascular calcification by independent mechanism of calcium-phosphorus dynamics.

## F-PO1713

**Eicosapentaenoic Acid Reduces Vascular Calcification In Vitro and In Vivo** Saeko Kanai, Kenta Uto, Chiharu Aoki, Sekiko Taneda, Kazuho Honda, Hideaki Oda. *Department of Pathology, Tokyo Women's Medical University, Tokyo, Japan.*

**Background:** Vascular calcification is associated with elevated cardiovascular disease risk and poor prognosis in patients with chronic kidney disease. Eicosapentaenoic acid (EPA), a major n-3 polyunsaturated fatty acid, has been shown to have protective effects against cardiovascular disease. However, little is known about the effects of EPA on vascular calcification. **Methods and Results:** Vascular calcification was induced by the administration of warfarin (3 mg/g food) and vitamin K1 (1.5 mg/g food) to inhibit γ-carboxylation of matrix Gla protein in Sprague-Dawley rats consisting of 2 groups based on a diet with EPA (1g/kg/day) (EPA group) or without (control group). After 2 weeks, histological evaluation using von Kossa staining revealed a marked reduction of arterial medial calcification in EPA rats**,** compared with that in the control rats (calcification ratio: control vs. EPA = 6.9 ± 4.3% vs. 1.5 ± 0.9%, p<0.05). Immunohistochemical analysis showed that EPA reduced the infiltration of macrophages expressing matrix-metalloproteinase (MMP)-2 or MMP-9 in adventitia around calcification. EPA also reduced MMP-9 activity as well as the mRNA expression of monocyte chemotactic protein-1 in the aorta. Additionally, calcification in A7r5 cells (rat aorta smooth muscle cell line) was induced by the addition of Pi (3 mM) to serum-supplemented medium for 8 days and was evaluated using the o-cresolphthalein complexone method and von Kossa staining. Pre-treatment of the A7r5 cells for 48 h with 10 μM of EPA significantly decreased phosphate-induced calcification. Flow-cytometric analysis using annexin V and TUNEL staining revealed that phosphate-induced apoptosis was markedly reduced by the pre-treatment with EPA. Furthermore, RT-PCR analyses revealed that pre-treatment with EPA suppressed MMP-9 expression in A7r5 cells as well as in RAW264.7cells (murine macrophage cell line) stimulated with TNF-α (10 ng/mL) for 24h. **Conclusion:**[/bold]These observations indicate that EPA reduces vascular calcification through the suppression of MMP-9 activity and adventitial macrophage infiltration in addition to inhibiting the apoptosis of vascular smooth muscle cells.

## F-PO1714

**Iron Enhances Adhesion of Mononuclear Cells to Human Aortic Endothelial Cells by Increasing Reactive Oxygen Species Generation and Redox-Sensitive Pathways** Ko-Lin Kuo,[1,2] Szu-Chun Hung,[2] Der-Cherng Tarng.[1,3] *[1]Institute of Physiology, National Yang-Ming University, Taipei, Taiwan; [2]Division of Nephrology, Buddhist Tzu Chi General Hospital, Taipei Branch, Xindian, Taiwan; [3]Division of Nephrology, Taipei Veteran General Hospital, Taipei, Taiwan.*

**Aim** Our previous data showed that higher cumulative dose of iron supplementation was associated with increased cardiovascular mortality and events in dialysis patients. Therefore, we test the hypothesis whether iron can exert pro-oxidant property and further induce adhesion of mononuclear cells (MNCs) to human aortic endothelial cells (HAECs), an early sign of atherogenesis.

**Methods and Results** HAECs were incubated with various concentrations of iron sucrose (FeS) and the cell viability were measured by MTT assay. The non-cytotoxic working concentrations of FeS (≤160μg/ml) were used to avoid interference on cell viability in the following tests. Adherence of monocytic cells U937 to activated HAECs by FeS was examined first. There was a significant time-dependent increase of U937 adhesiveness to HAECs at 1, 2, and 4 h compared to the baseline ($P$ <0.05). Dose-dependent effect of FeS on adhesiveness significantly increases at 4 h following incubation with FeS of 40, 80, and 160 mg ($P$<0.05). Co-treatment of HAECs with N-acetylcysteine (NAC, 100 mM), DPI (NADPH oxidase inhibitor; 30μM), pyrrolidine dithiocarbamate (PDTC, an antioxidant and NF-κB inhibitor; 100μM) and U0126 (AP-1 inhibitor; 50μM) significantly inhibited U937 adhesiveness to HAECs treated with FeS of 160μg/ml for 4 h. In addition, an increase of intracellular ROS production on HAECs treated with FeS 160μg/ml for 3 h can be significantly inhibited by NAC, DPI, PDTC and U0126 ($P$ <0.05). Furthermore, HEACs treated with FeS significantly increased endothelial vascular cell adhesion molecule -1 in a time and dose-dependent manner, but the expression of intercellular adhesion molecule-1 was modest.

**Conclusion** FeS can significantly induce endothelial adhesiveness of MNCs by increasing intracellular ROS production, and cell adhesion molecules expression via redox-sensitive pathways. Our results suggest that iron supplementation plays a role in the initiation of atherosclerosis.

**Endothelial Dysfunction Impairs Vascular Integrity and Delays Recovery in Mesenteric Venules of Pkd2 Heterozygous Mice Following Ischaemia-Reperfusion Injury** Sony Prasad,[1] Zoe L. Brookes,[2] Albert C. Ong.[1] *[1]Kidney Genetics Group, Academic Unit of Nephrology, University of Sheffield, Sheffield, S. Yorkshire, United Kingdom; [2]Microcirculation Group, University of Sheffield, Sheffield, S. Yorkshire, United Kingdom.*

Cardiovascular abnormalities are a prominent extrarenal feature of the ADPKD phenotype and are most commonly expressed as an increased prevalence of hypertension. The pathogenesis of hypertension is likely to be multifactorial in ADPKD though abnormalities in both vascular smooth muscle contractility and endothelial dependent vasodilatation have been reported for studies performed on isolated human and murine ADPKD arteries. In a recent study, we reported that mesenteric arterioles from $Pkd2^{+/-}$ mice had a profound baseline defect in acetylcholine (Ach) stimulated vasodilatation *ex vivo* which was endothelial dependent and nitric oxide mediated (Ong et al, JASN 2009). Here we demonstrate that the endothelial dysfunction present in $Pkd2^{+/-}$ mice extends to venular endothelium *in vivo* and moreover is further exaggerated by ischaemia-reperfusion injury (IRI). Wild-type and $Pkd2^{+/-}$ female mice (n=5-7) were subjected to mesenteric IRI by clamping the superior mesenteric artery (15 min) or a sham procedure. Intravital microscopy was employed to study macromolecular leak (FITC-BSA) in the post-capillary venules (20-40μm diameter). No difference in baseline leak was seen in sham operated mice from both genotypes but the extent of the post I/R leak induced in $Pkd2^{+/-}$ mice was significantly higher than in wild-type. To investigate whether this difference was a consequence of loss of endothelial function, the same venules were analysed for Ach induced dilatation. In sham vessels, the Ach response was strikingly reduced in $Pkd2^{+/-}$ compared to wild-type. Following IRI, the Ach response was significantly more impaired in $Pkd2^{+/-}$ venules and was almost absent following IRI. We conclude that endothelial dysfunction is likely to be a widespread feature of both arteries and veins in ADPKD and that this impairs vascular integrity and recovery following injury.

**F-PO1716**

**Globotriaosylceramide (Gb3)-Induced Endothelial-to-Mesenchymal Transition as a Novel Mechanism of Vascular Damage in Fabry Disease** Mina Yu,[1] Yang Hee Jang,[1] Eun Sun Ryu,[1] Jin Ok Choi,[2] Sung Cheol Jung,[2] Duk-Hee Kang.[1] *[1]Nephrology, Ewha Womans University, School of Medicine, Seoul, Korea; [2]Biochemistry, Ewha Womans University, School of Medicine, Seoul, Korea.*

The lysosomal storage disorder Fabry disease is characterized by excessive Gb3 accumulation in major organs such as the heart and kidney. Defective lysosomal alpha-galactosidase A (Gla) is responsible for excessive Gb3 accumulation, and vascular endothelium is one of the sensitive cells to the effects of Gb3 accumulation. Although endothelial dysfunction is known to be associated with Fabry disease, it is not known whether it plays any roles in the development of organ damage or whether Gb3 per se is related to endothelial dysfunction. Recent data suggest that endo-MT, which is characterized by the loss of endothelial cell markers and an acquisition of mesenchymal cell markers, is a potential mechanism of endothelial dysfunction. We investigated whether Fabry kidney showed an evidence of endo-MT and whether Gb3 induced endo-MT in cultured HUVEC. Immunostaining with RECA or CD-31 in the kidney of Gla deficient mice, showed a decreased microvascular endothelial staining both in glomerular and peritubular capillaries compared to wild type mice with an appearance of α-SMA (+) endothelial cells. However, a loss of glomerular and peritubular endothelial cells was not demonstrated by electron microscopy, suggesting that not a loss of endothelial cells but a phenotypic transition is present in Fabry mice. Treatment of Fabry mice with of recombinant adeno-associated virus vector encoding alpha-Gal A cDNA (rAAV2/8-hAGA) resulted in the clearance of accumulated Gb3 in kidney with concomitant elevation of alpha-Gal A enzyme activity. rAAV2/8-hAGA therapy also ameliorated endo-MT of glomerular and peritubular capillary endothelial cells. Stimulation of HUVEC with Gb3 (0.1-10 uM) down-regulated the expression of CD31 and VE-cadherin with an up-regulation of α-SMA from 48 hrs in a dose-dependent and time-dependent manner. Gb3 also induced a decrease in nitric oxide production from HUVEC. These finding suggest that Gb3-induced endo-MT is one of the mechanisms of endothelial dysfunction and nephropathy in Fabry disease.

**Macrophages and VEGF-C Contribute to Lymphangiogenesis in the Progressive Renal Fibrosis Model** Jung Eun Lee,[1] Aesin Lee,[1] Yujin Jung,[1] Duk Hoon Kim,[1] Ki Dong Lee,[1] Mi Jeong Sung,[2] Kyung Pyo Kang,[1] Sik Lee,[1] Sung Kwang Park,[1] Won Kim.[1] *[1]Internal Medicine, Chonbuk National University Medical School, Jeonju, Republic of Korea; [2]Food Function Reseach Center, Korea Food Research Institute, Songnam, Republic of Korea.*

Lymphatic and lymphangiogenesis are involved in many pathological conditions such as tumor metastasis, wound healing, and lymph edema. A recent study has reported that density of lymphatic vessel was correlated with fibrotic area in human chronic renal disease and idiopathic pulmonary fibrosis model. However, there is a paucity of data regarding the role of macrophages in lymphangiogenesis and progressive renal interstitial fibrosis. We investigated whether there is lymphangiogenesis and lymphatic remodeling in fibrotic area in a unilateral ureteral obstruction (UUO), a progressive renal fibrosis model and evaluated the roles of macrophages and growth factors in obstructed kidney.

Our results demonstrated that the density of LYVE-1-positive lymphatic vessels was increased at 1, 2 and 4 w after ureteral obstruction in the tubulointerstitial area. Density of PECAM-1-positive vasculature was slightly increased at 1 and 2 w after ureteral obstruction. Thereafter, PECAM-1-positive vasculature was gradually decreased at 3 and 4 w after ureteral obstruction. LYVE-1–positive lymphatic endothelial cells were colocalized with podoplanin, Prox-1 and vascular endothelial cell growth factor (VEGF) receptor 3 in fibrotic kidney. The proliferation of LYVE-1-positive lymphatic endothelial cells was increased at 1 w after ureteral obstruction compared to sham-operated mice kidney. VEGF-C expression was colocalized with F4/80(+) macrophages in fibrotic area. VEGF-c mRNA expression was significantly increased after ureteral obstruction compared to the sham-operated mice kidney whereas angiopoietin-2, VEGF-B, and VEGF-D mRNA expression was not changed after ureteral obstruction.

Our results show that F4/80(+) macrophage and VEGF-C have a role in lymphangiogenesis in a kidney fibrosis model.

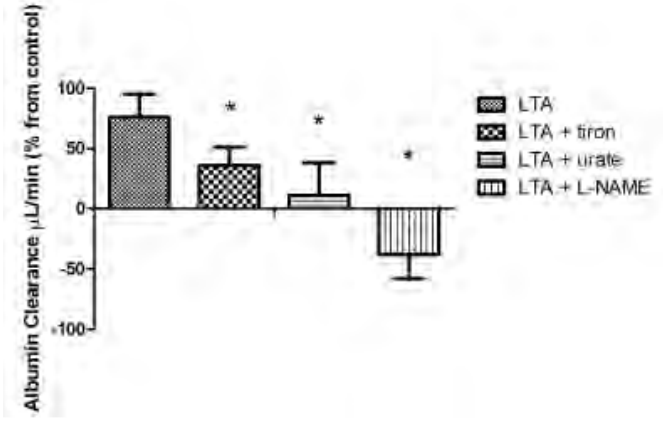
**Lipoteichoic Acid-Induced Lung Endothelial Barrier Dysfunction: Role of Endothelial Nitric Oxide Synthase (eNOS)** Amy B. Pai, Arnold Johnson. *Albany College of Health of Health Sciences, Albany, NY.*

Gram-positive organisms are the leading cause of sepis in hemodialysis patients. We have shown that lipotechoic acid ( LTA, a Gram positive cell wall component) induces increased lung permeability (in vitro and in vivo). Mechanisms for LTA associated endothelial barrier dysfunction have not been investigated.

Rat lung microvessel endothelial cell (RLMEC) monolayers were cultured and treated with ultrapure LTA from *Staphylococcus aureus* 30 μg/mL ± tiron 5mM (reactive oxygen species (ROS) scavenger), urate (reactive nitrogen species (RNS) scavenger) and L-NAME 100 μM (eNOS inhibitor) for 24 hours Clearance rate of Evans Blue-labeled albumin used to determine permeability. ROS were quantitated in RLMEC treated LTA (as above) for 30 minutes incubated with dihydroethidium (DHE) (10 μM, 0.5 h). Values reported as mean fluorescence intensity (MFI). eNOS activation was determined in lysate by immunochemistry and analyzed using the ratio of anti-p-eNOS-$ser^{1177}$ (an activation site) and p-eNOS-$thr^{495}$ (an inactivation site). Results are mean values ± SEM of n > 3 experiments.

Incubation of RLMECM with LTA\ increased endothelial permeability compared to untreated controls that was prevented by tiron, urate and L-NAME. (*p<0.05 vs. LTA alone see Figure)



LTA induced eNOS activation evidenced by an increased p-eNOS-$ser^{1177}$:p-eNOS-$thr^{495}$ (mean ± SEM relative density units; 0.7 ± 0.05 vs. control 0.93 ± 0.06, respectively, p < 0.05 IS vs. control). LTA increased ROS generation, with an 59 ± 18% increase in DHE MFI vs. untreated controls (p < 0.05, LTA vs. controls), that was effectively mitigated by urate and tiron (p<0.05 LTA vs LTA + urate and LTA + tiron)

LTA increased endothelial permeability to albumin, eNOS activation and ROS generation. These data indicate that LTA has the potential to induce lung injury via an eNOS/ROS/RNS mediated pathway.

**Loss of Glycocalyx Barrier Properties in Dialysis Patients** Carmen A. Vlahu,[1] Marion G. Koopman,[1] Raymond T. Krediet,[1] Hans Vink.[1, 2] *[1]Department of Medicine, Academic Medical Center, Amsterdam, Netherlands; [2]Department of Physiology, Cardiovascular Research Institute Maastricht, Maastricht, Netherlands.*

The endothelial glycocalyx exerts a wide range of vasculoprotective effects and is a main regulator of vascular homeostasis. In the present study we investigated whether the microvascular glycocalyx is damaged in dialysis patients as compared to healthy controls.

**Methods**: Investigations were carried out in 7 male HD patients (age 45.9 (27.1-59.9) years; time on renal replacement therapy (RRT) 176.2 (17.4-352.9) months), 9 male PD patients (age 43.7 (18.25-57.0) years; time on RRT 54.2 (2.1-300.8) months) and 9 age and sex-matched healthy controls. Exclusion criteria: diabetes mellitus, use of antioxidants, statins, ACE-inhibitors and ARBs. The status of endothelial glycocalyx in individual blood vessels was assessed by measuring the dimension of the cell poor region (CPR) near the vessel wall. In healthy conditions only the luminal part of the glycocalyx is accessible to red blood cells (RBC). When glycocalyx barrier properties are impaired, the RBC can penetrate further into the glycocalyx, thereby resulting in an increase in the dimension of CPR. This was measured using Sidestream DarkField imaging of the sublingual vasculature with a MicroScan videomicroscope. Measurements were repeated after the administration of 0.4mg of nitroglycerine (NTG) sublingually.

**Results**: Compared to healthy controls, CPR increased in patients by 0.63±0.31 μm (p=0.05) in PD patients and 0.98±0.32 μm (p=0.01) in HD patients. In HD patients the magnitude of glycocalyx barrier loss correlated with total time on RRT (r=0.86, p=0.01). Furthermore, exposure to NTG increased the CPR by 0.3 (-0.2-1.1) μm in healthy controls and 1.3 (0.3-3.4) μm in HD patients indicating increased susceptibility to challenge mediated increases in glycocalyx permeability in HD patients.

**Conclusions**: Dialysis patients have a loss of glycocalyx barrier properties as compared to healthy controls. This alteration is more pronounced in HD patients. Impaired glycocalyx barrier properties may be an early indicator of pathogenic activation of vascular endothelium as a marker of increased cardiovascular risk.

**Association between Renal Microvascular Sclerosis and Asymmetric Dimethylarginine (ADMA) in Normotensive Patients with Primary Glomerulopathy** Keiji Kono, Kentaro Nakai, Shunsuke Goto, Hideki Fujii, Shinichi Nishi. *Division of Nephrology and Kidney center, Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Renal microvascular sclerosis is a critical pathological finding, which is related to prognosis of renal function. The etiology, however, remains unclear because this finding can be observed even in the absence of clinical risk factors, such as hypertension and aging. A novel marker of endothelial dysfunction and atherosclerosis, ADMA, has been reported to be a risk factor for the progression to ESRD. We examined the relationship between renovasculopathy associated with primary glomerulopathy and clinical parameters including ADMA.

Methods: 60 patients were performed renal biopsy in our department between March 2009 and December 2009. Of these patients, the patients with the history of hypertension, diabetes mellitus and vasculitis were excluded. 15 normotensive patients (age:41±15 years old) with biopsy-proven primary glomerulopathy were included in this study. The ratio of arterial intimal fibroplasia thickening to outer diameter (R(f)) as well as the proportion of the number of arterioles with hyalinization (Hy) were evaluated in each biopsy specimen. Laboratory tests, including plasma ADMA, were carried out.

Results: The mean value of eGFR, R(f) and Hy in all patients were 77.2±19.4ml/min/1.73m2 ,21.7±15.2% and 6.0±18.4%, respectively. R(f) was significantly correlated with plasma ADMA levels(r=0.691,p<0.005) and age (r=0.521,p<0.05) in all patients. In contrast, Hy was correlated with systolic BP(r=0.593,p<0.05). In multivariate analysis, plasma ADMA levels were independently associated with R(f) (β=0.624, p<0.05). Furthermore, plasma ADMA levels were significantly correlated with R(f) even in the patients who had only mild interstitial fibrosis ( r=0.891, p<0.005).

Conclusion: Our findings suggest that ADMA may affect the progression of early renal microvascular sclerosis producing the interstitial fibrosis independently of hypertension in primary glomerulopathy.

**Endothelial Cell and Pericyte Co-Cultures in an In Vitro Spheroid Model** William Gee Chang, Jordan S. Pober. *Immunobiology, Yale University School of Medicine, New Haven, CT.*

Microvessels are composed of an endothelial cell inner lining that is invested by pericytes. Communication between these two cell types via cell-cell contacts and paracrine signaling are key to vascular formation, remodeling, and stability. In order to better understand these interactions we adapted the Augustin three-dimensional spheroid model to examine cellular interactions between human umbilical vein endothelial cells (EC) and human placental pericytes (PC) in vitro. Both cultured cell types spontaneously form spheroids when suspended in 0.25% methylcellulose in non-adherent 96 well U-bottomed plates, and remain viable for days when embedded in type I collagen gels. EC spheroids do not spontaneously sprout but respond to exogenous VEGF treatment with robust sprout formation. In contrast, PC sprout in the absence of exogenous VEGF. Spheroids formed by mixing EC with PC organize into PC cores coated by EC. Without addition of VEGF, EC/PC mixed spheroids demonstrated PC sprouting alone, while the addition of VEGF led to multiple sprouts consisting of either PC or EC. However, little contact between the EC and PC sprouts was observed. These results suggest that close proximity is not sufficient to foster EC/PC cell-cell contact in vitro.

**F-PO1722**

**Glomerular Expression of ADAMTS13 in Renal Thrombotic Microangiopathies** Jan U. Becker,[1] Friedrich Modde,[1] Svjetlana Lovric,[2] Mario Schiffer,[2] Anke Schwarz,[2] Verena Broecker,[1] Clemens L. Bockmeyer.[1] *[1]Medizinische Hochschule Hannover, Institut für Pathologie, Hannover, Lower Saxony, Germany; [2]Medizinische Hochschule Hannover, Klinik für Nieren- und Hochdruckerkrankungen, Hannover, Lower Saxony, Germany.*

Introduction:

Diminished ADAMTS13 activity due to inhibitory antibodies or congenital defects plays a critical role in the development of thrombotic microangiopathies (TMA). Glomerular endothelial cells (GECs) and podocytes are known to express ADAMTS13. The hypothesis, that decreased glomerular expression of ADAMTS13 could contribute to the development of renal TMAs is examined in renal biopsies from native kidneys.

Subjects and Methods: 30 kidney biopsies with various acute and chronic forms of TMA (19 idiopathic, 3 ADAMTS13 deficiency, 4 chemotherapy-induced, 1 shiga toxin-associated hemolytic uremic syndrome, 3 calcineurin inhibitor (CNI)-induced) and 6 normal renal control specimen were examined by immunohistochemistry and quantitative real time PCR of microdissected glomeruli for the glomerular expression of ADAMTS13.

Results:

No differences in ADAMTS13 expression between TMA biopsies and control kidneys were found by immunohistochemistry or quantitative real time PCR except for three cases with CNI-induced TMA. These three cases showed significantly reduced mRNA levels and reduced immunostaining of GECs when compared to TMAs of other causes and controls.

Conclusion:

These results from a limited number of renal biopsy proven TMAs show, that the majority of biopsied renal TMAs do not seem to be associated with decreased glomerular expression of ADAMTS13. The exception were the small subgroup of CNI-induced TMA which did show decreased glomerular mRNA levels and GEC immunostaining of antithrombotic ADAMTS13. This potential novel pathomechanism for the development of CNI-induced TMA should be examined in larger cohorts.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1723**

**Racial Differences in the Association of Pentraxin-3 with Kidney Dysfunction: The Multi-Ethnic Study of Atherosclerosis (MESA)** Ruth F. Dubin,[1] Michael Shlipak,[2] Yongmei Li,[2] Joachim H. Ix,[3] Ian H. de Boer,[4] Nancy Jenny,[5] Carmen A. Peralta.[2] *[1]Internal Medicine, Division Nephrology, University of California San Francisco, San Francisco, CA; [2]Internal Medicine, San Francisco VA Medical Center, San Francisco, CA; [3]Internal Medicine, Division Nephrology, University of California San Diego, San Diego Veterans Affairs Healthcare System, San Diego, CA; [4]Kidney Research Institute and Division of Nephrology, University of Washington, Seattle, WA; [5]Laboratory for Clinical Biochemistry Research, University of Vermont College of Medicine, Colchester, VT.*

Pentraxin-3 (PTX3), an inflammatory marker thought to be specific to vascular injury, is elevated in advanced chronic kidney disease (CKD). Whether PTX3 is associated with mild to moderate kidney dysfunction is unknown.

We tested associations of proteins in the pentraxin family (PTX3, C-reactive protein (CRP) and serum amyloid protein (SAP) with estimated glomerular filtration rate by cystatin C (eGFRcys) and microalbuminuria among 2824 participants in MESA. Associations were tested using multivariable linear regression with adjustment for demographics, comorbidities, and systemic inflammation (interleukin-6 (IL-6)).

Among 2824 white, black, Hispanic and Chinese participants, mean eGFRcys was 94 ml/min/1.73m2. Overall, higher PTX3 was significantly associated with lower eGFRcys after full adjustment (β -3.0 ml/min/1.73m2 per unit increase in lnPTX3, p<0.001). CRP and SAP were not associated with eGFRcys after adjustment for comorbidities and inflammation. There was a significant interaction with race/ethnicity (p<0.001) in the association of PTX3 and eGFRcys. After adjustment for demographics, comorbidities and IL-6, this association was significant in blacks (β -6.2 ml/min/1.73m2 per unit increase in lnPTX3, p=0.001) but not in Hispanics, Chinese, or whites. PTX3 and CRP, but not SAP, had correlations with microalbuminuria in unadjusted models, but these were attenuated after full adjustment.

Endovascular inflammation may be an important mechanism associated with early kidney dysfunction, particularly among blacks.

**F-PO1724**

**Elevated Levels of Plasma Microparticles in Dialysis Patients Are Associated with a Pro-Coagulant State** James O. Burton,[1,2] Hassan A. Hamali,[3] Ruth Stansfield,[2] Nigel J. Brunskill.[1,2] *[1]John Walls Renal Unit, Leicester General Hospital, United Kingdom; [2]Infection, Immunity & Inflammation; [3]Cardiovascular Sciences, University of Leicester, United Kingdom.*

Cardiovascular (CV) death is the largest cause of mortality in dialysis patients but is not fully explained by traditional CV risk models. Plasma microparticles (MPs) are membrane-bound vesicles shed from cells upon activation or apoptosis. Endothelial MPs (EMPs) are

elevated in patients with traditional CV risk factors while platelet MPs (PMPs) are associated with atherosclerosis. This study sought to compare circulating MPs in dialysis patients to matched controls and investigate association with thromboembolic risk.

MPs were isolated from platelet free plasma and their presence confirmed using electron and confocal microscopy. Samples were obtained from HD (n=20) and PD (n=17) patients and matched controls (n=19). Relative concentrations of EMPs (CD144+) and PMPs (CD42b+) were measured by Western blotting. Thrombin generation was measured in plasma before and after filtration (which removes MPs and therefore acts as a negative control) using the continuous automated thrombogram. MPs had the most effect on endogenous thrombin potential (ETP) and peak thrombin (PT) so these data are presented.

EMP and PMP concentrations were higher in dialysis patients than controls (P<0.01). Both dialysis modalities were associated with higher concentrations of EMPs and PMPs (P<0.05). PT was higher in HD and PD patients versus controls (57.1nM vs. 34.8nM; P<0.004 and 76.7nM vs. 34.8nM; P<0.001). Similarly ETP was higher in both patient groups (928nM/min vs. 637nM/min; P<0.02 and 1121nM/min vs. 637nM/min; P<0.001). Following filtration PT and ETP were significantly lower (P<0.0001) and no observed difference remained between patients and controls.

Dialysis patients have higher circulating MP concentrations than matched controls. These MPs are pro-coagulant and promote thrombin generation. Removal of MPs by filtration eliminates this pro-coagulant effect demonstrating that it is not due to soluble mediators or uraemia alone. MPs could be a factor in the increased incidence of cardiovascular events in dialysis patients.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1725**

**Uric Acid as a Predictor of Vascular Function in Healthy Adults** Diana I. Jalal,[1] Kristen L. Jablonski,[2] Kim Mcfann,[1] Michel B. Chonchol,[1] Douglas R. Seals.[2] *[1]Renal Division, University of Colorado Denver, Aurora, CO; [2]Department of Integrative Physiology, University of Colorado Boulder, Boulder, CO.*

High serum uric acid levels are associated with endothelial dysfunction in high risk populations such as patients with congestive heart failure. It is unclear if uric acid and endothelial function are related in healthy adults. We studied 107 healthy adult volunteers from a community based cohort (20-78 years). Baseline characteristics were compared across serum uric acid quartiles defined as: 0-5.2, 5.3-6.1, 6.2-7.0, >7.0mg/dL. Endothelium-dependant dilation (EDD) was assessed using the % change in brachial artery flow mediated dilation. Endothelial independent dilation (EID), a measure of vascular smooth muscle sensitivity to nitric oxide (NO), was defined as % change in brachial artery dilation to sublingual nitroglycerin. The association between serum uric acid levels and EDD and EID was evaluated by linear regression models, first in unadjusted analysis, then in 2 consecutive models: model 1 adjusting for age, gender, and ethnicity, and model 2 adjusting for model 1 + body mass index (BMI), systolic blood pressure, LDL- cholesterol, and fasting glucose levels. In this cohort, 23 subjects (21%) had uric acid levels in the highest quartile. Compared to the lowest quartile of uric acid, these individuals were more likely to be male and had higher BMI and fasting glucose levels. Uric acid levels and EDD were not related in unadjusted or adjusted models in the overall group. There was a tendency for EID to decrease among uric acid quartiles that did not achieve statistical significance. However, there was a significant unadjusted correlation between uric acid and EID in the pooled sample (r= -0.34, p= 0.005). This correlation remained significant after adjusting for covariates in model 1 (p=0.042) and was near significant after adjusting for covariates in model 2 (p=0.071). In conclusion, serum uric acid levels are not associated with EDD among healthy adults, but are related to EID. These results provide the first evidence that uric acid is a determinant of vascular smooth muscle sensitivity to NO in community-dwelling adults free of clinical disease.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1726**

**Differential Expression of Uric Acid Transporters, GLUT9 and URAT1, in the Blood Vessels of the Normal Rat** Diana I. Jalal,[1] Carlos Alberto Roncal-Jimenez,[1] Wei Chen,[1,2] Chris Altmann,[1] Miguel A. Lanaspa,[1] Christopher J. Rivard,[1] Richard J. Johnson.[1,3] *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Department of Nephrology, The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China; [3]Division of Nephrology, Hypertension, and Transplantation, University of Florida, Gainesville, FL.*

Serum uric acid levels have been linked to endothelial dysfunction and cardiovascular disease in several patient populations. We have previously shown that URAT1 (SLC22A12) transports uric acid into the vascular smooth muscle cells. GLUT9 (SLC 2A9) has been shown to transport uric acid from the proximal tubular cells to the circulation. The expression of uric acid transporters, however, has not been characterized in different blood vessels in vivo. Male Sprague Dawley rats were sacrificed and the following arteries were harvested: the carotid arteries, the thoracic aorta, the abdominal aorta, the renal arteries, and the femoral arteries. The expression of URAT1 and GLUT9 was examined by quantitative RT-PCR,western blot, and immunofluorescence (IF). All western blots were normalized for GAPDH. Secondary antibody staining was performed to control for background in IF. We found that URAT1 expression was significantly lower in the thoracic aorta than all the other harvested arteries. The expression of URAT1 was greatest in the abdominal aorta, where it was detected in the vascular smooth muscles and the endothelium. Contrary to URAT1 expression, GLUT9 expression, was greatest in the thoracic aorta. These studies provide the first evidence that URAT1 and GLUT9 are differentially expressed in different arterial segments of the normal rat, and suggest that the vascular effects of uric acid may vary in different vascular beds. Further studies are needed to examine the functional role of uric acid transporters in the different vascular beds.

**Adjunct Progenitor Cells Infusion after Revascularization of Renal Artery Stenosis Improves Renal Oxygenation** Behzad Ebrahimi, John R. Woollard, John A. Crane, Lizette Warner, Xiang-Yang Zhu, Stephen C. Textor, Lilach O. Lerman. *Nephrology & Hypertension, Mayo Clinic, Rochester.*

Background: Renal artery stenosis (RAS) may lead to regional renal ischemia, dysfunction, and fibrosis, which are often irreversible after percutaneous transluminal renal angioplasty (PTRA). We have shown that endothelial progenitor cells (EPC) decrease renal injury in untreated RAS. This study tested the hypothesis that EPC would further enhance renal oxygenation after PTRA.

Methods: Pigs were studied after 10 weeks of untreated unilateral RAS (n=4), RAS treated 4 weeks earlier with PTRA alone (n=4), or followed by intra-renal EPC infusion (10^7, n=4). Normal pigs served as controls (n=5). Stenotic kidney blood oxygenation (R2*, reciprocal to blood relaxation) and energy-dependent tubular function were assessed by blood oxygen-level-dependent (BOLD) magnetic resonance imaging (MRI) before and 15 min after the medullary loop diuretic furosemide (0.05 ml/kg IV).

Results: RAS tended to be smaller than normal kidneys (99±6 vs 119±6 cc, p=0.058) but their size was restored after PTRA. Blood pressure was increased in RAS but decreased similarly in RAS+PTRA and RAS+PTRA+EPC (-16 and -13 mmHg). In normal kidneys medullary R2* significantly declined after furosemide (-16.6±3.4%, p<0.05) suggesting decreased O2 consumption. The response to furosemide was blunted in RAS medulla (2.0±5.4%, p>0.05 vs baseline), but improved in pigs treated with PTRA (+13.3±2.5% p<0.05 vs baseline). In RAS+PTRA+EPC, decrease in R2* was significantly greater than in normal or RAS+PTRA (p<0.005 vs both groups). Cortical R2* remained unchanged after furosemide in all groups.

Conclusion: Infusion of EPC immediately after successful PTRA improves recovery of renal oxygenation after revascularization, supporting this adjunct intervention for preservation and improved viability of stenotic kidney.

**F-PO1728**

**Expression of Senescence Markers in Accelerated Atherogenesis of Uninephrectomized ApoE-/- Mice** Luis Eduardo Becker,[1] Anette Melk,[2] Martin G. Zeier,[1] Marie-Luise Gross.[3] *[1]Nephrology, University of Heidelberg, Heidelberg, Germany; [2]Pediatrics, Hannover Medical School, Hannover, Germany; [3]Pathology, University of Heidelberg, Heidelberg, Germany.*

Atherosclerotic processes are accelerated in patients with chronic kidney disease (CKD), even in children. It is supposed that a premature cellular aging process in CKD functions as a permissive factor for the occurrence of atherosclerosis on the uremic state. In order to evaluate this hypothesis, we investigated the evolution of atherosclerosis by spontaneously atherosclerotic "young" and "old" ApoE-/- mice after Uninephrectomy (UNX) and sham-op. Additionally the expression of the cell cycle inhibitors p53, $p21^{WAF1/CIP1}$ and $p16^{INK4a}$ which are associated to telomere dependent cellular senescence was analyzed.

Methods: Sixty-four ApoE-/- mice receiving normocholesterol diet were divided into 4 groups: UNX and Sham-op, observation period of 16 or 32 weeks (wk) post-operative. UNX was performed at 8 weeks of age. Hearts and aortas were harvested for analysis through stereology and immunohistoschemistry. Aortic p16, p21, p53 and telomerase were accessed through RT-PCR.

Results: Compared to Sham-op (16 and 32wk) aorta and heart remodeling were more pronounced in UNX 32wk animals, which presented a significant increase in wall to lumen ratio, plaque size and a reduced heart capillary length density despite no significant alterations in blood pressure. TGFß expression in the aorta was significantly higher in UNX animals (both 16 and 32wk) compared to sham-op. Plaque total collagen content was overall low and similar between groups. However, collagen I and fibronectin expression in plaques were significantly higher by UNX 32wk animals compared to Sham-op and UNX 16 wk. RT-PCR of aortic material showed a higher expression of p21 in the UNX 32wk animals compared to all other groups (10.4±4.6 vs. 3.1±0.43, 4.5±3 and 6.2±2.3 ratios/HPRT, p<0.05) and a lower telomerase expression compared to Sham-op 16 and 32wk.

Conclusions: UNX promoted significant aortic and cardiac remodeling, which was paralleled by increased expression of p21 and reduced telomerase activity after a 32 week observation period.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1729**

**Endothelial Progenitor Cells (EPCs) in a Human Model of Vascular Hyporeactivity: Relationship with Hypertension and Cardiovascular Remodeling** Lorenzo Calo, Elisa Pagnin, Monica Facco, Elisa Boscaro, Carlo Agostini, Achille Pessina. *Clinical and Experimental Medicine, University of Padova, Padova, Italy.*

Altered endothelial function is critical in the pathophysiology of hypertension and long-term complications (cardiovascular (CV) remodeling). Ang II-induced oxidative stress (OxSt) causes endothelial dysfunction via senescence of EPCs, reduction of NO and secretion of inflammatory cytokines. NO bioavailability and eNOS activation are critical for EPCs activity that is reduced in EPCs of hypertensives and correlates with accelerated EPC senescence while ARBs increase the number of circulating EPCs. In Bartter's/Gitelman's patients (BS/GS) who have increased levels of Ang II yet normo/hypotension, we demonstrated blunted Ang II type 1 receptor (AT1R) signaling (Kidney Int 2006, JCEM 2004, J Hypertens 2007 and 2008), activation of AT2R signaling (J Hypertens 2010) explaining their reduced OxSt (J Hypertens 1998, NDT 2003) increased NO production, high insulin sensitivity, absence of endothelial dysfunction (NDT 2008, Diabetes Care 2006, J Hum Hypertens 2007) and lack of CV remodeling (NDT 2008, JEI 2009) depicting the opposite picture of the Ang II signaling/insulin-glucose relationships of diabetes and hypertension and intrinsecally reproduce the effect of ARBs. There are no data in BS/GS on EPCs number. Peripheral blood progenitor cells were analyzed in 10 genetically characterized BS/GS and 10 normotensive healthy subject (C) for the expression of cell surface antigens via direct three-color analysis using fluorescein isothiocyanate-, phycoerythrin- and allophycocyanin-conjugated monoclonal ABs by flow cytometry analysis. EPCs were defined as CD34+KDR+ or CD133+KDR+ and CD133+CD34+KDR+ cells. In BS/GS CD34+KDR+ cells did not differ from C: 50.00±36.32 vs 29.33±14.38 while both CD133+KDR+ and CD133+CD34+KDR+ cells were higher: 22,55±11.46 vs 12.00±9.54, p=0.049 and 10.33±3.53 vs 3.53±3.00, p=0.0003. These data in a human model opposite of hypertension contribute to clarify mechanisms involved in the ARBs effect on EPCs and support the therapeutic strategy based on stimulation of circulating EPCs proliferation for the prevention of atherosclerotic CV diseases.

**The Unprecedented Proliferative Changes on Renal Arteriolar Walls Induced by a Long-Term Administration of an Angiotensin II Receptor Blocker in Rats** Yohko Nagai,[1,2] Kazushige Nakanishi,[2] Nobuaki Yamanaka.[1] *[1]Tokyo Kidney Research Institute, Tokyo, Japan; [2]Department of General Medicine and Emergency Care, Toho University, Faculty of Medicine, Tokyo, Japan.*

**Introduction**: Angiotensin II type 1 receptor blockers (ARBs) are widely known for having nephro-protective effects; decreasing intraglomerular pressure in various primary and secondary kidney diseases. However, the histopathological studies on renal arterioles by the ARB treatment have not been reported. We examined the morphological changes on afferent arterioles in rats after a long-term administration of an ARB.

**Method**: Eight 6-week-old male Wistar Kyoto rats (WKY) and 16 age-matched Zucker Fatty Rats (ZFR) were divided into the following four groups: the WKY+ARB group (n=4) and the ZFR+ARB group (n=8) fed a standard diet (0.4%NaCl) containing ARB (olmesartan, 5mg/Kg/day) for 12 weeks, the WKY group (n=4) and the ZFR group (n=8) fed a standard diet without ARB as controls. All of their kidneys were examined by light and electron microscopes and immunohistochemistry using anti-αSMA, SM-1,SM-2 and renin antibodies, especially focusing on the renal vessels.

**Results**: Unprecedented concentric proliferative changes and marked morphological irregularities of smooth muscle cells (SMCs) in afferent arteriolar walls were observed in the WKY+ARB and ZFR+ARB groups (45±5.0%, 77.3±10.3% of observed arterioles, respectively). The changed arteriolar lumens narrowed extremely. The proliferative SMCs were considered to be activated and dedifferentiated. Elastic and collagen fibers could be observed between the multiplying SMCs. In the control WKY and ZFR groups no abnormal findings were shown in the afferent arterioles.

**Conclusion**: It is indicated that the long-term administration of ARB induces unusual proliferative changes in afferent arterioles and has a risk of obliterating of them over a longer period.

**The Role of Apolipoprotein A1 in Uremic Atherosclerosis** Saleem H. Bharmal, Manish P. Ponda. *Division of Nephrology, Department of Medicine, New York University School of Medicine, New York, NY.*

**Purpose:**

To determine the effect of human ApoA1 over expression in uremic ApoE$^{-/-}$ mice.

**Background:**

Atherosclerosis is accelerated in chronic kidney disease. Studies of the ApoE knockout mouse model corroborate clinical observations. Animal models have shown that the pathogenesis of accelerated atherosclerosis may be due to decrease in rates of plaque regression. Human trials of intervention with statins did not show any benefit in cardiovascular outcomes in end-stage renal disease patients despite significant reductions in LDL cholesterol levels; emphasizing the need for investigating alternate mechanisms and potential treatments. We wanted to further study the importance of reverse cholesterol transport in uremic atherosclerosis by comparing atherosclerotic plaque size in human ApoA1 transgenic/ApoE knockout (hApoA1tg/ApoE-/-) mice that were made uremic to those that had normal renal function.

**Methods:**

hApoA1tg/ApoE-/- mice underwent surgical reduction of renal mass (uremic N=5) or sham operation (controls N=7). The mice were maintained on a Western diet for 16 weeks. Aortic roots were harvested, sectioned, and stained for quantification of plaque size.

**Results:**

Uremic mice had significantly higher serum BUN compared to the controls (72±26 vs. 33±13 mg/dl, P<0.001). The average blood pressures between the two groups were the same (97/58 vs. 102/66). There was a trend towards increase in absolute plaque size in the uremic mice compared to the controls (461,721±37,124 vs. 373,221±130,716 μm2 P=0.06). There was no significant difference in % plaque within an aortic root section (42%±10 uremic vs. 38%±12 controls P=0.29).

**Conclusion:**

Uremic hApoA1tg/ApoE-/- mice showed a trend toward increased aortic root plaque size compared to non-uremic controls. However, the increase was of a smaller magnitude than expected from prior studies of atherosclerosis in uremia. The results suggest that ApoA1, and thus enhanced reverse cholesterol transport, maybe protective against accelerated atherosclerosis seen in uremia.

**Myogenic Reactivity Is Decreased in Renal Arteries of the Zucker Diabetic Fatty (ZDF) Rat** Peter Vavrinec, Robert H. Henning, Richard P. Van Dokkum, Hendrik Buikema. *Department of Clinical Pharmacology, University Medical Centre Groningen, University of Groningen, Groningen, Netherlands.*

Introduction: On average, one out of six Europeans with up to one in three in some EU countries suffers from a condition referred to as the metabolic syndrome. These individuals are at increased risk for development of type 2 diabetes mellitus (DM-2) and the complications of renal end-organ damage associated herewith. In obese Zucker diabetic fatty (ZDF) rats with DM-2, early metabolic abnormalities confer into structural and functional kidney damage. Myogenic constriction (MC), one of the autoregulatory mechanism that protects the kidney from excessive pressure, was found to be impaired in several models of renal failure, but has not been previously studied in the ZDF rat model of DM-2.

Methods: Renal arteries isolated from 25 weeks old ZDF and lean control rats were transferred to a arteriograph to asses agonist and pressure induced (MC) contractile properties. Furthermore blood glucose, proteinuria and focal glomerulosclerosis FGS were assessed.

Results: Compared to lean controls, ZDF had significantly increased plasma glucose levels (9.6±1 vs 23,9±2 mmol/L, resp.; p<0,0001), and displayed renal failure in terms of proteinuria (15,1±2,1 vs 337,3±39,7 mg/24h resp.; p<0,0001) and FGS (6,3±1,6 vs 27,9±1,3 % resp.; p<0,0001). Renal arteries isolated from ZDF rats showed impaired myogenic constriction (23,6±3,4 vs 14,5±1,9 %(max.), resp.; p<0,05.), whereas sensitivity to the α1 agonist phenylephrine was significantly increased compared to lean controls ( pD2: 6,7±0,03 vs 6,4±0,03; p<0,0001 ).

Conclusion: Impaired myogenic constriction of renal arteries in ZDF rats suggests that deterioration of autoregulatory mechanisms in the kidney might be the cause of renal failure in this model of DM-2. Targeting this problem may be a therapeutic approach for prevention from renal failure in this model.

**Epidermal Growth Factor Receptor Inhibitor PKI-166 Governs Cardiovascular Protection without Renal Protection in 5/6 Nephrectomized Rats** Peter Vavrinec,[1] Gemma M. Mulder,[2] Richard P. Van Dokkum,[1] Hendrik Buikema,[1] Sjoerd Landheer,[1] Maaike Goris,[1] Harry Van Goor,[2] Hakan Gurdal,[3] Robert H. Henning,[1] Nadir Ulu.[3] *[1]Department of Clinical Pharmacology, University Medical Centre Groningen, University of Groningen, Groningen; [2]Departments of Pathology, University Medical Centre Groningen, University of Groningen, Groningen, Netherlands; [3]Department of Medical Pharmacology, Faculty of Medicine, University of Ankara, Ankara, Turkey.*

Epidermal growth factor receptor (EGFR) signaling has been implicated in hypertension and chronic kidney disease (CKD) via transactivation by angiotensin II type 1 receptor- and/or α1-adrenoceptor. As the therapeutic potential of EGFR inhibition in these conditions is unknown, we studied effect the EGFR kinase inhibition in CKD and associated hypertension in the rat remnant kidney model. Experimental CKD was induced by 5/6 nephrectomy (5/6Nx) and 6 weeks after 5/6Nx rats were treated either with EGFR kinase inhibitor PKI-166 (50mg/kg/day) or lisinopril (5mg/kg/day) or vehicle until week 12. Sham animals received either PKI-166 or vehicle. Blood pressure, parameters of cardiac and renal damage, aortic contractility and myogenic reactivity of small mesenteric artery were investigated. Nephrectomized rats displayed characteristic features of CKD including severe proteinuria, significantly higher plasma creatinine and focal glomerulosclerosis score, increased fluid intake, elevated urine production and renal hypertrophy. PKI-166 treatment prevented the progression of hypertension without any effect on the progression of renal injury. Moreover,

the impaired contraction of isolated thoracic aortic rings to phenylephrine or angiotensin II in vehicle-treated nephrectomized rats was restored by PKI or lisinopril treatment. Small mesenteric arteries of vehicle-treated nephrectomized rats failed to develop myogenic tone which was also completely restored by PKI or lisinopril treatment.In conclusion, blockade of the EGFR pathway displays a therapeutic benefit in kidney disease associated hypertension which was independent of limiting the progression of renal injury. Our findings extend the evidence on EGFR signaling as a target in arterial hypertension.

**The Changes on Renal Vessels Introduced by the Long-Term Administration of an Angiotensin II Receptor Blocker in Zucker Fatty Rats** Kazushige Nakanishi,[1] Yohko Nagai,[1,2] Nobuaki Yamanaka.[2] *[1]Department of General Medicine and Emergency Care, Toho University, Faculty of Medicine, Tokyo, Japan; [2]Tokyo Kidney Research Institute, Japan.*

**Introduction** : The nephro-protective effects of angiotensin II receptor blockers (ARBs) are widely known. However, there are few reports focusing on the renal vessels for long-term effects. We clarified afferent arteriolar changes induced by the long-term administration of an ARB.

**Materials and Methods** :Thirty-two 6-week-old male Zucker Fatty Rats (ZFR) were divided into following four groups (n=8 in each): ZFR Group and ZFR+High Group fed a standard or high-salt diet respectively; ZFR+ARB Group and ZFR+High+ARB Group fed a standard or high-salt diet with ARB (olmesartan, 5mg/Kg/day), respectively. Blood pressure, proteinuria, morphological examinations and glomerular hemodynamics in vivo were studied.

**Results :**Remarkable proliferative changes in the afferent arteriolar smooth muscle cells (SMCs) were frequently observed in the two groups given ARB; in the ZFR+ARB group (77.3±10.3%) compared with the two groups without ARB (1.7%, $p<0.005$; 1.2%, $p<0.0005$).They were 37.4±15.6% in the ZFR+High+ARB group. Proteinuria markedly decreased in the two groups treated ARB. The glomerular erythrocyte velocities showed no differences.

**Conclusions** :It was indicated that long-term ARB administration induced unusual proliferative changes of SMCs in afferent arterioles of ZFR. These changes could narrow arteriolar lumens and reduce intraglomerular pressure, but they could cause irreversible damage on the arterioles.

**Novel, Non-Invasive Vascular Assessment Tools Can Enhance Cardiovascular Risk Profiling at the Bedside in CKD** Gavin Dreyer,[1] Arthur Tucker,[2] Martin J. Raftery,[1] Magdi Yaqoob.[1] *[1]Renal Unit, Royal London Hospital, London, United Kingdom; [2]Microvascular Department, Barts and the London NHS Trust, United Kingdom.*

Introduction

Traditional risk factors for cardiovascular disease in CKD including eGFR, blood pressure, cholesterol, calcium and phosphate do not give a comprehensive assessment of cardiovascular risk in individual patients. Novel clinical assessments of circulatory function are required to enhance risk stratification and therapeutic management in CKD.

Methods

We piloted 3 operator independent techniques to provide bedside measures of circulatory function in patients with CKD – skin auto-fluorescence (skin AF) for advanced glycation end products, aortic pulse wave velocity (aPWV) for arterial stiffness and iontophoresis (IOP) of acetylcholine with laser Doppler monitoring for endothelial function. Thirty eight patients (25 male) with stage 3-4 CKD and 15 healthy volunteers (9 male) underwent two assessments of each technique. Time taken for all assessments was 10-15 minutes per patient.

Results

In the CKD group, the mean creatinine was 192 µmol/L (eGFR 35.7ml/min/1.73m$^2$). aPWV and skin AF were higher in the CKD group. Area under the curve by laser Doppler flowmetry for IOP of acetylcholine was lower in the CKD patients reflecting impaired endothelial function.

Vascular assessments

| | Healthy | CKD | p value |
|---|---|---|---|
| BP (mmHg) | 106/64 | 119/79 | <0.001 |
| aPWV (m/s) | 7.3 | 8.5 | <0.001 |
| Skin AF (AU) | 2.0 | 2.9 | <0.001 |
| AUC IOP | 71335 | 36436 | <0.001 |

AUC IOP = area under curve for iontophoresis of acetylcholine

These results demonstrate significantly impaired vascular function in patients with CKD compared to healthy controls. There is no correlation between methods indicating they each add independent information to the clinical assessment. Coefficient of variance for all techniques demonstrates acceptable reproducibility.

Conclusion

Three simple, rapid and non-invasive bedside tests provide additional information on vascular function in CKD beyond what is normally available in a standard clinical environment. This information can assist with risk stratification and enhance targeted therapies and monitoring in patients with CKD.

**Sex Difference in the Association of Renal Arteriolar Hyalinosis and Hyperuricemia in Chronic Kidney Disease Patients** Kentaro Kohagura,[#1] Masako Kochi,[#1] Yusuke Ohya,[#1] Kunitoshi Iseki.[#2] *[1]Cardiovascular Medicine, Nephrology and Neurology, University of the Ryukyus, Nishihara-cho, Okinawa, Japan; [2]Dialysis Unit, University of the Ryukyus, Nishihara-cho, Okinawa, Japan.*

We have previously reported that hyperuricemia was a risk factor for ESRD only in women among general population in Okinawa. Hyperuricemia causes renal arteriopathy in animals. However, an association of serum uric acid with renal arteriopathy in patients with chronic kidney disease (CKD) and its relationship to sex difference has not been investigated. In the present study, we examined the cross-sectional association between the levels of serum uric acid and renal arteriolar hyalinosis using renal biopsy specimen both in men and women. Arteriolar hyalinosis was assessed by semi quantitative grading for arterioles among 180 patients with CKD (mean age, 43.4 yrs; 99 men and 81 women). The mean age and eGFR were similar in both sexes, but the levels of serum uric acid were significantly higher in men than in women (6.9 vs. 5.8 mg/dL, $P<0.0001$). With increasing tertiles of serum uric acid, the proportions of higher-grade hyalinosis were increased only in women ($P=0.004$ for trend). Multiple logistic analysis adjusted for age and hypertension showed that the 2nd and 3rd tertiles of uric acid were significantly associated with higher risk for the presence of renal arteriolar hyalinosis than the lowest tertile only in women. The adjusted odds ratios (95% CI) were 29.15 (4.64 to 183.17) and 8.62 (1.72 to 43.32), respectively.

In conclusion, significant association between renal arteriolar hyalinosis and increased level of serum uric acid was observed only in women. Such difference in association might explain the sex-associated difference in susceptibility to CKD progression previously shown in epidemiologic studies.

**Kidney Function and Multiple Hemostatic Biomarkers: The Multi-Ethnic Study of Atherosclerosis** Ruth F. Dubin,[1] Mary Cushman,[2] Aaron Folsom,[3] Linda F. Fried,[4] Walter Palmas,[5] Carmen A. Peralta,[6] Christina Wassel,[7] Michael Shlipak.[6] *[1]Internal Medicine, Division Nephrology, University of California San Francisco, San Francisco, CA; [2]Internal Medicine, University of Vermont, Burlington, VT; [3]Epidemiology and Public Health, University of Minnesota, Minneapolis, MN; [4]Medicine, Epidemiology, VA Pittsburgh Healthcare System, Pittsburgh, PA; [5]Medicine, Columbia University, New York, NY; [6]Internal Medicine, University of California San Francisco, San Francisco VA Medical Center, San Francisco, CA; [7]Family and Preventive Medicine, University of California San Diego, San Diego, CA.*

Cystatin C has a strong association with cardiovascular and overall mortality in persons with and without CKD, independent of inflammation. Abnormalities of hemostasis may play an important role in this association.

We tested cross-sectional associations between glomerular filtration rate (eGFR) and multiple hemostatic markers among 6751 participants representing a broad spectrum of kidney function in the Multi-Ethnic Study of Atherosclerosis (MESA). Kidney function was measured using cystatin C (eGFRcys) or creatinine (CKD-EPI). Hemostatic markers included soluble thrombomodulin (sTM), soluble tissue factor (sTF), D-Dimer, plasmin-antiplasmin complex (PAP), tissue factor pathway inhibitor (TFPI), E-selectin and CD40 ligand. Associations were tested using multivariable linear regression with adjustment for demographics and comorbidities.

The biomarkers most strongly associated with eGFR were of small molecular weight. In comparison to the reference group with eGFRcys >90 ml/min/1.73m2, subjects with eGFRcys < 60 ml/min/1.73m2 had adjusted levels of sTM, sTF, D-Dimer and PAP that were respectively 86%, 68%, 44%, and 22% higher. Subjects with eGFRcys 60-90 ml/min/1.73m2 had adjusted levels that were respectively 16%, 14%, 12%, and 6% higher ($p< 0.05$ for all).

Throughout a broad spectrum of kidney function, lower eGFR is associated with elevations in selected hemostatic markers. Dysregulation of hemostasis may be a mechanism by which reduced kidney function leads to higher cardiovascular risk.

### F-PO1738

**Antigen Specificity and Functionality of CD4$^+$CD28$^-$ T Cells in Pre-Dialysis CKD Patients** Behnam Zal,[2] Nihil Chitalia,[1] Juan Carlos Kaski,[2] Christina Baboonian,[2] Debasish Banerjee.[1] *[1]Renal Medicine, St. George's Hospital, London, United Kingdom; [2]CV Sciences, St. George's University of London, London, United Kingdom.*

**Background**

Cardiovascular disease (CVD) is common in CKD, often in the absence of traditional risk factors with inflammation being implicated in the pathogenesis. An aggressive and unusual CD4$^+$ T cell subpopulation (CD4$^+$CD28$^-$) expand in coronary artery disease (CAD). These cells exhibit significant proinflammatory and cytotoxic functions activated by human heat shock protein 60 (hHSP60; a stress protein upregulated in inflammation). The activating Killer Immunoglobulin-like Receptor 2DS2 (KIR2DS2) mediates the effector function of these T cells.

**Aims**

We investigated the frequency and effector function of $CD4^+CD28^-$ cells in predialysis CKD patients.

**Methods and Results**

14 non-diabetic CKD patients (age 55±13), men 57%, hypertension 93%, eGFR 27±11 ml/min/1.73m$^2$, current smokers 14% and 10 healthy controls were investigated for the presence of $CD4^+CD28^-$ cells using FACS.

Four patients had $CD4^+CD28^-$ cells constituting 8-11% of the $CD4^+$ compartment. None of the controls had these T cells. T cell clones (n=80) established from 2 patients and analyzed by RT-PCR revealed presence of KIR2DS2 in 35 & 38% with co-expression of inhibitory KIR2DL3 in 16 & 18% of cells. We investigated the effector function of these cells upon exposure with autologous hHSP60 pulsed target cells. Only 2DS2+ clones co-expressing the adaptor protein DAP-12 (70%) and lacking KIR2DL3 reacted by releasing perforin. This is significant as our previous study in CAD showed that the inhibitory KIRs had no protective role in $CD4^+CD28^-$ cells.

Presence of these killer cells was lower in these patients (15%) compared to ESRD patients (41%; studied separately) indicating clonal expansion with progressive renal failure.

**Conclusion**

We propose a mechanism of gradual loss of inhibitory role, with acquisition of killer function in $CD4^+CD28^-$ T cells with progressive renal failure. This is the first report on antigen specificity and killing potential of $CD4^+CD28^-$ in CKD and their potential role in the development and progression of CVD in these patients.

**F-PO1739**

**Effects of Shock Wave Therapy in Chronic Kidney Diseases** Jean-Jacques Boffa, Pierre-Antoine Michel, Matthieu Colin, Christos Chatziantoniou, Pierre M. Ronco. *U702, INSERM, Paris, France, Metropolitan.*

Neoangiogenesis can be involved in renal repair. Extracorporeal low-energy shock wave therapy (SWT) is a new effective, noninvasive proangiogenic therapy which has been used for ischemic heart and limb diseases in animals and humans. In ischemic tissues, SWT enhances the expression of vascular endothelial growth factor (VEGF) and its receptor FLT-1, the production of NO, the blood flow, the capillary density and the circulating endothelial progenitor cells (EPC). The objective our study was to investigate whether SWT could protect from the development of chronic kidney disease (CKD). To this end, CKD was induced by L-NAME in 13 rats for 4-5 weeks. After reaching the level of proteinuria over creatininuria of 1000 g/mol, SWT was performed in the left kidney 3 times/week for 4 weeks.

SWT did not change hypertension (206 ± 5 before SWT vs 194 ± 5 mmHg after 4 weeks of SWT), nor proteinuria (1004 ± 138 vs 1146 ± 235 g/mol). The renal function (urea and creatininemia) remained unchanged. The treated kidney with SWT did not show an improvement in the rarefaction of peritubular capillaries (8,4 ± 1,1 % LK SWT vs 8,1 ± 1,0% RK CTRL) or an increase of the VEGF and of its receptors compared to the contralateral kidney. SWT did not reduce renal fibrosis, but decreased macrophage infiltration evidenced by CD 68+ staining : 7,3 ± 1,3 in LK SWT vs 12,1 ± 1,9 in RK CTRL, p< 0,005. In addition, SWT decreased cellular proliferation, 11,8 ± 1,8 cells in LK SWT vs 23,8 ± 5,5 in RK CTRL, p< 0,01.

In conclusion, SWT did not enhance the expression of proangiogenic factors in L-NAME treated rats. In contrast we observed an important reduction of inflammation associated with a reduction of renal cell proliferation in the treated kidney suggesting that SWT could be useful against inflammatory renal disease.

**F-PO1740**

**Soluble Epoxide Hydrolase Inhibition Decreases Blood Pressure Independent of Nitric Oxide in Mice with Renovascular Hypertension** Libor Kopkan,[1] Bruce D. Hammock,[2] John D. Imig,[3] Ludek Cervenka.[1] *[1]Department for Experimental Medicine, Institute for Clinical and Experimental Medicine, Prague, Czech Republic; [2]Department of Entomology and UCD Cancer Center, University of California, Davis, CA; [3]Department of Pharmacology and Toxicology, Medical College of Wisconsin, Milwaukee, WI.*

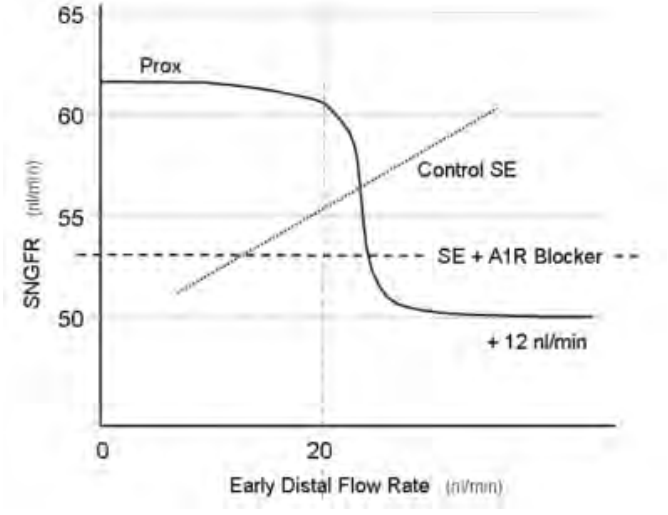
Inhibition of soluble epoxide hydrolase (sEH) induces substantial antihypertensive responses in several hypertensive models. The present study was performed to determine antihypertensive effects of sEH inhibition in mice with renovascular hypertension. Male C57Bl6 (wild type; WT) and mice lacking gene for endothelial nitric oxide synthase (eNOS-KO) were implanted with transmitters to monitor systolic blood pressure (SBP) continuously by radiotelemetry. Renovascular hypertension was induced by placing a silver clip on the right renal artery in these mice (two-kidney, one clip model). After clipping for 25 days, animals were treated with the novel sEH inhibitor, *cis*-4-[4-(3-adamantan-1-yl-ureido)-cyclohexyloxy]-benzoic acid (*c*-AUCB; 26 mg/L in drinking water) or left untreated for two weeks. Animals were placed into metabolic cages to determine 24-hrs sodium excretion throughout the treatment period. Renal artery clipping caused significant SBP increases in both WT (121±2 to 158±4 mmHg; n=6) and eNOS-KO mice (141±3 to 169±7 mmHg; n=7). However, *c*-AUCB treatment given for two weeks from day 25 significantly reduced SBP in WT (147±3 mmHg, n=6) and also in eNOS-KO mice (154±2 mmHg, n=7). During second day of the treatment, both WT and eNOS-KO animals exhibited transiently higher sodium excretion (0.141±0.008 and 0.127±0.006 mmol/day, respectively) compared to untreated WT and eNOS-KO mice (0.118±0.007 and 0.092±0.005 mmol/day, respectively) but not at the end of the treatment period. These data indicate that inhibition of sEH displayed appreciable blood pressure reductions in a mouse model with established renovascular hypertension and moreover these antihypertensive and transient natriuretic effects seemed to be NO independent as observed responses to c-AUCB were present also in mice lacking eNOS.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1741**

**Tubuloglomerular Feedback (TGF) Is Maintained after Acute Saline Expansion (SE) and Inhibited by Adenosine 1 Receptor (A1R) Blockade** Roland C. Blantz, Prabhleen Singh, Scott C. Thomson, Volker Vallon. *Nephrology, UCSD and VA, La Jolla, CA.*

Previous studies suggest that acute SE suppresses or eliminates TGF, however our current closed-loop analyses reveal that TGF is maintained and reset with a new relationship between nephron GFR (SNGFR) and early distal tubular flow rate (EDFR). After SE (10% body weight) for 1 hour we evaluated TGF by assessing proximal and distal SNGFR in the same nephrons and also changes in distal tubule SNGFR before and after adding 12 nl/min to free flowing late proximal tubule in Fromter-Wistar rats. After SE distal SNGFR was increased and EDFR also increased fourfold to 21 nl/min, but TGF activity was maintained. The proximal-distal SNGFR difference was +7±2 nl/min ($p<0.01$) and the reduction in distal SNGFR after addition of fluid to proximal flow was -8±4 nl/min ($p<0.05$) suggesting normal TGF after SE, but reset at higher values. After blockade of A1R by systemic administration of DPCPX, TGF activity was absent with no proximal-distal SNGFR difference (2±2 nl/min, NS) and no reduction in distal SNGFR after addition of fluid (-3±5 nl/min, NS).



Both distal SNGFR and EDFR (21±1 vs 22±2 nl/min) were not altered by A1R blockade. However whole kidney GFR was higher during SE with A1R blockade compared to control SE (1.6±0.2 vs 2.5±0.3 ml/min, $p<0.02$) as was urine flow rate (77±11 vs 127±15 ul/min, $p<0.02$). This suggests that inhibition of A1R 1) exerts greater effect on SNGFR in deeper nephrons (possibly via TGF) and 2) inhibits Na and water transport. Conclusions: 1) TGF after acute SE adapts and is reset to a new relationship between SNGFR and EDFR. 2) During acute SE, A1R blockade inhibits TGF and increases whole kidney GFR and decreases transport beyond the early distal tubule and/or in deeper nephrons. TGF persists and resets after SE and may act to limit changes in GFR and diuretic response.

**P2 Receptor-Mediated Changes in Vasa Recta Diameter by In Situ Pericytes: Evidence for Tubular/Vascular Cross-Talk?** Teresa M. Kennedy-Lydon,[1] Holly B. Callaghan,[1] Carla Sprott,[1] Carol Crawford,[1] Robert J. Unwin,[2] Harriet M. Syme,[1] Scott S. P. Wildman,[1] Claire M. Peppiatt-Wildman.[1] *[1]Royal Veterinary College, London, United Kingdom; [2]UCL Medical School, London, United Kingdom.*

We hypothesise that tubular/vascular cross-talk is important in the pericyte-mediated regulation of vasa recta diameter and therefore medullary blood flow. We have developed a live kidney slice model to study interactions between vasa recta pericytes *in situ* and adjacent renal tubules. ATP is released by tubular epithelial cells and ATP-activated P2 receptors (P2R) are expressed on pericytes. We investigated the effect of exogenous extracellular nucleotides on vasa recta pericytes in our live slice model.

Kidney slices (200 μm thick) from adult male Sprague Dawley rats were maintained in PSS, bubbled with 95% $O_2$/5% $CO_2$. Real-time images of vasa recta (~50 μm below the surface of the live tissue) were recorded using video imaging. Vasa recta diameter at pericyte and non-pericyte sites was measured following application of nucleotides+/-antagonist.

ATP (100 μM) evoked a significantly greater vasoconstriction of vasa recta at pericyte sites (12.4±1.3%) than at non-pericyte sites (3.8±1.3). 2meSATP (10 μM giving a maximal effect) and UTP (100 μM giving a maximal effect) also caused a significantly greater constriction of vasa recta at pericyte sites (8.5±0.7% and 12.7±1.3%, respectively) than at non-pericyte sites (1.5±0.4% and 2.9±1.3%, respectively). BzATP (1 mM) caused complete occlusion of the vessel at pericyte sites. The constriction evoked at pericyte sites by ATP (100 μM) was significantly attenuated (~15%) by the P2R antagonist RB2 (100 μM) but not by suramin (100 μM) or PPADS (100 μM). UTP-evoked constriction was not significantly altered by PPADS, suramin or RB2.

Nucleotides acting on P2R expressed on pericytes cause vasoconstriction of *in situ* vasa recta.That nucleotides are released from tubular epithelial cells in close proximity to vasa recta suggests that tubular/vascular cross-talk may regulate medullary blood flow.Our data also goes some way to pharmacologically characterizing the P2R on pericytes and include the UTP-sensitive $P2Y_2R$, the RB2-sensitive $P2Y_4R$, and the BzATP-sensitive $P2X_7R$.

**PPARγ Is a Master Regulator of Circadian Rhythms of Behavior and Metabolism** Guangrui Yang,[1,2] Toshinori Aoyagi,[1,2] Zhanjun Jia,[1,2] Tianxin Yang.[1,2] *[1]Internal Medicine, University of Utah, Salt Lake City, UT; [2]Veterans Affairs Medical Center, Salt Lake City, UT.*

Both human and animal studies have established a physiological link between the circadian rhythm and metabolism. However, the molecular basis of coordinated control of the circadian clock and the metabolic pathways is not well understood. Here we describe a novel role of PPARγ, a key regulator of energy metabolism, in the control of physiological and behavioral rhythms by analyzing two strains of whole-body PPARγ null mouse models. Systemic inactivation of PPARγ was generated constitutively by using Mox2-Cre mice (Mox PPARγ KO) or inducibly by using the tamoxifen system (TM PPARγ KO). The floxed mice exhibited nocturnally activated rhythms in food and water intake, urine and feces production, locomotor activity, blood pressure and heart rate, oxygen consumption, CO2 production, and heat production. The circadian variations of most of these parameters were nearly abolished in Mox PPARγ KO mice and significantly attenuated in TM PPARγ KO mice. qRT-PCR detected impaired rhythmicity of Bmal1, Per1, Per3 and Per2, rev-erbα in the apididymal fat depot and Bmal1, Per1-3, Cry1-2, and rev-erbα in the liver contrasting unaltered rhythmicity of any of the clock genes in the skeletal muscle and the kidney. PPARγ inactivation in isolated preadipocytes following in vitro exposure to tamoxifen led to a similar blockade of the rhythmicity of the clock gene expression. Both null strains exhibited elevated baseline heart rate and a marked increase in urinary excretion of epinephrine and norepinephrine, which exhibited blunted circadian variations. The baroreflex response during infusion of sodium nitroprusside was blunted but remained intact during infusion of phenylephrine. Together, these results demonstrate that PPARγ integrates circadian rhythms and metabolism likely through a direct interaction with the clock system in the peripheral tissues.

**Preservation of Renal Vascular Function Despite Increases in Blood Pressure in the Ageing Fawn-Hooded Rat Model of Hypertension-Associated Renal Damage** Richard P. Van Dokkum, Peter Vavrinec, Robert H. Henning. *Clinical Pharmacology, University Medical Center Groningen, Groningen, Netherlands.*

*Background.* In humans, the risk for cardiovascular diseases increases with age. The effect of age on vascular function and the relation between blood pressure and renal damage in a model of hypertension-associated renal damage, the Fawn-Hooded (FH) rat, is unknown. Therefore, we studied myogenic constriction in 52-wks. old FHH and control FHL strains, the latter not developing increased systolic blood pressure (SBP), proteinuria and glomerulosclerosis at a young age.

*Methods.* Small renal (interlobular) and mesenteric resistance arteries isolated from FHH and FHL rats in an established phase of their disease (52-wks. old) were mounted in a perfused vessel set-up. Myogenic reactivity was assessed constructing pressure-diameter curves in the presence and absence of calcium. Blood pressure and proteinuria were measured using the tail-cuff method and nephelometry, respectively.

*Results.* At 52 wks, SBP was similar in both strains (169.7 ± 5.4 vs 166.0 ± 5.4 mmHg in FHH and FHL, respectively). However, FHH rats showed overt proteinuria compared to FHL rats (213.4 ± 20.7 vs. 48.9 ± 5.6 mg/24h), as well as decreased creatinin clearance (9.7 ± 0.7 vs. 13.8 ± 0.4 ml/min) and increased FGS (43.5 ± 3.9 vs. 7.9 ± 1.5 %). Moreover, FHH renal arteries developed significantly lower myogenic tone compared to FHL (5.1 ± 0.6 vs. 10.9 ± 1.4 % of max. MC). Therefore, preserved MC of FHL despite an increase in blood pressure is most likely involved in the mechanism by which the FHL kidney is protected from developing renal failure.

*Conclusion.* The present study shows that preserved MC of renal arteries from FHL in the presence of hypertension protects the kidneys in renal end-organ damage in a spontaneous model of hypertension-associated renal damage.

**Lutheran/BCAM Controls Glomerular Permeselectivity and Glomerulosclerosis during Hypertension** Jin Huang,[1] Cécile Rahuel,[2] Anne Filipe,[2] Yves Colin,[2] Pierre-Louis F. Tharaux.[1] *[1]Paris-Cardiovascular Research Center - PARCC, Inserm and Université Paris-Descartes, Paris, France; [2]Institut National de la Transfusion Sanguine -INTS, Inserm and INTS, Paris, France.*

The Lutheran (Lu) blood group/ basal cell adhesion molecule (BCAM) antigen is highly expressed in endothelial cells and has been recognized as the receptor for the a5 chain of laminins 10/11. Lu -/- mice display mild abnormalities of the glomerular basement membrane with normal proteinuria, renal function and blood pressure. We investigated whether Lu/BCAM could contribute to glomerular permselectivity in hypertensive conditions. Methods: Hypertension and glomerulosclerosis were induced by chronic infusion of Angiotensin II (1 μg/kg/d) for 28 days. Lu-/- mice and their wild-type (WT) male littermates were compared (n=11-13/group). Because dysregulation of nitric oxide (NO) may favour weak glomerular permselectivity, we also challenged Lu (-/-) mice with the NO synthase inhibitor L-NAME for 16 weeks (n=9 /group) in a distinct set of experiments.

Results: High level of Lu/BCAM was found in the glomerular endothelium and to a milder extent in podocytes. Both group developed similar degree of systolic hypertension throughout the course of the study (mean SBP:172±9 vs. 186±6 mmHg on day 28 in Lu -/- and WT, respectively). Upon AngII infusion, Lu -/- mice, exhibited a larger increase in albuminuria (541±177 g/mol creatinine on day 14 and 1722±601 g/mol on day 21) than WT mice (163± 43 g/mol creatinine on day 14 and 461± 179 g/mol on day 21, $p<0.01$). L-NAME for 16 weeks promoted a similar rise in systolic pressure in Lu (-/-) than in WT animals but also induced unusually high albumin urinary output ($p<0.01$) in the absence of Lu/BCAM. Interestingly, whereas hypertensive Lu/BCAM (-/-) animals displayed major albuminuria, the development of glomerulosclerosis was markedly alleviated in both models of hypertension, indicating that albuminuria per se is not a major factor of glomerulosclerosis. We conclude that Lu/BCAM that is highly expressed in the renal microvascular endothelium did play a critical role in limiting glomerular permselectivity under hypertensive condition in a NO-independent fashion.

**Albuminuria Associated with Genetically-Induced Podocyte Defects Is Not Accompanied by Changes in the Plasma Elimination of Dextran Mol wt 70,000 or Albumin** Wayne Comper,[1] Leileata M. Russo.[1] *[1]Exosome Diagnostics Inc, New York, NY; [2]Pathology and Immunology, Washington University School of Medicine, St Lous, MO.*

It has previously been established that the increase in plasma elimination (PE) of albumin in nephrotic states is due to the increase in urinary excretion of albumin (Kaysen et al 1982). In nephrotic rats the PE rate of albumin increases by >160%. Therefore in order to test the hypothesis that a genetically-induced podocyte defect results in nephrotic-like changes in plasma albumin elimination we examined the PE of fluorescently labeled albumin in CD2AP ko mice. PE of dextran mol wt 70,000 was also measured to estimate changes in glomerular permeability. 5 week old CD2AP ko mice exhibited significant albuminuria (>20-fold by electrophoresis) and hypoalbuminemia but normo-proteinemia. The percentage of material lost 3h post iv injection for albumin was 28.2±3.9 for WT and 25.6±5.6 for KO ($P$=0.545, n=3) and for dextran 68.1±6.6 for WT and 55.1±7.9 for KO ($P$=0.095, n=3). Urinary total protein was 35.8±6.0 (WT) and 35.2±2.8 (KO) ($P$=0.882,n=3). Similar dextran and albumin PE results were obtained in an earlier series of experiments (n=2). The lack of change in the dextran PE demonstrates that the increase in albuminuria due to the genetic podocyte defect is not directly due to changes in glomerular permeability as these changes were small. The albumin PE results demonstrate that albumin processing pre-urinary excretion is identical in both WT and KO. These results are consistent with the fact that albuminuria n CD2AP KO is primarily the result of the inhibition of the proximal tubular cell (PTC) albumin degradation pathway due to the loss of CD2AP from the PTC.

**Glutamine Supplementation Alleviates Vasculopathy and Alters the Profile of Plasma Metabolome in an In Vivo Model of Endothelial Cell Dysfunction (ECD)** Francesco Addabbo,[1] Qun Chen,[2] Brian B. Ratliff,[3] Tammer Ghaly,[3] Dhara P. Patel,[3] Michael S. Wolin,[3] Steven S. Gross,[2] Michael S. Goligorsky.[3] *[1]University of Bari, Bari, Italy; [2]Weill Cornell Medical College, NY, NY; [3]New York Medical College, Valhalla, NY.*

Using a mouse model of ECD, triggered by continual sub-pressor dosing with L-NG-methylarginine (L-NMMA), we previously demonstrated that the renal microvasculature displays an abnormal protein profile, including diminished expression of two key enzymes of the Krebs cycle (aconitase-2 and enoyl-CoA-hydratase-1) and consequently a Warburg-type suppression of mitochondrial metabolism. We hypothesized that supplementation with metabolites such as glutamine (GLN), that enters the Krebs cycle downstream of this enzymatic blockade, would normalize vascular function and alleviate mitochondrial dysfunction. Mice with chronic L-NMMA treatment-induced ECD were co-treated with GLN. L-NMMA-treatment resulted in defect in acetylcholine-induced relaxation of aortic rings that was dose-dependently prevented by GLN supplementation. Using an LC/MS platform for broad untargeted metabolite profiling, we detected 4,098 plasma molecules with 100% frequency in mice from at least one treatment group. Among these molecules, 372 were found to be differentially expressed in a 4-way comparison of Control vs. L-NMMA

vs. GLN vs. GLN+L-NMMA groups ($p < 0.05$). In isolated renal microvasculature, 1360 metabolites were detected with 100% frequency in at least one group, 19 of them overlapping on Venn's diagram and 20 and 45 being highly specific for L-NMMA and L-NMMA+GLN groups, respectively. Paradoxically, hippuric acid, an established uremic toxin, was found to be significantly increased in these non-uremic mice receiving L-NMMA, and normalized by the concomitant treatment with GLN. In conclusion, functional and metabolic profiling of animals with early ECD reveal that the truncation of Krebs cycle, characteristic of this condition, is associated with the development of macrovasculopathy and that supplementation of these mice with the intermediary of Krebs cycle, downstream of the enzymatic block, is capable of significantly improving vasculopathy.

**Losartan Concentration-Dependently Attenuates Angiotensin-II-Evoked Constriction of Vasa Recta by *In Situ* Pericytes: Studies Using a Novel Live Kidney Slice Model** Carol Crawford,[1] Scott S. P. Wildman,[1] Robert J. Unwin,[2] Claire M. Peppiatt-Wildman.[1] *[1]Royal Veterinary College, London, United Kingdom; [2]UCL Medical School, London, United Kingdom.*

Angiotensin-II (Ang-II; 10 nM) causes pericyte-mediated vasoconstriction (~40% constriction) of isolated descending vasa recta (1). We have proposed that tubular/vascular cross-talk is important in the regulation of vasa recta diameter and therefore medullary blood flow. We have developed a live kidney slice model to investigate the effects of vasoactive substances on vasa recta pericytes *in situ*. Here we have investigated the effects of Ang-II in our live slice model.

Kidney slices (200 μm thick) were obtained from adult (~300 g), male Sprague Dawley rats and maintained in PSS, bubbled with 95% $O_2$/5% $CO_2$. Real-time images of vasa recta (~50 μm below the surface of the live tissue) were recorded using video imaging. Vasa recta diameter at pericyte and non-pericyte sites was measured following application of Ang-II+/-losartan.

Superfusion of kidney slices with Ang-II (10 - 100 nM) significantly constricted vasa recta at pericyte sites (by ~15%), but not at non-pericyte sites. In contrast, the $AT_1$ receptor antagonist losartan (10 nM and 100 nM) did not alter vasa recta diameter at either pericyte or non-pericyte sites. Losartan (10 nM) significantly and reversibly inhibited 100 nM Ang-II-evoked vasoconstriction by ~30%. Higher concentrations of Losartan (100 nM) irreversibly abolished the Ang-II-evoked vasoconstrictrion.

In summary, Ang-II evokes vasoconstriction of vasa recta specifically at pericyte sites, in our live slice model. Vasoconstriction was less than previously reported using isolated vasa recta. The inhibition of Ang-II-evoked vasoconstriction by losartan indicates that vasoconstriction is mediated by $AT_1$ receptors (presumably expressed on pericytes). Furthermore, given that vasa recta diameter is unaltered by losartan application it suggests that Ang-II is not required for maintenance of vasa recta tone.

**Identification and Characterisation of *In Situ* Vasa Recta Pericytes** Carol Crawford, Carla Sprott, Teresa M. Kennedy-Lydon, Scott S. P. Wildman, Claire M. Peppiatt-Wildman. *Royal Veterinary College, London, United Kingdom.*

Pericytes have been identified along isolated vasa recta capillaries of the renal medulla and have been shown to regulate vessel diameter of isolated descending vasa recta (1). Here we have identified pericytes along vasa recta in kidney slices using an anti-NG2 (neural-glial-2) antibody and present morphological characterisation of *in situ* vasa recta pericytes in the inner and outer medullary regions.

Kidney slices (~200 μm thick) were obtained from adult, male Sprague Dawley rats (250-300 g). Pericytes were labelled with an anti-NG2 antibody and probed with an alexa 555-conjugated secondary antibody; and vasa recta capillaries labelled with an Alex 488-conjugated isolectin $B_4$. Fluorescent images of both inner and outer medulla were taken with a Zeiss LSM 510 confocal microscope, and used to calculate the density of pericytes and measure pericyte cell body length, and pericyte process length in the inner and outer medulla.

The density, per 100 $\mu m^2$, of pericytes in the outer medulla was 12±1, which was significantly greater than in the inner medulla, 9±1. The average distance between pericyte cell bodies was 15.1±1.1 μm and 16.0±1.2 μm in the outer and inner medulla, respectively. Mean pericyte cell body length in the outer medulla was 9.0±0.2 μm, which was not significantly different to that in the outer medulla 8.7±0.3 μm. Similarly, mean pericyte process length in the outer medulla was 8.6±0.5 μm, which was not significantly different to that in the inner medulla 9.3±0.6 μm. Process length ranged from 2 μm to 18 μm, with some processes running along the vasa recta before wrapping around the vessel, and others wrapping around the vessel directly from the cell body.

Given the distance between cell bodies, and mean process length, it is likely that pericytes form a complex network, intertwined around the entire length of the vasa recta. These physical characteristics, together with their ability to regulate capillary diameter, further emphasise the importance of pericytes in the regulation of blood flow in the renal medulla.

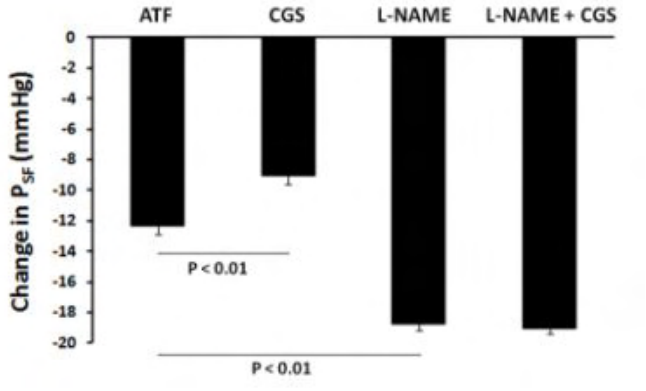
**Adenosine $A_2$ Receptors Attenuate Tubuloglomerular Feedback Response Via Stimulation of Nitric Oxide** Mattias Carlstrom, Christopher S. Wilcox, William J. Welch. *Department of Medicine, Division of Nephrology and Hypertension, Georgetown University Medical Center, Washington, DC.*

**Objective:** Adenosine can mediate the tubuloglomerular (TGF) response via activation of $A_1$ receptors on the afferent arteriole. We have recently shown that adenosine $A_2$ receptors modulate the TGF response by counteracting the effects of adenosine $A_1$ receptors. We tested the hypothesis that $A_2$ receptor mediated dilatation is linked to release of nitric oxide (NO).

**Methods:** Maximal TGF responses were measured in male Sprague-Dawley rats as changes in proximal stop-flow pressure ($\Delta P_{SF}$) in response to increased perfusion of loop of Henle (0 to 40 nl/min) with artificial tubular fluid (ATF). The maximal TGF response was studied after 5 min intratubular perfusion (10 nl/min) with ATF alone, or with ATF plus the $A_{2A}$ receptor agonist (CGS 21680; $10^{-7}$ mol/l), the nitric oxide synthase (NOS) inhibitor (L-NAME; $10^{-3}$ mol/l), or with a combination of L-NAME ($10^{-3}$ mol/l) and CGS 21680 ($10^{-7}$ mol/l).

**Results:** Blood pressure, heart rate, urine flow, $P_{FF}$ and $P_{SF}$ (at 0 nl/min) were similar among the groups. The maximal TGF response ($\Delta P_{SF}$) with ATF alone was 12.3 ± 0.6 mmHg. Specific $A_2$ stimulation attenuated the maximal TGF response (9.0 ± 0.6 mmHg). L-NAME enhanced the response ($\Delta P_{SF}$: 18.7 ± 0.5 mmHg). Stimulation of $A_2$ receptors, during simultaneous NOS inhibition, did not attenuate the maximal response ($\Delta P_{SF}$: 19.0 ± 0.4 mmHg).



**Conclusion:** Adenosine $A_2$ receptors modulate the $A_1$ mediated TGF response via stimulation of NOS-derived NO in the juxtaglomerular apparatus.

**F-PO1751**

**Large Increases in Glomerular Permeability Following Atrial Natriuretic Peptide (ANP) Infusion in Rats** Josefin Axelsson, Anna Rippe, Bengt Rippe. *Department of Nephrology, Lund University, Lund, Sweden.*

Plasma volume overload, in conjunction with e.g. congestive heart failure (HF), is associated with an increased release of atrial natriuretic peptide (ANP), which may be partially responsible for the microalbuminuria seen in HF. The present study was performed to investigate the effects of systemic ANP infusion on the glomerular permeability to macromolecules in rats. In anaesthetized Wistar rats (250-280g) the left urether was cannulated for urine collection while simultaneously blood access was achieved. Rats were continuously infused i.v. with ANP, 30 ng/min/kg (Lo-ANP; n=8) or 800 ng/min/kg (Hi-ANP; n=10) or 0.9% NaCl (SHAM; n=16), respectively, and with polydisperse fluorescein isothiocyanate (FITC)-Ficoll-70/400 (mol.radius 13-90Å) and $^{51}$Cr-EDTA for 2 h. Plasma and urine samples were taken at 5, 15, 30, 60 and 120 min of ANP infusion, and analyzed by high performance size exclusion chromatography (HPLC) for determination of glomerular sieving coefficients (θ) for Ficoll. GFR was also assessed ($^{51}$Cr-EDTA). In Hi-ANP there was a rapid (within 5 min), but bimodal, increase in glomerular permeability. θ to high MW Ficoll thus reached a maximum at 15 min, after which θ returned to near control at 30 min, to again increase moderately at 60 and 120 min. Max. θ increase for $Ficoll_{70Å}$ was from $3.48 \cdot 10^{-5} \pm 1.01 \cdot 10^{-5}$ to $3.88 \cdot 10^{-4} \pm 7.63 \cdot 10^{-5}$ (Hi-ANP). In Lo-ANP there was also a rapid, reversible increase in glomerular θ, returning to near control at 30 min, followed by just a tendency of a sustained increase in permeability, but with a significant increase in "large pore" radius. In conclusion, in Hi-ANP there was a rapid increase in glomerular permeability, with an early, partly reversible permeability peak, followed by a (moderate) sustained increase in permeability. In Lo-ANP animals, only the initial permeability peak was evident. For pharmacological ANP-doses (Hi-ANP), the glomerular sieving pattern observed was found to mainly reflect an increase in the number and radius of "large pores" in the glomerular filter, while for physiological doses, increases in large pore radius dominated, particularly during the last 60 min of the ANP infusion.

**GDF15, a TGF-beta Family Member, Impairs Vascular Responsiveness in Wild Type and GDF15 Knockout Mice** Magdalena Mazagova, Robert H. Henning, Leo E. Deelman. *Clinical Pharmacology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands.*

Background: Alterations in hemodynamics and (intrarenal) vascular dysfunction contribute to the development of cardiovascular and diabetic kidney disease. Growth differentiation factor 15 (GDF15), a member of the TGF-beta superfamily, is an early response gene upregulated after induction of renal injury. Furthermore, increased plasma GDF-15 levels have been associated with cardiovascular dysfunction in patients suffering from type I and II diabetes. In this study, we investigated whether GDF15 modulates vascular function in wild type and GDF15 knockout mice.

Methods: Aortic rings were obtained from healthy C57BL/6 (wt) and GDF15 k.o and measured in a wired myograph (Danish Myo Technology). Aortic rings were preincubated with GDF15 (50ng/ml) or TGF-β (3ng/ml). Contraction to phenylefrine (PE) and relaxations to acetylcholine (Ach) were assessed in all groups. To evaluate the contributions of different relaxant pathways, Ach-mediated responsiveness was also studied in the presence of indometacine and L-NMMA.

Results: Contractions to PE and relaxations to ACh were not significant different between wt and GDF15 k.o mice. Preincubation with GDF15 impaired the contraction to PE (6.29±1.19 AUC in wt mice and 5.9±1.03 AUC in k.o mice with control treatment, 3.68±0.81 AUC in wt mice and 3.04±0.64 AUC in k.o mice with GDF15 treatment). Denudation restored PE responses to control levels, suggesting that the GDF15 mediated impaired contraction is endothelium-dependent. Preincubation with TGF-beta did not affect vasoconstriction and vasodilatation. Further, GDF15 treatment impaired total Ach (141±13.59 AUC in wt mice and 142±36.5 AUC in k.o mice in control treatment, 90±20.7 AUC in wt mice and 63±27.5 in k.o mice with GDF15 treatment).

Conclusion: We demonstrated for the first time that GDF15 plays an important role in inhibition of vascular contraction and relaxation in both wildtype and GDF15 knockout mice.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1753**

**Globally-Altered Permeability in Rat Models of Proteinuria** Andy Salmon,[1,2] Joanne Ferguson.[1] *[1]Physiology and Pharmacology, Univeristy of Bristol, Bristol, United Kingdom; [2]Clinical Science @ North Bristol, University of Bristol, Bristol, United Kingdom.*

Widespread vascular dysfunction accompanies albuminuria in both diabetic- and non-diabetic nephropathies. One facet of this widespread dysfunction is excessive leak from blood vessels throughout the body. In the kidney this is manifest as albuminuria, but leak also occurs from extra-renal blood vessels (e.g. excessive sodium fluorescein leak from skin microvessels in diabetic patients).

Increased capillary pressure and increased capillary wall permeability will both cause excessive leak. I have measured capillary wall permeability coefficients directly, in structurally distinct capillary beds (fenestrated capillary: glomeruli, and continuous capillary: gut mesentery) in two rat models of proteinuria: Munich-Wistar-Fromter (MWF) rats (that spontaneously develop focal segmental glomerulsosclerosis) and streptozotocin-induced diabetes mellitus, to test the hypothesis that altered capillary permeability occurs in diverse microvessels in proteinuria.

Adult male MWF rats were examined at 15-24 weeks, and adult male Sprague-Dawley rats were examined 7 days after streptozotocin (45 mg/kg iv). Animals were anaesthetised, the gut mesentery exteriorised, single microvessels cannulated and perfused with 4% bovine serum albumin (BSA) at known hydrostatic pressure, and hydraulic conductivity ($L_p$: $10^{-7}$ $cm.s^{-1}.cmH_2O^{-1}$) calculated. For glomerular experiments, single glomeruli were harvested by sieving, and exposed to an oncotic pressure gradient in a flow-controlled observation chamber, allowing calculation of hydraulic conductivity-area product ($L_pA$: $nl.min^{-1}.mmHg^{-1}$), adjusted for glomerular volume ($L_pA/V_i$).

Mesenteric $L_p$ (MWF: 6.4±4.6; Wistar: 2.8±0.4; $p<0.05$, unpaired t-test) and glomerular $L_pA/V_i$ (MWF: 1.5±0.1; Wistar: 1.0±0.1; $p<0.05$, unpaired t-test) were both increased in proteinuric MWF rats. Mesenteric $L_p$ (2.56±0.15 vs 2.13±0.11; $p<0.05$, unpaired t-test) and glomerular $L_pA/V_i$ (1.56±0.29 vs 0.93±0.07; $p<0.05$, unpaired t-test) were also both increased in proteinuric diabetic rats.

Widespread alterations in permeability occur early in these proteinuric animals. Future work will examine the structural correlates of these functional changes.

**Healthy Intraglomerular Arteriolar Function Predicts Doxorubicin-Induced Proteinuria, Which Can Be Reduced Using Angiotensin-II** Richard P. Van Dokkum, Peter Vavrinec, Robert H. Henning. *Clinical Pharmacology, University Medical Center Groningen, Groningen, Netherlands.*

*Background.* Susceptibility to renal injury varies among individuals. Previously, it was shown that individuals with pronounced baseline endothelial dilatory ability (measured *in vitro*) developed more renal damage after doxorubicin (doxo) injection. We tested whether constrictive ability of afferent (aff.) and efferent (eff.) glomerular arterioles in response to angiotensin-II (AII) predicts and whether AII limits the development of proteinuria after doxo injection.

*Methods.* Using an intravital microscopy set-up to envision *in vivo* glomerular arteriolar responses, three doses of AII were infused in an experimental group (n=15) and only saline throughout the entire protocol in a control group (n=16). Thereafter, proteinuria was induced in both groups by a doxo injection. During the intravital protocol, blood pressure (BP), heart rate (HR) and renal blood flow (RBF) were measured. Images of glomeruli were recorded for measurements of changes in glomerular arteriolar diameter. BP and proteinuria were followed for 6 wks. using the tail-cuff method and nephelometry, respectively.

*Results.* AII infusion significantly changed all measured hemodynamic parameters from baseline except HR (BP $p<0.05$; RBF $p<0.001$) and similarly when compared to the control group and induced significant contraction of afferent and efferent glomerular arterioles ($p<0.001$). Regression analysis on the change in aff. and eff. glomerular arteriolar diameter upon AII infusion and proteinuria 6 wks. after doxo injection showed a significant positive correlation ($p=0.04$ and $p=0.03$, respectively), which was also found between RBF at the time of injection and proteinuria 6 wks. thereafter. The group that received AII prior to the injection with doxo developed significantly less proteinuria than the saline treated group.

*Conclusion.* We conclude that glomerular arteriolar constrictive ability in response to AII predicts the development of doxo-induced proteinuria. Moreover, limiting blood supply to the kidney by infusion of AII diminishes the development of proteinuria, creating opportunities in reducing anti-cancer drug induced side effects.

**Effects of Chronic SDMA Infusion on Hemodynamics, Myocardial Function, GFR and Microvascular Fibrosis in C57 Black 6/J-Mice** Hendrik Veldink,[1] Robert Faulhaber-Walter,[1] Jens Martens-Lobenhoffer,[3] Arash Haghikia,[2] Harald Schuett,[2] Denise Hilfiker-Kleiner,[2] Joon-Keun Park,[1] Hermann G. Haller,[1] Jan T. Kielstein.[1] *[1]Department of Nephrology and Hypertension, Medical School Hannover, Hannover, Germany; [2]Department of Cardiolology and Angiology, Medical School Hannover, Hannover, Germany; [3]Institute of Clinical Pharmacology, Otto-von-Guericke-University, Mageburg, Germany.*

Background: Symmetrical dimethylarginine (SDMA), the structural isomer of the NOS inhibitor ADMA has long been regarded as an inert substance. Recent preclinical and epidemiological data suggest that it might be involved in the pathophysiology or renal and cardiovascular disease. Therefore we aimed to investigate the effect of chronic SDMA infusion on renal and cardiac function in mice. Methods: Vehicle controlled, infusion of SDMA at 250 micromol/kg/d for 28d using osmotic minipumps in 8 week old male C57Bl/6 mice (n=10 / group). Following parameters were monitored: GFR (FITC-inulin excretion kinetic), cardiac function (echocardiography), blood pressure (tail cuff). Blood samples for SDMA determination were obtained at baseline, 2 and 4 weeks. Mice were euthanized at 4 to obtain tissue for renal histology.Results: Chronic SDMA infusion lead to a significant increase of SDMA levels from 0.264±0.100 to 3.495±1.655 µmol/l ($p<0.001$) at 4 weeks. Despite this SDMA increase GFR did not change (1224±351 vs. 1017±345 ml/min/g bw, n.s.) at 4 weeks, as compared to baseline. We did not find histological changes, especially no effect on fibrosis or NOS expression. There was neither an effect of SDMA on blood pressure (106±12 vs. 111±18 mmHg, n.s.) nor on ejection fraction (54.2±1.7 vs. 58.4±1.9%, n.s.). Conclusion: SDMA exposure over 4 weeks in mice did not result in major changes in renal and cardiac function. Future studies have to clarify whether SDMA might have an effect in the presence of other cardiovascular risk factors.

**mPGES-1-Derived PGE2 Mediates Thiazolidinedione-Induced Vascular Hyperpermeability in the Adipose Tissue** Zhanjun Jia,[1,2] Toshinori Aoyagi,[1,2] Tianxin Yang.[1,2] *[1]Internal Medicine, University of Utah, Salt Lake City, UT; [2]Veteran Affairs Medical Center, Salt Lake City, UT.*

Adipose-specific increases capillary permeability contributes to thiazolidinedione (TZD)-induced fluid retention. We examined the role of microsomal prostaglandin E synthase-1 (mPGES-1) in this phenomenon. RGZ-induced body weight gain in WT mice was 1.72 ± 0.24 gm on day 7 and 1.62 ± 0.53 gm on day 14. In contrast, the BWG in mPGES-1 KO mice was absent on day 7 and reduced by 60% on day 14. RGZ-treated WT mice had a 60% increase in apidydimal water content, which was significantly attenuated in the KO mice. In parallel, the apididymal capillary perbeability (ACP), as assessed by Evans blue leakage assay, exhibited a 60% increase in WT mice after RGZ treatment. The KO mice had 60% and 62.5% reductions of ACP at baseline and after RGZ treatment, respectively. Interestingly, neither water content nor capillary permeability in the skeletal muscle was affected by RGZ or the genotype. In separate experiments, we examined time-dependent effects of RGZ on expression of key enzymes in the PGE2 synthesis pathway along with PGE2 production in the adidydimal fat depot (AFD). Adipose COX-2 induction was detected at day 1 of RGZ treatment and peaked at day 2 and declined at day 14. On day 2, qRT-PCR detected an 104-fold increase in COX-2 mRNA and immunoblotting a 98-fold increase in COX-2 protein, in parallel with a 2.5-fold increase in mPGES-1 mRNA and a 64-fold increase in PGE2 production in the AFD. At baseline, adipose mPGES-1 protein expression was suppressed by endothelial but not smooth muscle deletion of PPARγ. RGZ upregulated mRNA of apididymal VEGFB and VEGF receptor B, which was blocked by mPGES-1 deletion. In cultured endothelial cells, 1 µM RGZ induced increases in mPGES-1 mRNA and PGE2 release. mPGES-1 KO mice were intolerant to alive oil loading in term of the increased plasma levels of triglyceride, free fatty acid, and glycerol, a phenotype almost analogous to endothelial PPARγ KO mice. This study has elucidated PPARγ/COX-2/mPGES-1/PGE2/VEGFB pathway as a key determinant of adipose capillary permeability that influences transport of fluid as well as nutrients for metabolism.

**The Angiotensin II Receptor Type 2 Polymorphism Influences Hemodynamic Function and Circulating RAS Mediators in Normotensive Humans** David Cherney, Judith A. Miller, James W. Scholey, Heather N. Reich. *Medicine, University Health Network, Toronto, ON, Canada.*

**Background:** The hemodynamic responses to angiotensin II type 1 receptor blockade may be mediated by interactions between angiotensin II and the angiotensin II type 2 receptor (AT2R). An AT2R G1675A gene polymorphism has been described, but the functional effects of this polymorphism are unknown.

**Methods:** Hemodynamic function, circulating renin angiotensin system mediators and norepinephrine were measured in healthy subjects at baseline and at 2 and 4 weeks after treatment with irbesartan (75 mg daily). Subjects were divided into 2 groups on the basis of the AT2R G1675A gene polymorphism: AA/GA subjects (n=22) and GG subjects (n=12).

**Results:** AA/AG subjects exhibited hypotensive (mean arterial pressure decline from 86±3 to 81±3 mmHg, p<0.05) and renal vasodilatory responses to irbesartan at 4 weeks but GG subjects did not . In accord with hemodynamic effects, circulating aldosterone levels were suppressed in AA/AG subjects (89±10 to 59±19 pmol/L, p<0.05), while circulating norepinephrine levels were augmented only in GG subjects. In contrast, increases in circulating renin, angiotensin II and plasma renin activity after irbesartan were exaggerated in AA/AG subjects (p<0.05 vs. GG subjects).

Table 1: Renal hemodynamic function responses to irbesartan in subjects with and without the AT2R G1675A gene polymorphism (mean±SD)

| | Baseline | 4 weeks |
|---|---|---|
| | AA/AG group | |
| ERPF (ml•min -1•1.73 m-2) | 697±45 | 749±53* |
| GFR (ml•min -1•1.73 m-2) | 118±6 | 112±5 |
| FF | 0.18±0.01 | 0.15±0.01* |
| RBF (ml•min -1•1.73 m-2) | 1097±68 | 1215±82 |
| RVR (ml•l -1•min -1) | 0.083±0.006 | 0.070±0.005* |
| | GG group | |
| ERPF (ml•min -1•1.73 m-2) | 719±37 | 750±42 |
| GFR (ml•min -1•1.73 m-2) | 120±7 | 120±7 |
| FF | 0.17±0.10 | 0.16±0.01 |
| RBF (ml•min -1•1.73 m-2) | 1214±59 | 1221±67 |
| RVR (ml•l -1•min -1) | 0.072±0.005 | 0.069±0.005 |

* p<0.05 for effect of irbesartan

**Conclusions:** The AT2 G1675A polymorphism is a determinant of hemodynamic responses to AT1 receptor blockade, an effect that may be due to influences on aldosterone escape.

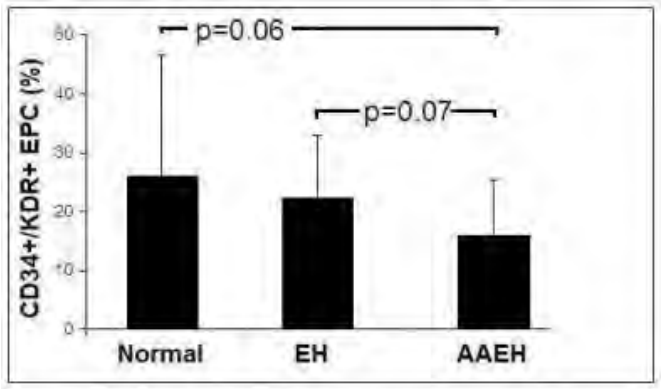
**Ethnic Differences in the Number of Endothelial Progenitor Cells and Inflammatory Biomarkers in Patients with Essential Hypertension** Alfonso Eirin,[1] Monika L. Gloviczki,[1] Mario Gossl,[2] Hui Tang,[1] Kyra L. Jordan,[1] Amir Lerman,[2] Stephen C. Textor,[1] Lilach O. Lerman.[1] *[1]Division of Nephrology and Hypertension, Mayo Clinic; [2]Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

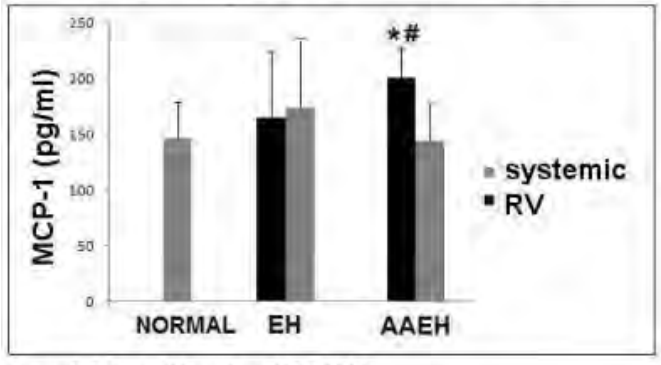
**Introduction:** Morbidity and mortality associated with hypertension are higher in African American (AAEH) compared to Caucasian (EH) patients, possibly related to increased inflammation. Because circulating endothelial progenitor cells (EPC) promote vascular repair after injury and might thereby curtail target organ damage, we hypothesized that plasma EPC levels would be lower and inflammatory biomarkers higher in AAEH compared to EH patients.

**Methods:** Hypertensive subjects treated with blockade of the renin-angiotensin system were studied during 150 mEq sodium intake . We measured renal vein (RV) and inferior vena cava (IVC) levels of tumor necrosis factor alpha (TNF-), interleukin (IL)-6, IL-10, monocyte chemoattractant protein-1 (MCP-1), and vascular endothelial growth factor (VEGF), as well as circulating CD34+/KDR+ EPC, in treated EH (n=17), AAEH (n=13), and normotensive control (n=7) subjects.

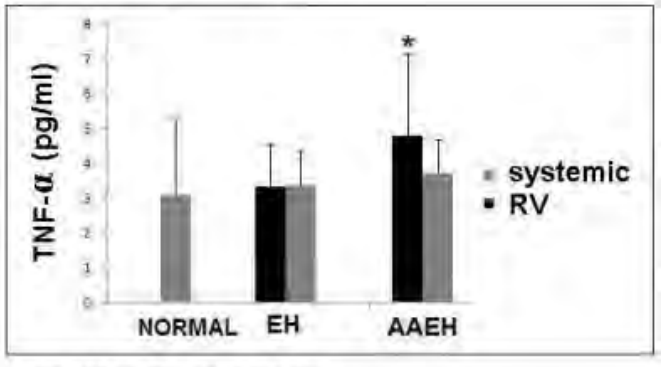
**Results:** Mean arterial pressure, serum creatinine, eGFR, cholesterol fractions, and antihypertensive medications did not differ between EH and AAEH patients. Renal vein levels of MCP-1 and TNF-were higher in AAEH compared to normal and EH patients (p<0.05). These differences were eliminated in the IVC. The number of circulating CD34+/KDR+ EPC tended to be lower in AAEH (p=0.06 vs. normal, p=0.07 vs. EH) (Figure).

**Conclusion:** Lower circulating levels of CD34+/KDR+ cells were associated with increased levels of inflammatory biomarkers in AAEH patients from the renal vein, suggesting greater potential for inflammatory kidney injury and impaired repair mechanisms. These mechanisms may contribute to the poorer outcomes of hypertension in AAEH compared to Caucasian EH patients.





* p<0.05 vs EH and vs NORMAL
\# p<0.05 vs systemic AAEH



* p<0.05 vs EH and vs NORMAL

**Normal Values for Arterial Stiffness in a Large Cohort of Healthy Children and Adolescents** Daniela Kracht,[1] Anke Doyon,[3] Christoph Jacobi,[1] Franz S. Schaefer,[3] Bernhard M. W. Schmidt,[2] Sajoscha A. Sorrentino,[2] Elke Wuehl,[3] Anette Melk.[1] *[1]Pediatric Nephrology, Medical School, Hannover, Germany; [2]Nephrology, Medical School, Hannover, Germany; [3]Pediatric Nephrology, University Hospital, Heidelberg, Germany.*

Study purpose: Aortic pulse wave velocity (aPWV), an indicator of arterial stiffness predicts cardiovascular mortality in adults. Arterial stiffening advances with age and is accelerated in specific diseases. In childhood aPWV has not been investigated in larger cohorts. The aim of this study is to provide normal values and prove the suspected increase with age.

Methods: Pulse waves were captured by oscillometry simultaneously on the right carotid and femoral artery (Vicorder) in 405 healthy school children aged 6 to 18 years. Intima-media thickness (IMT) and elasticity on both carotid arteries by B-and M-mode ultrasound was measured.

Results: aPWV significantly increased with age: 6-8 year olds (n=97): 4.2±0.4 m/s; 9-11 year olds (n=135): 4.5±0.4 m/s; 12-14 year olds (n=97): 4.9±0.5 m/s; 15-18 year olds (n=76): 5.2±0.5 m/s (p<0.0001). aPWV significantly correlated with age (r=0.63, p<0.0001, fig.1A). Further significant correlations existed for weight, height, mean systolic and diastolic blood pressure. We found no correlation of aPWV with IMT, but significant correlations with elasticity markers: distensibility coefficient (r=-0.42, p<0.0001, fig.1B)

and incremental elastic modulus (r=0.43, p<0.0001, fig.1C). Independent predictors for aPWV in multiple regression analysis were found for age, gender, diastolic blood pressure and elasticity parameters.

Conclusions: This study defines aPWV normal values in children and adolescents using a new non-invasive

oscillometric method. Even in healthy children correlations to cardiovascular risk factors can be seen.

Interestingly, a connection of aPWV to functional parameters of arterial elasticity was observed.

**Apical Lumen Formation Is Disrupted by Rosiglitazone in MDCK Cells through Inhibition of Cdc42 Activation** Zhiguo Mao,[1,2] Andrew J. Streets,[1] Albert C. Ong.[1] *[1]Academic Unit of Nephrology, Medical School, University of Sheffield, Sheffield, United Kingdom; [2]Division of Nephrology, Kidney Institute of CPLA, Changzheng Hospital, Second Military Medical University, Shanghai, China.*

Thiazolidinediones have been reported to retard cystic disease in rodent models by uncertain mechanisms. To clarify potential mechanisms of action, we investigated the effect of the highly selective PPAR gamma agonist, rosiglitazone, in the well-established MDCK model of cyst formation. The inhibitory effect of rosiglitazone on overall cyst expansion was accompanied by a reduction in basal cell proliferation and an increase in apoptosis. In addition, we observed a striking early abnormality in apical lumen formation resulting in a characteristic multiple lumen or loss of lumen phenotype in treated cells at doses which did not inhibit cell proliferation. These changes were preceded by mislocalisation of the apical marker protein gp135, misorientation of the mitotic spindle and retardation in centrosome reorientation. We observed later changes in primary cilia length and mislocalisation of E-cadherin in treated cysts. Cdc42 activation was profoundly inhibited by rosiglitazone and its cellular localization was randomised in parallel with gp135. We conclude that rosiglitazone influences MDCK cyst growth by multiple mechanisms involving dosage-dependent effects on proliferation, apoptosis, spindle orientation, centrosome migration and apical lumen formation. The loss of Cdc42 activation and its spatial mislocalisation is the earliest defect that underlies the observed abnormality in apical lumen formation. These changes could underlie the inhibitory effect of these compounds on cystic disease in vivo.

***In Vivo* Phosphorylation Status of Polycysytin-2 Correlates to the Formation of Polycystin-2 Associated Complexes in Kidney Tissue** Yiqiang Cai, Xin Tian, Seung H. Lee, Xiaoli Xie, Ming Ma, Stefan Somlo. *Internal Medicine, Yale University School of Medicine, New Haven, CT.*

Loss of polycystin-2 (PC2), a cation channel, results in autosomal dominant polycystic kidney disease (ADPKD). PC2 has been localized to cilia and is abundantly expressed in the endoplasmic reticulum. Loss of signaling by the PC1/PC2 complex underlies the pathogenesis of ADPKD. Our previous studies have shown that PC2 is constitutively phosphorylated at residue $Ser^{812}$, and that loss of phosphorylation at $Ser^{812}$ results in a 10-fold decrease in sensitivity to $Ca^{2+}$ activation of PC2 but has no effect on PC2 localization at the ciliary membrane. We recently employed a screen using phosphoproteomic analysis of TiO2 enriched immunoprecipitated PC2, and identified two novel phosphorylation sites in cultured epithelial cells. To gain further understanding of the functional role of PC2 phosphorylation in native tissues, we have now carried out a phosphoproteomic analysis of PC2 in mouse kidney. PC2 immunoprecipitated from mouse kidney yielded two PC2-positive bands with respective apparent molecular masses of ~110 kDa and ~200 kDa. Phosphoproteomic analysis of these bands revealed that the 200-kDa containing PC2 was not phosphorylated, whereas the 110-kDa PC2 had two residues that were phosphorylated. One of the two identified phosphorylation sites was the previously described $Ser^{812}$, whereas the other site is novel and was not detected in the cell culture-based screen. Taken together with the previous studies, these data suggest several conclusions. First, $Ser^{812}$ is constitutively phosphorylated in native kidney tissues. Second, phosphorylation of PC2 in cultured cells is different from that in the native kidney. Third, PC2 migrating as a monomer is phosphorylated, whereas multimeric PC2 appears to be dephosphorylated. Discovery of the mechanisms controlling PC2 phosphorylation in kidney tissues will provide novel insights into functional regulation of PC2 *in vivo*.

**Ciliary Localization of Retinitis Pigmentosa 2 (RP2) Is Regulated by Importin Beta-2** Shuling Fan, Toby W. Hurd, Benjamin L. Margolis. *Internal Medicine, University of Michigan Medical School, Ann Arbor, MI.*

Ciliopathies represent a newly emerging group of human diseases that share a common etiology, dysfunction of cilium or centrosome. We have been examining the RP2 protein which is mutated in X-linked Retinitis Pigmentosa. It has been demonstrated that RP2 localizes to primary cilia and this requires the dual acylation of the amino-terminus, but the precise mechanism by which RP2 is trafficked to the cilia is unknown. Here we have characterized a novel interaction between RP2 and importin beta-2 (transportin-1), a member of the importin beta family that regulates nuclear-cytoplasmic shuttling. We demonstrate that importin beta-2 is necessary for localization of RP2 to primary cilia as ablation of importin beta-2 by shRNA blocks entry both of endogenous and exogenous RP2 to the cilium. Furthermore, we identify two distinct binding sites of RP2 which interact independently with importin beta-2. One binding site is a Nuclear Localization Signal (NLS) like sequence that is located at the amino-terminus of RP2 and another is an M9-like sequence within the Tubulin Folding Cofactor C (TBCC) domain. We find that the NLS like sequence is not essential for RP2 ciliary targeting, since mutation of NLS like consensus sequence does not abolish the localization of RP2 to cilia. Interestingly, we find that several missense mutations that cause human disease fall within the M9-like sequence of RP2 and these mutations block entry of RP2 to the cilium as well as its interaction with importin beta-2. Together this work demonstrates a novel role of importin beta-2 that regulates entry of RP2 and likely other proteins into the ciliary compartment and this process may be analogous to the shuttling of proteins between the cytosol and nucleus.

**Inversin Modulates the Cortical Actin Network during Mitosis** Robert L. Bacallao,[1] Heather H. Ward,[1] Vincent H. Gattone,[2] Michael Werner.[1] *[1]Medicine, Indiana University and Richard Roudebush VAMC, Indianapolis, IN; [2]Anatomy and Cell Biology, Indiana University, Indianapolis, IN.*

Mutations in inversin cause Nephronopthisis type II, an autosomal recessive infantile form of polycystic kidney disease associated with situs inversus, dilatation of renal tubules and kidney cyst formation. Inversin regulates Wnt signaling by targeting Dishevelled for APC/C mediated degradation; however the underlying mechanisms by which inversin prevents cyst formation are unknown. Since cyst formation may represent a planar polarity defect we investigated whether inversin plays a role during cell division. Depletion of inversin by RNAi in mammalian tissue culture cells leads to an increase in bi- or multinucleated cells. While spindle assembly, contractile ring formation or furrow ingression appear normal in the absence of inversin, mitotic cell rounding and the underlying rearrangement of the cortical actin cytoskeleton are perturbed. In particular we find that loss of inversin causes the formation of extensive filopodia in both interphase and mitotic cells. Failure to properly round up in metaphase and ensuing spindle positioning defects lead to frequent misalignment of the division plane and unequal cell division. Similarly we observe an increase in binuclear cells, an increase in overall cell area and spindle positioning defects in nephritic tubules from inv-/- mouse embryos. Together these data suggest that inversin is a regulator of the cortical actin cytoskeleton that is required for proper cell rounding and spindle positioning during mitosis. By participating in mitotic spindle control, inversin contributes to the integrity of tubular epithelium during kidney development.

**Loss of microRNAs Reduces Polycystic Kidney Disease Severity in an ADPKD Mouse Model** Carol G. Carlton,[1] Klaus B. Piontek,[2] Gregory G. Germino,[3] Gregory B. Vanden Heuvel.[1] *[1]Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS; [2]Medicine, Johns Hopkins University, Baltimore, MD; [3]NIDDK, Bethesda, MD.*

The processing enzyme Dicer1 is essential for the production of microRNAs (miRNAs). Complete deletion of Dicer1 is embryologically lethal prior to gastrulation indicating the importance of this protein in development. To determine the role of miRNAs in kidney development, we used a conditional allele of Dicer1 to specifically delete miRNA processing in the ureteric bud derivatives. These mice, called $Dicer^{CD}$, exhibited hydronephrosis and cortical cysts, demonstrating the importance of miRNAs in kidney development. Recent studies have shown that Polycystin-2 is regulated by the miRNA miR-17 (Development 137:1107-1116, 2010). To begin to determine whether miRNAs interact with Polycystin-1, we deleted both Dicer and Pkd1 in the ureteric bud derivatives. Mice carrying floxed alleles of both Dicer and Pkd1 were crossed with Hoxb7cre mice to generate $Dicer^{CD}$/$Pkd1^{CD}$ mice. $Dicer^{CD}$/$Pkd1^{CD}$ mice were compared with mice carrying only the $Dicer^{CD}$ or the $Pkd1^{CD}$ mutations at postnatal day 0 (P0), P7, and P14. At all stages, $Dicer^{CD}$/$Pkd1^{CD}$ mice showed fewer renal cysts with an overall reduction in kidney size than $Pkd1^{CD}$ mice. Moreover, while Pkd1CD mice died between P14 and P17, $Dicer^{CD}$/$Pkd1^{CD}$ mice survived until P31. Taken together, these results suggest that miRNAs are involved in polycystic kidney disease progression.

**The Role of Fibrocystin in Post-Developmental Renal Homeostasis and Repair of Injury** Rachel Gallagher,[1] Seung H. Lee,[1] Sorin V. Fedeles,[1] Stefan Somlo.[1, 2] *[1]Internal Medicine, Yale School of Medicine, New Haven, CT; [2]of Genetics, Yale School of Medicine, New Haven, CT.*

Human autosomal recessive polycystic kidney disease (ARPKD) is largely a developmental disorder that results from mutations in a single gene locus, *PKHD1*. The *PKHD1* protein product, fibrocystin/polyductin (FPC) has been implicated in mitotic spindle orientation during postnatal kidney tubule elongation, a process thought to be governed by planar cell polarity (PCP) pathways. The predominant kidney presentation in ARPKD is severe perinatal or juvenile-onset collecting tubule dilation which coincide with *in utero* development and postnatal growth of the kidneys, respectively. These are periods when developmental PCP processes are active. Studies of *Pkhd1* have focused on its pathogenic role in ARPKD, however its role in adult kidney homeostasis independent of any polycystic disease has yet to be elucidated. In the current study, we sought to examine whether loss of FPC plays a role in post-developmental recovery from kidney injury. *Pkhd1*$^{del4/del4}$ mice and littermate controls were subjected to acute kidney injury (AKI) by 3 days of unilateral ureteral obstruction (UUO) followed by recovery periods of 4 days and 14 days after release of UUO. The *Pkhd1*$^{del4/del4}$ mice had comparable injury to their wild type littermates following 3 days of UUO but had impaired recovery with sustained tubule dilation in collecting duct segments following release of UUO. Histochemical staining and quantitative PCR analysis show increased fibrosis in the *Pkhd1* mutant mice 14 days after release of UUO. In addition there were significantly increased levels of inflammatory infiltrates including myofibroblasts and macrophages in the injured *Pkhd1* mutant kidneys. In aggregate, the data demonstrate aberrant repair following 3 day injury by UUO in the absence of FPC and therefore implicate FPC in normal renal homeostasis and repair following AKI. Further elucidation of the pathways involved will lend insight into the function of FPC and the mechanisms of repair after injury.

**Constitutive Up-Regulation of IL-8 in ADPKD by AP-1 and β-Catenin Activation** Ram Singh,[1] Wei Wei,[2] Elsa Bello-Reuss.[1] *[1]Internal Medicine, Texas Tech University Health Sciences Center, Lubbock, TX; [2]Internal Medicine, UTMB, Galveston, TX.*

Angiogenesis is prominent in ADPKD and a major factor for cyst growth. We studied the mechanisms of activation of the angiogenic cytokine IL-8 in ADPKD kidneys, cyst-cell primary cultures (CC) and cell lines with defined genotypes: normal human kidney (UCL93/3) and ADPKD (SKI-001 and OX161). We found constitutive up-regulation of IL-8 and IL-8 receptor-B in cysts of ADPKD kidneys. IL-8 mRNA was ~100% higher in CC than in normal tubule cells (NTC, $P<0.001$) and, by ELISA, the secretion of IL-8 was increased 3-4 fold ($P<0.001$ *vs.* NTC). IL-8 promoter activity (luciferase assay) increased 4-fold in MDCK cells transfected with polycystin-1 (PC1) *vs.* control cells ($P< 0.001$) as well as after transfection with a truncated PC1 that, in humans, causes ADPKD. Immunostaining with anti-PC1 C-terminus antibody 46-2 (CTab) showed increased expression of PC1 in cysts of ADPKD kidneys and no expression in normal kidneys. PC1 C-terminus (CT) activates the IL-8 promoter containing multiple AP1 binding sites. Expression of β-catenin (β-cat) in normal kidney cells also activates the IL-8 promoter. Western blots showed that the CTab detects full length PC1 in UCL93/3 and in SKI-001 cells but not in OX161 cells. CT fragments were present in nuclear extracts of normal and ADPKD cell lines. Transcriptional activity of β-cat, measured by lenti-TCF/LEF luminescence assay, was increased in ADPKD cell lines ($P<0.001$ *vs.* control). Co-immunoprecipitation showed β-cat pulldown by PC1 in lysates of normal cells but not in lysates of ADPKD cell lines. In cyst cells, silencing IL-8 inhibited cyst growth; silencing β-cat decreased expression of β-cat and IL-8 and inhibited cyst growth. In summary: 1. IL-8 is increased in ADPKD. 2. CT fragments activate AP-1 binding sites of the IL-8 promoter 3. β-cat is activated in ADPKD cyst cells and does not co-precipitate with PC1. 4. Transactivation of the TCF/LEF site by β-cat activates the IL-8 promoter. The inhibition of β-cat activation by CT, found in normal cells, is absent in ADPKD cyst cells. 5. Silencing IL-8 or β-cat inhibits *in-vitro* cyst growth.

**Cystogenesis of ARPKD Results from Increased Apoptosis in Collecting Duct Epithelial Cells of *Pkhd1* Mutant Kidneys** Bo Hu, Ao Li, Dan Liang, Guanqing Wu. *Medicine and Cell & Developmental Biology, Vanderbilt University, Nashville, TN.*

Mutations of *PKHD1* result in autosomal recessive polycystic kidney disease (ARPKD) in humans. To determine the molecular mechanism of cystogenesis in ARPKD, we have recently generated a mouse model for ARPKD which carries a targeted mutation on the mouse orthologue of human *PKHD1* gene (*JASN 2008:19;455*). The homozygous mutant mice display hepatorenal cysts whose phenotypes are similar to human ARPKD patients. Using littermates of this mouse model, we developed a pair of immortalized renal collecting duct cell lines with or without *Pkhd1*. Under nonpermissive culture conditions, *Pkhd1*$^{-/-}$ renal cells display aberrant cell-cell contact, ciliogenesis, and tubulomorphogenesis compared to wildtype littermate cells. We also found significant reduction in cell proliferation and elevated apoptosis when *Pkhd1* is absent. To determine which factor was the primary cause of ARPKD phenotypes, cell proliferation or apoptosis, we analyzed multiple putative signaling regulators affected by *Pkhd1* absence. We demonstrated that loss of *Pkhd1* disrupts focal adhesion kinase (FAK) phosphorylation, which inhibits the Ras/C-Raf pathways, and causes suppressed MEK/ERK activity, ultimately contributing to reduced cell proliferation. These observations indicate that cell proliferation may not be a necessary factor to induce cystogenesis in ARPKD. We therefore assume that apoptosis may act as a major player to induce cyst formation in ARPKD. Compared to wildtype cells, *Pkhd1*-deficient cell lines showed significantly increased apoptosis via inhibition of PDK1/AKT and upregulation of Bax/caspase-9/caspase-3. To validate this finding *in vivo*, we examined proliferation and apoptosis between the kidneys of *Pkhd1*$^{-/-}$ and their wildtype littermates. Using proliferation (PCNA and Histone-3) and apoptosis (TUNEL and caspase-3) staining makers, we also found significantly increased apoptosis and decreased proliferation in the *Pkhd1*$^{-/-}$ kidneys. The finding indicates that apoptosis may act as a major player for cyst formation in ARPKD, which can guide us to establish new therapeutic strategies for ARPKD.

**F-PO1768**

**Overexpression of Polycystin-1 Alters Morphogenetic Rearrangements of Cultured Renal Tubular Cells** Valerie Leroy,[1] Udo Hasler,[1] Pierre-Yves F. Martin,[2] Eric Feraille.[1] *[1]Cell Physiology and Metabolism, University of Geneva, Geneva, Switzerland; [2]Internal Medicine, University Hospital of Geneva, Geneva, Switzerland.*

Autosomal dominant polycystic kidney disease (ADPKD) is caused by mutations of polycystin (PC)-encoding genes PKD1 or PKD2 that upset a genetically defined program that controls the size and geometry of renal tubules. Cysts which frequently emanate from the collecting duct (CD) result from cell proliferation and fluid secretion. Either invalidation or overexpression of PKD1 results in polycystic kidney disease in transgenic mouse models, suggesting a major role of imbalanced PC1/PC2 expression in ADPKD. To test this hypothesis, we used mCCDcl1 cells, a differentiated mouse CD principal cell line, to generate cells conditionally overexpressing the full-length PC1 in the presence of doxycyclin (Dox). Microscopy analysis of cells grown in collagen/matrigel matrix showed that while PC1 overexpression is not sufficient to induce cyst formation, it deeply alters morphogenetic rearrangement. We observed an inhibition of the initial elongation of cells rods, that resulted in decreased number and length of tubular structures, a delay of tubular lumen development and a decreased number of tubular branching events. To investigate the underlying mechanisms of altered tubulogenesis, we assessed the effects of PC1 overexpression on cell proliferation, migration and terminal differentiation. PC1 overexpression reduced density-dependent growth, promoted cell adhesion on collagen and stimulated cell migration in a wound-healing assay. Neither total nor cell surface abundance of key ion and water transporters nor the polarized distribution of Na,K-ATPase was altered. However, PC1 overexpression increased transepithelial resistance under basal conditions and promoted its recovery in calcium switch experiments. These effects were associated with increased E-cadherin protein expression and lateral membrane localization. These results do not support the idea that imbalanced expression of PC1/PC2 per se is responsible for cyst development by collecting duct cells, but rather shed light on the important role of PC1 in branched tubular morphogenesis and intercellular junctions dynamics.

**Role of Integrin-β1 in the Cystogenesis and Hyperproliferation of ADPKD Cells** Kim Lee, Lorenzo Battini, Carles Martinez-Romero, Lin Geng, G. Luca Gusella. *Division of Renal Medicine, Mount Sinai School of Medicine, New York, NY.*

Dysregulation of the PKD1 gene, encoding polycystin-1 (PC-1), leads to autosomal polycystic kidney disease (ADPKD), a disease characterized by formation and progressive expansion of renal cysts, and renal failure. Cystic renal epithelia are hyperproliferative and characterized by increased expression of integrin-α2β1. We have previously shown that integrin-α2β1 mediate the resistance of PC1 knockdown cells to anoikis. The purpose of this study is to determine the role of integrin-β1 in the cystogenic process and hyperproliferation of ADPKD cells.

As a model system of ADPKD, we used the inner medullary collecting duct cell line, IMCD3, and the canine Madine-Darby collecting duct cell line, MDCK, in which the expression of PC1 is constitutively knocked down following the transduction with a lentivirus carrying a specific anti-*PKD1* siRNA. This model system recapitulates features that characterize ADPKD, such as hyperproliferation and cystic growth, centrosome amplification, and increased apoptosis. We show that the increased integrin-β1 expression in PC1 knockdown cells heightens their sensitivity to stimulation with collagen type I. In addition, the knockdown of PC1 expression is associated with the increased extracellular deposition of fibronectin (FN), a ligand of integrin-β1 heterodimers. Interference with the expression of FN lead to the reduction of the proliferation of PC1 knockdown cells, indicating that a positive feed-back signaling mechanism between FN and integrins contributes to the stimulation of cystic growth in ADPKD.

We also show that the siRNA-mediated inhibition of integrin-β1 reverted the proliferation, adherence, centrosome integrity, and migratory function of PC1 knockdown cells to the levels of control parental cells. No adverse effects on the cell viability were observed during integrin-β1 suppression. Overall, these observations support the essential role of integrin-β1 and extracellular matrix components in a new mechanism of cystic cells proliferation. Furthermore, our findings suggest that the targeting the integrin-β1 signaling pathway may be an effective approach to slow down ADPKD progression.

**A Single Amino Acid Residue Constitutes the Third Dimerization Domain Essential for the Assembly and Function of the Polycystin-2 (TRPP2) Channel** Shuang Feng,[1] Lise Rodat-Despoix,[2] Patrick Delmas,[2] Albert C. Ong.[1] *[1]Kidney Genetics Group, Academic Nephrology Unit, University of Sheffield Medical School, Sheffield, South Yorkshire, United Kingdom; [2]Centre de Recherche en Neurophysiologie et Neurobiologie de Marseille, CNRS, Université de la Méditerranée, Marseille, France.*

Autosomal dominant polycystic kidney disease (ADPKD), the most common inherited cause of kidney failure, is caused by mutations in either *PKD1* (85%) or *PKD2* (15%). The PKD2 protein, polycystin-2 (PC2 or TRPP2), is a member of the transient receptor potential (TRP) superfamily and functions as a non-selective calcium channel. PC2 has been found to form oligomers in native tissues suggesting that similar to other TRP channels, it may form functional homo- or heterotetramers with other subunits. We have recently demonstrated that the homodimerisation of PC2 is mediated by both N-terminal and C-terminal domains and it is known that PC2 can heterodimerise with PC1, TRPC1 and TRPV4.

In this paper, we report that a single cysteine residue, C632, mutated in a known PKD2 pedigree, constitutes the third dimerisation domain for PC2. PC2 truncation mutants lacking both N- and C-termini could still dimerise under non-reducing conditions. Mutation of C632 alone completely abolished dimerisation in these mutants indicating that it was the critical residue mediating disulphide-bond formation between PC2 monomers. Full-length PC2 channels with a C632A mutation showed diminished ATP-sensitive ER $Ca^{2+}$ release in HEK293 and in combination with mutations in the C-terminal coiled coil domain (4M) completely abolished channel activity. However, unlike the 4M mutation, a C632A mutant could still heterodimerise with polycystin-1 (PC1). Our results indicate that PC2 homodimerisation is regulated by three distinct domains and that these events regulate formation of the tetrameric PC2 channel.

**F-PO1771**

**The Polycystin-1 PLAT Domain Acts as a Binding Scaffold for Phospholipids and Targets Polycystin-1 to the Basolateral Membrane of Epithelial Cells** Yaoxian Xu, Andrew J. Needham, Albert C. Ong. *Kidney Genetics Group, Academic Unit of Nephrology, University of Sheffield Medical School, Sheffield, S. Yorkshire, United Kingdom.*

The PLAT (Polycystin-1, Lipoxygenase and Alpha Toxin) or LH2 (Lipoxygenase Homology 2) domain is a signature domain of polycystin-1 (PC1), the protein product of *PKD1*, the gene mutated in 90% of patients with autosomal dominant polycystic kidney disease (ADPKD). It is highly conserved in the polycystin protein family, being present in all PC1 homologues (PKD1L1, PKD1L2, PKD1L3, PKDREJ) and shows evolutionary conservation in orthologues down to nematodes. PLAT is predicted to have a β-sandwich fold but its precise structure has not been elucidated. In addition, little is known about the function of mammalian PLAT though the PLAT domain of the *C. elegans* PC1 orthologue, *LOV1*, is reported to bind to the β-subunit of CK2 and to ATP-2, the β-subunit of ATP synthase. Here, we report the first experimental evidence that PC1 PLAT can act as a lipid binding scaffold. Recombinant PLAT proteins bound to two plasma membrane phospholipids, phosphatidylserine (PtdSer) and phosphoinositol-4-phosphate (PI-4P) but not to PI-4,5P2 or PI-3,4,5P3 on lipid arrays and this was verified by liposome sedimentation assays and lipid bead pull-down. Mutation of two predicted charged residues abolished binding to PtdSer but not to PI-4P. A PLAT-YFP fusion showed basolateral plasma membrane localisation in stably transfected MDCK cells which overlapped most closely with desmoplakin but did not localise to primary cilia. Mutation of the PtdSer binding residues alone did not alter basolateral expression of the PLAT-YFP fusion. We conclude that PC1 PLAT can function both as a membrane associated scaffold for phospholipid signalling and provides independent targeting information for PC1 localisation to the basolateral membrane via discrete lipid-protein and protein-protein interactions.

**PCP Proteins Vangl2 and Dvl Regulate a Novel Apical Localization of Polycystin-1** I.-Chun Tsai,[1] Zheng D. Lan,[1] Feng Qian,[1] Gregory G. Germino.[1,2] *[1]Division of Nephrology, Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; [2]NIDDK, NIH, Bethesda, MD.*

Recent studies suggest that the planar cell polarity pathway (PCP) may play an important role in regulating renal tubule diameter. This pathway is activated by a subset of Wnts and Frizzled receptors and is mediated by membrane and intracellular proteins, including Vangl2 and Dishevelled (Dvl). Downstream of Vangl2 and Dvl, small GTPases such as Rho and Rac then join to facilitate cytoskeleton rearrangement. PCP signaling is thought to produce oriented tubular extension during the tubular growth phase of renal development. There also is emerging evidence indicating that disruption of PCP signaling within the kidney can result in renal cystic disease. As a first step in determining the role of PC1 in this process, we developed an MDCK cell culture system with inducible expression of EGFP-tagged PC1 and used this system to identify a previously undescribed apical pool of PC1 that co-localizes with Dishevelled (Dvl) and Vangl2. We confirmed this pattern for endogenous PC1 in IMCD cells. Disruption of PCP activity by over-expressing dominant negative Dvl, silencing Vangl2 or inhibiting aPKC prevents PC1 from localizing to this apical pattern. Importantly, this localization appears to be essential for proper tubule formation since a PC1 mutant that does not localize apically is also defective in forming tubules in vitro. In addition, PC1 cell fails to form tubule when Vangl2 expression is knocked down. Finally, we investigated PC1 signaling downstream of PC1 and found enhanced RhoA activation, localized to the apical membrane near PC1. Our findings directly link PC1 to canonical PCP proteins and suggest that PC1 is one of the effector molecules downstream of PCP signaling.

**Morpholino-Mediated Knockdown of a Novel RP2-Interacting Centrosomal Protein, OSTF1, Results in Cystic Kidneys and Microphthalmia in Zebrafish** Toby W. Hurd,[1] Weibin Zhou,[1] Benjamin L. Margolis,[2] Friedhelm Hildebrandt.[1,3,4] *[1]Department of Pediatrics, University of Michigan, Ann Arbor, MI; [2]Department of Internal Medicine, University of Michigan; [3]Department of Human Genetics, University of Michigan; [4]Howard Hughes Medical Institute.*

Cilia dysfunction has been linked to an ever expanding group of human diseases that have been termed ciliopathies. Within the kidney primary cilia protrude from the apical side of renal epithelia into the tubular lumen. Abnormal function or formation of these cilia may underlie the cystic kidney disease phenotype as found in a number of different disorders including both autosomal recessive and autosomal dominant polycystic kidney disease (ARPKD and ADPKD, respectively) and nephronophthisis. In many ciliopathies, cystic kidneys are accompanied by extra-renal manifestations such as retinal degeneration, polydactyly and mental retardation. We have been examining the function of the Retinitis Pigmentosa 2 (RP2) protein in renal cilia. We have previously demonstrated that RP2 localizes to renal cilia and forms a complex with Polycystin 2. Loss of RP2 results in accumulation of Polycystin 2 within the cilia and gives rise to cystic kidneys in Zebrafish. Here we identify a novel RP2-interacting protein, OSTF1, that localizes to centrosomes but not cilia. Interestingly, a pathogenic missense mutation in RP2, L253R, abolishes this interaction. Similar to RP2, knockdown of OSTF1 by shRNA results in golgi fragmentation but does not perturb ciliogenesis in cell culture. Finally we demonstrate that in zebrafish loss of OSTF1 gives rise to pronephric cysts and retinal degeneration. These data indicate that OSTF1 and RP2 represent an important complex that may regulate cilia function in both kidney and eye. Further understanding of these proteins may provide unique insight into the etiology of retinitis pigmentosa and cystic kidney disease especially in syndromic ciliopathies such as Senor Loken syndrome (SLS) where there is involvement of both organs.

**In Vivo Analysis of the Drosophila PKD2 (TRPP2) Homolog** Michael Kottgen,[1] Alexis Hofherr,[1] Weizhe Li,[2] Kristy Chu,[2] Terry J. Watnick.[2] *[1]Nephrology, University Hospital Freiburg, Freiburg, Germany; [2]Nephrology, Johns Hopkins School of Medicine, Baltimore, MD.*

Autosomal dominant polycystic kidney disease (ADPKD) is caused by mutations in either one of two genes, PKD1 or PKD2, which encode for Polycystin-1 and TRPP2, respectively. TRPP2 functions as a non-selective cation channel in the primary cilium. Activation of TRPP2 triggers cytosolic Ca2+ signals, but its physiological function in vivo remains unknown. The Drosophila melanogaster homolog of TRPP2 is a testis-specific protein that is localized at the tip of the sperm tail. We used Drosophila as a model organism to study TRPP2 function.

In order to test the function of PKD2 patient mutations in vivo we expressed wild-type (wt) and mutant TRPP2 in TRPP2 knock-out flies. Wt and mutant sperm were studied using multiple approaches, including fertility tests, immunofluorescence and in vivo confocal live imaging.

Male TRPP2 deficient flies are sterile although they produce fully differentiated, motile sperm, which are effectively transferred to the female upon mating. Sterility is caused by impaired directed movement of mutant sperm to the female sperm storage organs. TRPP2 mutant sperm were found to lack the up-regulation of tail beating frequency and sperm speed in the uterus that we observed in the wt sperm.

Furthermore, we identified a patient mutation that is expressed normally in the endoplasmic reticulum (ER) of spermatocytes but fails to traffic to the sperm tail. Absence or mis-localisation of the TRPP2 protein equally impaired fertility in Drosophila melanogaster, suggesting that the localization in cilia rather than in the ER is critical for TRPP2 function.

In conclusion, we have established versatile model system to investigate polycystin proteins in vivo. TRPP2 is required for directed movement and regulation of sperm speed in the female reproductive tract of Drosophila melanogaster. Real time analysis of TRPP2 mutant sperm provided new insights into sperm chemotaxis and TRPP2 signalling. These results provide indirect evidence for the existence of yet to be identified ligands regulating the polycystin complex.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1775**

**Protein Kinase D Mediated Phosphorylation of Polycystin-2 (TRPP2) Is Essential for Its Effects on Cell Growth and Channel Activity** Andrew J. Streets, Andrew J. Needham, Albert C. Ong. *Academic Unit of Nephrology, Sheffield Kidney Institute, Kidney Genetics Group, University of Sheffield, Sheffield, United Kingdom.*

PKD2 is mutated in 15% of patients with autosomal dominant polycystic kidney disease (ADPKD). The PKD2 protein, polycystin-2 or TRPP2, is a non-selective Ca2+-permeable cation channel which has been shown to function at several locations including primary cilia, basolateral membrane and at the ER. Nevertheless, the factors that regulate the channel activity of polycystin-2 are not well understood. Reversible protein phosphorylation has been shown to regulate the structure and function of many other members of the TRP family of ion channels. Accordingly, polycystin-2 has been shown to be regulated by phosphorylation at two serine residues (Ser812 and Ser76) with distinct functional consequences.

We noted however that mutation of both Ser76 and Ser812 residues did not abolish polycystin-2 phospholabelling in vivo. This led us to seek other potential phosphorylation sites and to define their functional significance. Using a combination of site-directed mutagenesis and phospho-antibody mapping we have identified a previously unrecognised phosphorylation site within the polycystin-2 C-terminus (Ser801) and have demonstrated that it can be phosphorylated by Protein Kinase D. Phosphorylation at this site was detectable in serum starved cells but was significantly increased in response to serum and EGF stimulation.

In order to ivestigate the functional significance of phosphorylation at this site we generated a series of inducible MDCK cell lines expressing polycystin-2 or Ser801 phosphomutants. Using these cell lines we show that inducible expression of polycystin-2 inhibited cell proliferation and resulted in a significant increase in ATP-stimulated Ca2+ release from ER stores. Mutagenesis at Ser801 abolished these effects of polycystin-2 on cell growth and also significantly reduced ATP-stimulated Ca2+ release from ER stores. Our results suggest that growth factor stimulated, Protein Kinase D mediated phosphorylation of ER polycystin-2 channels is essential for its function and links extracellular stimuli to intracellular calcium regulation.

**F-PO1776**

**Co-Ordinated Regulation of Rho-GTPase and PKHD-1 in Ureteric Bud-Mediated Morphogenesis** Patricia D. Wilson,[1] Nadezhda N. Zheleznova.[2] *[1]Medicine, University College London (UCL), London, United Kingdom; [2]Physiology, Medical College Wisconsin, Milwaukee, WI; [3].*

The cystic proteins polycystin (PC)-1,-2 and PKHD1-encoded Fibrocystin(FC)-1 are developmentally regulated, highly expressed in the developing mammalian ureteric bud epithelial cell membranes and primary cilia where they form multi-molecular, mechanosensory complexes with integrin and focal adhesion(FA) proteins. Inhibition of PC-1, -2, or FC-1 due to endogenous mutation, or transfection with dominant negative or si/shRNA constructs leads to increased ureteric bud-derived epithelial cell-matrix (ECM) adhesion, decreased growth factor-mediated migration, and cystic tubulogenesis in 3-dimensional collagen gels and fetal mouse kidneys in organ culture and in vivo. Rho-GTPases regulate the actin cytoskeleton via integrin/FA kinase (FAK) ineractions. In vitro and ex vivo studies were conducted using the specific RhoA inhibitor Y-27632. In mouse inner medullary collecting duct (mIMCD) cells, RhoA inhibition significantly altered cell shape, decreased cell-spreading, cell-cell attachment, proliferation and wound-healing. Quantitative Western blot analysis showed time-dependent decreases in FAK and pY397-FAK after 30min and 4 hr of ECM attachment as well as decreases in paxillin and pY31-paxillin after 30 min of attachment. In ex vivo mouse embryonic day (E) 12.5-13.5 kidneys in organ culture Rho-GTPase inhibition led to cystic disruption of organogenesis. Transfection with pMyr-EGFP-PKHD1-CTD induced increased levels of expression of full length (>460kDa) FC-1 and but decreased levels of β1-integrin, FAK, c-src and cleaved (<20kDa) FC-1. FACS-sorted PKHD1-over-expressing cells showed increased ECM adhesion at 4hr, decreased growth-factor-induced migration in Boyden chamber (Fuoroblock) assays and increased tubulogenesis in 3D collagen gels. All of these effects were reversed by specific inhibition of Rho-GTPase by Y-27632. We conclude that coordinated regulation of Rho-GTPase activity and FC-1 are required for normal ureteric bud branching morphogenesis and differentiation of the mammalian kidney

**Depletion of Macrophages in Pkhd1-Cre-Mediated Pkd1 Null Mice Results in Reduced Cyst Load and Improved Renal Function** Anil K. Karihaloo,[1] Farrukh M. Koraishy,[1] Stefan Somlo,[1] Lloyd G. Cantley.[1] *[1]Internal Medicine, Section of Nephrology, Yale University School of Medicine, New Haven, CT; [2]Department of Pathology, Yale University School of Medicine, New Haven, CT; [3]Deapartment of Biomedical Engineering, Yale University, New Haven, CT.*

Polycystic kidney disease (Pkd) is characterized by progressive growth of multiple cysts that eventually replace the renal parenchyma that may lead to loss of renal function. Cell proliferation plays an important role in the progression of this debilitating genetic disorder. Several studies in the recent past have indicated an existence of inflammatory component in Pkd. Our laboratory has recently determined that macrophages contribute to the tubular cell proliferation following an ischemic injury. We thus hypothesized that macrophages in a polycystic kidney may contribute to the proliferation of the cyst-lining cells and that depletion of macrophages should impede the cyst growth. To test this we used mice in which Pkhd1-Cre mediated deletion of Pkd1 results in large cystic kidneys with end stage cystic disease by ~ 4 weeks of age.

Pkd1 null mice, received liposomal clodronate (LC) or liposomal vehicle (LV) i.p. from post-natal day10 until day 24. Mice were sacrificed on day 24 and kidney sections stained with either H&E, the macrophage marker F4/80, TUNEL or Ki-67 for cell proliferation. The cystic index was determined using metamorph. LC treatment led to better preservation of renal parenchyma and 40% drop in the cystic index. This translated to a modest but statistically significant improvement in renal function as was determined by lower BUN values (151 v 109, $p<0.05$). F4/80 staining revealed an average of 50% fewer macrophages in the kidneys from LC treated mice. Further we determined that LC treatment led to a significant decrease in the proliferation of the cyst-lining cells as identified by Ki-67 and dolichos-biflorus lectin (DBA) co-staining. There was no appreciable change in the number of apoptotic cells. Taken together, these data demonstrate that depleting macrophages leads to better preservation of renal parenchyma, reduced cyst load and improved renal function.

**ADPKD-Associated F4145V Mutation in Polycystin-1 Disrupts Its Dephosphorylation by Protein Phosphatase-1** Stephen C. Parnell,[1] Sanjeev Puri,[2] Lance C. Brandenburgh,[1] Darren P. Wallace,[3] James P. Calvet.[1] *[1]Department of Biochemistry and Molecular Biology and the Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [2]Biotechnology Institute; University Institute of Engineering and Technology, Panjab University, Chandigarh, India; [3]Department of Medicine and the Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

The C-terminal cytosolic tail of polycystin-1 (PC1) contains a highly conserved, putative protein phosphatase-1 (PP1) binding motif (R/KVxF; KVRF between K4142 and F4145 in mouse PC1) located in close proximity to a cAMP-dependent protein kinase (PKA) phosphorylation site 14 residues downstream at S4159. PP1 is a broadly expressed serine/threonine phosphatase that regulates numerous cellular functions including ion channel activity, cytoskeletal organization, cell cycle progression, and gene transcription. PP1 activity is regulated by its interactions with a diverse set of regulatory protein binding partners that form unique holoenzyme complexes with PP1. We had previously demonstrated that PC1 interacts with and is dephosphorylated by PP1 and that alanine-mutagenesis of critical hydrophobic residues in the R/KVxF motif (V4143A; KARF and F4145A; KVRA) disrupted the ability of PP1 to dephosphorylate PKA-phosphorylated PC1. We now show that an ADPKD-associated mutation corresponding to mouse F4145V (KVRV; Tan YC *et al.* 2009, Hum Mutat 30:264-273) also blocks the ability of PP1 to dephosphorylate PC1, and that KVRF mutations increase the ability of PC1 to activate nuclear factor of activated T-cell (NFAT) transcriptional activity. Our results suggest that a critical function of PC1 is to regulate the enzymatic activity of PC1-associated PP1, and in particular that PP1 antagonizes the ability of PC1 to activate NFAT. These results suggest that perturbation of PC1-PP1 holoenzyme activity may be sufficient to cause ADPKD.

**Wnt5a Is Upregulated in ADPKD Cyst Epithelial Cells and Stimulates cAMP Production and In Vitro Cyst Growth** Katherine Swenson-Fields,[1] Darren P. Wallace,[1] Carolyn J. Vivian,[1] Cibele S. Pinto,[1] Gail Reif,[1] Brenda S. Magenheimer,[1] James P. Calvet,[1] Timothy A. Fields.[1] *[1]The Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [2].*

Gene expression profiling of cyst epithelial cells from human ADPKD kidneys showed upregulation of Wnt5a transcripts compared to normal human kidney cells. Increased Wnt5a message was confirmed by qRT-PCR, and immunohistochemistry demonstrated that Wnt5a protein was present in cyst-lining epithelial cells. Wnt5a is a non-canonical member of the Wnt family of secreted glycoproteins that influences morphogenesis and can regulate both cell proliferation and migration in adult tissues. Wnt5a has been shown to activate a number of different signaling pathways depending on the cell type and cell surface receptor repertoire, including those that elevate intracellular Ca2+ and cAMP levels. Since these second messengers are known to affect cyst growth in ADPKD, we sought to determine the affect of Wnt5a on ADPKD cells. ADPKD cyst cells were seeded within polymerized collagen gels and treated with either Wnt5a or forskolin, an activator of adenylate cyclase leading to increased levels of cAMP. cAMP is known to stimulate both ADPKD cell proliferation and transepithelial fluid secretion to promote cyst enlargement. Notably, Wnt5a treatment alone stimulated cyst growth. While the total number of cysts in the Wnt5a-treated cells was lower relative to forskolin-treated cells (56 vs. 116), the total cyst area in the Wnt5a-treated cells was greater than that achieved by forskolin (1.17 ± 0.11 vs 0.77 ± 0.08 cm2/well; $p=0.014$). To investigate the mechanism underlying the Wnt5a effect on cyst growth, we directly measured cAMP levels in ADPKD epithelial cells after treatment with purified recombinant Wnt5a. Strikingly, Wnt5a stimulated a 2.5-fold increase in cellular cAMP relative to vehicle. Thus, Wnt5a can promote ADPKD cell cyst enlargement in vitro, and the effect may be related to its ability to promote cAMP production. Since Wnt5a is upregulated in ADPKD cells, these data suggest the intriguing possibility that expression of Wnt5a in ADPKD cyst cells promotes cystogenesis and disease progression.

**F-PO1780**

**Role of Integrin Signaling in Cystic Kidney Diseases** Balaji Karthick Subramanian,[1,2] David Kaplan.[2] *[1]Biomedical Engineering and Biotechnology, University of Massachusetts, Lowell, MA; [2]Biomedcial Engineering, Tufts University, Medford, MA.*

Cystic kidney diseases are a heterogeneous group of problems leading to kidney failure. Studies with animal models have attributed kidney failure to the expansion of cysts and extensive interstitial fibrosis. Aberrant integrin expressions were observed in cystic kidney tissues and have been hypothesized to play a major role in cyst progression. Though many attempts have been made to understand the role of integrin signaling in cyst initiation and progression, the lack of relevant models has left the mechanisms elusive. The purpose of this study was to advance the understanding of integrin signaling in cystogenesis using an engineered tissue model. The model was developed using tissue engineering principles by culturing normal and polycystin-1 silenced mouse kidney epithelial cells in extracellular matrix molecules infused into porous silk scaffolds in perfusion bioreactor systems. Silk biomaterial scaffolds are used due to the slow degradation, bio-compatibility and demonstrated utility in 3D tissue model systems, able to maintain transport and function in perfusion bioreactor systems for sustained time periods. Structural and functional relevancies of the cystic structures developed were evaluated by polarity marker distribution and transport assays. In addition, abnormal expression of beta 1 integrin and its intracellular mediator Integrin Linked Kinase (ILK) were observed in the engineered 3D cystic tissues developed from silenced cells, unlike in the normal cell systems, similar to in vivo cystic kidney tissues. Further modulation of integrin signaling to understand the role in cystogenesis is achieved by either inducible silencing or over-expression of ILK in cystic structures to evaluate outcomes.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1781**

**Gli3 Repressor Inhibits Collecting System Development in a Murine Model of Pallister-Hall Syndrome** Josh Blake,[1,2] Jason Cain,[1] Norman D. Rosenblum.[1,2,3] *[1]Prog Dev & Stem Cell Biol, Hosp Sick Child, Canada; [2]Dept Physiology, U Toronto, Canada; [3]Div Neph, Dept Peds, U Toronto, Toronto, Canada.*

Pallister-Hall Syndrome (PHS), characterized by renal hypodysplasia and hydronephrosis, is caused by truncating mutations in *GLI3*. Full-length *Gli3* mRNA encodes a transcriptional activator (GLI3A) that is proteolytically processed to form the transcriptional repressor GLI3R to an extent dependent on Hedgehog (HH) signaling activity. Gli3R controls renal development in a temporal, spatial and lineage-specific manner, inhibiting early inductive tissue interactions (Hu *et al.*, 2006) but promoting *Wnt11* expression in ureteric tip cells (Cain *et al.*, 2009). Here, we define Gli3R functions during collecting system development in mice in which the WT *Gli3* allele is replaced by a $Gli3^{\Delta 699}$ allele (Bose *et al.*, 2002) that produces a truncated GLI3 protein as in PHS. Whereas $Ptc1^{lacZ}$ expression in the periureteric mesenchyme, medullary stroma and ureteric bud (UB) cells indicated robust HH activity in WT mice, $Ptc1^{lacZ}$ expression was markedly reduced in $Gli3^{\Delta 699/\Delta 699}$ (mutant) kidneys. Mutant mice died shortly after birth with severe hydronephrosis. Phenotypic analysis prior to birth revealed nonobstructive hydronephrosis, defined by intrapelvic dye injection at E18.5. A double collecting system was observed in 43% of mutants at E15.5 with a loss of periureteric alpha-smooth muscle actin expression in all mutants but with varying degrees of severity. Examination of nephrogenesis at E15.5, prior to the onset of hydronephrosis, revealed simple hypoplasia (4/7 mice) characterized by a 55% decrease in kidney volume ($p<0.001$) with a 49% decrease in glomerular number ($p<0.05$). While gene expression in metanephric mesenchyme (WT1, Cited1) and stroma (*Raldh2*, *Foxd1*) was comparable in mutant and WT kidney tissue, renal hypoplasia was preceded by a 46% reduction in ureteric branching at E12.5 ($p<0.0001$). Remarkably, the mutant phenotype was completely rescued in $Gli3^{\Delta 699/-}$ and $Gli3^{\Delta 699/+}$ mice. We conclude that decreased ureteric branching and delayed smooth muscle differentiation during collecting system development are caused by increased Gli3R and not by decreased Gli3A in a murine model of PHS.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1782**

**Epithelial-to-Mesenchymal Transition (EMT) in *cpk* Mouse, a Model of ARPKD** Hiroko Togawa,[1] Koichi Nakanishi,[1] Hironobu Mukaiyama,[1] Taketsugu Hama,[1] Yuko Shima,[1] Masayasu Miyajima,[2] Kandai Nozu,[3] Hisahide Takahashi,[4] Shizuko Nagao,[4] Kazumoto Iijima,[3] Norishige Yoshikawa.[1] *[1]Department of Pediatrics, Wakayama Medical University; [2]Laboratory Animal Center, Wakayama Medical University, Wakayama; [3]Department of Pediatrics, Kobe University, Hyogo; [4]Education and Research Center of Animal Model for Human Disease, Fujita Health University, Aichi, Japan.*

The cyst-lining epithelial cell pathophysiology in PKD is characterized by dedifferentiation and perturbations of the polarized phenotype with consequent renal cyst formation and progressive enlargement. Some of these features resemble an early developmental epithelial cell phenotype.

The PCK rat, an orthologous model of human ARPKD is characterized by slowly progressive cyst formation and fibrosis. Previously, we showed that epithelial cells in cysts acquired mesenchymal features in response to cyst enlargement and demonstrated pathological significance of tubular EMT in PCK rat. It's not clear whether EMT is consistently present in PKD or a secondary phenomenon associated with fibrosis. Therefore, we examined the role of EMT in *cpk* mouse, another ARPDK model with a rapid progression.

Formaldehyde fixed, paraffin embedded kidneys from 5 male *cpk* and control mice(day 0,7,14,21) were sectioned and stained with antibodies to epithelial markers, mesenchymal markers and Snail1, a transcriptional repressor of E-cadherin. We also evaluated the involvement of TGF-β and Smad3, which were thought to be key mediators of EMT, using real-time PCR methods. E-cadherin and β-catenin in cyst were attenuated and localized to lateral cell-cell contact according to cyst enlargement in *cpk*. Vimentin and fibronectin were de novo expressed in cystic epithelial cells. Snail1 was predominantly expressed in the nuclei of tubular epithelial cells in *cpk*, while there was no significant staining in controls. Smad3 was also increased in the nuclei in *cpk*. The mRNA levels of TGF-β and Smad3 were up-regulated, which suggested the activation of TGF-β/Smad3 pathway. In conclusions, these findings suggested that EMT is also involved in *cpk*, and EMT may be a common key pathophysiology in PKD and a target for a disease-specific intervention.

**F-PO1783**

**Abl Interactor-1 Induces Cytoskeleton Reorganization, MT1-MMP Re-Localization and Tubular Structure Formation of ADPKD Cells** Yunxia Tao, Zonghan Dai, Chenghai Li. *Internal Medicine, Texas Tech University Health Sciences Center, Amarillo, TX.*

Autosomal Dominant Polycystic Kidney Disease (ADPKD) is caused by mutations in *PKD1* and *PKD2* genes, which encode polycystin 1 and polycystin 2 proteins, respectively. Both polycystins have been shown to interact with actin cytoskeleton, localize to lamellipodia, and induce cell scattering and motility. These data suggest that dysregulation of cytoskeleton remodeling and lamellipodia formation may contribute to cyst formation. The present study was aimed to determine the effect of overexpression of Abl Interactor-1 (Abi1), a key regulator of actin cytoskeleton remodeling and lamellipodia formation, on cyst and tubule formation of ADPKD cells cultured in three-dimensional (3D) collagen gel.

An Abi1 expression vector was stably transfected into WT 9-7 cells, a cell line derived from human ADPKD cyst. The effect of Abi1 expression on actin cytoskeleton reorganization was studied by staining the cells with rhodomine-coupled phalloidin. We show that Abi1 significantly induced cell scattering and increased the number of lamellipodia compared to control cells. Both control and Abi1 transfected WT9-7 cells were cultured in 3D collagen gels for 6 days to allow cyst and tubule formation. Under this condition we found that the control WT 9-7 cells forms mainly cysts (72% of cyst and 28% tubule), whereas Abi1 WT 9-7 cells forms mainly tubules (2% cyst and 98% of tubule). Because MT1-MMP has been shown to localize at lamellipodia and play a critical role in regulating cell migration and morphogenesis; we examined the effect of Abil overexpression on subcellular localization of MT1-MMP by immunostaining cyst and tubule structures. Significantly, we observed that in cysts formed by control WT 9-7 cells, MT1-MMP is polarized and localized to the basal membrane of the cyst cells, however, in tubules formed by Abi1 WT9-7 cells, MT1-MMP was found in both basal and lateral membrane as well as in cytoplasm of the tubule cells.

These studies suggest that the dysregulated MT1-MMP localization resulted from the disorganization of cytoskeleton may be implicated in the pathogenesis of ADPKD.

***AHI1* and *CC2D2A* Genetically Interact – Zebrafish Models of Nephronophthisis and Joubert Syndrome** Roslyn Jane Simms, Lorraine Eley, Ann Marie Hynes, Colin Miles, Bill Chaudhry, John A. Sayer. *Institute of Human Genetics, Newcastle University, Newcastle-upon-Tyne, United Kingdom.*

Nephronophthisis (NPHP) is an autosomal recessive cystic kidney disease (CKD) and is a common cause of childhood renal failure. It is clinically heterogenous with extra-renal manifestations that include the cerebello-oculo-renal disorder Joubert Syndrome (JS). NPHP and JS are ciliopathies, since all genes implicated in these syndrome express their protein products in the primary cilium / basal body complex. Mutations in *AHI1* and *CC2D2A* are the leading causes of JS. These genes are highly conserved throughout evolution, including zebrafish (ZF). Using gene knockdown in ZF, we evaluated the role and potential genetic interactions of *AHI1* in the pathogenesis of NPHP and JS.

Antisense morpholino oligonucleotides (MOs) directed towards splice donor site exon 8 or 5'UTR blocking the translation of *AHI1* (Gene Tools) were injected into 1-4 cell stage wild type, claudin-b-GFP (transgenic) and *sentinel* (*CC2D2A* mutant) ZF embryos. mRNA rescue was performed by co-injecting capped mouse *AHI1* mRNA (mMessage Machine, Ambion). Embryos were incubated at 28.5ºC and phenotyped using light microscopy at 72 hours post fertilisation (hpf). Using mRNA from injected ZF, RT-PCR and direct sequencing was performed. Immunofluorescent (IF) microscopy and histology were used to evaluate pronephric cysts.

*AHI1* knockdown with both splice site and translation blocking MOs created a phenotype with a spectrum of dysmorphology including curly tail, cardiac oedema, hydrocephalus and pronephric cysts. Claudin-b-GFP embryos facilitated imaging of pronephric cysts. RT-PCR and sequencing confirmed an in-frame deletion of exon 8 from *AHI1*. Co-injection of *AHI1* MO and mouse *AHI1* mRNA rescued the mutant phenotype. Histology identified pronephric duct dilatation. IF demonstrated cloacal cysts in *AHI1* MO injected ZF. *AHI1* knockdown in *sentinel* ZF resulted in synergy of the mutant phenotype.

*AHI1* knockdown in ZF recapitulates the human cystic kidney disease NPHP and JS. Synergy of the mutant phenotype in *sentinel* ZF implicates a novel genetic interaction between *AHI1* and *CC2D2A*.

**F-PO1785**

***MKS3* Knockdown in Zebrafish Models the Ciliopathy Meckel Gruber Syndrome** Roslyn Jane Simms,[1] Lorraine Eley,[1] Ann Marie Hynes,[1] Colin Miles,[1] Matthew Adams,[2] Bill Chaudhry,[1] Colin A. Johnson,[2] John A. Sayer.[1] *[1]Institute of Human Genetics, Newcastle University, Newcastle-upon-Tyne, United Kingdom; [2]Ophthalmology and Neurosciences, Medical and Molecular Genetics, Leeds Institute of Molecular Medicine, St James's University Hospital, Leeds, United Kingdom.*

Meckel-Gruber syndrome (MKS) is an autosomal recessive disorder characterised by occipital encephalocele, cystic renal dysplasia and congenital hepatic fibrosis. MKS is clinically and genetically heterogenous and defined as a ciliopathy because all mutated genes express their protein products in the primary cilium/basal body complex. Mutations in *MKS3* frequently cause MKS, its protein product Meckelin also colocalises at the actin cytoskeleton, where it interacts with the actin binding protein Filamin A. Using gene knockdown in zebrafish (ZF), we aimed to create a model of MKS and evaluate genetic interactions between *MKS3* and *Filamin A*.

Antisense morpholino oligonucleotides (MOs) were designed to splice selected exons in ZF *MKS3* and *Filamin A* (Gene Tools). MOs were injected alone and in combination, into wild type and claudin-b-GFP (transgenic) ZF embryos. mRNA rescue was performed by co-injecting capped human *MKS3* mRNA (mMessage Machine, Ambion). Embryos were phenotyped using light microscopy at 72 hours post fertilisation. Using mRNA from *MKS3* injected ZF, RT-PCR and direct sequencing were performed.

*MKS3* knockdown created a mutant phenotype: curly tail, hydrocephalus, meningocele, notochord malformation and pronephric cysts. RT-PCR and sequencing of *MKS3* MO injected ZF embryos identifed inclusion of an intron in MKS3 mRNA, leading to a premature stop codon. Co-injection of *MKS3* MO with human *MKS3* mRNA rescued the mutant phenotype. An increased frequency of mutant characteristics occurred after co-injection of *MKS3* and *Filamin A* MOs.

*MKS3* MO knockdown in ZF creates a novel model of the human ciliopathy MKS. Synergy of the MKS mutant phenotype by co-injection with *Filamin A* supports a genetic interaction and suggests that mutations in actin binding proteins may contribute to the pathogenesis of ciliopathies. These ZF models may be useful to evaluate oligogenicity and triallelism in the clinical disorder MKS.

**VIP17: A Modulator of Cyst Formation and Ciliogenesis** Vinita Takiar, Kavita Mistry, Monica Carmosino, Michael J. Caplan. *Cellular and Molecular Physiology, Yale University School of Medicine, New Haven, CT.*

Epithelial cell polarity is a fundamental requirement for vectorial transport in mammalian tissues, which is disrupted in renal cystic diseases such as polycystic kidney disease. Vesicle integral protein of 17 kD (VIP17) is involved in the apical transport and delivery of carrier vesicles. Originally identified in mature T-cells and myelin producing cells, VIP17 overexpression *in vivo* results in renal cysts (originating primarily from distal nephron segments) surrounded by pseudostratified epithelial cells with amplified apical membranes.(Frank, M et al., 2000) The mechanism responsible for this cyst formation is not clear. In the collecting duct, VIP17 co-localizes and interacts with aquaporin-2 (AQP2). VIP17 increases surface expression of AQP2 by decreasing the channel's internalization. Thus, VIP17 overexpression could lead to cyst formation by increasing the potential for AQP2-mediated fluid secretion. However, it is also well-established that renal cystogenesis occurs in association with defects of the primary cilium. To explore the role of VIP17 in renal cystogenesis and ciliogenesis, we examined the polarization and ciliary morphology of wild-type and VIP17-overexpressing cells grown in two-dimensional (2D) culture and three-dimensional (3D) suspension in Matrigel. VIP17-overexpressing MDCK cells display apical localization of VIP17 both in 2D and 3D cyst culture. Interestingly, VIP17-overexpressing cell cysts are more multi-lumen compared to controls ($p<0.01$). We next localized membrane markers including E-cadherin, β-catenin, and zona occludens 1 by immunofluorescence and found that VIP17 expression has no effect on their distribution. Examination of the lumens in 3D cyst culture reveals shortened or absent cilia with VIP17 overexpression. Immunohistochemistry on kidney sections from VIP17 transgenic mice also demonstrates fewer and shortened cilia within dilated lumens ($p<0.01$) Collectively, these studies demonstrate that VIP17 overexpression results in abnormal cyst and cilium development, *in vitro* and *in vivo*, suggesting that VIP17 overexpressing mice may develop cysts secondary to a ciliary defect.

**c-MET Over-Expression and mTOR Hyperactivation in ADPKD** Shan Qin,[1] Mary E. Taglienti,[1] Jing Zhou,[2] Jordan A. Kreidberg.[1] *[1]Nephrology, Children's Hospital Boston, Harvard Medical School, Boston, MA; [2]Renal Division, Brigham And Women's Hospital, Harvard Medical School, Boston, MA.*

Autosomal Dominant polycystic kidney disease (ADPKD) is a common life-threatening genetic disorder that causes chronic renal failure. mTOR, a major regulator of cell growth and metabolism, has been shown to be hyperactivated in ADPKD. mTOR inhibition via rapamycin is among the emergent therapies for ADPKD currently being tested in clinical trials, but the mechanism of mTOR hyperactivation in ADPKD is not fully understood. We found that the expression of c-MET, a tyrosine kinase receptor for hepatic growth factor (HGF), was increased at the protein level in pkd1 knock out cells (pkd1 -/-). Akt, a kinase downstream of c-MET and known to be an activator of mTOR, is also hyperactivated in our pkd1 -/- cells. Administration of a c-MET inhibitor abrogates hyperactivation of Akt and mTOR in pkd1 -/- cells. Remarkably, in an organ culture model of cystic kidney disease, c-MET inhibitor can also inhibit Akt activity and cyst formation in pkd1 mutant embryonic kidney explants. Our results demonstrate that c-MET can activate mTOR via the Akt pathway. We hypothesize that the c-MET signaling pathways represent a promising therapeutic targets to prevent cyst formation in PKD.

**Analysis of *Cys40*: A Novel Gene Required for Ciliogenesis in Both Zebrafish and Mice** Lisa M. Swanhart, Neil A. Hukriede. *Developmental Biology, University of Pittsburgh, Pittsburgh, PA.*

Renal abnormalities are common structural birth defects that are observed in as many as 1 in 500 pregnancies and can cause perinatal death or chronic disease. The primary cilium has emerged as a key player in the development of polycystic kidney disease and it is now appreciated that ciliary defects underlie nearly all forms of this disease in humans, mice and zebrafish. A preliminary screen for mice with congenital heart disease identified several mutations that also caused kidney defects. The kidney defects in these animals included polycystic kidney disease, renal agenesis and hypogenesis, hydronephrosis and hydroureter. One such mutant, *Cys40*, displayed evidence of kidney duplication and cyst formation as well as a low incidence of left-right defects. Immunocytochemisty demonstrated that Cys40 protein localized to both the axoneme and the basal body of the primary cilium in IMCD cells, suggesting a role for this gene in the development of this organelle. To further elucidate the function of Cys40 and its role in ciliogenesis, morpholino oligonucleotides were used to knockdown protein levels in zebrafish embryos. Cys40 morphants displayed several phenotypes that are indicative of aberrant ciliary function, including a curved axis, hydrocephaly, pericardial edema, and the development of kidney cysts by 120 hours post-fertilization. In the zebrafish pronephros, the functional larval kidney, cilia appear disorganized and normal motility is compromised. Analysis of Kupffer's vesicle, a structure analogous to the mouse node, demonstrated both a reduction in number and length of the cilia in this organ. These changes in cilia structure may explain why Cys40 morphants display mild left-right defects, such that heart looping and normal positioning of the liver are disrupted. Similar to what was observed in mammalian cell culture, Cys40 protein localizes to both the basal body and the axoneme of the cilia within the pronephros. Taken together, these data suggest that the function of Cys40 is not only conserved among vertebrates but appears critical for ciliogenesis.

**Effects of ER Stress, PERK and eIF2α on Regulation of Polycystin-2** Jungwoo Yang, Zuocheng Wang, Carlos Lara, Xing Z. Chen. *Physiology, University of Alberta, Edmonton, AB, Canada.*

Autosomal dominant polycystic kidney disease (ADPKD) is associated with numerous cellular abnormalities such as cell over-proliferation and apoptosis. Mutations in polycystin-2 (PC2), a Ca permeable non-selective cation channel present in ER membrane, plasma membrane and cilia, account for ~10% of ADPKD cases. How PC2 expression is regulated and how it regulates cell growth are not well understood. We reported that PC2 is regulated by the ER-associated degradation pathway through the ubiquitin–proteasome system (Liang et al, Hum Mol Genet, 17:1109-, 2008) and that PC2 down-regulates cell proliferation and protein synthesis through promoting the phosphorylation of eukaryotic initiation factor 2α (eIF2α) by pancreatic ER eIF2α kinase (PERK) (Liang et al, HMG, 17:3254-, 2008). ER stress is induced by disruptions of ER homeostasis such as alterations in cellular Ca concentrations and ER protein glycosylation, and leads to acumulation of unfolded proteins in the ER lumen. Cells respond to the situation by a number of ways together termed unfolded protein response (UPR). One way of UPR is induction of PERK auto-phosphorylation, which stimulates its kinase activity and phosphorylates eIF2α, thereby shutting down global protein synthesis and regulating cell proliferation and apoptosis. We found that PC2 is up-regulated in HEK and HeLa cells under ER stress induced by thapsigargin or tunicamycin. Using cells with over-expression of WT or mutant PERK, siRNA or knockout, we showed that PC2 expression is up-regulated by PERK kinase activity. In MEF cells with PERK-/-, but not in control MEF cells, ER stress failed to up-regulate PC2. These data together indicate that ER stress up-regulates PC2 expression through increased PERK activity. We are currently examining 1) whether eIF2α activity is sufficient to up-regulate PC2 expression, using eIF2α over-expression, knockdown and induction of eIF2α activity by other eIF2α kinases; and 2) whether ATF4, an activating transcription factor up-regulated by phosphorylated eIF2α and PERK, is sufficient to up-regulate PC2. These studies together will shed light on how PC2 is regulated and its cellular functions in the ER. Supported by KFoC and CIHR (to XZC).

**mTORC2 Signalling Is Independent of HIF-1α in Polycystic Kidney Diseases** Iram Zafar, Kameswaran Ravichandran, Franck A. Belibi, Charles L. Edelstein. *Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO.*

mTORC2 is a complex of mTOR and Rictor that, unlike mTORC1, is rapamycin-independent. Increased proliferation of cyst epithelial cells plays a crucial role in cyst formation and mTORC2 signaling induces proliferation. First we determined mTORC2 signaling in rat and mouse models of PKD. 112 day PKDWS25/- mice and 8 w old male Han:SPRD rats (Cy/+) with PKD were studied. Phospho-Akt (serine 473) (60 kDa), the functional readout of the mTORC2 activity was measured in kidney. On immunoblot, p-Akt (60 kDa) was not different between ++ and PKDWS25/- mice but was more than 3-fold increased in Cy/+ compared to +/+ rats ($P<0.01$, n=4). Unexpectedly the increase in pAkt was inhibited by rapamycin ($P<0.01$, n=4). Cyst formation in PKD kidneys results in localized hypoxia in the kidney that can activate HIF-1α. The mTORC2 pathway can activate HIF-1α. Thus, we measured HIF-1α by ECL using the ultrasensitive singleplex kit from Meso Scale Discovery (MSD). HIF-1α (units corrected for protein) was 54.8 4.2 in ++, 52.3 3.3 in Cy/+, 88.4 3 in 4 w old homozygous Han rats (Cy/Cy) with very large kidneys ($P<0.001$ vs.+/+, Cy/+). Thus the increase in pAkt in Cy/+ was not associated with an increase in HIF-1. However, HIF-1α was increased in Cy/Cy. To determine whether HIF-1α plays a role in the pathogenesis of cyst formation, Cy/Cy rats were treated with the HIF-1α inhibitor, 2-methoxyestradiol (2ME2) 2mg/kg/d IP from 2-4 weeks of age. Immunoblot of Cy/Cy kidneys demonstrated a decrease in HIF-1α protein in 2ME2-treated rat kidneys. Two kidney to total body weight ratio (%) was 25 in Cy/Cy treated with vehicle and 22 in Cy/Cy treated with 2ME2 (NS). Cyst volume density was 73 in Cy/Cy treated with vehicle and 65 in Cy/Cy treated with 2ME2 (NS). In summary 1) the large increase in pAkt in Cy/+ rats is not associated with an increase in HIF-1α , 2) rapamycin reduced pAkt, 3) despite an increase in HIF-1α in Cy/Cy rats, HIF-1α inhibition in Cy/Cy rats did not reduce kidney or cyst volume. In conclusion, the proliferative mTORC2 pathway merits further study in PKD.

**Activation of the Replicative Stress Response as a Possible Therapeutic Target in Triplex DNA-Associated Diseases** Anastasia K. Ketko, Bradley P. Dixon. *Division of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Polypurine·polypyrimidine tracts can form triplex DNA that can disrupt promoters and silence genes. Such a mechanism has been postulated to regulate expression of the γ-hemoglobin gene. Hydroxyurea (HU) can induce fetal hemoglobin expression and can also cause replication arrest, thus activating replicative stress proteins such as BLM, a RecQ helicase that is known to unwind triplex DNA. We postulated that such induction of replicative stress and DNA damage response proteins may release gene silencing and cause the expression of fetal hemoglobin.

K562 cells, an erythroleukemia cell line which can be induced to express γ-hemoglobin, were exposed to graded concentrations of HU (25μM to 1mM). Single strand DNA breaks representing stalled replication forks were quantified by single cell gel electrophoresis (comet assay) under alkaline lysis conditions. Expression of γ-hemoglobin was measured by western blot of cell lysates and benzidine staining of treated cells. Activation of the DNA damage response and replicative stress pathways were also assessed by western blot analysis.

A dose-dependent increase in γ-hemoglobin expression was identified in K562 cells exposed to HU. Single-strand DNA breaks also increased in a dose-dependent manner following exposure to HU. Activation of the DNA damage response mediated by ATM kinase and apoptosis occurred at high concentrations of HU (400μM to 1mM). However, activation of the replicative stress protein BLM, presumably mediated through the ATR-Chk1 pathway, occurred at lower concentrations of HU (25μM to 200μM).

These results demonstrate that activation of BLM can be modulated by hydroxyurea, and is associated with an increase in γ-hemoglobin expression in K562 cells, suggesting a possible role for the unwinding of triplex DNA by BLM in the promoter region of the γ-hemoglobin gene in its mechanism of action. Implications of this work include the possibility that activation of BLM could reduce somatic mutation in triplex-associated diseases, such as ADPKD, and therefore serve as a novel therapeutic agent for these diseases.

**TGF-β Is an Inhibitor of ADPKD Cell Cystogenesis** Gerard Elberg, Dorit Elberg, Siddarth Jayaraman, Martin A. Turman. *Pediatrics/Nephrology, University of Oklahoma, Health Sciences Center, Oklahoma City, OK.*

The purpose of this study is to determine a possible role of extracellular factors secreted by epithelial cells in modulating cyst formation in autosomal dominant polycystic kidney disease (ADPKD). To analyze the presence of such factors, we used conditioned media (CM) from monolayer of normal kidney (NK) and ADPKD epithelial cells from human kidneys in primary cultures. The effect of CM was tested in a 3D model of cyst formation using human ADPKD cells. Results indicate that incubation of CM at 80°C induces inhibitory activity on cyst formation. Importantly, this treatment affects the process of cyst formation but has little effect on cyst growth and expansion. The effect of high heat suggests activity of a latent factor, which prompted us to assess the expression of transforming growth factor β (TGF-β) in CM and possible inhibitory function of TGF-β on cystogenesis. We found that high heat induced TGF-β activity in CM as measured by immuno-assay and expression of known TGF-β target genes in 3D cultures of ADPKD cells. Analysis of level of expression of 3 different mammalian TGF-β isoforms indicates that TGF-β2 is mainly secreted in CM of NK and ADPKD cells. The inhibitory effect of heat-activated CM on cyst formation is hampered by TGF-β2 blocking antibody and TGF-β receptor I kinase inhibitor. Recombinant TGF-β1, 2 and 3 have a similar ability to inhibit cyst formation at low concentrations (IC50=15-26 pg/ml). Our data suggest that activation of TGF-β2 secreted by renal epithelial cells regulates cystogenesis. Therefore, the fibrotic process in ADPKD induced by massive secretion of TGF-β is likely to be a failed, excessive mechanism of healing.

**Curcumin Inhibits cAMP-Mediated Cystic Dilation in Pkd1-Deficient Kidneys in Metanephric Organ Culture** Robin L. Maser, Andreea Chiselita, Brenda S. Magenheimer, James P. Calvet, Donna Ziemer, Melissa Johnson, Dianne Vassmer. *The Kidney Institute, Univ of Kansas Medical Center, Kansas City, KS.*

We have reported that antioxidant gene expression is abnormally reduced in multiple animal models of PKD, suggesting that inadequate antioxidant protection and dysregulated cellular redox homeostasis may influence cellular pathways important in PKD pathology. We tested whether antioxidant treatment could affect cyst pathogenesis. Curcumin is a food spice shown to have antioxidative, antiproliferative, and anti-inflammatory properties and to be an effective chemotherapy against multiple forms of cancer. We chose the metanephric organ culture model as an initial experimental system. Kidneys from embryonic day 15.5 Pkd1 mutant mice were placed in culture in the presence of DMSO or of 20 or 30 μM curcumin. 8-Br-cAMP was added to all cultures to induce cystic dilation. Kidneys were loaded with fluorescein on the last day in culture, photographed, and then fixed in methanol for whole mount staining with DBA- or LTA-FITC. Percent cystic index was determined by measuring the total surface area and the cystic surface area using analySIS software. Cyst-like structures that stained with DBA or LTA were visible in all three genotypes, however, a Pkd1 gene dosage-dependent effect was observed as reported previously. Curcumin treatment significantly reduced tubule dilation in all genotypes and was able to reduce % cystic area of Pkd1-deficient kidneys to DMSO-treated wildtype levels. Confluent mouse embryonic kidney epithelial cell cultures were treated with varying concentrations of curcumin for 24 hrs, and lysed for protein. Western blot analyses demonstrated induction of heme oxygenase-1 and NAD(P)H-oxidoreductase 1 proteins in these cultures. In addition to upregulation of antioxidant defenses, curcumin is reported to have effects on multiple cellular pathways including the cell cycle, Wnt/beta-catenin signaling, the mTOR pathway, and intracellular calcium levels, all processes that are reported to be dysregulated in PKD. These experiments suggest that curcumin or curcumin-like compounds may have beneficial effects in PKD.

**Ouabain Activates the Na,K-ATPase Signalosome in Autosomal Dominant Polycystic Kidney Disease Cells** Kyle Jansson, Anh Nguyen, Darren P. Wallace, Gustavo Blanco. *Department Molecular and Integrative Physiology and Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

The Na,K-ATPase is part of a cell signaling complex (Na,K-ATPase signalosome), which upon activation by the hormone ouabain, stimulates the proliferation of several cell types. Our previous results show that ouabain induces proliferation in epithelial cells derived from renal cysts of patients with autosomal dominant polycystic kidney disease (ADPKD). This effect suggests that ouabain is a factor that can contribute to ADPKD cyst progression. At present, the signaling pathways involved in the response of ADPKD cells to ouabain are unknown. Understanding the mechanisms by which ouabain exerts its action is important. In this study, we investigated the signaling pathways responsible for mediating ouabain's effect on ADPKD cell proliferation. Ouabain concentrations such as those found in blood (3nM), stimulated phosphorylation and increased the activity of the kinase Src. In addition, ouabain stimulated phosphorylation of the epidermal growth factor receptor (EGFR) in the cells. Accordingly, tyrphostin AG1478 and PP2, inhibitors of EGFR and Src respectively, blocked the proliferative effects of ouabain. Treatment of ADPKD cells with ouabain also caused phosphorylation of the caveolar protein caveolin-1, and disruption of cell caveolae with methyl-β-cyclodextrin prevented ouabain-induced proliferation of the cells. This suggests that ouabain's effect requires the integrity of the plasma membrane caveolae. Downstream effects of ouabain in ADPKD cells included phosphorylation of the kinase B-Raf, activation of MEK and of the extracellular regulated kinase ERK. Finally, ouabain reduced the expression of the cyclin-dependent kinase inhibitors p21 and p27, which are suppressors of cell proliferation. In conclusion, this study shows that ouabain uses the Na,K-ATPase signalosome to stimulate proliferation of ADPKD cells and identifies intracellular mediators of ouabain dependent ADPKD proliferation. [Supported by NIH grant DK081431].

**Role of Phosphodiesterases on cAMP-Dependent ERK Activation and Cyst Formation in PKD** Cibele S. Pinto, Brenda S. Magenheimer, Gail Reif, James P. Calvet, Darren P. Wallace. *The Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

cAMP plays a central role in the pathogenesis of polycystic kidney disease by promoting cell proliferation and fluid secretion. Intracellular cAMP is regulated by a balance between its production by adenylyl cyclases and its degradation by phosphodiesterases (PDEs). We found that ADPKD cells have a higher basal cAMP level compared to normal human kidney (NHK) cells ($1.17 \pm 0.12$ vs. $0.75 \pm 0.06$ pmol/monolayer, $P < 0.02$). 3-isobutyl-1-methylxanthine (IBMX), a non-specific PDE inhibitor, increased basal cAMP levels in NHK and ADPKD cells, and amplified AVP-induced cAMP accumulation. IBMX alone or in the presence of AVP significantly increased ERK phosphorylation in ADPKD cells, but decreased ERK phosphorylation in NHK cells. In metanephric organ culture, IBMX alone increased the level of phosphorylated ERK and induced cyst-like dilations in $Pkd1^{-/-}$ embryonic kidneys. These results demonstrate that PDE activity plays an important role in regulation of cAMP-dependent ERK activation in PKD. Using microarray analysis, we found that mRNA levels for PDE1, a $Ca^{2+}$-activated PDE, and PDE4 were elevated in human ADPKD cells compared to NHK cells; however, no significant difference in protein levels was observed. Rolipram, a selective PDE4 inhibitor, caused a higher increase in basal cAMP and a greater effect on AVP-mediated cAMP accumulation compared to vinpocetine, a PDE1 inhibitor. On the other hand, vinpocetine had a significantly greater effect on AVP-induced ERK activation compared to either IBMX or rolipram, suggesting that PDE1 may be involved in the cross talk between the cAMP and MAPK pathways. These data show that PDE inhibition alone increases cAMP accumulation and ERK activation in cyst derived epithelial cells, and induces cyst-like dilations in embryonic $Pkd1^{-/-}$ kidneys. These data support the hypothesis that decreased activity of PDE1 due to lower intracellular $Ca^{2+}$ levels may partially account for higher intracellular cAMP and a greater effect of AVP on cAMP accumulation and ERK activation in ADPKD cells.

**Metabolite of Sir2 Reaction Modulates Polycystin-2 Ion Channel Activity** Lucy X. Fan,[1] Tengis S. Pavlov,[2] Alexander Staruschenko,[2] Xiaogang Li.[1] *[1]Department of Pediatrics and Physiology, Medical College of Wisconsin, Milwaukee, WI; [2]Department of Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Autosomal dominant polycystic kidney disease (ADPKD) is an age-related genetic disorder characterized by renal cyst formation and progression to end stage renal failure. Our microarray analysis has shown that Sirt1 and Sirt2, the members of class III histone deacetylases (HDACs) and age-related regulators, are upregulated in *Pkd1*$^{null/null}$ mouse embryonic kidney (MEK) cells, which has also been confirmed by Western blot analysis. Sirt1 and Sirt2 have been found to modify and silence the transcription of integrated reporter genes by histone deacetylation. They also deacetylate nonhistone proteins such as some transcriptional factors including Rb, E2F1, p53 to regulate cell cycle and cytoskeleton proteins, such as α-tubulin, to regulate mitotic exit. In addition, it has been reported that O-acetyl-ADP-ribose (OAADPr), a metabolite of the Sir2 reaction which is formed when Sir2 removes an acetyl group from a protein target and transfers the moiety to NAD, acts as a secondary messenger or a cofactor to regulate the activation of TRPM2, a nonselective cation channel. We found that Sirt1 formed a complex with Rb and E2F1 and Sirt2 formed a complex with HDAC6 in MEK cells. Since Sirt1 and Sirt2 were upregulated in Pkd1 mutant MEK cells, thus, more OAADPr may be produced through deacetylating Rb, E2F1, and a-tubulin by Sirt1 and Sirt2 in these cells. To test the effect of OAADPr on polycystin-2 (PC2) channel, we reconstituted PC2 channel either alone or together with polycystin-1 (PC1) in chinese hamster ovary (CHO) cells and performed whole cell patch clamp analysis when 2'-NAADPr or 3'-NAADPr, analogs of 2'-OAADPr and 3'-OAADPr, were included in the pipette solution. We demonstrated that rather 2'-NAADPr or 3'-NAADPr activated PC2 currents in CHO cells when PC2 alone or PC1/PC2 heterologously expressing these channels. In addition, ADPr, the hydrolyzed product of OAADPr, has the similar effects on the PC2 channel activation as 2' or 3'-NAADPr does. These results suggest that Pkd1 mutation may be through OAADPr to regulate PC2 channel activity.

**F-PO1797**

**Stable Suppression of Glis2/Nephrocystin-7 Results in Aberrant Centrosome Duplication and Nuclear Division in Kidney Tubular Cells In Vitro** Binghua Li,[1] Alysha Rauhauser,[1] Massimo Attanasio.[1,2] *[1]Department of Internal Medicine; [2]Eugene McDermott Center for Growth and Development, UT Southwestern Medical Center at Dallas, Dallas, TX.*

Nephronophthisis (NPHP), an autosomal recessive cystic kidney disease, is the most frequent genetic cause of chronic renal insufficiency in the first three decades of life (1). Glis2/Nephrocystin-7 loss of function causes NPHP type 7 in humans and an alike cystic kidney phenotype in mice (2). We have previously reported that Glis2 is localized at the centrosomes, the mitotic spindle and the midbody of kidney epithelial cells in vitro with a cell cycle dependent pattern, suggestive of a possible role of this protein in controlling centrosome duplication and cell division.

To test this hypothesis, we generated IMCD3 cells stably knocked-down for Glis2 by lentiviral delivered shRNAs. High knockdown efficiency (more than 70%) was verified by quantitative real-time PCR and was obtained with two different targeting constructs. Centrosomes were labeled with antibodies against the specific centrosomal marker γ-tubulin and evaluated by immunofluorescence confocal microscopy; nuclei were counterstained with DAPI. Cells were grown in standard conditions (37 °C, 5% CO2 in DMEM/F-12 plus 10% FBS).

Stable suppression of Glis2 in IMCD3 cells resulted in the aberrant generation of multiple centrosomes that became more evident after several passages. Nuclei appeared to be either multilobulated or abnormally fused in a single megakarion, indicating an impairment of the nuclear division. The aberrant centrosomes conserved the ability of nucleating microtubules, as demonstrated by the concomitance of multiple associated spindles.

Our results indicate that Glis2 is necessary for the correct centrosomal and nuclear duplication in kidney tubular cells in vitro. Analogous centrosome amplification has been recently associated with the loss of function of another NPHP protein, MKS3/NPHP11, suggesting that defects of centrosome duplication can be implicated in the pathogenesis of cystic kidney diseases.

**Aberrant Regulation of Planar Cell Polarity Pathway in Human and Mouse Polycystic Kidney Disease** Annouck Luyten, Xuefeng Su, Sarah Lynn Gondela, Ying Chen, Ayumi Takakura, Jing Zhou. *Medicine, Renal Division, Brigham and Women's Hospital, Boston, MA.*

Autosomal dominant polycystic kidney disease (ADPKD), characterized by the formation of fluid-filled cysts in the kidney, is a major cause of end stage renal disease in adults. Mutations in the PKD1 gene, which encodes polycystin-1 (PC1), contribute to more than 85% of ADPKD cases. The planar cell polarity (PCP) pathway has recently been implicated to be necessary for convergent extension and oriented cell division in the establishment and maintenance of kidney tubule diameter. Here, we show that inactivation of Pkd1 in postnatal developing kidney leads to a defect in oriented cell division in pre-cystic kidney tubules. This defect is also seen in pre-cystic Pkd1 inactivated mature kidneys after receiving ischemic reperfusion injury (IRI) as a "third-hit". Frizzled proteins play a critical role in the regulation of PCP. We find striking upregulation and activation of Frizzled 3 (Fz3) and its downstream effector CDC42 in cystic kidneys. Fz3 is expressed on the cilia in cystic kidneys although it is barely detectable on the cilia of normal kidneys. We also show that PC1 and Fz3 antagonize each other to control CDC42 expression and cell migration rate in HEK293T cells. Our data suggest that PC1 controls oriented cell division and that aberrant PCP signaling contributes to cystogenesis.

**E2F Family Transcription Factors Regulate the Polycystic Kidney Disease-1 Gene Promoter through an ETS Binding Element** Anuj Gupta,[1] Veena Puri,[3] James P. Calvet,[2] Sanjeev Puri.[1] *[1]Panjab University, Chandigarh, India; [2]Univ. of Kansas Medical Center, Kansas City, KS; [3]DAV College, Chandigarh, India.*

E2F transcription factors are key regulators of cell-cycle progression and function in a wide range of biological processes including DNA replication, mitotic and DNA-damage checkpoints, DNA repair, differentiation, development and apoptosis. They can stimulate or repress target genes. We have analyzed a 3.3 kb 5' upstream region of the human *PKD1* promoter using transient transfection in HEK293T and COS-1 cells to demonstrate that the *PKD1* promoter is a target of E2F family transcription factors. Our studies demonstrated that *PKD1* promoter–luciferase reporter gene expression is downregulated by E2F family transcription factors (E2F1, E2F2, E2F4 and E2F6). A time course study demonstrated highest repression at 24 hrs post-transfection. E2F transcriptional effects are mediated after their release from retinoblastoma (RB). Overexpression of RB, which sequesters E2F, enhanced *PKD1* promoter activity. RT-PCR analysis further corroborated E2F-mediated repression of the endogenous *PKD1* gene in HEK293T cells. Deletion-construct analysis demonstrated that the sequences responding to E2F lie within -200 bp of the proximal *PKD1* promoter, which in previous studies was reported to respond to a number of transcription factors, including Ets, Sp1, RXR, and p53. Sequence analysis suggested the presence of several potential E2F binding elements in a GC rich region (5'-CGCGCCGCGCGG-3' -31 to -42). EMSA supershift assays demonstrated binding of E2F proteins to this region. However, site-directed mutagenesis indicated the involvement of a more distant Ets site at -129 to -133, rather than the candidate E2F binding elements, in regulating the *PKD1* promoter. These results thus suggest a complex regulatory mechanism for the *PKD1* gene that may involve concerted action of several transcription factors. Among several possibilities is that E2F may upregulate an Ets transcription factor which in turn causes transcriptional repression of the *PKD1* gene.

**F-PO1800**

**Reduced Notch Signaling in Autosomal Dominant Polycystic Kidney Disease** Karen Tamano,[1] Carol G. Carlton,[2] Binu M. Paul,[2] Seth V. Vande Kamp,[2] Madhulika Sharma,[2] Gail Reif,[1] Darren P. Wallace,[1] Gregory B. Vanden Heuvel.[2] *[1]Medicine, University of Kansas Medical Center, Kansas City, KS; [2]Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS.*

Recombination signal binding protein for immunoglobulin kappa J region (RBPJ/k) is a transcription factor that interacts with the Notch intracellular domain (Notch-IC) and is required for canonical Notch signaling of all the Notch receptors. Mice carrying a conditional RBPJ/k allele were crossed with Hoxb7/cre mice to specifically delete RBPJ/k in the developing ureteric bud and collecting duct. Newborn RBPJ/$k^{CD}$ mice exhibited cortical and medullary cyst-like dilations, and by postnatal day 14 these mice showed extensive medullary dilations. Preliminary analysis of planar cell polarity using anti-phospho-Histone H3 antibodies showed a disruption of spindle orientation in the collecting ducts of RBPJ/$k^{CD}$ mice. This is consistent with recent studies showing that reduced Notch signaling in developing proximal tubules results in cystic disease (JASN 21:819-832, 2010). To further evaluate the role of Notch signaling pathway in polycystic kidney disease, we analyzed Notch signaling in human ADPKD cells. We found decreased Notch3-IC in ADPKD cells, compared to normal human kidney cells. In addition, Hes1, a Notch pathway effector protein, was also downregulated in ADPKD patient samples compared to controls. Taken together, these results suggest that Notch signaling is required for the normal development of the collecting duct system in the kidney, and that reduced Notch signaling may contribute to the development of renal cysts.

**Disruption of Mouse AQP11 Induces Endoplasmic Reticulum Stress, Followed by Apoptosis and Cellular Proliferation, in the Proximal Tubule Cells of the Kidney** Katsuki Kobayashi,[1] Sei Sasaki.[2] *[1]Division of Molecular Genetics, Clinical Research Center, Chiba-East National Hospital, Chiba City, Chiba, Japan; [2]Department of Nephrology, Tokyo Medical and Dental Universtity, Bunkyo-ku, Tokyo, Japan.*

Aquaporin-11 (AQP11) is established as member of aquaporin water channel family, but its cellular and molecular function remains unclear. In an earlier study on mice harboring ablated coding regions of the AQP11 gene, our group observed vacuolation of the renal proximal tubule cells, followed by the formation of renal cortical cysts originating from the proximal tubule. In the present study we sought to identify the cellular and molecular mechanisms by which renal cysts are generated in AQP11-disrupted mouse. We initially noticed that the proximal tubule cells at the surface to mid cortex became vacuolated and apoptotic, whereas those deeper within the cortex proliferated vigorously and eventually formed cysts. Then by staining kidneys with antibodies against ER-stress-responsive factors, we recognized a strong activation of CHOP expression in the vacuolated and apoptotic proximal tubule cells. This was evidence that the apoptosis was the result of ER stress. In contrast to CHOP, GRP78 expression was augmented exclusively in the deep-cortex proximal tubule cells, a sign of a similar induction of ER stress in these cells. Yet in these cells, the ER stress was followed by cellular proliferation. Moreover, the cystogenesis of AQP11-disrupted mouse kidney was driven by mTOR activation and inhibited by the administration of rapamycin (a potent mTOR inhibitor). Taken together, our data suggested that the deletion of AQP11 elicits ER stress which in turn induces apoptosis and cellular proliferation in different parts of the renal proximal tubule. This PKD mouse model is likely to become a valuable tool for clarifying the complex mechanisms underlying PKD cystogenesis.

**Differential Laminin alpha Chain Expression in an ADPKD Mouse Model** Binu M. Paul,[1] Patricia St. John,[1] Klaus B. Piontek,[2] Gregory G. Germino,[3] Dale R. Abrahamson,[1] Gregory B. Vanden Heuvel.[1] *[1]Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS; [2]Medicine, Johns Hopkins University, Baltimore, MD; [3]NIDDK, Bethesda, MD.*

Alterations in the tubular basement membrane (TBM) including thickening, splitting, fraying, and multilayering have been described previously in human polycystic kidney disease (PKD). Cystic kidneys from several animal models of PKD also showed basement membrane abnormalities including thickened and laminated basement membranes as well as increased expression of α1 type IV collagen and the laminin β1 and β2 chains. Moreover, mice carrying a hypomorphic mutation in the laminin α5 chain develop PKD (JASN 17:1913-1922, 2006). We used chain specific antibodies to analyze the expression of laminin in a collecting duct specific Pkd1 knockout mouse model (Pkd1$^{CD}$) during early and late stages of cystogenesis. During normal kidney development we observed a reduction in expression of the laminin α1 chain during collecting duct maturation, with minimal expression in mature collecting ducts. In contrast, we observed a complete loss of the laminin α1 chain in the collecting duct derived cysts. Moreover, the rapidly expanding cysts showed intense labeling for the laminin α5 chain. In contrast to laminin α chain expression, no differences were observed in the expression of laminin β1 or the α1 or α2 chains of type IV collagen between cystic and wild type mice. Taken together, these results suggest that laminin α chain expression is disrupted in polycystic kidney disease, which may result from an accelerated switching of laminin isoforms in the cystic collecting ducts.

**Differential Expression of Ras-GTPase Isoforms in an Orthologous Model of Autosomal Dominant Polycystic Kidney Disease** Ayesha Irtiza-Ali,[1] Richard N. Sandford,[2] Dorien J. M. Peters,[3] Claire C. Sharpe,[1] Bruce M. Hendry.[1] *[1]Renal Medicine, King's College London, United Kingdom; [2]Cambridge Institute of Medical Research; [3]Leiden Univ Medical Center.*

Previous work by our group demonstrates that distinct patterns of Ras GTPase isoform expression occur in different kidney cell types, and inhibition of specific Ras isoforms has marked anti-proliferative actions in both *in vitro* and in *in vivo* models of renal disease. We have most recently shown this *in vivo* in the rat unilateral ureteric obstruction model, where antisense targeting Kirsten Ras had dramatic anti-fibrotic effect. Aberrant renal tubular epithelial cell proliferation is critical to cystogenesis in autosomal dominant polycystic kidney disease (ADPKD). The role of Ras isoforms in ADPKD has not previously been defined.

In this work we demonstrate differential expression of Ras GTPase isoforms occurs in the orthologous *PKD1$^{nl/nl}$* mouse model. On a C57/Bl6 CD1 genetic background, renal cystic disease progresses from postnatal weeks 3 with development of grossly enlarged kidneys by weeks 6-8. On qPCR and western blot analysis, *PKD1$^{nl/nl}$* cystic kidneys at postnatal weeks 4 to 6 predominantly express Kirsten(Ki) and Neural(N) Ras, with up to 5 and 3.5 fold increases in Ki- and N-Ras mRNA respectively in comparison to wild type kidneys. Activated Ras, as detected by Ras-GTP assay, is strongly upregulated in cystic kidneys compared to wild type. Further studies in mouse collecting duct cells (mIMCD3) show predominant expression of Ki- and N-Ras isoforms, correlating with findings in cystic kidneys. These cells were treated for up to 48 hours with farnesylthiosalicylic acid (FTS), a pan-Ras antagonist. FTS inhibited cell proliferation, as measured by MTS assay, in a dose dependent manner indicating proliferation to be Ras-dependent.

These findings suggest Ras GTPases are important in renal tubular epithelial cell proliferative responses, with roles specifically for Ki- and N-Ras isoforms in cystic kidney disease pathogenesis in an orthologous *PKD1* mouse model. The precise actions of Ras GTPase isoforms in the abnormal proliferative responses that underlie cystogenesis in ADPKD is under our further investigation.

**Characterization of a Hypomorphic *Pkd1* Mouse Model of ADPKD** William E. Sweeney, Jr.,[1,2] Kandai Nozu,[1,2] Dorien J. M. Peters,[3] Ellis D. Avner.[1,2] *[1]Pediatrics, Medical College of Wisconsin, Wauwatosa, WI; [2]Children's Research Institute, Childrens Hospital Health System, Wauwatosa, WI; [3]Human and Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands.*

Purpose: A *Pkd1* hypomorphic mouse model of ADPKD was phenotypically characterized to assess its utility for testing potential therapeutic interventions for human ADPKD.

Methods: A recently described *Pkd1* hypomorphic mouse model of ADPKD (J of Path 216: 120, 2008) was backcrossed onto C57BL/6J strain for > 10 generations in order to develop a pure inbred background to control for any phenotypic variability from strain effects. As the C57BL/6J strain is fully sequenced strain, the resultant congenic *Pkd1* mouse will permit future high resolution interrogration by genetic and proteomic chips.

Genotypically, proven wildtype (WT), heterozygous (HET) and homozygous *Pkd1* null (CY) mice, were weighed and kidney, liver, spleen and heart were harvested from each at seven day intervals from PN-0 to PN-63. Kidney and liver were assessed by Western analysis for expression of EGFR, p-EGFR, ERK1/2, p-ERK 1/2, b-Raf and p-b-Raf. Kidneys were examined by immunohistochemistry for cyst localization with nephron specific markers, proliferation (Ki-67 and BrdU), and polarity with EGFR, and NaK ATPase. Trichrome staining was used to assess renal fibrosis.

Results: There were no differences found between WT and HET mice in any parameter assessed up to PN-63. Small proximal tubule (PT) cystic lesions along with small collecting tubule (CT) cystic lesions were present in PN-0 CY kidneys that were 60% larger (KW/BW ratio=1.99±.23) than age matched WT kidneys. PN-7 CY kidneys showed decreased PT cysts and increasing size and number of CT cysts. The size of the kidneys and the KW/BW ratio increased steadily to PN-35 due to increasing CT cyst size and number, reaching a KW/BW ratio of 22.85±2.0 ($p<0.01$ vs control). Thereafter a steady, significant decline in KW/BW and kidney size occurred due to increasing renal fibrosis. Through PN-35, IHC and Western analysis demonstrated abnormalities consistent with human ADPKD thereby making this orthologous *Pkd1* model uniquely suited for preclinical therapeutic testing.

**F-PO1805**

**Metabolomic Profiling of Pkd1 Mutant Cells Reveals a Switch to Anaerobic Glycolysis in PKD** Isaline Rowe,[1] Valeria Mannella,[1] Silvia Mari,[1] Marco Chiaravalli,[1] Musco Giovanna,[1] Alessandra Boletta.[1] *[1]Division of Genetics and Cell Biology, Dibit-San Raffaele Hospital, Milano, Italy; [2]Biomolecular NMR, Dibit-San Raffaele Hospital, Milano, Italy.*

Polycystin-1 (PC-1), the product of the PKD1 gene, mutated in the majority of cases of Autosomal Dominant Polycystic Kidney Disease (ADPKD), is a very large plasma membrane receptor. In previous studies we have shown that PC-1 regulates the mTOR pathway, a major actor in cellular metabolism regulation.

During routine culturing of Pkd1-/- mouse embryonic fibroblasts (MEF) we noticed that the culture medium tended to acidify faster than the one from wild-type (wt) MEF. Furthermore, overexpression of the PKD1 gene resulted in the opposite phenotype suggesting a role for PC-1 in regulating the cellular metabolism. To test this possibility, we performed metabolomic profiling of the extracellular medium (metabolic footprinting) of mutant and wt MEFs. 1H-NMR experiments have been done using a 600-MHz Bruker Biospin spectrometer. 2D 1H-NMR spectra were acquired in order to further assign peaks to metabolites in the 1H-NMR spectra using either databases available. Preliminary data had shown different profiles of metabolites. We observed a greater uptake of glucose and increased production of lactate in Pkd1-/- MEF compared to the controls. Next, we confirmed a significant increase in the production of lactate in several independent Pkd1-/- MEFs. Conversely, cells overexpressing PC1 showed reduced lactate production. This effect correlated with the amount of intracellular ATP detected. In fact, the Pkd1-/- MEFs had increased ATP content. Next, we looked at mitochondrial potential using two different techniques and found that this is not altered in mutant versus wt cells. These results suggest cells lacking a functional PC-1 have enhanced glucose consumption and ATP production, due to a switch towards the anaerobic glycolysis. Preliminary data performed in a PKD mouse model suggest that a similar switch might occur in vivo. Our data uncover a previously unrecognized role for the PKD1 gene in regulation of cellular energy balance and might help identifying biomarkers that could be used to define the ADPKD phenotype.

**Over-Expression of Mxi1 Represses Renal Epithelial Tubular Growth by Transcriptional Regulation of MMP9** Jong Hoon Park, Seon Ah Song, Kyung Hyun Yoo. *Department of Biological Sciences, Sookmyung Women's University, Seoul, Korea.*

Autosomal dominant polycystic kidney disease (ADPKD) is the most common hereditary kidney disease. The major characteristic of ADPKD is the cyst formation along the renal epithelial tubular cells, and this renal cyst leads to abnormal kidney architectures and renal insufficiency. Renal tubules are fundamental unit of architecture, so controls of tubular growth and formation are important for renal function. To find out new ways of treatment and diagnosis for ADPKD, recently mechanisms of tubulogenesis are being actively studied. Mxi1 is a member of MAD family proteins functioning in terminal differentiation, inhibition of cell cycle progression and tumor suppression. While Myc protein, antagonized by Mxi1, is known to cause the renal cystogenesis. Based on these molecular relationships between Mxi1 and Myc proteins, we confirmed that Mxi1 has an effect to ADPKD through lack of Mxi1 gene expression could cause cyst formation in Mxi1-deficient mice. And then to determine whether Mxi1 affects to renal epithelial cell tubulogenesis, we performed three-dimensional cultures using mIMCD-3 cells and stably Mxi1 over-expressed mIMCD-3 cells. As a result, over-expression of Mxi1 gene suppresses renal tubulogenesis by regulating several genes playing a key role in renal epithelial branching tubulogenesis, such as MMP9, integrins, E-cadherin and so on, in mIMCD-3 cells. Also we verified that MMP9 is tightly affected by expression level of Mxi1. Taken together, we concluded that stably Mxi1 over-expressed mIMCD-3 cells fail to renal epithelial tubule formation because of abnormally reduced expression of MMP9.

**F-PO1807**

**Genotype-Phenotype Correlation in 368 Individuals with NPHP-Related Ciliopathies** Moumita Chaki, Julia Hoefele, Susan J. Allen, Gokul Ramaswami, Sabine Janssen, Edgar Otto, Friedhelm Hildebrandt. *Pediatric Nephrology, University of Michigan, Ann Arbor, MI.*

Nephronophthisis (NPHP), an autosomal recessive cystic kidney disease, is the most frequent genetic cause for end-stage renal failure in the first 3 decades of life. Mutations in thirteen genes (*NPHP1-11*, *AHI1*, *CC2D2A*) have been identified to cause NPHP. Recently, it became evident that in some NPHP-related ciliopathies (NPHP-RC), the nature of the mutations determines the disease severity (Delous *et al*., *Nat Genet* 2007): whereas truncating mutations cause severe, early-onset, dysplastic, multiorgan phenotypes, missense mutations result in milder, late-onset, degenerative phenotypes with limited organ involvement. Besides multiple allelism, the broad spectrum of organ involvement in NPHP could also be explained by the broad heterogeneity in NPHP.

Our aim was to evaluate genotype-phenotype correlation in 368 families with NPHP-RC, in which both disease-causing alleles were detected in: *NPHP1* (235 families), *NPHP2* (12), *NPHP3* (8), *NPHP4* (23), *NPHP5* (26), *NPHP6* (18), *NPHP7* (1), *NPHP8* (8), *NPHP9* (1), *NPHP10* (8), *NPHP11* (20), *AHI1* (5) and *CC2D2A* (3). Phenotypes were ranked in the order of severity from mild/degenerative [NPHP, Senior-Loken syndrome (SLSN)] to degenerative/dysplastic [Joubert syndrome (JBTS)] to severe/dysplastic [Meckel-Gruber syndrome (MKS)].A genotype of 2 null alleles caused a range of phenotypes in the following ascending order of increasing severity [phenotype in brackets]: *NPHP1* [NPHP, SLSN], *NPHP4* [NPHP, SLSN], *NPHP5* [early-onset SLSN], *NPHP2* [infantile NPHP], *NPHP10* [SLSN with other organ involvement], *NPHP6* [SLSN and JBTS] and *AHI1* [JBTS]. For *NPHP8* and *NPHP11*, we never found patients with 2 truncating mutations. In *NPHP6, NPHP8, NPHP11, AHI1* and *CC2D2A*, allelic influences on the phenotypes were compatible with the literature i.e. the presence of 2 truncating mutations caused dysplastic phenotypes (JBTS/MKS), whereas at least one missense allele "rescued" the phenotype to a milder degenerative form (NPHP/SLSN/JBTS). These data have important implications for genetic counseling and management of renal replacement therapy.

**F-PO1808**

**Deep Sequencing of the *PKD1* and *PKD2* Genes by Bar-Coded and Multiplexed Illumina Next-Generation Sequencing** Sandro Rossetti,[1] Jamie L. Sundsbak,[1] Bruce W. Eckloff,[2] Robert A. Sikkink,[2] Yean Kit Lee,[2] Vicente E. Torres,[1] Peter C. Harris.[1] *[1]Nephrology Research, Mayo Clinic, Rochester, MN; [2]Genome Center, Mayo Clinic, Rochester, MN.*

Autosomal Dominant Polycystic Kidney Disease is caused by mutations in the *PKD1* and *PKD2* genes, with high allelic heterogeneity and genomic duplication of *PKD1*. Next-generation sequencing is potentially well suited to analyze these genes in large populations, for diagnostic or research purposes, but the cost and labour associated with it require the development of more efficient frameworks. We have developed a framework for next-generation sequencing of the *ADPKD* genes by using degenerate bar-codes (indexes) and the Illumina GA platform. The genomic regions of both genes were amplified as 14 long-PCR amplicons (8 for *PKD1* and 6 for *PKD2*, 1.2 to 12.9 Kb long) for a total of 76 Kb of sequence (all coding exons and most introns). After amplicon equimolar assembly, different levels of pooling and multiplexing were tested. To test pooling, 2, 4, 6, and 8 samples were pooled in the same indexed library per individual flow cell lane; to test multiplexing, 2, 3, and 4 indexed libraries of 4 samples each were run per individual flow cell lane. The system was validated using 16 known controls carrying 283 *PKD1/2* sequence variants (range 5-30 per sample, 33-66 per flow cell lane), including single nucleotide changes and small indels. Paired-end, 51 bp-long reads were obtained that were mined using the package NextGENe, and filtered using as cut-off the lowest score of a known variant for each library. An average of twenty-six million effective reads were realigned for each lane, with an average of 14,000 reads for each of the known variants (range 397-72467). All the known variants were detected, with a sensitivity of 100%. A low level of false positives was detected, particularly when pooling 6 or 8 samples in the same indexed library (precision 90 and 76%). This experiment suggests that 4 samples may be pooled per indexed library, but that at least 12 such libraries may be run per lane (384 samples total). We are now using this approach to characterize a cohort of 249 uncharacterized and mutation-negative ADPKD samples.

**F-PO1809**

**Mutation Screening of HALT PKD Population** Jamie L. Sundsbak,[1] Christina M. Heyer,[1] Robert W. Schrier,[2] Arlene B. Chapman,[3] Vicente E. Torres,[1] Ronald D. Perrone,[4] Jared J. Grantham,[5] Theodore I. Steinman,[6] William E. Braun,[7] Kyong Tae Bae,[8] Kaleab Z. Abebe,[8] James E. Bost,[8] Peter C. Harris.[1] *[1]Mayo Clinic; [2]U Colorado; [3]Emory U; [4]Tufts U; [5]Kansas U; [6]Beth Israel Deaconess Med Ctr; [7]Cleveland Clinic; [8]U Pittsburgh Med Ctr.*

Genetic characterization of the HALT PKD population is required to help understand the role that RAAS and hypertension may play in disease progression. Once complete, it will be >4X larger than any previous genetic study of ADPKD (1018 patients) and hence the most complete view of the genetics of this disorder.

Using conventional sequencing of the exonic and flanking intronic region of *PKD1* and *PKD2*, we have identified mutations in 614 subjects from 551 families (84% *PKD1*, 16% *PKD2*). A total of 434 different mutations were identified (85% *PKD1*, 15% *PKD2*); 22% were recurrent within the study and comparison with the ADPKD Database showed that 60% were novel. Overall, 399 families had mutations predicted to truncate the protein (318 *PKD1*, 81 *PKD2*), while 152 (143 *PKD1*, 9 *PKD2*) were non-truncating. Mutations were classified as frameshifting insertions/deletions (33% *PKD1*, 29% *PKD2*), in-frame insertions/deletions (6% *PKD1*, 0% *PKD2*), missense (27% *PKD1*, 10% *PKD2*), nonsense (27% *PKD1*, 45% *PKD2*), or splicing (8% *PKD1*, 16% *PKD2*). Study A (18-50y, with a GFR > 60ml/min/1.73m$^2$) and Study B (18-60y with a GFR 25-60ml/min/1.73m$^2$) did not significantly differ in the level of *PKD1* and *PKD2* cases. eGFR was significantly greater ($p<0.001$) and total kidney volume smaller (62.5 ml/min/1.73m$^2$ $p<0.001$) in the *PKD2* group. In *PKD1*, truncating mutations were associated with a lower eGFR than non-truncating changes (69.5 ml/min/1.73m$^2$ $p<0.001$).

Some interesting cases noted included one with two *PKD1* nonsense mutations in cis and a family with a *PKD2* nonsense mutation and in-frame deletion (2 amino acids) in *PKD1*. No likely mutations were identified in 59 (8.7%) families that will now be screened for larger deletions/insertions. The characterization of the mutations in this clinically well defined population will greatly aid molecular diagnostics of ADPKD and other genetic studies of this disorder. [22]

**F-PO1810**

**The *Pkd1* Hypomorphic Allele, R3277C, Modifies the *Pkd1*$^{+/-}$ Phenotype to Early Onset Disease, Suggesting a Dose Dependent Pathogenesis of ADPKD** Katharina Hopp,[1] Christopher James Ward,[2] Sandro Rossetti,[2] Cynthia J. Hommerding,[2] Vicente E. Torres,[2] Peter C. Harris.[2] *[1]BMB, Mayo Clinic; [2]Nephrology Research, Mayo Clinic, Rochester, MN.*

ADPKD develops in patients with a single inactivating mutation to *PKD1* or *PKD2*. Recently, a role has been suggested for hypomorphic *PKD1* alleles that may result in very mild PKD in heterozygotes but modify the typical adult disease presentation to severe, *in utero* onset disease when found *in trans* with a truncating mutation. To prove the significance of hypomorphic alleles in ADPKD, we have made a knock-in mouse model carrying the *PKD1* R3277C mutation. After removal of the selection cassette, detailed analysis of *Pkd1*$^{R3277C/+}$ ES cells at the RNA level showed no abnormal splicing due to the mutation or

the residual loxP site. We crossed our outbred *Pkd1*$^{R3277C/+}$ model with a well established *Pkd1* null model, *Pkd1*$^{del2/+}$, to further characterize the pathological effects of the incomplete penetrant allele. In the first two litters although five compound heterozygotes (*Pkd1*$^{R3277C/del2}$) were born, only one pup survived past perinatal (P) day six. At P18 the surviving pup had a visibly enlarged abdomen and dissection showed grossly enlarged cystic kidneys with a 10-fold weight increase compared to WT, *Pkd1*$^{+/-}$ and *Pkd1*$^{R3277C/+}$ mice. This phenotype mimics precisely the *in utero* onset cases and shows the pathogenic but hypomorphic nature of the R3277C allele. Analysis is underway of the phenotype in homozygous R3277C animals. This model provides strong evidence for a dosage dependent disease mechanism in ADPKD where the level of functional polycystin-1 is the key determinant of whether cysts develop in the kidneys. It seems certain in this model, at least, that no second-hit mutation is required for cystogenesis.

### F-PO1811

**Mutations in *Pkhd1* Splice Enhancer Motifs Impact *Pkhd1* Alternative Splicing: A Potential Mechanism for ARPKD Pathogenesis** Ravindra Boddu,[1] Gregory G. Germino,[2] Luiz Fernando Onuchic,[3] Lisa M. Guay-Woodford.[1] *[1]Genetics, UAB, Birmingham, AL; [2]NIDDK, NIH, Bethesda, MD; [3]Medicine, Univ of Sao Paulo, Sao Paulo, SP, Brazil.*

*PKHD1*, the gene disrupted in ARPKD, and its mouse orthologue are transcriptionally complex. In previous studies, we catalogued exon usage in 22 unique *Pkhd1* transcripts from a kidney-specific plasmid library. Informatic analysis revealed: 1) several uniquely positioned exon splice enhancers (ESE), including a 3' SC35 motif in exon 6 and a 5' SRp40 motif in exons 49, 51 and 52; and 2) fewer intron splice enhancers (ISE) in IVS6 than in IVS48, IVS50 and IVS51. In the current study, we sought to validate the predicted alternative splice variants in mouse kidney, characterize the *Pkhd1* enhancer motifs, and evaluate human *PKHD1* missense variants that disrupt these motifs. **Methods/Results:** RT-PCR analysis of membrane-bound polysome fractions prepared from whole kidney lysates identified the expected exon 6-7 junction, as well as the predicted novel junctions 6-49, 6-51 and 6-52, indicating that these splice variants are likely to be translated. Rat monoclonal antibodies were generated against a peptide encoded by exons 3/4/5/6. In initial characterization, these immunoreagents each recognize a unique pattern of peptides in IMCD cell lysates. Minigene assays confirmed canonical splicing between exons 6-7, as well as alternative splicing between exons 6-49, 6-51 and 6-52. In assays where site directed mutagenesis disrupted the target ESE and ISE motifs, alternative splicing was abolished. Finally, we evaluated 311 *PKHD1* missense variants (ARPKD Mutation Database; www.humgen.rwth-aachen.de) and identified two variants of indeterminant pathogenicity that disrupt SRp40 and SC35 motifs: R760H and P805L. We are currently examining these missense variants using minigene assays. **Conclusions:** Our data: 1) add to the cumulative evidence that *Pkhd1* is transcriptionally complex; and 2) demonstrate that *Pkhd1* ESE and ISE motifs direct alternative exon usage. We are evaluating the impact of naturally-occurring human *PKHD1* missense variants on alternative splicing. We propose that altered *PKHD1* splicing may contribute to ARPKD pathogenesis.

### F-PO1812

**Proteomic Signature Profiles in Autosomal Dominant Polycystic Kidney Disease** Nikolay Bukanov,[1] Sarah E. Moreno,[1] Xuewen Song,[2] Steven R. Ledbetter,[1] Oxana Beskrovnaya,[1] York P. Pei.[2] *[1]Department of Cell Biology, Genzyme Corporation, Framingham, MA; [2]University Health Network, Toronto, ON, Canada.*

As the number of clinical trials for ADPKD increases, there is a need to monitor renal disease progression in response to therapy. Magnetic resonance imaging (MRI) is an adequate method to track the progression of ADPKD. However, MRI evaluations are expensive and require specialized facilities for analysis. Our goal was to establish a set of anonymous biomarkers that are robust, reproducible, and correlate with progression of ADPKD. As a source of biomarkers, we used urine and plasma samples which can be conveniently collected by non-invasive methods.

We applied a three-step approach to achieve our goal. First, we used SELDI-TOP technology for proteome profiling of urine and plasma samples from ADPKD patients with known MRI kidney values. Second, we performed comparative analysis of spectra from ADPKD samples and normal controls to identify anonymous biomarker signatures specific to diseased individuals. Finally, we performed statistical analysis to identify a subset of anonymous markers which are in correlation with disease progression.

In total, we generated a set of 18 plasma and 6 urinary biomarkers with good correlation ($R^2$>0.5) to the progression of ADPKD. Several markers from this panel are characterized by >8-10-fold difference in expression levels between ADPKD and normal samples. This data is in the same range as MRI measurements, which indicate an 8-fold difference in total kidney volume in patients representing earlier and late stages of ADPKD. Replication of these results in an independent cohort of patients is in progress. In conclusion, the availability of such disease progression biomarkers should improve the ability to monitor efficacy of experimental therapies for ADPKD.

### F-PO1813

**Comparison of the PKD-ELV Proteome in Normal and ADPKD Individuals** Marie C. Hogan,[1] Cristine Charlesworth,[2] Kenneth L. Johnson,[2] Linda Page,[1] Peter C. Harris,[1] H. Robert Bergen,[2] Christopher James Ward.[1] *[1]Div. Nephrology & Hypertension, Mayo Clinic; [2]Mayo Proteomics Research Center, Mayo Clinic, MN.*

Exosome-Like Vesicles (ELVs), are 50-200nm diameter membrane bound structures found in all biological fluids, including urine and bile. We showed that there are multiple subpopulations in urine, one of which is enriched in polycystin-1 (PC1), polycystin-2 (PC2) and fibrocystin/polyductin -the PKD-ELV. A 5-30% sucrose heavy water ($D_2O$) gradient method allowed the reproducible isolation of of PKD-ELVs. First or 2nd morning urines from 7 normal individuals (Age=28 sd+/-3.3 years) and 9 individuals with ADPKD (Age=27.7 sd+/-6.2 years) were collected, PKD-ELVs isolated and analyzed by label-free proteomics. Four of the ADPKD individuals are known to have PKD1 mutations; we are presently genotyping the remainder. Our initial results show that there are 27 proteins that are differentially regulated between normals and PKD ELVs with p values ranging from 0.0007 to 0.01. Twenty-three out of 27 are underexpressed in ADPKD vs controls, with -1.98 to -6.28 fold differences in mean relative abundance. Four proteins are overexpressed in PKD1 ranging from 2.54 to 16.56 fold. The PKD proteins are consistently under expressed in ADPKD individuals vs controls: PC1 protein 2.2 fold (p=0.0007), PC2 2.2 fold (p=0.008) and fibrocystin 1.98 fold (p=0.004). We have developed a ratiometric western blot assay using a Mab to PC1 (7e12) and a commercially available Mab to a protein which is upregulated in ADPKD. Initial results indicate that the assay can distinguish normal from ADPKD individuals in unpurified urine exosome preparations.

**Urinary Monocyte Chemotactic Protein-1 (MCP1) Predicts Progression in Autosomal Dominant Polycystic Kidney Disease (ADPKD)** Jared J. Grantham,[1] Vicente E. Torres,[2] Arlene B. Chapman,[3] Kyong Tae Bae,[7] Cheng Tao,[7] Lisa M. Guay-Woodford,[4] Peter C. Harris,[2] Michal Mrug,[4] William M. Bennett,[5] Marva M. Moxey-Mims,[6] James E. Bost.[7] *[1]Kansas U; [2]Mayo; [3]Emory; [4]UAB; [5]Legacy Good Samaritan; [6]NIDDK; [7]UPitt.*

The progression to ESRD begins in ADPKD long before changes in GFR are clearly recognizable, complicating prognosis counseling and impeding the implementation of novel treatments targeted to specific molecular pathogenetic mechanisms. Inflammation and fibrosis begin relatively early and have been associated with renal chemokines and cytokines. In ADPKD patients with normal GFR and varying degrees of renal insufficiency, MCP1 was excreted in the urine to a greater extent in those with advanced disease than in those with normal GFR (Zheng, D. et al Kid Int 14:2588, 2003). MCP1 is produced by cyst epithelial cells, moves into the urine and accumulates to high levels within cysts. The Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease (CRISP) has followed 241 subjects (15-46 y.o. and eGFR at entry >70 ml/min) between Jan 5, 2001 and December 1, 2009 in a prospective study including measurements of total kidney volume relative to height (htTKV) by MR and GFR by iothalamate clearance. Urine MCP1 (pg/mg creatinine) was measured at baseline to determine the extent to which the chemokine predicted progression of htTKV increase and GFR decrease over the next 7.3 years. Baseline urine MCP1 in women and men was 687±641 pg/mg, n=138 and 465±403 pg/mg, n=89, respectively (P=0.0016) and GFR was 99±26 and 96±22 ml/min/1.73 $m^2$, respectively (P=0.2792). Urine MCP1 (pg/mg) was greater in PKD1 (655±610, n=175) than in PKD2 (365±283, n=34) (P<0.001). Baseline urine MCP1 correlated positively with baseline htTKV (R=0.436, P<0.0001, n=227) and inversely with baseline GFR (R=-0.184, P=0.0059, n=222). In a multivariable model including baseline htTKV, age, BMI, gender, race, htTKV slope, and GFR, baseline urine MCP1 associated significantly with declining GFR (OR 1.13, P=0.000) and K/DOQI Stage 1-4 (OR 1.11, P<0.001). On the basis of these findings we conclude that urinary MCP1 predicts disease progression in patients with ADPKD.

### F-PO1815

**Vascular Endothelial Growth Factor Level Correlates with Disease Severity in Young Patients with Autosomal Dominant Polycystic Kidney Disease** Berenice Y. Gitomer, Melissa A. Cadnapaphornchai, Wei Wang, Amirali Masoumi, Kim Mcfann, Xiang-Dong Yan, Robert W. Schrier. *Department of Medicine, University of Colorado Denver, Aurora, CO.*

Renal cysts are often evident on ultrasound imaging in children with autosomal dominant polycystic kidney disease (ADPKD), who may become symptomatic in young adulthood. However, we have previously shown that hypertensive (95th percentile for blood pressure) and borderline hypertensive (75th -95th percentile for blood pressure) ADPKD children have a significantly higher left ventricular mass index (LVMI) than children with ADPKD and normal blood pressure. Moreover, hypertensive children with ADPKD have larger renal volumes than children with lower blood pressure. Therefore it is apparent that vascular changes including expansion and remodeling must occur in order to support the renal and cardiac structural changes in ADPKD patients As vascular endothelial growth factor (VEGF) is a potent regulator of angiogenesis and has been demonstrated in cyst fluid from human ADPKD kidney, we hypothesized that up-regulated expression of VEGF might be related to disease severity. Thus, serum levels of VEGF were measured in 71

young ADPKD patients (mean age 16 ± 4 years) and correlated with renal and cardiac structure (measured by magnetic resonance imaging) and renal function. Because of the skewed distribution, renal and cyst volume, left ventricular mass index and serum VEGF were reported as $\log_{10}$. Serum $\log_{10}$ VEGF was positively correlated with total renal ($P = 0.007$) and cyst volumes ($P = 0.003$) and LVMI ($P < 0.0001$) and negatively correlated with creatinine clearance ($P = 0.022$). In conclusion, the correlation between serum VEGF and both renal and cardiac disease severity reflects a possible role for angiogenesis in early progression of renal and cardiovascular disease in ADPKD.

## F-PO1816

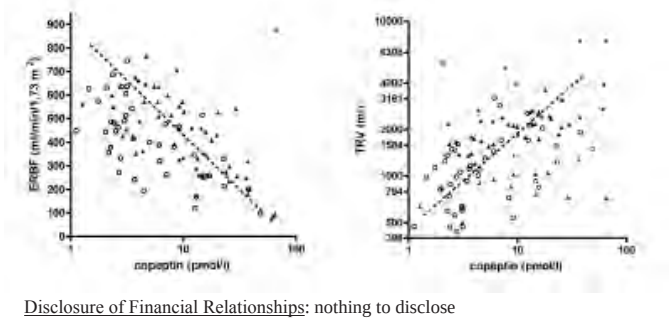
**Copeptin, a Surrogate Marker of Vasopressin, Is Associated with Disease Severity in Autosomal Dominant Polycystic Kidney Disease** Esther Meijer,[1] Stephan J. L. Bakker,[1] Gerjan Navis,[1] Joachim Struck,[2] Paul E. de Jong,[1] Ron T. Gansevoort.[1] *[1]UMCG, Netherlands; [2]BRAHMS, Germany.*

Experimental studies suggest a detrimental role for vasopressin (VP) in the pathogenesis of Autosomal Dominant Polycystic Kidney Disease (ADPKD). It is, however, unknown whether endogenous VP concentration is associated with disease severity in patients with ADPKD.

Because measurement of VP is problematic, we measured plasma copeptin concentration (a marker of endogenous VP levels) in 102 ADPKD patients (Ravine criteria) by immunoassay. Plasma- and urinary osmolarity were also measured. To assess disease severity, we measured glomerular filtration rate (GFR) and effective renal blood flow (ERBF) by continuous infusion of $^{125}$I-Iothalamate and $^{131}$I-Hippuran, resp., total renal volume (TRV) by MRI and 24h urinary albumin excretion (UAE) by nephelometry.

In these ADPKD patients (age 40±11y, 56% male, GFR 77±31 mL/min per 1.73 m$^2$, TRV 1.5 (0.9-2.2)L), median copeptin concentration was 7 (3-15) pmol/L. Copeptin was associated with plasma osmolarity ($R=0.53$, $p<0.001$), but not with 24h urinary volume, 24h urinary osmolarity or fractional urea excretion ($p=0.7$, $p=0.9$, $p=0.3$, resp.). Copeptin was associated with the various markers of disease severity in ADPKD (with TRV $R=0.45$, UAE $R=0.39$, GFR $R=-0.58$ and ERBF, $R=-0.52$ all $p<0.001$, figure). These associations were independent of age, gender and use of diuretics.

In conclusion, plasma osmolarity is associated with copeptin levels in ADPKD, but copeptin is not associated with its normal physiologic effects (24h urinary volume, -osmolarity and fractional urea excretion). Most importantly, in this cross-sectional analysis, copeptin levels are associated with severity of ADPKD. Together with prior experimental studies showing renoprotective properties of VP antagonism in ADPKD, these data support a possible pathogenetic role for VP in ADPKD.



Disclosure of Financial Relationships: nothing to disclose

## F-PO1817

**Copeptin, a Surrogate Marker for Vasopressin, Is Associated with Renal Function Decline in Patients with ADPKD** Wendy E. Boertien,[1] Esther Meijer,[1] Ton J. Rabelink,[2] Joachim Struck,[3] Stephan J. L. Bakker,[1] Dorien J. M. Peters,[2] Paul E. de Jong,[1] Ron T. Gansevoort.[1] *[1]Nephrology, Groningen, Netherlands; [2]Nephrology, Leiden, Netherlands; [3]BRAHMS, Germany.*

Experimental studies suggest a detrimental role for vasopressin in Autosomal Dominant Polycystic Kidney Disease (ADPKD). It is, however, unknown whether endogenous vasopressin concentration is associated with renal function decline in patients with ADPKD.

We measured plasma copeptin (a marker of endogenous vasopressin) by immunoassay in 79 ADPKD patients who participated in a study on renal disease progression during 1994-1999 (1). During this study, GFR was assessed by inulin clearance. Plasma creatinine was measured to determine eGFR (MDRD). After completion of the study, patients were followed and the last available plasma creatinine value was obtained. If applicable, start date of renal replacement therapy (RRT) was reported.

In these patients (57% female, age 36.8 ±10.1 y, GFR 106.6 ±25.9 mL/min) median copeptin level was 2.7 (IQR 1.6 – 5.5) pmol/L. Copeptin was associated with change in GFR (inulin) during the study (median follow-up 3.3 (3.1 - 3.5) y, $R=-0.3$, $p<0.01$) and with change in eGFR (MDRD) during follow-up (median 11.4 (4.5 - 14.3) y, $R=-0.3$, $p<0.01$). On average, patients with a copeptin level of 10 pmol/L had a fall in eGFR of 4.4 ml/min/1.73m$^2$/yr compared to no loss of eGFR in patients with a copeptin level of 1 pmol/L. These associations were independent of age, gender and baseline (e)GFR. Nine patients started with RRT during follow-up. A twofold higher copeptin was associated with a hazard ratio for start of RRT of 2.0 (95%CI 1.2-3.4, $p=0.01$).

These data show that in ADPKD patients a higher vasopressin concentration is associated with renal function decline, suggesting that in these patients blockade of the vasopressin receptor may have a renoprotective effect.

## F-PO1818

**Renal Blood Flow (RBF) Is an Underestimated Tool To Monitor the Progression of Autosomal Dominant Polycystic Kidney Disease (ADPKD)** Vicente E. Torres,[1] Arlene B. Chapman,[2] Bernard F. King,[1] Diego R. Martin,[2] Jared J. Grantham,[3] Michal Mrug,[4] Kyong Tae Bae,[5] William M. Bennett,[6] Marva M. Moxey-Mims,[7] Li Jie,[5] James E. Bost,[5] CRISP Consortium.[1-7] *[1]Mayo, Rochester, MN; [2]Emory U, Atlanta, GA; [3]Kansas U, Kansas City, KS; [4]U of Alabama, Birmingham, AL; [5]U of Pittsburgh, Pittsburgh, PA; [6]Legacy Good Samaritan, Portland, OR; [7]NIDDK, Bethesda, MD.*

Polycystic kidneys exhibit media thickening, increased wall-to-lumen ratio, vascular rarefaction and global glomerulosclerosis suggesting ischemia, possibly due to cyst compression, *PKD1* or *PKD2* mutation linked vascular abnormalities, or both. Ischemic damage has been proposed as the final common pathway to ESRD in CKD. Implementation/evaluation of treatments aimed at protecting RBF and preventing hypoxia is hampered by lack of non-invasive methods to monitor RBF in diseased kidneys. Technological innovations allow high-resolution breath-held RBF imaging with improved signal-to-noise ratio and cardiac cycle synchronization. Strict image acquisition and analysis standardization are essential. CRISP seeks to determine whether RBF reduction predicts ADPKD progression. RBF decreased more rapidly than GFR: % changes (*$p<0.05$) from baseline were -4.0*, -10.9*, -8.5*, -33.9*, and -32.6* vs +0.5, +2.0, -3.4*, -18.1*, and -22.0%* at 1 (n 118), 2 (n 106), 3 (107), 6 (n 99) and 8 (n 38) years, respectively. RBF significantly added to the predictive value of total kidney volume (TKV) on rate of GFR decline when controlling for baseline GFR (Table). Higher TKV and lower RBF correlated with GFR decline; higher GFR at baseline associated with steeper GFR slopes during BL-YR3 due to regression to the mean.

| Covariates | GFR slope ($R^2$) | |
|---|---|---|
| | BL-YR3 | BL-YR8 |
| lnTKV0 | 0.15* | 0.22* |
| GFR0 | 0.07* | 0.03 |
| Mean RBF | 0.06* | 0.08* |
| lnTKV0, GFR0 | 0.33* | 0.34* |
| lnTKV, Mean RBF | 0.16* | 0.23* |
| lnTKV, GFR0, Mean RBF | 0.45* | 0.43* |

*significant predictor in the model

Reduction in RBF precedes GFR decline. RBF adds to the predictive value of TKV on rate of GFR decline. Properly standardized measurement of RBF is an underestimated tool to monitor ADPKD and CKD progression.

## F-PO1819

**Diagnostic Accuracy of Positron-Emission Computed Tomography in the Diagnosis of Kidney and Liver Cyst Infection in Patients with Autosomal Dominant Polycystic Kidney Disease** Francois Jouret,[1] Renaud Lhommel,[2] Claire Beguin,[3] Olivier Devuyst,[1] Yves A. Pirson,[1] Ziad Hassoun,[4] Nada Kanaan.[1] *[1]Nephrology, Université Catholique de Louvain, Brussels, Belgium; [2]Nuclear Medicine, Université Catholique de Louvain, Brussels, Belgium; [3]Medical Informatics and Statistics, Université Catholique de Louvain, Brussels, Belgium; [4]Gastro-enterology, Université Catholique de Louvain, Brussels, Belgium.*

Cyst infection (CI) remains a challenging issue in patients with autosomal dominant polycystic kidney disease (ADPKD). In most cases, conventional imaging techniques remain inconclusive. Recent observations have suggested that $^{18}$fluorodeoxyglucose ($^{18}$FDG) positron-emission computed tomography (PET-CT) might help detect kidney and liver CI in ADPKD patients. Here, the systematic assessment of databases from 01/2005 to 12/2009 identified 27 PET-CT performed in 24 patients for suspicion of CI. These episodes were further categorized upon the following 4 criteria: temperature >38°C for >3 days, loin or liver tenderness, C-reactive protein plasma level >5 mg/dl, and microbiological documentation. Thirteen infectious events in 11 patients met all criteria for kidney (n=3) or liver (n=10) CI (group A), whereas 14 episodes in 13 patients only encountered 2 to 3 of them (group B). In group A, PET-CT proved CI in 11 cases (84.6%), while CT was contributive in one case. Still, PET-CT overlooked one liver CI in a 74-year-old renal transplant recipient (RTR) and one kidney CI in a 62-year-old patient with stage IV chronic kidney disease. In group B, PET-CT identified the source of abdominal infection in 9 cases (64.3%). Among these, two kidney CI were found in an 81-year-old patient under chronic haemodialysis and a 58-year-old RTR. Conversely, PET-CT showed no abnormal $^{18}$FDG uptake in 5 cases, including 2 renal intracystic bleedings. The median delay between the onset of symptoms and PET-CT procedure was 9 days. The sensitivity and specificity of PET-CT imaging in CI diagnosis reach 86.7% and 100%, respectively. In conclusion, PET-CT nowadays represents the optimal tool to (i) confirm and locate cyst infection, and (ii) identify alternative sources of abdominal infection in ADPKD patients.

**A Unique Urine Proteomic Pattern in Autosomal Dominant Polycystic Kidney Disease** Andreas D. Kistler,[1] Harald Mischak,[2] Justyna Siwy,[2] Arlene B. Chapman,[3] James E. Bost,[4] Rudolf P. Wuthrich,[1] Andreas L. Serra.[1] *[1]Division of Nephrology, University Hospital, Zurich, Switzerland; [2]Mosaiques Diagnostics and Therapeutics AG, Hannover, Germany; [3]Renal Division, Emory University School of Medicine, Atlanta; [4]Department of Medicine, University of Pittsburgh.*

Using capillary electrophoresis coupled to mass spectrometry (CE-MS), we have previously found a unique urinary polypeptide profile characteristic for autosomal dominant polycystic kidney disease (ADPKD). Here, we validated these findings from a Swiss cohort in a large North American ADPKD cohort and tested whether urinary biomarkers correlate with total kidney volume (TKV) progression of polycystic kidneys. Spot urine samples of 48 patients from the control arm of the SUISSE ADPKD study, 124 patients from the CRISP cohort (all PKD1) and 86 healthy controls were analyzed. All ADPKD patients were followed with serial magnetic resonance imaging (MRI) based TKV every 6 (SUISSE) or 12 (CRISP) months for 18-36 months. Our previously published diagnostic biomarker model for ADPKD performed well in the CRISP cohort (sensitivity 91.9%, specificity 90.7%, AUC 0.964). A refined diagnostic model based on proteomic data of all 48 analyzed samples from the SUISSE ADPKD study achieved an even higher performance upon validation in the CRISP cohort (sens. 93.5%, spec. 94.2%, AUC 0.974). Using LC-MS/MS we were able to identify 30% of these diagnostic biomarkers. Most of them represent collagen fragments mirroring drastic changes of extracellular matrix turnover in ADPKD. We then used 110 patients from both studies as a training and 62 CRISP patients as a validation cohort to identify prognostic biomarkers. Although a few markers showed significant correlation with annual TKV progression after adjustment for multiple testing, the correlation was weak and not sufficient to yet establish a clinically useful prognostic biomarker model. In conclusion, we have now validated and refined our previously established diagnostic urinary biomarker model for ADPKD in an independent cohort. We continue to evaluate potential prognostic biomarkers, utilizing additional follow up time and other markers of disease severity.

**F-PO1821**

**HALT-PKD Clinical Trials, Analysis of Baseline Parameters** Vicente E. Torres,[1] Robert W. Schrier,[2] Arlene B. Chapman,[3] Ronald D. Perrone,[4] Kyong Tae Bae,[5] Marva M. Moxey-Mims,[6] Theodore I. Steinman,[7] William E. Braun,[8] Franz Winklhofer,[9] Kaleab Z. Abebe,[5] James E. Bost,[5] HALT PKD Study Group.[1-9] *[1]Mayo Clinic; [2]U Colorado; [3]Emory U; [4]Tufts; [5]Pittsburgh U; [6]NIH/NIDDK; [7]Beth Israel; [8]Cleveland Clinic; [9]Kansas U.*

HALT-PKD comprises two randomized trials: A (n=548, eGFR >60 ml/min/1.73 m², 2-by-2 design randomization to ACEi/ARB *vs* ACEi alone and to low *vs* standard BP targets) and B (n=470, eGFR 25-60 ml/min/1.73 m², randomized to ACEi/ARB *vs* ACEi alone). Primary outcomes are % change in kidney volume (TKV) by MR in A and time to 50% eGFR reduction, ESRD, or death in B. All A patients underwent MR measurements of TKV and liver volume (TLV); 268 had MR measurements of renal blood flow (RBF). We sought to identify associations of baseline factors with TKV and TLV in A and with eGFR in both studies. TKV adjusted for height (htTKV) were larger in men (779±415 *vs* 611±368 mL, p<0.0001), whereas liver cyst volumes were greater in women (148±706 vs 343±801 mL, p=0.006). There was no significant correlation between htTKV and htTLV. HtTKV significantly correlated with eGFR (r=-0.31), BSA (0.24), urine albumin excretion (UAlbE, 0.21), RBF (-0.17), systolic BP (0.14), urine sodium excretion (0.11) and age (0.09). Multiple regression showed independent associations of eGFR, BSA, UAlbE and gender with htTKV. eGFR were similar in men and women. eGFR significantly correlated with age (-0.63), RBF (0.44), htTKV (-0.31), serum potassium (-0.22), UAlbE (-0.18), urine aldosterone (0.17), urine sodium/potassium ratio (0.15), office systolic BP (-0.09), weight (-0.09), urine volume (-0.08) and urine potassium excretion (-0.08). Age, htTKV and RBF independently associated (all p<0.001) with eGFR in A. In A and B without htTKV and RBF covariates, age, serum potassium, UAlbE, urine aldosterone and weight independently associated with eGFR.

*Conclusion*: The factors that modulate the severity of PKD are different from those modulating severity of PLD; male gender, large body size, reduced eGFR and increased UAlbE are associated with larger htTKV; older age, larger htTKV, and reduced RBF are independently associated with reduced eGFR in ADPKD.

**F-PO1822**

**TEMPO 2/4 Update: Changes in ADPKD Total Kidney Volume and eGFR with 3 Years of Tolvaptan and after Withdrawal** Vicente E. Torres,[1] Arlene B. Chapman,[2] Jared J. Grantham,[3] Terry J. Watnick,[4] John Ouyang,[5] Holly B. Krasa,[5] Frank S. Czerwiec,[5] TEMPO 2/4.[1-5] *[1]Mayo Clinic; [2]Emory U; [3]U of Kansas; [4]The Johns Hopkins Univ School of Med; [5]Otsuka Pharma Devel & Comm, Inc.*

TEMPO 2/4 is an open-label, randomized, dose-ranging study monitoring long-term effects of tolvaptan on patient safety, tolerability and efficacy (renal volume and function). After baseline evaluation; 46 subjects entered a 1-month dose ranging titration phase. They were then randomized 1:1 to open-label, split-dose tolvaptan regimens for 3 years. Tolerability, safety and clinical labs were evaluated every 4 months; renal MRI annually. After dose ranging, 46 subjects were randomized to low (L=45/15mg, N=22) or high (H=60/30mg, N=24) daily dose regimens for 3 years. In the L and H, mean ages were 39 and 43, and 1/3 in each group were male. Hypertension was seen in 82 and 71%, respectively, and ~80% in each group used ACEi/ARB agents. Baseline mean total kidney volume (TKV) and eGFR (MDRD) were 1.57 and 1.67 L and 63 and 57 mL/min/1.73m² for the 46 L and H subjects, respectively. Follow-up data for 35 subjects (L=17, H=18) at 3-7 months after withdrawal are available. Seven subjects discontinued: loss to follow-up (1 each), adverse event (2 and 1, respectively), met withdrawal criteria (1 in H), subject withdrew consent (1 in L). Six subjects down-titrated from H to L. Four subjects did not have withdrawal data.

ADPKD Outcomes in 35 Subjects

| Visit/Treatment | TKV-L | TKV-H | TKV-All | eGFR-L | eGFR-H | eGFR-All |
|---|---|---|---|---|---|---|
| Baseline/Off | 1.48 | 1.54 | 1.51 | 64 | 56 | 60 |
| 2 mo/On | 1.49 (-1.0%) | 1.52 (-1.4%) | 1.51 (-1.2%) | 61 (-3.1) | 56 (-0.3) | 58 (-1.7) |
| 3 yr/On | 1.61 (7.9%) | 1.63 (3.8%) | 1.62 (5.8%) | 60 (-3.7) | 53 (-2.7) | 57 (-3.2) |
| 4 mo/Off | 1.72 (14.1%) | 1.70 (8.4%) | 1.71 (11.2%) | 59 (-4.7) | 55 (-1.2) | 57 (-2.9) |

Mean and change from baseline TKV (L), eGFR (mL/min/1.73M²)

The data suggest that tolvaptan slows ADPKD patients' cyst growth. On withdrawal, TKV growth resumes at expected rates, but overall eGFR appears stable. Other analyses suggest earlier treatment may confer a larger benefit.

**Somatostatin Analog Therapy for Severe Polycystic Liver Disease: Results after Two Years** Marie C. Hogan,[1] Tetyana V. Masyuk,[2] Linda Page,[1] David R. Holmes,[3] Xujian Li,[4] Eric J. Bergstralh,[4] Sandro Rossetti,[1] Bohyun Kim,[5] James Glockner,[5] Peter C. Harris,[1] Nicholas Larusso,[2] Vicente E. Torres.[1] *[1]Nephrology Division; [2]GI Research; [3]Biomedial Imaging Core; [4]Biostatistics; [5]Radiology, Mayo Clinic, Rochester, MN.*

In our randomized, double-blind, placebo-controlled trial, Octreotide LAR® reduced kidney and liver growth in patients with severe PLD through 12 months. To substantiate long-term safety & clinical benefits of OctLAR patients we completed an open-label extension through year 2. **Methods:** Primary endpoint was % change in liver volume (TLV) from baseline to Yr 2 (MRI); 2° endpoints were changes in total kidney volume (TKV), GFR, quality of life, safety, vital signs, and laboratory tests. 40 patients (26 OctLAR; 14 placebo) received OctLAR during Yr2 (max dose 40 mg). Patients already on OctLAR continued therapy. **Results:** There was a significant reduction in TLV during the first year of OctLAR therapy in both groups. Patients originally randomized to placebo showed substantial reduction in TLV during treatment with OctLAR in Yr 2 (Δ% -7.66 ± 9.69%; p= 0.011). The reduction in TLV in the OctLAR treated group was maintained, but did not increase significantly, during Yr2 (Δ% -5.96 ±8.90%; p =0.002). OctLAR inhibited renal enlargment during Yr1 but not significantly during Yr2. OctLAR treated individuals experienced improvements in QOL. Changes in GFR were similar in both groups. **Conclusions:** Over a two year period OctLAR significantly reduced the rate of TLV & possibly TKV increase. OctLAR improved health perception and had an acceptable side effect profile in patients with PLD.

**F-PO1824**

**Short-Term Effects of Tolvaptan on Renal Function and Volume in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD)** Maria V. Irazabal-Mira,[1] Vicente E. Torres,[1] Marie C. Hogan,[1] James Glockner,[1] Bernard F. King,[1] Troy G. Ofstie,[1] Holly B. Krasa,[2] John Ouyang,[2] Frank S. Czerwiec.[2] *[1]Mayo, Rochester, MN; [2]Otsuka Pharm. Devel. & Comm., Inc.*

The AVP V2 receptor antagonist tolvaptan slightly and reversibly elevates serum creatinine in clinical subjects with ADPKD. We studied the mechanisms of this effect after daily, split-dose tolvaptan (45/15 mg) for one week in 20 ADPKD patients, 12 with estimated creatinine clearance (eCrCl) >60 ml/min (Group 1) and 8 with eCrCl 30-60 ml/min (Group 2). On Days 0 and 8, subjects underwent iothalamate and para-amino-hippurate (PAH) clearances and renal blood flow (RBF) measurements by MRI. Tolvaptan-induced aquaresis was accompanied by 8.6% GFR (p=0.018) reduction, 13.0% increase in serum uric acid (p=0.002), 26.8% reduction in uric acid clearance (p<0.001), and 4.8% reduction in serum potassium (p<0.001), without change in RBF measured by PAH clearance (-5.9%, NS) or MRI (+1.0%, NS). Underlying mechanisms may include attenuation of urine concentrating activity and tubuloglomerular feedback (V2 receptor blockade); decreased glomerular ultrafiltration (reflex V1 receptor activation); proximal sodium-linked uric acid reabsorption (compensating distal sodium loss); distal potassium loss (increased distal sodium/water delivery). Post-hoc, blinded analysis of renal MRIs showed that tolvaptan

induced a 3.1% reduction (p<0.001) in total kidney volume (TKV), more marked in group 1 (-4.1%, p<0.001) than in group 2 (-1.7%, NS), and in volume of individual cysts ≥10 mL (-4.1%, n= 79, p<0.001) without a significant change in those <10 mL (n=59). Total body water (TBW) decreased by 1.1% (p=0.001). No significant correlation was detected between the change in TKV and TBW. These results are consistent with effects of tolvaptan on glomerular hemodynamics, explaining the increase in serum creatinine, and on fluid secretion into the cysts, explaining the rapid reduction in kidney and cyst volume.

**An Open-Label Long-Term Administration Study of Tolvaptan in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD) in Japan: Three-Year Results** Eiji Higashihara,[1] Kikuo Nutahara,[1] Shigeo Horie,[2] Fumitake Gejyo,[3] Akira Hishida.[4] *[1]Urology, Kyorin University, Tokyo, Japan; [2]Urology, Teikyo University, Tokyo, Japan; [3]Nephrology, Niigata University, Niigata, Japan; [4]Nephrology, Hamamatsu University, Hamamatsu, Japan.*

**Background:** Tolvaptan was shown to inhibit cyst enlargement in animal models orthologous to human ADPKD. At last year's ASN annual meeting we reported the second-year results of a 3-year administration study of tolvaptan. Here we report on the safety and efficacy of tolvaptan at completion of the third year of the study.

**Methods:** Of 18 patients with ADPKD who participated in a phase 2 study of tolvaptan conducted from December 2004 to May 2005, 17 consented to participate in a 3-year extension study, and tolvaptan was administered at 15 mg twice a day beginning from April 2006.

**Results:** Of the 17 patients enrolled in the study, there were 5 discontinuations: one patient died due to intracranial hemorrhage, 2 withdrew due to renal impairment, and 2 withdrew for non-medical reasons. Baseline values and changes from baseline for serum sodium, serum creatinine, creatinine clearance (estimated by Cockcroft-Gault equation), and renal volume (measured by MRI) are shown below.

Table

| | Baseline | Change from Baseline | | |
|---|---|---|---|---|
| | (n=17) | 48W (n=14) | 96W (n=13) | 156W (n=12) |
| Serum sodium (mEq/L) | 141.2±1.4 | 1.1±1.5 | 1.4±2.1 | 1.3±2.3 |
| Serum creatinine (mg/dL) | 0.966±0.311 | 0.048±0.111 | 0.022±0.083 | 0.094±0.183 |
| Creatinine clearance (mL/min) | 85.7±29.5 | -3.1±8.8 | -0.6±7.7 | -5.0±8.4 |
| | Baseline (n=17) | 52W (n=14) | 104W (n=12) | 156W (n=12) |
| Renal volume (mL) | 1831±1095 | -58±149 | -84±174 | -69±219 |

Common adverse events included nasopharyngitis, thirst, contusion, blood ADH increased, and hypertension, but none of these events were serious enough to discontinue administration.

**Conclusions:** In a 3-year phase 2 extension study in patients with ADPKD, tolvaptan was well tolerated and demonstrated beneficial effects on renal enlargement (ClinicalTrials.gov identifier: NCT00841568; off-label: Tolvaptan for ADPKD).

## F-PO1826

**Vitamin D Deficiency and Renal Volume in Autosomal Dominant Polycystic Kidney Disease** Berenice Y. Gitomer, Melissa A. Cadnapaphornchai, Amirali Masoumi, Michel B. Chonchol, Kim Mcfann, Wei Wang, Xiang-Dong Yan, Robert W. Schrier. *Department of Medicine, University of Colorado Denver, Aurora, CO.*

**Purpose:** Increased renal volume in autosomal dominant polycystic kidney disease (ADPKD) correlates with early onset and persistent hypertension and ultimately left ventricular hypertrophy and decline in kidney function. Activation of the renin-angiotensin-aldosterone system plays a central role in the hypertension in ADPKD patients and active vitamin D is a well-established potent regulator of renal renin. However, despite emerging evidence on the role of vitamin D deficiency in cardiovascular disease and renal disease progression no studies have addressed the role of vitamin D on renal disease progression in an ADPKD patient population. We hypothesized that lower serum levels of 25(OH)D in ADPKD would be associated with more severe renal disease as assessed by renal volume measured by magnetic resonance imaging (MRI).

**Methods:** Study subjects comprised 30 young adult ADPKD patients (15 men and 15 women) aged 18-24 years. Renal volumes were measured by MRI and serum 25(OH)D levels measured by ELISA assay.

**Results:** Patients mean (SD) age and creatinine clearance were 20.3 (1.6) years and 112 (28) ml/min/1.73m$^2$ respectively. For this analysis the patient population was categorized on the basis of a clinically significant cutoff for 25(OH)D deficiency (less than 30 ng/ml vs. higher). Thus, 14 ADPKD patients whose serum 25(OH)D level was >30 ng/ml were compared with 16 deficient patients with serum 25(OH)D ≤30 ng/ml. The vitamin D deficient subjects had higher total renal volume than those who were 25(OH)D sufficient after adjustment for sex, height, hypertension and season [1044 (765-1427)cm$^3$ vs. 680 (524-882)cm$^3$, p = 0.03] (Reported as geometric mean and 95% CI).

**Conclusion:** These results indicate that vitamin D deficiency is associated with larger kidneys in this ADPKD population with normal renal function. Further studies are needed to determine if correction of vitamin D deficiency significantly impacts renal volume in ADPKD.

## F-PO1827

**Left Ventricular Hypertrophy in the HALT PKD Study** Ronald D. Perrone,[1] Robert W. Schrier,[2] Arlene B. Chapman,[3] Vicente E. Torres,[4] Theodore I. Steinman,[5] James E. Bost,[6] Kaleab Z. Abebe,[6] William E. Braun,[7] Jared J. Grantham,[8] Diana Kaya,[6] Marva M. Moxey-Mims,[9] Kyong Tae Bae.[6] *[1]Tufts; [2]U Colorado; [3]Emory U; [4]Mayo Clinic; [5]BIDMC; [6]U Pittsburgh; [7]Cleveland Clinic; [8]Kansas U; [9]NIH/NIDDK.*

Left ventricular hypertrophy (LVH) is found in ADPKD children and associates with hypertension (HTN). Prior echocardiographic studies in ADPKD revealed a 41% prevalence of LVH by age 41. The present study focuses on 543 HALT PKD Study A subjects aged 15-49 with eGFR >60mL/min/1.73m$^2$ who underwent baseline magnetic resonance (MR) measurement of total kidney volume and left ventricular mass (LVM). LVM was measured using a semi-automated program from ECG-gated dynamic cardiac MR (true-FISP or FIESTA). LVM and LVM indexed by body surface area (LVMI), height$^2$ (H$^2$), H$^{2.7}$, and a new allometric H-weight (W) index calculated using H, W, and sex (ppLVmass$_{HW}$) (pp % predicted) are shown; the 95$^{th}$ percentile from Int J CV Imaging (26:259,2010) defines the upper limit of normal§. HTN was of similar duration in M (male) (N=279) and F (female) (N=273) (years: M 5.8±6; F 5.7±6). At baseline, 59 (11%) subjects took ACE-I; 171 (31%) took ARB. Office BP was well-controlled (M 127±14/80±11; F 123±15/79±12). M were significantly (P<0.005) younger (M 35±8; F 37±8), taller (cm: M 181±8; F 166±8), and heavier (kg: M 90.2±16.2; F 74.5±17.0) than F; BMI was similar (kg/m$^2$: M 27.6±4.7; F 27.2±10.4).

LMV and LVH

| Gender | LVM (gm) | LVM/BSA (gm/m$^2$) | LVM/H$^2$ (gm/m$^2$) | LVHH$^{2.7}$ (gm/m$^{2.7}$) | ppLVM$_{HW}$ |
|---|---|---|---|---|---|
| M | 153.0+29.9 | 73.0+13.2 | 46.8+8.7 | 31.0+6.0 | 0.9+0.2 |
| F | 105.8+24.3 | 58.3+12.2 | 38.4+9.3 | 27.0+7.5 | 0.9+0.2 |
| 95$^{th}$ percentile (M/F)§ | 203.5/140.3 | 106.2/84.6 | 65.7/53.0 | 45.1/38.0 | 1.31/1.31 |
| **Prevalence of LVH %, (N)** | 6.6 (36) | 1.8 (10) | 4.1 (22) | 3.7 (20) | 1.6 (9) |

LVM expressed as Mean+SD

Indices of LVM that account for body W show a lesser degree of LVH than indices not including weight. The prevalence of LVH in hypertensive ADPKD <50 yo with good BP control, short duration of HTN, and use of ACE-I/ARB is low. Early BP intervention in ADPKD may have decreased LVH and potentially decrease cardiovascular mortality.

## F-PO1828

**Follow-Up of Unruptured Intracranial Aneurysms (UIA) Detected by Presymptomatic Screening in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD)** Maria V. Irazabal-Mira, John Huston, Vickie J. Kubly, Sandro Rossetti, Marie C. Hogan, Peter C. Harris, Robert D. Brown, Vicente E. Torres. *Mayo Clinic, Rochester, MN.*

Feasibility and success of screening for UIA depends on their rates of growth and rupture. ADPKD patients found to have an UIA by MRA screening at the Mayo Clinic during 1989-2009 were recommended surveillance (except in one patient in whom surgery was deemed indicated), initially at 6 months and yearly, and less often after showing stability. At initial screening, 48 saccular aneurysms were detected in 40 patients from 38 families (16 men, 24 women, 50.7±10.4 y.o.). Genotype was *PKD1* in 10, *PKD2* in 1, not determined in 29 patients. There was a family history of UIA in 5 (12.5%), subarachnoid hemorrhage in 13 (32.5%) and both in 2 (5.0%). Eighteen patients were or had been smokers at the 1$^{st}$ MRA and of those 5 continued to be active smokers. Hypertension was present in 38 (33 treated with ACEI, ARBs or both) and hyperlipidemia in 24 (18 treated with statins). Most UIA were small (mean diameter 3.9 mm, range 1.0 to 10.0 mm); only 2 had a diameter ≥7mm at baseline. The majority (83.3%) were in the anterior circulation. Eight patients (20.0%) had 2 aneurysms on their 1$^{st}$ MRA. During cumulative imaging FU of 238 years, 1 de novo UIA was detected and increased in size from 2 to 4.4 mm over 144 months. An UIA in a second patient grew from 4.5 mm to 5.9 mm after FU of 69 months. Ten patients did not have imaging FU (2 died from unrelated causes shortly after diagnosis, 3 have only clinical FU, 5 recently diagnosed). No change was detected in the remaining 28 patients. During cumulative clinical FU of 315 years, no aneurysm ruptured. Five patients died from unrelated causes and 1 patient was lost to FU after 120 months. Three patients underwent surgical clipping of UIA measuring 10 mm (at Mayo) and 3 and 5 mm (elsewhere). Conclusion: Extended FU of these patients confirms that most UIA detected by presymptomatic screening in ADPKD patients are small, in the anterior circulation, and with risks for growth/ rupture not higher than those of UIA in the general population. These data do not support widespread screening for UIA in ADPKD.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1829

**The Calcimimetic R-568 Inhibits Renal Pathology in Rodent Nephronophthisis (NPHP) and Autosomal Recessive Polycystic Kidney Disease (ARPKD)** Neal X. Chen,[1] Sharon M. Moe,[1,2] Xianming Chen,[1] William Hoffmeyer,[1] Vincent H. Gattone.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Roudebush Veterans Medical Center, Indianapolis, IN.*

Cystic kidney diseases are common causes of chronic kidney disease (CKD) for which there is no treatment. We have previously demonstrated that calcimimetics, an allosteric activators of the calcium sensing receptor (CaSR, a G-protein linked receptor) inhibits cyst

progression in the Cy/+ rat, likely due to increased intracellular calcium and decreased cAMP. In the present study we sought to test the efficacy of the calcimimetic R-568 in two orthologous rodent models. We treated pcy mice, orthologous with human nephronophthisis (NPHP), from 4 -15 weeks (prevention) or 20 -35 weeks (treatment after disease was established) with the calcimimetic R-568 (0.05% in food). PCK rats, orthologous with human ARPKD, were similarly treated from 8 -18 weeks. Renal pathology and serum biochemistry were evaluated. The results demonstrated that R-568 treatment from 4-15 weeks was efficacious in inhibiting the progression of rodent NPHP by reducing kidney weight as a percent of the total body weight (KW%BW, 3.3±0.8 vs. 4.8±1.1, $p<0.001$); cyst volume density (27.7±10 vs. 40.9±9.1, $P<0.001$) and fibrosis (3.0±0.3 vs. 4.0±0.01, $p<0.002$). Early treatment of pcy mice was more effective that the later treatment, but both stages of the disease responded positively to treatment. In PCK rats, we also found R568 significantly reduced KW%BW (1.1±0.1 vs. 1.3±0.1, $p<0.02$); Cyst volume density (14.5±1.4 vs.19.8±2.7, $p<0.02$) and fibrosis (3.1±0.2 vs. 3.8±0.2, $p<0.05$). In all treatments, R-568 also lowered serum PTH. We further demonstrated that CaSR mRNA is expressed in epithelial cells lining renal cysts in kidney from both the pcy mice and PCK rats. In conclusion, treating renal cystic disease with the calcimimetic R-568 was efficacious in two rodent models of childhood cystic disease, suggesting that calcimimetics may be a potential therapeutic intervention for these conditions.

**Inhibition of Angiogenesis Decreases ADPKD Cyst Growth in Nude Mice Xenografts** Wei Wei,[1] Elsa Bello-Reuss.[2] *[1]Internal Medicine, University of Texas Medical Branch, Galveston, TX; [2]Internal Medicine, Texas Tech University Health Sciences Center, Lubbock, TX.*

Primary cultures of Autosomal Dominant Polycystic Kidney Disease (ADPKD) cyst cells were grown *in vitro*, included in a collagen matrix (growth factor reduced (GFR)-Matrigel) and grafted into immunoincompetent (nude) mice. We found that the cells form cysts that develop in about two weeks and that mouse blood vessels invade the implant. We studied the effect of inhibitors of the angiogenic factors IL-8 and VEGF on the formation and growth of the cysts. Systemic administration to the animals of anti-IL-8 antibody (inhibitor of IL-8); bevacizumab (BMab, an anti-VEGF) or dexamethasone, (Dexa, a nonspecific IL-8 inhibitor), decreased the number and size of the cysts in the implants. Cyst volume of treated animals *vs.* control decreased by 65% (anti-IL8), 47% (BMab), 61% (Dexa), 46% (BMab + antiIL-8) and by 62% by BMab + Dexa, all $P<0.001$. The decrease in cyst volume by anti-IL-8 was significantly larger than those elicited by BMab, Dexa and BMab + anti IL-8 ($P < 0.04$, $< 0.02$ and $< 0.04$, respectively) but not for BMab + Dexa. Cyst cell immunostaining in control implants was positive for VEGF, PDGF and IL-8, as well as their receptors. In the cysts still growing in treated animals, expression of VEGF, PDGF, IL-8 and their receptors was not different from control. The presence of red blood cells in the implants' vasculature indicates functional circulation. Vascular invasion decreased by about 50% by antiangiogenic treatments. Summary: 1. Implants containing ADPKD cyst cells develop cysts and functional vasculature. 2. Inhibition of angiogenesis decreases the number and size of the cysts. 3. The viable cysts in treated animals continue expressing angiogenic factors and their receptors. 4. Antiangiogenic treatment significantly decreases implant vascularization. Thus, this system can be used as a model of ADPKD for testing treatments. Our studies confirm the importance of secretion of angiogenic factors by cyst cells in the recruitment of vasculature, creating a positive feedback for ADPKD cyst growth.

### F-PO1831

**Vasopressin V2 Receptor Antagonism in a Mouse Model for Autosomal Dominant Polycystic Kidney Disease. Optimal Timing and Dosing of the Drug** Esther Meijer,[1] Ron T. Gansevoort,[1] Paul E. de Jong,[1] Wouter N. Leonhard,[2] Anne Marike Van der Wal,[2] Jacob Van den Born,[1] Harry Van Goor,[1] Emile De Heer,[2] Dorien J. M. Peters.[2] *[1]UMCG, Groningen, Netherlands; [2]LUMC, Leiden, Netherlands.*

The renoprotective effect of a vasopressin V2 receptor antagonist (V2RA) presently is tested in a clinical trial in early ADPKD. If efficacious, this warrants life long treatment with V2RA, however with associated physiologic side effects as polydipsia and polyuria. We questioned whether we can modify the side effects without influencing the renoprotective effect by starting the treatment later in the disease, or by lowering drug dose. In addition, we evaluated the time course of the effects.

We administered the V2RA OPC-31260 at high (0.1%) and low (0.05%) dose to a tamoxifen-inducible kidney epithelium-specific *Pkd1*-deletion mouse model (*Pkd1*-gene deletion at post natal day 11) starting treatment at day 21 (early) or 42 (late). After 3 and 6 wks of treatment, we monitored physiologic effects, e.g. water intake and potential renoprotective effects, e.g. kidneyweight and cystogenesis.

Initiation of V2RA treatment late in the disease lacked renoprotective effects. It also had less pronounced physiologic effects. When started early, both after 3 and 6 wks of treatment, the V2RA caused dose-dependent physiologic effects. On high dose, water intake at both timepoints was 2-fold higher than on low dose ($p<0.001$). After 3 wks on high dose, cystratio and kidneyweight were reduced vs. untreated controls (18 vs.25%, $p=0.05$ and 0.33 vs. 0.45g, $p=0.03$, resp.). After 6 wks of treatment however, administration of the V2RA lacked renoprotection, even at high dose (kidneyweight 0.55 vs. 0.66g, $p=0.12$ and cystratio 24 vs. 27%, $p=0.38$, resp.). After 6 wks of treatment, mice receiving high dose also exhibited less polydipsia than after 3 weeks (2-fold vs. 4-fold increase resp. compared to untreated controls, $p=0.001$).

These data suggest that intervention with a V2RA should be instituted early in ADPKD and at high dose, and that it might be necessary to increase the dosage of this drug later in the disease to reach renoprotection, however at the expense of physiologic side effects of the drug.

### F-PO1832

**Thiazolidinedione Ameliorates Autosomal Recessive Polycystic Kidney and Liver Disease in the PCK Rat, an Orthologous Model of Human ARPKD** Daisuke Yoshihara,[1,2] Hiroki Kurahashi,[2] Miwa Morita,[1] Masanori Kugita,[1] Yoshiyuki Hiki,[3] Harold M. Aukema,[4] Tamio Yamaguchi,[1] James P. Calvet,[5] Darren P. Wallace,[5] Shizuko Nagao.[1] *[1]Education and Research Center of Animal Models for Human Diseases, Fujita Health University, Toyoake, Aichi, Japan; [2]Division of Molecular Genetics, Fujita Health University, Toyoake, Aichi, Japan; [3]School of Health Sciences, Fujita Health University, Toyoake, Aichi, Japan; [4]Department of Human Nutritional Sciences, University of Manitoba, Winnipeg, MB, Canada; [5]The Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

Polycystic kidney disease (PKD) is characterized by progressive enlargement of numerous fluid-filled cysts and aberrant proliferation of tubule epithelial cells in the kidneys often leading to end-stage renal disease. Liver cysts are the most common extrarenal manifestation in PKD, and can lead to massive liver enlargement and congenital hepatic fibrosis. Peroxisome proliferator-activated receptor gamma (PPAR-gamma), a member of the ligand-dependent nuclear receptor family, is expressed in a variety of tissues, including the kidneys and liver, and plays important roles in cell proliferation, fibrosis and inflammation. In the current study, we determined the effect of thiazolidinedione, a PPAR-gamma agonist on polycystic kidney and liver disease progression in the PCK rat, an orthologous model of human autosomal recessive PKD (ARPKD). Daily treatment with 10 mg/kg pioglitazone, a thiazolidinedione derivative, for 16 weeks significantly decreased kidney weight (% of body weight), renal cystic area, SUN and the number of Ki67-, pERK1/2- and pS6-positive cells in the kidney. There also was a significant decrease in liver weight (% of body weight), liver cystic area, hepatic fibrosis index, and the number of Ki67-, pERK1/2-, pERK5- and TGF-beta-positive cells in the liver tissue. These results demonstrate that pioglitazone inhibits the progression of polycystic kidney and liver disease in a model of ARPKD by inhibiting cell proliferation, fibrosis and inflammation. Current findings suggest that thiazolidinediones may have therapeutic value in the treatment of the renal and hepatic manifestations of ARPKD.

### F-PO1833

**Proteasome Inhibition Leads to Reduced Cyst Growth in a Mouse Model with Inactivation of the ADPLD Gene, *PRKCSH*** Sorin V. Fedeles,[1] Seung H. Lee,[1] Xin Tian,[1] Craig M. Crews,[2] Stefan Somlo.[1] *[1]Internal Medicine/Nephrology, Yale University, New Haven, CT; [2]Molecular, Cellular, and Developmental Biology, Yale University, New Haven, CT.*

Isolated Autosomal Dominant Polycystic Liver Disease (ADPLD) is characterized by the presence of bile-duct cysts spread throughout the liver parenchyma. *PRKCSH*, one of the genes mutated in ADPLD, encodes the β subunit of the ER glucose-trimming enzyme glucosidase II (GIIβ) which functions in the post-translational processing of integral membrane and secreted glycoproteins. We have previously shown absence of GIIβ results in decreased stability and ciliary trafficking of PC1 and that kidney selective inactivation of *Prkcsh* causes polycystic disease that is made worse by polycystin-1 (PC1) haploinsufficiency and improved by PC1 over-expression. Since loss of GIIβ is expected to increase the burden of misfolded proteins, we tested the effects of proteasome inhibitors in cell and animal models of ADPLD. *Prkcsh*$^{-/-}$ cells treated with the proteasome inhibitors MG132 and carfilzomib showed ~3.5-fold increase in rates of apoptosis as compared to wild-type cells. Additionally, levels of PC1 in *Prkcsh*$^{-/-}$ cells increased in the presence of MG132. We used carfilzomib (5 mg/kg) to treat *Prkcsh*$^{flox/flox}$*;Ksp-Cre;Pkd1*$^{+/-}$ mice from P21 until P42. Treatment resulted in significantly decreased kidney/body weight ratio, cystic index and blood-urea nitrogen levels indicating improvement in the polycystic disease progression. The levels of apoptosis in the DBA positive kidney tubule segments was significantly increased (~2-fold) in the carfilzomib treated mice whereas proliferation was decreased (~1.4-fold). These data suggests that *Prkcsh*$^{-/-}$ cyst cells are more sensitive to proteasomal inhibition leading to enhanced apoptosis. Proteasome inhibition also increased steady state levels of PC1, which may be contribute to the reduced proliferation seen in cyst cells. Proteasome inhibitors are effective in reducing cyst growth in orthologous models of ADPLD and may define a potential target for therapy in human ADPLD.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1834**

**Therapeutic Potential of Combination of the Novel Dual PI 3-Kinase/mTOR Inhibitor and MAPK Inhibitor in the Han:SPRD Rat Model of PKD** Yang Liu,[1] Rudolf P. Wuthrich,[1] Andreas L. Serra.[1] *[1]Institute of Physiology, University of Zürich, Zürich, Switzerland; [2]Experimental Infectious Diseases and Cancer Research, University Children's Hospital, Zürich, Switzerland.*

The mTOR and Akt pathway are aberrantly activated in PKD. NVP-BEZ235 is a novel dual PI3K/mTOR inhibitor. We analyzed the the mechanism of NVP-BEZ235 on proliferation and apoptosis in renal primary tubular epithelial cells derived from Han:SPRD rats (Cy/+ TECs).

The effect of BEZ (c= 0.01nM to 1000nM) alone or combination with UO126, a mitogen-activated protein kinases (MAPK) inhibitor (c= 5μM to 25μM), on Cy/+ TECs proliferation, apoptosis, mTORC1, mTORC2 and MAPK signaling pathway was assessed.

BEZ reduced total cell numbers, cell viability and DNA synthesis of Cy/+ TECs without inducing complete inhibition at 1μM, which is the highest concentration tested in these studies. Cleavage fragments of caspase 3 could not be detected and the proportion of PI–/Annexin V+ and PI+/Annexin V+ cells treated with BEZ remained substantially unchanged. The phosphorylation of the downstream effectors of mTORC1 (4EBPThr37/46, S6KThr421/Ser424, S6Ser235/236) were prevented at a concentration lower than the one blocking upstream regulators of mTORC1 (such as AktThr308). BEZ suppressed phosphorylation of Akt at Ser473 site, the readout of mTORC2 activity. Phosphorylation of the MAPK increased (indicating activation) upon BEZ treatment in a dose-dependent way. Combined BEZ with UO126 completely decreased proliferation, inhibited the activation of downstream effectors of mTORC1 and down-regulated the phosphorylation of the MAPK which triggered by BEZ treatment.

BEZ inhibited the proliferation of Cy/+ TECs incompletely and apoptosis was not observed in vitro. A partial lack of sensitive of mTORC1 upstream regulators, as well as an activation of the MAPK signaling pathway occurs in parallel with these effects. Combination treatment of BEZ and UO126 significantly blocked the proliferation of Cy/+ TECs due to inhibit the activation of mTORC1 downstream effectors and MAPK signaling pathway. Our data suggest that combined dual PI3K/mTOR inhibitor with MAPK inhibitor could have a synergistic effect on Cy/+ TECs.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1835**

**Progression of Polycystic Kidney Disease (PKD) in *jck* Mice in the Absence of Cyclin-Dependant Kinase 2 (Cdk2)** Jane S. Burgess,[1] Philipp Kaldis,[2] David C. Harris,[1] Gopala K. Rangan.[1] *[1]Centre for Transplant and Renal Research, Westmead Millennium Institute and The University of Sydney, Sydney, NSW, Australia; [2]Institute of Molecular and Cell Biology, Singapore.*

**Background:** Loss of polycystin function promotes Cdk2 activity and this may mediate the increased proliferation and cyst enlargement in PKD. Here, we tested the hypothesis that the progression of cystic renal disease is reduced by Cdk2 deficiency.

**Methods:** *jck* mice are homozygous for a single point mutation in *Nek8* (a mitotic kinase downstream of polycystin-dependent cell cycle activation) and develop PKD. Compound mice deficient in both $Nek8^{jck}$ and *Cdk2* were compared with $Nek8^{jck/jck}/Cdk2^{+/+}$ mice. $Cdk2^{-/-}$ mice are sterile due to a defect in gonad meiosis, and therefore heterozygous $Nek8^{+/jck}$C57/BL6 mice were crossed with $Cdk2^{+/-}$C57/BL6 mice. Progeny that were $Nek8^{+/jck}/Cdk2^{+/-}$ were then crossed to produce $Nek^{jck/jck}/Cdk2^{-/-}$ and $Nek8^{jck/jck}/Cdk2^{+/+}$ mice. Data from $Nek8^{jck/jck}/Cdk2^{-/-}$(n=6), $Nek8^{jck/jck}/Cdk2^{+/+}$(n=6), and $Nek8^{+/+}/Cdk2^{+/+}$(n=8) was collected at week 12.

**Results:** $Nek8^{jck/jck}/Cdk2^{-/-}$ mice were viable and indistinguishable from their littermates. As expected, ovaries and testes were markedly atrophic in Cdk2 deficient mice. Renal function, as assessed by serum creatinine (Table 1), was worse in $Nek^{jck/jck}/Cdk2^{-/-}$ compared to $Nek8^{jck/jck}/Cdk2^{+/+}$ mice. Kidneys from all $Nek8^{jck/jck}$ groups exhibited PKD. However, the pattern was different, and cysts were more numerous in $Nek8^{jck/jck}/Cdk2^{-/-}$ mice and almost all were round in shape, in contrast to the typical rectangular cystic dilatation present in $Nek8^{jck/jck}/Cdk2^{+/+}$. The %cyst area was higher in the $Nek8^{jck/jck}/Cdk2^{-/-}$ group compared to $Nek8^{jck/jck}/Cdk2^{+/+}$, but this did not reach statistical significance (p=0.14).

Table 1.

| | jck (Cdk2 null) | jck (Cdk2+/+) | Wild-type |
|---|---|---|---|
| BW(g) | 20.5±3.2 | 21.9±4.1 | 22.5±3.2 |
| KW/BW (%) | 4.8 ±3.6* | 3.3 ±3.0* | 0.7±0.1 |
| Serum Cr (μmol/L) | 40.0±27.1# | 17.6±6.1 | 16.7±4.9 |
| Cyst Area (%) | 52.1±13.7 | 40.4± 9.9 | - |

Mean+/-SD; *P<0.05 compared to wild-type; #P<0.05 compared to jck (Cdk2+/+)

**Conclusion:** Cdk2 deficiency unexpectedly exacerbates renal function and also alters the nephron-segment specificity of cyst burden in *jck* mice.

**F-PO1836**

**Silencing of RAGE Suppresses Cystogenesis in Polycystic Kidney Disease** Jong Hoon Park, Bo Hye Kim, Eun Young Park. *Department of Biological Science, Sookmyung Women's University, Seoul, Korea.*

Autosomal dominant polycystic kidney disease (ADPKD) is a hereditary and chronic kidney disease characterized by cyst formation. ADPKD is developed due to the malfunction of PKD1/2. PKD1 encodes a GPCR-like receptor, and PKD2 produces a transient receptor potential (TRP)-like calcium channel. They are localized on the primary cilia of the renal epithelial cells and form a complex to regulate intracellular [$Ca^{2+}$]. By the fluid flow, they are activated and initiate intracellular signal pathway. In general, ADPKD is caused by loss of function of PC1/2. However, overexpression of PKD1 or PKD2 gives rise to cystogenesis in the kidney. In our laboratory, we generated PKD2 overexpression transgenic mice. These TG mice developed the cyst formation since one year.

To find candidate genes responsible for cyst development in PKD2 TG mice, microarray was performed and S100A8/A9 and RAGE (receptor for advanced glycation end product) were chosen as the interesting genes. In our previous study, qRT-PCR and western blot results said that expression level of RAGE and S100A8/A9 was elevated. Also, immunohistochemistry (IHC) showed strong expression of RAGE and S100A8/A9 on the renal cyst epithelial cells. S100A8/A9-RAGE signaling was involved in inflammation around the cyst, indicating inflammation was the one of factors aggravating ADPKD. On the basis of previous result that treatment of anti-RAGE siRNA and adenovirus to mIMCD cells reduced p-ERK level and suppressed cyst formation on 3D culture, we tried to apply anti-RAGE adenovirus to mice. We have PKD2 knockout mice which were rescued by overexpression of hPKD2. These rescued mice can survive until one month in spite of bearing cyst-filled kidneys. To these mice, anti-RAGE adenoviruses were intravenously injected. After that, improved renal function and reduction in cyst development were detected. Furthermore, both MAPK and NF-kB signaling were silenced.

These data showed that silencing of RAGE suppresses cystogenesis in ADPKD, indicating the value of RAGE as the new therapeutic target of ADPKD.

**Lonidamine Derivatives Have Properties Expected of Effective Drugs for Treating ADPKD** Brenda S. Magenheimer,[1] Shirin Sundar,[1] Dar B. Shah,[1] Sumanth Mulamalla,[1] Gail Reif,[1] Darren P. Wallace,[1] Joseph S. Tash,[1] Gunda I. Georg,[2] James P. Calvet.[1] *[1]Univ. of Kansas Medical Center, Kansas City, KS; [2]Univ. of Minnesota, Minneapolis, MN.*

A lead compound for the treatment of ADPKD should effectively block both abnormal cell proliferation and cyst-filling fluid secretion in addition to having favorable safety/toxicity and biodistribution profiles. Previously, we showed that the novel lonidamine derivative JWS 1-190 inhibits cell proliferation and fluid secretion. In this study, we further examined JWS 1-190 and eleven other lonidamine compounds to generate comparative data profiles and to find new compounds to inhibit cyst initiation and/or progression in ADPKD, using cell-based and metanephric organ culture assays. The MTT assay was used to generate dose response curves with primary human ADPKD cells. Nine candidate compounds showed an IC50 at 1-15 μM (IC50 for lonidamine = 5.7 μM). Mouse embryonic organ cultures made use of kidneys at E15.5 from Pkd1m1Bei heterozygous crosses. When E15.5 cultures were treated with 8-Bromo-cAMP in the presence of the compounds for 4 days, several drugs strongly inhibited cyst formation. The compounds that had a low μM IC50 in ADPKD cells were the most effective at inhibiting cyst growth in metanephric kidneys. Fluorescein competition in embryonic kidneys indicated that the drugs may be transported by organic anion transporters and thus may accumulate to high concentrations in kidneys. Short circuit current experiments were conducted on M-1 cell monolayers to determine whether the candidate compounds inhibit CFTR channel activity, which is required for cyst-filling fluid secretion. The bioavailability of JWS 1-190 was determined by administration of 100 mg/kg by i.p. injection, and heart, lungs, kidneys, urine, serum, and testes were harvested at 6 and 24 hrs for mass spectrometry, which showed high amounts of the drug in the kidney at both time points. JWS 1-190 was also shown to significantly ($p < 0.01$) inhibit wound closure in a cell motility scratch assay at 1 μM and 5 μM. We conclude that JWS 1-190 and several other lonidamine derivatives have properties expected of effective therapeutic drugs for ADPKD.

**TCF/β-Catenin Activity Is Suppressed Normally in Two Independent Models of ADPKD** Michelle Miller,[1] Diana Iglesias,[2] Stefan Somlo,[3] Gregory G. Germino,[4] Paul R. Goodyer.[1] *[1]Human Genetics, McGill University, Montreal, QC, Canada; [2]Pediatrics, McGill University Health Center, Montreal, QC, Canada; [3]Internal Medicine, Yale University, New Haven, CT; [4]National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD.*

Autosomal dominant polycystic kidney disease (ADPKD) results from mutations in either the *PKD1* or *PKD2* genes, which encode the cilial proteins PC1 and PC2. In ADPKD, it has been proposed that during kidney development a subset of cells acquire second "hits" to the wildtype allele and cysts are thought to arise when mechanosensory stimuli fail to initiate cilial signalling that normally suppresses the canonical WNT/β-catenin signalling pathway. This hypothesis predicts that cystogenesis is driven by aberrant WNT/β-catenin activity. To test this theory, we crossed a TCF/β-catenin reporter mouse to mice with mutations in *Pkd1* or *Pkd2*. We then assessed the onset of cyst formation relative to the ontogeny of primary cilia and the normal downregulation of TCF/ β-catenin reporter activity.

By E15.5, the primary cilia were present and ureters had connected with the bladder, allowing the onset of flow in normal mice. In *Pkd1* null mice, kidney cysts appeared at E16 but suppression of the TCF/β-catenin reporter was normal. Since the *Pkd1* null mice die at E18, we also studied the *Pkd2/WS25* mice, which carry one null and one hypomorphic allele of the *Pkd2* gene. The *WS25* allele undergoes somatic recombination to form the second null allele, permitting perinatal survival and delaying cyst formation until roughly 2 weeks of age. By 8 weeks, renal cysts are widespread but no activity of the TCF/β-catenin reporter was seen.

In conclusion, suppression of the canonical WNT signalling pathway appears normal in both the *Pkd1* null and *Pkd2/WS25* mouse models. We speculate that the pathogenesis of ADPKD may be driven by a failure to activate non-canonical WNT signalling pathways, however the developmental regulation of WNT/β-catenin signalling activity remains intact.

**PPARγ Agonists Decrease CFTR Expression in the Apical Membranes of Liver Cysts from the PCK Rat Model of Polycystic Kidney Disease (PKD)** Bonnie L. Blazer-Yost,[1, 3] Jey-Hsin Chen,[2] Vincent H. Gattone.[3] *[1]Biology, Indiana University - Purdue University, Indianapolis, IN; [2]Pathology & Laboratory Medicine, IUSM, Indianapolis, IN; [3]Anatomy and Cell Biology, IUSM, Indianapolis, IN.*

In PKD, cyst growth involves secretion of electrolytes and fluid by the cyst-lining epithelial cells. One mediator of electrolyte/fluid secretion is the $Cl^-$ channel, cystic fibrosis transmembrane-conductance regulator (CFTR). We previously found that PPARγ agonists decrease renal CFTR mRNA and inhibit vasopressin-stimulated $Cl^-$ secretion in MDCK-C7 renal principal cells. In the current studies, we used immunohistochemical techniques to examine expression of CFTR in apical membranes of biliary cysts from PCK rats, an orthologous model of autosomal recessive (AR) PKD. Control (untreated) animals were compared with littermates that had been treated with 20 mg/kg body weight of pioglitazone (Pio), a PPARγ agonist, from weaning (4 weeks) to 18 weeks. We previously showed that this treatment resulted in a decrease in cystic burden in both kidney and liver. To elucidate a mechanism of action of pioglitazone inhibition of cyst growth, apical membrane expression of CFTR in cholangiocytes lining liver cysts were stained, using the monoclonal CFTR antibody, 596, on formalin-fixed paraffin-embedded tissue. In comparison to control animals, the staining intensity for CFTR in apical membranes was diminished in Pio-treated rats. To provide a better quantitative approach, gold-labeled immuno-electron microscopy was used to assess the density of CFTR expression at the apical plasma membrane of cyst cholangiocytes. Sections were subjected to analysis by counting the number of gold particles bound to the surface of the apical membrane and expressed as number per linear μm of apical surface. Cholangiocytes from Pio-treated rats had a statistically significant decrease ($p = 0.009$) in apically-localized immunogold labeled CFTR. The biliary cysts from animals on control diet had an average 1 gold particle per 0.23 μm of apical surface versus 1 per 6.04 μm in Pio-treated rats. Based on these studies, we suggest that PPARγ agonists may be useful for treating PKD.

**Kidney-Specific Inactivation of the Tsc1 Gene Reveals a Time Disconnect between mTORC1 Upregulation and Renal Cystogenesis** Monika Pema, Claas Wodarczyk, Marco Chiaravalli, Alessandra Boletta. *Dibit-San Raffaele Hospital, Milan, Italy.*

ADPKD is a genetic disorder characterized by bilateral renal cyst formation, caused by mutations in the PKD1 or PKD2 genes. Their products (the polycystins) function as a complex to prevent cyst formation. Previous studies have suggested that the mTORC1 cascade might play an important role in renal cyst formation and in line with this the mTOR inhibitor rapamycin has beneficial effects in rodent models of PKD. We have recently shown that Polycystin-1 (PC-1) inhibits mTORC1 and its downstream effectors in an ERKs-TSC2 dependent, but Akt-independent manner (Distefano et al,MCB.29:2359,2009).

To better understand the role of mTORC1 activity and the TSC genes in renal cystogenesis, we crossed mice carrying a kidney-specific Cre (Ksp-Cre) with mice harbouring either a Tsc1 floxed or a Pkd1 floxed allele and compared the resulting models (Tsc1kKO and Pkd1kKO, respectively). As previously reported, Pkd1kKO mice develop massive renal cystogenesis starting at P1 and leading to death by P14. Biochemical analysis showed upregulation of mTORC1 and IHC revealed that the majority of cyst-lining epithelia stain positive for P-S6Rp. However, a considerable number of cysts (10-20%) stained negative for P-S6Rp, suggesting that upregulation of mTORC1 might not be necessary for cysts to form.

Interestingly, Tsc1kKO mice survive much longer than the Pkd1kKO (>50 days). Biochemical analysis revealed an upregulation of mTORC1 at P9, P14, P26, P40. Surprisingly, mTORC1 hyperactivation did not correlate with cyst formation or tubular dilatation, since neither can be observed at P9. By P14 a strong expansion of the renal medulla can be appreciated, with only small cortical tubular dilatations appearing. Medullary expansion can be observed also at P56 when massive cystogenesis is also present. Notably, we observed major morphological differences both of whole kidneys and the cystic epithelia between the Pkd1kKO and Tsc1kKO. These data suggest that there is a disconnect between the time of mTORC1 upregulation and renal cystogenesis and highlight a more complex interplay between the Pkd and Tsc genes than anticipated.

**Effect of Angiotensin Converting Enzyme (ACE) Inhibition and Angiotensin Receptor Blockade on Urinary pH in ADPKD** Amirali Masoumi,[1] Berenice Y. Gitomer,[1] Robert W. Schrier,[1] Wei Wang,[1] Arlene B. Chapman,[2] Ronald D. Perrone,[3] Vicente E. Torres,[4] Theodore I. Steinman,[5] Dana C. Miskulin.[3] *[1]U. Colorado Denver, Aurora, CO; [2]Emory U.; [3]Tufts; [4]Myao Clinic; [5]Beth Israel.*

Autosomal dominant polycystic kidney disease (ADPKD) affects an estimated 600,000 Americans. The prevalence of nephrolithiasis is approximately 5-fold higher in ADPKD patients than in the general population. Approximately 50% of the stone burden is attributed to uric acid stones. The major risk factor for uric acid stone formation in ADPKD appears to be low urine pH (especially urine pH<pH 5.5). Recent studies have shown that angiotensin II stimulates the vacuolar $H^+$-ATPase (V-ATPase) in renal type-A acid secretory intercalated cells. We thus hypothesized that ADPKD patients who were treated with ACE inhibitors (ACEI) or ACEI plus angiotensin receptor blockers (ARB) may have increased urinary pH and thus decreased risk for uric acid formation. The HALT-PKD clinical trial assesses the effect of ACEI vs ACEI + ARB therapy on slowing the progression of renal disease in patients with ADPKD. We measured urine pH in 106 subjects who were enrolled in the HALT-PKD study at the University of Colorado at baseline and at 12 months after initiation of therapy. Among those 106 patients, 20 patients (18.8%) had a urine pH<5.5 (pKa for uric acid) at baseline and 6 patients had previously had a kidney stone. In these 20 patients treatment with ACEI or ACEI + ARB resulted in a significant increase in urine pH (baseline 5.2±0.1 vs 12 month 5.9±0.1, $p<0.0001$). A similar trend was seen for 22 patients with baseline pH between 5.5 and 6.0 (baseline pH 5.7±0.1, 12 month 5.9±0.4, $p=0.06$). However, in patients with baseline pH≥6.0 no effect with therapy was observed (baseline pH 6.5±0.4 vs 12 month 6.2±0.5). There was no significant difference in urine pH between patients whose estimated glomerular filtration rate (eGFR) was>60 ml/min/1.73 $m^2$ and those with eGFR<60 ml/min/1.73 $m^2$. Thus patients with low urinary pH<5.5 may benefit from ACE inhibitor and/or ARB therapy by reduction in risk for uric acid stone formation.

**ADPKD Is Associated with a Central and Peripheral Defect in Osmoregulation** Thien Anh Ho, Yves A. Pirson, Olivier Devuyst. *Nephrology, Universite Catholique de Louvain Medical School, Brussels, Belgium.*

Introduction

Autosomal dominant polycystic kidney disease (ADPKD) is associated with an impaired urine concentrating ability (Umax, maximal urine osmolality after water deprivation), attributed to cystic alteration of the renal parenchyma. The existence of a central defect in vasopressin (AVP) release has also been suggested by studies in Pkd1 mouse. In this study we investigated the central and nephrogenic components of osmoregulation in ADPKD patients.

Patients and methods

We enrolled 10 ADPKD adults (44 ± 4 yr) and 10 ADPKD children (11 ± 1 yr) with normal renal function, and 20 age- and sex-matched controls (CTRL). Plasma and urine parameters were determined at baseline and after a 12-hour water deprivation. Total kidney volume was assessed by MRI in ADPKD adults.

Results

At baseline, renal function, plasma and urine osmolality and plasma AVP levels were similar in adult ADPKD and CTRL. After water deprivation, Umax was significantly lower in ADPKD than in CTRL (710 ± 68 vs. 920 ± 47 mOsm/kg $H_2O$). This difference reflects the significant increase (+37%) of plasmatic AVP level in the CTRL group, contrasting with an attenuated variation (+19%, non significant) in the ADPKD group, despite of a significantly higher maximal plasma osmolality (304 ± 1 vs. 300 ± 1 mOsm/kg $H_2O$, ADPKD vs CTRL). ADPKD patients showed a significantly lower Umax than CTRL for a same range of plasma AVP and urinary cyclic adenosine monophosphate (cAMP) levels. There was a significant inverse correlation between Umax and kidney volume. The urine concentrating defect was confirmed in ADPKD children.

Discussion

These results confirm the presence of a urine concentrating defect in early ADPKD. In adults, this defect is proportional to the kidney volume, and is distal to AVP secretion and cAMP production, possibly related to inefficient translocation of aquaporin-2. Furthermore, ADPKD patients show a central defect in osmoregulation, as revealed by the significantly attenuated reactivity of AVP to plasma osmolality.

These alterations of osmoregulation associated to ADPKD have important clinic and therapeutic implications, particularly for the use of aquaretic molecules.

**F-PO1843**

**Capecitabine Can Be Used in Patients with Severe Renal Impairment (GFR <30CC/Min) and in Patients with End Stage Renal Disease on Hemodialysis**

Sheron Latcha,[1] Kenar D. Jhaveri,[2] Carlos D. Flombaum.[1] *[1]Nephrology, Memorial Sloan Kettering Cancer Center, New York, NY; [2]Nephrology, North Shore Long Island Jewish Health System, Great Neck, NY.*

Capecitabine use is contraindicated in patients with severe renal impairment (GFR<30ml/min) based on a single Phase II trial, which included only 4 such patients. Retrospective chart review over a 5 year period identified 12 patients with a GFR<30ml/min, including 2 patients on hemodialysis, who received capecitabine.

The usual recommended dose is 1250mg/m$^2$ twice daily, administered orally for 2 weeks, every 21 days. The starting dose used ranged from 225-1100mg/m2 twice daily at varying intervals. In response to reports of AEs, dose reductions of 25- 50% of the starting dose were made, and occurred after completion of the first or second treatment cycle. Grade 2 diarrhea was the most common cause for dose reduction (25%), followed by grade 2 hand and foot syndrome (12%). One patient reported grade 3 diarrhea and one patient died while on treatment with capecitabine. Progression of disease was the most common reason for discontinuation of capecitabine (83%). Of the adverse events reported, fatigue and diarrhea were reported at equal frequencies, and when present, was generally reported as grade 1 in severity. Fifty percent of patients reported hand and foot syndrome; of these, 66% reported grade 1 symptoms.

Serum tumor marker levels and follow up imaging studies were available on 9 patients. Response to capecitabine was documented in 4 patients; stable disease in 2; and disease progression in 3. On average, patients tolerated capecitabine for 8.3 months (range 1-26 months) before requiring therapy change for progression of disease (POD). The 2 patients on HD received capecitabine for 16 and 20 months and had documented response to treatment.

The labeling prohibiting use of the drug in patients with a GFR<30ml/min may be unsupported. With close monitoring of their clinical and chemical data, capecitabine can be safely and administered be effective therapy at dose reductions of 50-80% of the usual starting dose, for patients moderate and severe renal impairment, including patients on hemodialysis.

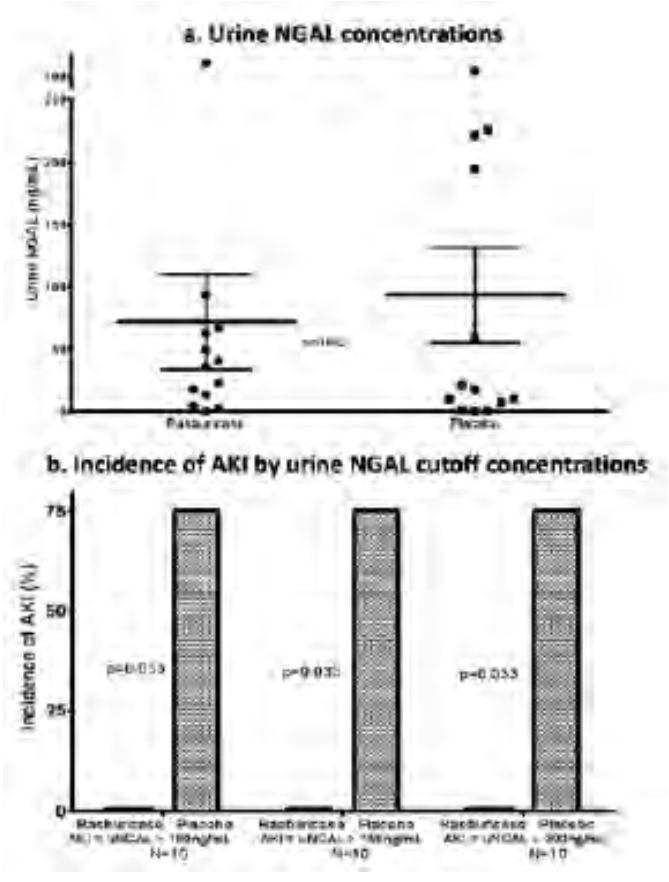
**The Rasburicase Pilot Study for the Prevention of Acute Kidney Injury in CV Surgery**

A. Ahsan Ejaz,[1] Bhagwan Dass,[1] Vijaykumar Lingegowda,[1] Michiko Shimada,[2] Richard J. Johnson.[3] *[1]Division of Nephrology, Hypertension and Transplantation, University of Florida, Gainesville, FL; [2]Department of Nephrology, Hirosaki University Graduate School of Medicine, Hirosaki, Japan; [3]Division of Renal Diseases and Hypertension, University of Colorado Health Sciences Center, Denver, CO.*

**Background:** Uric acid is an independent risk factor for acute kidney injury (AKI) and adversely affects renal blood flow autoregulation, glomerular filtration rate, inflammation and angiogenesis. The aim of the pilot study was to investigate the effect of lowering uric acid on AKI.

**Method:** In this prospective, double blind, placebo-controlled, randomized pilot trial, participants were randomized to receive rasburicase or placebo in the preoperative period.

**Results:** A convenience sample of 26 patients who underwent cardiac surgery was studied. Rasburicase was associated with a trend towards decreased AKI by urine neutrophil- associated lipocalin (uNGAL) concentrations (Fig.a; rasburicase 72.1±38.1 vs. placebo 93.8±38.1, p=0.692), and this trend persisted in those with higher serum uric acid levels, more severe renal (baseline GFR≤ 45mL/min/1.73m$^2$) and cardiac impairments (left ventricular ejection fraction ≤45%). The use of rasburicase was also associated with a trend towards a decreased incidence of AKI (rasburicase 7.7% vs. placebo 30.8%, p=0.322) by uNGAL cutoff concentrations. In the subset of patients with severely impaired renal function (GFR≤45ml/min/1.73m$^2$), rasburicase was associated with a dramatic 75% reduction in AKI (Fig b; rasburicase 0% vs., placebo 75%, p=0.033).



**Conclusion:** Rasburicase therapy was associated with a trend towards decreased AKI (defined by uNGAL excretion) in high-risk cardiac surgery patients which was significant in patients with GFR≤ 45mL/min/1.73m$^2$.

**Prognostic Indicators of Renal Disease Progression in Adults with Fabry Disease: Natural History Data from the Fabry Registry**

Christoph Wanner,[1] David G. Warnock.[2] *[1]Department of Medicine, Division of Nephrology, University Hospital of Würzburg, Würzburg, Germany; [2]Department of Medicine, Division of Nephrology, University of Alabama at Birmingham, Birmingham, AL.*

Renal involvement is an important manifestation of Fabry disease, an X-linked metabolic disorder caused by deficiency of a-galactosidase A activity. Data from the Fabry Registry from 462 untreated adults (121 males and 341 females age ≥18 years as of July 2009) who had 2 or more estimated glomerular filtration rate (eGFR) values over a span of ≥12 months before starting enzyme replacement therapy were included in these analyses. Most males (86 of 121, 71%) had more rapid loss of kidney function than the normal adult population (loss of eGFR > -1 mL/min/1.73m$^2$/year), whereas fewer females (133 of 341, 39%) had rapid loss of kidney function. Patients with rapid progression had significantly higher mean averaged urinary protein to urinary creatinine ratios (UP/Cr) than patients with slower progression (1.5 versus 0.2 for males; 1.4 versus 0.5 for females; p<0.0001). Patients were grouped into quartiles based on averaged UP/Cr; renal function in males declined more rapidly with higher UP/Cr, with the steepest declines observed in the quartile of males with UP/Cr >1.5 (mean eGFR slope -5.6 mL/min/1.73m$^2$/year, n=30). eGFR slope declined more slowly in females, with the steepest declines observed in the quartile of females with UP/Cr >1.2 (mean eGFR slope -1.3 mL/min/1.73m$^2$/year, n=85). Regression models of eGFR slope indicated that UP/Cr is the most important indicator of renal disease progression in adult Fabry patients. In addition to UP/Cr, lower baseline eGFR levels and age at baseline were associated with faster renal disease progression in female patients. Cardiac and cerebrovascular events were associated with increased UP/Cr in males but not females. Females who had clinical events had more rapid loss of kidney function. We acknowledge the members of the Fabry Registry Renal Outcomes Workgroup, who made important contributions to this work.

**Predictors of Mortality in Clostridium Difficile Infected Hospitalized Patients (Pts)** Venkata A. Suda, Lalathaksha Murthy Kumbar, Ashwini M. Shadakshari, Parampreet S. Ghuman, Sara Asadi, Paul A. Fein, Jyotiprakas Chattopadhyay, Morrell M. Avram. *Avram Division of Nephrology, Long Island College Hospital, Brooklyn, NY.*

There is increasing recognition of the importance of Clostridium Difficile (CDI) infection in hospitalized pts though predictors of mortality with this condition are not well studied. The objective of this study was to investigate the various factors predictive of mortality in pts with CDI. We retrospectively collected demographics, clinical, laboratory and outcome data of 142 pts with CDI. Eighteen percent (n=25) of the pts expired. The pts who expired were older than those who survived (77 vs. 61 years, p<0.0001). Admission albumin was lower (p<0.0001) and peak creatinine (p=0.029) was higher in pts who expired. By univariate logistic analysis, age (p=0.001), presence of hypertension (p=0.047), hypercholesterolemia (p=0.03), cardiovascular disease (CVD) (p=0.001), acute kidney injury (AKI) (p=0.004), hypotension (p=0.09), diuretics treatment (p=0.006), pressor treatment (p<0.0001), aminoglycoside treatment (p=0.034), peak creatinine (p=0.064) were predictors of mortality. By multivariate logistic regression analysis controlling for other variables, serum albumin (odds ratio=0.36, p=0.028), AKI (odds ratio=28.3, p=0.011), pressor treatment (odds ratio=9.39, p=0.001) were significant predictors of mortality.

Predictors of mortality: Multivariate logistic regression analysis

| Variables | Odds Ratio | p |
|---|---|---|
| Age (years) | 1.028 | 0.20 |
| Hypertension (Yes vs. No) | 1.64 | 0.60 |
| Hypercholesterolemia (Yes vs. No) | 1.32 | 0.72 |
| CVD (Yes vs. No) | 1.74 | 0.45 |
| AKI (Yes vs. No) | 28.3 | 0.011 |
| Albumin (g/dL) | 0.36 | 0.028 |
| Aminoglycoside (Yes vs. No) | 2.0 | 0.462 |
| Diuretics (Yes vs. No) | 3.31 | 0.088 |
| Hypotension (Yes vs. No) | 1.065 | 0.93 |
| Pressors (Yes vs. No) | 9.39 | 0.001 |

In conclusion, CDI in hospitalized pts is increasingly becoming a challenge. Low albumin, acute kidney injury and severe hemodynamic instability are significant predictors of mortality in hospitalized pts with CDI. Further studies are needed to address earlier recognition and intervention of these risk factors.

**Screening and Enrolling Children with Vesicoureteral Reflux: Preliminary Data from the RIVUR Trial** Tej K. Mattoo,[1] Myra A. Carpenter,[2] Russell W. Chesney,[3] Marva M. Moxey-Mims.[4] *[1]Children's Hospital of Michigan, Detroit, MI; [2]University of North Carolina, Chapel Hill, NC; [3]University of Tennessee, Memphis, TN; [4]NIDDK/NIH, Bethesda, MD.*

RIVUR is a double-blind placebo-controlled trial of TMP/SMZ prophylaxis in children with vesicoureteral reflux (VUR). Patient enrollment, which started in June 2007, is ongoing at 19 sites in the U.S. Through May 2010, 472 patients (93% female) with a mean age of 20 months (SD: 18; range: 2-71) have been randomized in the study.

Data collection on patient screening started later. Since November 2007, 7134 patients have been screened for the study, of which 365 (5%) have been randomized; 107 additional enrolled patients are not represented on screening logs due to incomplete data collection. The primary referral sources for patient screening are primary care practices (27%), radiology (25%) and urology (24%). Of 6769 patients screened but not randomized, 6245 (92%) were ineligible and 524 (8%) were eligible but did not consent for the study. Failure to meet RIVUR urinary tract infection (UTI) criteria (53%) and/or VUR criteria (67%) were the predominant reasons for ineligibility. Only 15% of screened patients had a non-UTI/VCUG-related reason for exclusion. Among those ineligible for VUR reasons, 56% had no VUR, 41% did not have a VCUG result available, 2% had VUR grade V and 2% failed to meet a VCUG timing criterion. In conclusion, RIVUR investigators are successfully identifying children with VUR and enrolling them following a first or second UTI. Preliminary data through May 2010 indicate that an average of 19.5 children have been screened for each patient recruited, which highlights the challenges faced in patient recruitment for the RIVUR study.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1848**

**Clostridium Difficile Infection in Hospitalized Patients with Chronic Kidney Disease** Muhammad Ali,[1] Nilay Kumar,[1] Gagan Kumar,[1] Shahryar Ahmad,[1] Khurram Nazeer.[2] *[1]MCW, Milwaukee, WI; [2]Bluegrass Kidney, Louisville, KY.*

**Purpose of the Study**: Risk factors for Clostridium Difficile Associated Diarrhea(CDAD) include antibiotic use, age & gastric acid suppression. Studies have indicated End Stage Renal Disease(ESRD) as a risk factor for CDAD. Purpose of our study was to determine association of CDAD with chronic kidney disease(CKD) & ESRD in hospitalized patients using a national database & to determine impact of CDAD on mortality in hospitalized patients with CKD and ESRD.

**Methods**: Retrospective cross sectional design was utilized to analyze the Nationwide Inpatient Sample from year 2007. Patients were identified using ICD-9-CM codes. Patients with a discharge diagnosis of C Diff formed the controls & patients with a discharge diagnosis of either CKD or ESRD along with C Diff formed the cases. Chi Square and Logistic Regression were used for comparing variables & calculating Odds ratios. $\alpha$ was set at 0.05.

**Results**: C. Diff infection was more prevalent in hospitalized patients with CKD (2.2% vs 0.83%) & ESRD (3% vs 0.83%) as compared to controls. Patients with C. Diff & CKD were more likely to fall in the >65 age group (84% vs 67%), whereas C. Diff & ESRD patients were less likely to fall in the >65 age group (59% vs 67%) as compared to controls. Patients with C Diff & ESRD were more likely to be admitted at a teaching institution (56% vs 47% for controls and CKD). Patients with CKD and ESRD were more likely to be males (49% vs 40%). Mortality was higher in C Diff patients with CKD (12% vs 8.2%) and ESRD (16% vs 8.3%). Patients with C Diff and CKD were more likely to die as compared to controls (OR 1.30, 95% CI 1.20-1.41). Hospitalized patients with C Diff and ESRD had higher odds of dying (OR 2.36,95% CI 2.12-2.63) vs. the controls.

**Conclusion**: The prevalence of C Diff is higher in hospitalized patient with CKD and ESRD. Among hospitalized patients who develop C Diff, the odds of dying are higher in patients with CKD and ESRD. Further studies need to be conducted looking at CKD and ESRD as independent risk factors for developing C Diff infection. We recommend vigilance in diagnosis & treatment of C Diff infection among hospitalized patients with CKD and ESRD.

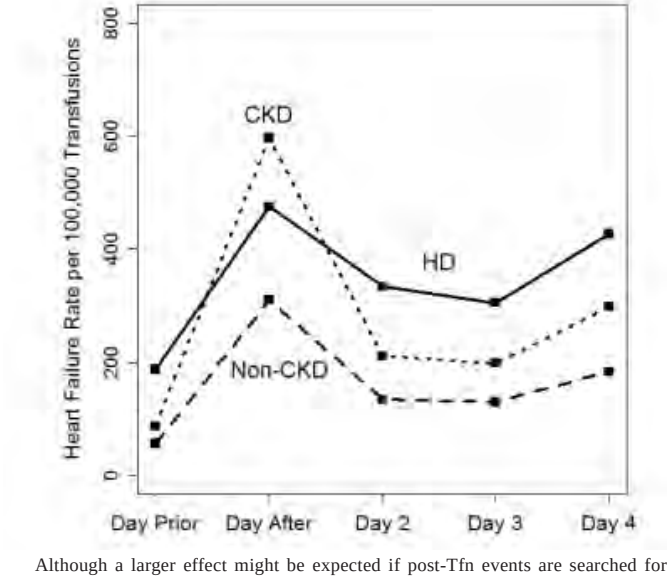
**Transfusion-Related Complications in Kidney Patients** David T. Gilbertson, Haifeng Guo, Tom Arneson, Stephan C. Dunning, Robert N. Foley, Allan J. Collins. *Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN.*

Transfusion (Tfn) avoidance is a major indication for ESA treatment in the dialysis population due to risk of iron overload, immunologic sensitization, fluid overload and hyperkalemia. Little is known about Tfn patterns in the CKD population and the types of complications that may occur beyond blood-borne infections. These data may be important when considering the potential risks and benefits of anemia treatment in the kidney disease population.

Using Medicare data on dialysis, CKD not on dialysis, and non-CKD patients, we searched for outpatient (OP) Tfns and possible adverse events during 2004-2008, including all-cause hospitalizations or ER visits, and cause-specific hospitalizations and ER visits for heart failure, fluid overload, pulmonary edema, and hyperkalemia.

During 2004-2008, there were 45,879, 8,049, and 65,360 OP Tfn events in dialysis, CKD non-dialysis, and non-CKD patients, respectively. The figure shows the heart failure hospitalization or ER visit rate per 100,000 outpatient Tfns the day prior, and days following the Tfn, for dialysis, CKD, and non-CKD Medicare pts. Lower rates of heart failure in HD pts compared to CKD pts may reflect the ongoing use of chronic dialysis in the HD population vs. diuretic use in the CKD population. Other complications also showed patterns of increased risk the day following the Tfn event.



Although a larger effect might be expected if post-Tfn events are searched for immediately after the Tfn, the temporal sequence of Tfns and presumed outcomes on the same day is not available. Thus, the results are most likely a conservative estimate of actual risk. Possible increased risk of adverse events following Tfn suggests that anemia treatment in CKD patients should take into consideration the risks and benefits of Tfns vs. other forms of anemia management.

**Resistive Index Predicts Histological Damage and eGFR in CKD Patients**
Kikuno Hanamura, Akihiro Tojo, Satoshi Kinugasa, Kensuke Asaba, Toshiro Fujita. *Division of Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan.*

**Purpose:** We evaluated whether renal function and histological changes could be predicted non-invasively by ultrasonography in chronic kidney disease (CKD) patients. **Method:** 202 CKD patients diagnosed with renal biopsy from 1999 to 2010 in our department were examined, including 81 patients with IgA nephropathy, 26 with FSGS, 24 with membranous nephropathy, 24 with MCNS, and 10 with diabetic nephropathy. Renal length, cortex area, volume, and resistive index were measured with ultrasonography. Renal biopsy samples were evaluated for the severity of glomerulosclerosis, arteriosclerosis and tubulointerstitial damages, using glomerulosclerosis (GS) score, arteriosclerosis (AS) score and tubulointerstitial damage (TI) score, a five-level scoring system. **Results:** Renal length, cortex area, and volume did not change until CKD stage 5, showing poor correlation with morphological scores. Renal function correlated better with TI score (R= -0.607 p<0.01) than with GS (R= -0.521 p<0.01) and AS scores (R= -0.528 p<0.01). Resistive index by Doppler ultrasonography showed a significant correlation with renal function (R= -0.501 p<0.01), and it increased with progression of CKD stage. Resistive index also correlated better with TI score than with GS and AS scores. **Conclusion:** Resistive index by Doppler ultrasonography could be a useful non-invasive tool to predict renal function and histological lesions in accordance with CKD stage.

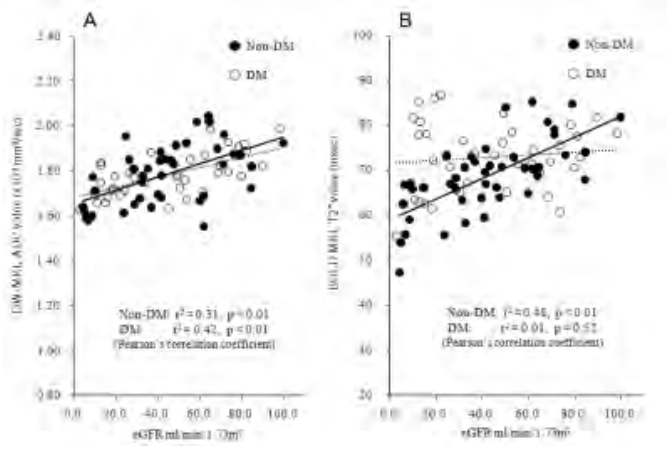
**Different Contribution Ratio of Hypoxia to Renal Insufficiency, Comparison between Diabetic and Non-Diabetic Nephropathy**
Tsutomu Inoue,[1] Eito Kozawa,[2] Hirokazu Okada,[1] Kouichi Inukai,[3] Tsuneo Takenaka,[1] Yusuke Watanabe,[1] Hiromichi Suzuki.[1] *[1]Nephrology, Saitama Medical University, Iruma-gun, Saitama, Japan; [2]Diagnostic Radiology, Saitama Medical University International Medical Center, Hidaka, Saitama, Japan; [3]Endocrinology and Diabetes, Saitama Medical University, Iruma-gun, Saitama, Japan.*

Evaluating the degree of renal parenchymal fibrosis and hypoxia in patients with chronic kidney disease (CKD) has remained challenging. Recent advances in magnetic resonance imaging (MRI), however, have made it possible to visualize these processes in situ. In the present study, we investigated the feasibility of using two different MRI techniques, namely, diffusion-weighted (DW)-MRI and blood oxygen level-dependent (BOLD)-MRI, to evaluate kidney function and reveal renal parenchymal hypoxia and tubulointerstitial fibrosis, respectively.

A total of 84 patients (54 males and 30 females) presenting with CKD, and a control group of 10 healthy volunteers (5 males and 5 females), were recruited. All subjects were subjected to MRI, and laboratory tests were performed. The eGFR was calculated using the modification of diet in renal disease (MDRD) formula.

The decreased eGFR was accompanied by reduced ADC (apparent diffusion coefficients) values of DW-MRI (graph A). BOLD-MRI demonstrated hypoxic conditions, as decreased T2* values, in patients with advanced renal dysfunction in non-diabetic nephropathy patients, but not in patients with diabetic nephropathy (graph B).



Our results demonstrated that eGFR was reflected by the ADC values from DW-MRI, independent of the primary disease. The BOLD-MRI T2* values revealed a hypoxic condition in the kidney associated with advanced renal dysfunction in patients with non-diabetic nephropathy. Functional MRI could contribute to a multilateral assessment of CKD in vivo, non-invasively and repeatedly.

**Factors Associated with Publication of Randomized Controlled Trials Presented at a Nephrology Conference**
Ranjani N. Moorthi,[1] Navdeep Tangri,[2] Martin Wagner,[3] Ahsan Alam.[4] *[1]Indiana University School of Medicine; [2]Tufts Medical Center; [3]University Hospital of Würzburg, Germany; [4]McGill University, Canada.*

Randomized controlled trials (RCTs) remain the gold standard for interventions in medicine; however there are fewer RCTs in Nephrology than in any other subspecialty of Internal Medicine. Given that evidence for many interventions in Nephrology is lacking, it would be important to determine publication rates of RCT data presented at national conferences and the characteristics of studies that are associated with their publication.

Methods: All abstracts submitted to the American Society of Nephrology (ASN) 2005 meeting reporting RCT data were included. Exclusion criteria were interim data and secondary safety endpoint analyses. Univariate logistic regression was used to compare characteristics between published RCTs and those not published.

Results: Seventy three completed RCTs were presented out of 4280 abstracts. Fifty three % of these were published; median time to publication (start date June 2005) was 24 months (IQR 13,36). Oral presentations were published more frequently (OR 3.66, p=0.01) as well as those with stated industry funding (OR 2.92, p=0.03) and larger sample sizes (OR2.1, p=0.01). Blinded RCTs had approximately 4 times the odds of being published. Only 45% of abstracts reported blinding and more than one third did not clearly state a primary outcome.

Conclusions: There were major differences in quality of abstract reporting for RCTs presented at the ASN 2005 meeting. Almost 50% of RCTs were not published up to 5 years later. Performing an RCT is often expensive and difficult, but if well-conducted they enhance the body of evidence needed to care for patients. It is important to identify characteristics associated with non-publication, to help us perform and report our studies better.

Disclosure of Financial Relationships: nothing to disclose

**Are Quarterly Serum Aluminum Levels Useful?**
David N. Djebali, Steven D. Smith, Germaine Z. Chan. *Division of Nephrology, St. Luke's-Roosevelt Hospital Center, New York, NY.*

**Background**: The incidence of abnormal aluminum levels in dialysis patients in prior studies has been reported to be as low as 2.1%. This calls into question the value of quarterly serum aluminum measurement as recommended by the KDOQI guidelines. However, there is concern that drugs such as iron dextrose, which contains small amount of aluminum, may be a cause of aluminum burden in the dialysis population.

**Methods**: We retrospectively analyzed the serum aluminum levels of all patients at our dialysis center in New York City between 01/01/2002 and 12/31/2009. Beginning on 01/01/2009, the intravenous iron supplementation agent used at our center was changed from sodium ferric gluconate to iron sucrose. 122 patients received 100mg iron sucrose load (1630 µg aluminum per load) in 2009.

**Results:** The table 1 illustrates the total number of aluminum levels checked per year and the number (percentage) of abnormal levels in 589 patients. Of the total 5674 aluminum levels, 32 levels (0.5%) were equal or above 20 µg/L in 25 patients.

These abnormal levels were sustained - 2 and 3 consecutive levels - for 4 and 1 patients respectively. The other elevated levels were isolated.

After a review of the medical records of the 25 patients, we identified a cause in only two patients (aluminum antacids).

None of the 122 patients (53.7 % of our patient population in 2009) who received iron sucrose load had an elevated aluminum level.

**Conclusion**: Our data show that the number of abnormal serum aluminum levels is exceedingly low. The routine quarterly measurement of serum aluminum level may no longer be necessary.

Results of the study

| Year | Number of Aluminum levels | Number of abnormal Aluminum level (%) |
|---|---|---|
| 2002 | 506 | 9 (1.7%) |
| 2003 | 780 | 6 (0.7%) |
| 2004 | 748 | 6 (0.8%) |
| 2005 | 577 | 4 (0.6%) |
| 2006 | 778 | 0 |
| 2007 | 766 | 6 (0.7%) |
| 2008 | 766 | 1 (0.1%) |
| 2009 | 753 | 0 |

## F-PO1854

### Declining Mortality in Children with Diarrhea Associated Hemolytic Uremic Syndrome – A Single Centre Experience

Melissa Morgunov, Lorraine A. Hamiwka, Susan M. Samuel, Silviu Grisaru. *Pediatric Nephrology, Alberta Children's Hospital, University of Calgary, Calgary, AB, Canada.*

Diarrhea associated hemolytic uremic syndrome (D+HUS) is a leading cause of childhood acute renal failure and is frequently associated with severe morbidity involving other systems. Reported mortality rates associated with this disease declined over the years since it was first described currently ranging from 2.5% to 5%. Central nervous system (CNS) involvement is reported in approximately 30% of cases and is considered the leading cause of mortality. Our objective was to define the mortality rate and outcome of CNS complications associated with D+HUS in our centre.

We identified and confirmed by chart review 123 cases of childhood D+HUS managed at our centre from April 1994 onwards. During this period, patients with D+HUS were offered only supportive therapy including primarily peritoneal dialysis.

There was one death recorded among the 123 reviewed cases ( mortality rate 0.8%) while in a previously published cohort from our centre describing 104 children with HUS presenting between 1980 and 1992 there were 4 deaths (mortality rate 3.8%). Among the reviewed 123 cases of D+HUS, 17(14%) had CNS complications ranging from severe lethargy to seizures, stroke and coma. Five of these cases had a more severe course requiring intubation and admission to the intensive care unit; two developed hemiparesis. All five had evidence of diffuse brain lesions resembling micro-infarcts, particularly in the basal ganglia. Sixteen of these patients including the severe cases eventually recovered with favorable neurological outcomes. The single case of death occurred in a patient who had seizures however the death was attributed to bowel necrosis and sepsis.

We conclude that despite the lack of specific therapy for D+HUS, in our centre the mortality has declined over the last 30 years to the lowest rate reported so far. In addition, in our experience CNS complications secondary to D+HUS had good outcomes and were not the major cause of mortality.

### Hemodynamic Factors Associated with Proteinuria in the Chronic Renal Insufficiency Cohort (CRIC) Study Population

Matthew R. Weir,[1] Raymond R. Townsend,[2] Jeffrey C. Fink,[1] Valerie L. Teal,[2] Marshall M. Joffe.[2] *[1]University of Maryland School of Medicine; [2]University of Pennsylvania.*

**Background:** Proteinuria is associated with the risk of adverse renal and cardiovascular outcomes in patients with chronic kidney disease (CKD). Brachial artery blood pressure has been shown to be a determinant of proteinuria. The relationship between proteinuria and measures of vascular stiffness or central aortic pressure is not known.

**Study Design:** Cross-sectional

**Setting and Participants:** Baseline data from the Chronic Renal Insufficiency Cohort (CRIC) Study was analyzed in 2,129 patients with estimated GFR (eGFR) 20-70 ml/min/1.73m2 at study entry.

**Outcomes:** 24 hour log transformed proteinuria among persons with (DM) and without (non-DM) diabetes.

**Measurements:** Baseline characteristics including demographics, body mass index, waistline, weight, fat-free mass, smoking history, use of ACE/ARB, and systolic blood pressure (SBP), diastolic blood pressure (DBP), pulse pressure (PP), along with central measures of vascular stiffness (compliance) including central systolic blood pressure(CSBP), central pulse pressure (CPP), and pulse wave velocity (PWV).

**Methods:** A step-wise multivariate regression model of the log transformed 24 hour urine protein was utilized. The final model included: age, gender, ethnicity, eGFR, smoking, waistline, SBP, PWV and CSBP. Data in the table are described as a beta coefficient.

**Results:** Increasing eGFR was associated with less proteinuria across all participants. Brachial SBP was associated with more proteinuria, especially in non-DM. However, in DM, increasing vascular stiffness (PWV) was associated with more proteinuria in contradistinction to non-DM. CSBP was associated with (p=.053) increased proteinuria in DM, unlike non-DM.

| | Non-DM | DM |
|---|---|---|
| Estimated GFR/10 ml/min/1.73m2 | -.38 /< .0001 | -.38 /< .0001 |
| SBP/10 mmHg | .13 /< .0001 | .11 / .04 |
| PWV/m2 | .02 / NS | .08 /< .0001 |
| CSBP/10 mmHg | .01 / NS | .11 / .053 |

**Conclusions:** In patients with CKD and DM, vascular stiffness and CSBP correlated with the level of proteinuria. This pattern was not evident in non-DM.

### Effect of Renin Angiotensin Aldosterone System Blockade Therapy on Incidence of Contrast Induced Nephropathy

Christin M. Spatz,[1] Apurva Lapsiwala,[1] Amin Parhizgar,[2] Lawand A. Saadulla,[1] Umar Farooq,[1] Nasrollah Ghahramani.[1] *[1]Nephrology, Hershey Medical Center, Penn State, Hershey, PA; [2]Internal Medicine, Hershey Medical Center, Penn State, Hershey, PA.*

BACKGROUND: Contrast induced nephropathy (CIN) is an iatrogenic disorder resulting from exposure to contrast media. The renal hemodynamic and direct cytotoxic effects are evident in its pathogenesis, whereas other mechanisms are still poorly understood. The incidence of CIN ranges between 10 – 50% depending on the presence of risk factors, with CKD being a major risk factor. It is not clear whether medications that block Renin Angiotensin Aldosterone System (RAAS) have any impact on CIN.

METHODS: We performed a retrospective study looking at the incidence of CIN in patients with CKD Stage 3 or 4 (January 1, 2007 – December 31, 2008) who were either on or off RAAS blockade therapy at the time of coronary angiogram. Serum creatinines were followed for five days post procedure.

RESULTS: 398 patients with CKD Stage 3 or 4 had a coronary angiogram between January 1, 2007 and December 31, 2008. 220 patients were excluded due to lack of sufficient follow up data. 178 patients were included in the study. 62 patients (35%) were on ACE Inhibitors, 12 patients (7%) were on ARB and 2 patients (1%) were on combination of ACE Inhibitors and ARB. Mean age 71.3 ± 10.7, estimated GFR 44 ± 11.5 and DM 108 (61%). The 5 day relative risk of acute renal failure with ACE inhibitors was 1.17 (95% CI: 0.57 to 2.42; p=0.66) and 0.50 (95% CI: 0.07 to 3.37; p=0.48) with ARB.

CONCLUSION: Patients treated with RAAS blockade therapy before contrast exposure did not have increased incidence of CIN.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1857

### Effects of Optimized Project of Traditional Chinese Medicine by Differentiation of Symptoms in Treating Chronic Glomerulonephritis in CKD Stage 3: A Randomized Double Blinded Controlled Trials

Yongjun Wang, Ying Lu, Bin Zhu, Xiao Tu, Hongyu Chen. *Department of Nephrology, Guang Xing Hospital, Zhejiang Chinese Medical University, Hangzhou, Zhejiang, China.*

**Objective.** To study the effects and safety of optimized project of traditional chinese medicine(TCM) by differentiation of symptoms in treating primary chronic glomerulonephritis in CKD stage 3 using an randomized double blinded controlled (RCT) method. **Methods.** 96 patients with CKD 3 stage primary glomerulonephritis were randomly assigned to three groups: Patients received TCM (TCM group), 10mg/d benazepril (Ben group), traditional Chinese medicine combined with 10mg/d benazepril (TCMB group). The differentiation of Chinese medicine was divided into four patterns assessed using a TCM measuring scale. eGFR, UAlb/Cr, Hb were measured. The primary endpoint was time to the composite of 50% increased of serum creatinine. **Results:** At week 24, eGFR in TCM group (46.56±1.70ml/min) was increased as compared with Ben group (43.65±1.76ml/min)(P>0.05). eGFR in TCMB group (49.48±1.67ml/min) was higher than TCM group (P>0.05) and Ben group(P<0.05). UAlb/Cr in Ben group(median:0.30 g/gcr)and TCMB group(median:0.26g/gcr) was lower than TCM group(median:0.70g/gcr) (P<0.05). UAlb/Cr on TCMB group was lower than Ben group (P>0.05). Hb in TCM group (127.49±1.21 g/L) was increased significantly compared with Ben(124.00±1.19 g/L)and TCMB group(123.78±1.13 g/L)(P<0.05). The accumulative survive rate in TCMB group was higher than the other 2 groups. Patients with hyperkalemia in TCMB group was more than the other 2 groups(P<0.05). **Conclusion:** This was the first RCT evaluating the effects of TCM in CKD stage 3 patients. TCM can improve eGFR and Hb. TCM integrated with benazepril can improve eGFR and decrease proteinuria significantly as compared with either TCM or Ben group. RCT registration code: ChiCTR-TRC-00000204.

**F-PO1858**

**Osmotic Nephrosis-Like Lesions after Hydroxyethylstarch (HES 130/0,4) Administration: Detection of HES in Renal Tubules by Raman Microscopy** Vincent Vuiblet,[1] Olivier Piot,[2] Alain Wynckel,[1] Tran Nguyen,[2] Michel Manfait,[2] Philippe Birembaut,[3] Philippe Rieu.[1] *[1]Nephrology, University Hospital, Reims, France; [2]UMR 6237, CNRS, Reims, France, Metropolitan; [3]Anatomo-Pathology, University Hospital, Reims, France.*

We observed two patients with persistent impaired renal function after post-ischemic acute renal failure. Renal biopsies of these 2 patients showed osmotic nephrosis-like lesions (ONLS). Hypovolemia and the administration of 3rd generation hydroxyethylstarch (HES 130/0,4) were the only factor we found to explain the ONLS. We therefore tried to identified by Raman microscopy the presence of HES in the kidneys of these two patients.

Methods: Raman spectrum was obtained for the pure commercial solution of HES 130/0,4. Raman spectral images acquired from renal biopsies of both patients and from control renal biopsies (normal kidney, amyloidosis , diabetes, chronic tubulo-interstitial renal disease) were examined to find out the HES spectral "fingerprints". Raman spectral images analysis were performed in a blinded fashion.

Results : Raman signal of HES 130/0.4 showed a characteristic spike at 480 cm-1 which was also found among the spectral images of tubular sections of the kidney with ONLS but not in control renal biopsies.

Discussion: While the renal consequence of the 1st and 2nd generation HES is well known, that of the 3rd generation HES remains controversial. A recent work performed in animal models finds ONLS after injection of 3rd generation HES. Our two observations show that renal impairment and ONLS may also occur in human after 3rd generation HES administration. HES is assumed to be present in empty-appearing intracytoplasmic vacuoles on light microscopy. However, HES deposition in kidney has never been demonstrated.

Conclusion: Our results obtained by Raman microscopy show for the first time that osmotic nephrosis like lesions are associated with the presence of HES in renal tubules.

**F-PO1859**

**Association of Urinary Arsenic Excretion with Albuminuria in a Low Level Arsenic Exposure Population** Ernesto Sabath,[1] Itzel Aviles-Romo,[1] Diana Isabel Montero-Perea,[1] Hebert Hernandez-Montiel,[1] Ivan Perez-Maldonado,[2] Ma. Ludivina Robles-Osorio.[1] *[1]Department of Nephrology, Universidad Autonoma de Queretaro, Queretaro, Mexico; [2]Facultad de Medicina, Universidad Autonoma de San Luis Potosi, San Luis Potosi, Mexico.*

Chronic arsenic toxicity has become a human health threat and several epidemiologic studies had shown that chronic exposure is associated with type 2 diabetes mellitus, peripheral vascular disease and arterial hypertension; however its effects on kidney function have been relatively unexplored. Therefore we evaluate the association of urinary arsenic excretion with renal function measures and urinary protein excretion in a non-endemic arsenic exposure population.

We enrolled 180 adults with GFR >60 ml/min living in Central Mexico, 38% with type 2 diabetes. Age of patients at baseline ranged from 26 to 73 years and BMI was 28.5 ± 5.2. Spot urine samples for arsenic analysis were collected in arsenic free-containers and there was no difference in the urinary arsenic excretion between diabetic (18.94 µg/L) and non-diabetic (23.5 µg/L) persons. Micro or macroalbuminuria was found in 50% of the diabetic patients and mean HbA1c was 9.1% (4.8-14%). Univariate correlations analyzed with Pearson coefficient showed that urinary arsenic excretion was directly correlated with urinary albumin excretion in the diabetic ($r=0.28$ $p= <0.05$) but not in the non-diabetic ($r=0.05$) population. There was no correlation between urinary arsenic excretion and age, sex, educational status, uric acid, HbA1c and calculated GFR. Univariate analysis showed urinary arsenic excretion as independent risk factor for urinary albumin excretion in diabetic population ($p=<0.05$). Currently we are measuring α1-microglobulin levels as a marker of tubular injury to look for correlation with arsenic excretion in this population.

In conclusion this findings show no evidence of increased risk of diabetes in this population but our results suggests that even low urinary arsenic levels may be considered as a risk factor for urinary albumin excretion in diabetic persons with low level arsenic exposure.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1860**

**Prevalence and Magnitude of Nephrotoxicity by Iron Chelator Deferasirox; a Single Center Experience** Minako Shimazaki, Masahiko Yazawa, Yugo Shibagaki, Kenjiro Kimura. *Division of Nephrology and Hypertension, St. Marianna University Hospital, Kawasaki, Kanagawa, Japan.*

[Background] Deferasirox (DFX) is a novel oral iron chelator used to treat iron overload. Pre-marketing clinical trials revealed a few cases of kidney dysfunction and electrolyte disturbance but its prevalence in practice was not well studied. We recently experienced acute kidney injury with Fanconi syndrome in a patient receiving DFX, which resolved completely after drug withdrawal.

[Purpose and Method] To elucidate the prevalence and magnitude of nephrotoxicity induced by DFX, we reviewed charts of our prevalent patients who were receiving DFX and without significant kidney dysfunction [serum creatinine (SCr) above 2 mg/dL] before taking DFX in the outpatient clinic at the St. Marianna University Hospital. We retrospectively analyzed renal function, urine dipstick in these patients.

[Result] All the 10 prevalent patients who received DFX and without severe kidney dysfunction agreed to the consent. Average age was 64.9±20.4 year-old, 6 were men. Average period of taking DFX was 7.9 months (1.5-14), and 3 had to discontinue because of rising SCr during observation. Absolute elevation of SCr level after taking DFX until the last clinic visits during observation was not significant (0.16±0.23 mg/dL, P=0.08), but absolute elevation of SCr after taking DFX to maximal level of Scr was significant (0.26±0.15, P<0.01), indicating transient reduction of kidney function. Urine dipstick test was obtained in 4 out of 10 study patients. Urinary protein and/or urinary glucose turned positive in all the 4 patients after taking DFX. One patient was diagnosed as Fanconi syndrome after additional tests (presence of normal anion gap acidosis, hypophosphatemia and hypouricemia due to excess urinary excretion). In all the 3 patients who discontinued DFX during observation period, kidney function improved and urine protein and glucose disappeared immediately after discontinuation.

[Conclusion] Although mostly transient and mild, deferasirox-induced nephrotoxicity was prevalent. Careful monitoring of renal function, urinalysis, and electrolytes are necessary.

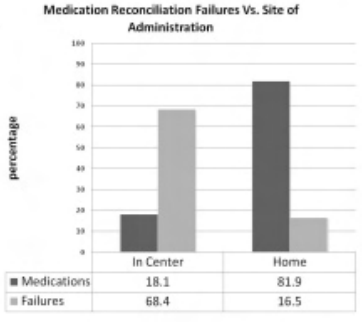
**F-PO1861**

**Medication Reconciliation in the End Stage Renal Disease Population (MrESRD)** Vijay Lapsia,[1] Ronald I. Shorr.[2] *[1]Medicine, University of Florida, Gainesville; [2]Geriatrics, Malcom Randall VAMC, Gainesville, FL.*

Medication reconciliation, comparing a patient's medication (RX) orders to RX a patient is taking, is recommended at every transition of care to reduce errors. Because they also receive in-center RX (ICRX), it is plausible that patients with End Stage Renal Disease (ESRD) on hemodialysis are at especially high risk for reconciliation failure, but this has not been well studied. **Methods**: Retrospective chart review of 75 patients with ESRD consecutively admitted at a University Hospital. Four sources of RX were ascertained: 1) home RX list, 2) hospital admission RX orders, 3) hospital discharge RX list, and 4) RX list maintained by the chronic dialysis unit. The RX list obtained from the chronic dialysis unit was presumed to be the "gold standard" for the purposes of reconciliation. If a RX was present *either* in the home RX list, hospital admission or discharge orders, *and* the chronic

dialysis unit RX list the RX was assumed to be reconciled. **Results:** The 75 patients (age 57 ± 13.8 yrs) were referred from 18 chronic dialysis units. Patient charactersitics are shown in figure. Patients were prescribed 11.3 ± 3.4 RX, of which 2 ± 1 were ICRX. Of these 75 patients, only 17 (22.7%) had perfect reconciliation. Reconciliation failure was most common in ICRX (Erythropoietin stimulating agents and vitamin D analogues) – see figure. Preliminary analysis revealed that neither patient demographics, dialysis unit, Medicare status, time of admission, elective admission, provider history, presence of dialysis records in the hospital chart, previous admission or type of dialysis were associated with reconciliation. **Conclusion:** Medication reconciliation among ESRD patients admitted to hospitals is poor, especially among medications administered in center. The health outcomes of poor medication reconciliation among hospitalized patients with ESRD are not yet known.

| Patient Characteristic | No | (%) |
|---|---|---|
| Female - Sex | 35 | (46.7) |
| Black - Race | 42 | (56) |
| Medicare Status | 47 | (62.3) |
| Dialysis records in hospital chart | 6 | (8) |
| Provider history | 18 | (24) |
| Elective Admission | 15 | (20) |
| Admission time (business hours) | 41 | (54.7) |
| Previous Adm | 53 | (70.7) |



Disclosure of Financial Relationships: nothing to disclose

**F-PO1862**

**Colestilan (MCI-196), a New Calcium-Free Phosphate Binder, Is Safe and Effective in Stage 5 CKD Dialysis Patients: Phase 3, Randomized, Double-Blind (DB), Placebo (PBO)-Controlled, Multicenter Study** Joachim E. Hertel,[1] Shigekazu Nakajima,[2] Hiroyuki Sano,[2] Forunato F. Senatore,[3] Dawn Buchanan.[3] *[1]Nephrology Associates, PC, Augusta, GA; [2]Mitsubishi Tanabe Pharma Corp., Tokyo, Japan; [3]Mitsubishi Tanabe Pharma Development America, Inc., Warren, NJ.*

**Objective**: Demonstrate superiority of colestilan (COL), a noncalcium-based, anion exchange resin phosphate (P) binder, over PBO in serum P control in stage 5 chronic kidney disease (CKD) pts on dialysis. Secondary measures: LDL-C, parathyroid hormone (PTH), calcium (Ca), Ca x P product, A1C, and safety/tolerability of COL.

**Methods:** After a 1-5 wk P-binder washout, pts received open-label (OL) COL (3-15 g/d; wkly flexible dose-titration to target P 3.5-5.5 mg/dL). After 12 wks, pts were randomized to COL or PBO for a 4-wk DB withdrawal period.

**Results:** Primary analysis demonstrated a statistically significant difference between COL (n=85) and PBO (n=83) in mean P of –1.01 mg/dL from wks 12 to 16 (or LOCF; *P*<.001). Statistically significant reductions were observed in P from baseline (wk 0) to wk 12 of –1.54 mg/dL with COL (*P*<.001). Pts with a baseline P ≥7.5 mg/dL (mean 8.76 mg/dL) showed a mean decrease of –2.41 mg/dL. During the OL phase, COL reduced mean LDL-C by 30.1% and mean A1C by –0.91% in pts with a baseline A1C ≥7% (mean 8.5%). Compared with PBO, COL significantly controlled LDL-C (mean difference, –51.9 mg/dL, *P*<.001), Ca x P (–7.91 mg/dL, *P*<.001), PTH (–66.6 pg/mL, *P*=.014), and A1C (mean difference, –0.28%; *P*=.002) with no difference in Ca (0.13 mg/dL, *P*=NS). Most frequently reported treatment-emergent AEs (%): during OL phase included nausea (9), diarrhea (9), vomiting (7.8), and constipation (6.1) and during DB phase (COL and PBO groups, respectively) were nausea (4.7 vs 0), diarrhea (3.5 vs 3.6), and vomiting (3.5 vs 0). Of 3 pts in the COL group who reported GI bleeds, 2 had a previous history.

**Conclusions:** COL was generally safe, well tolerated, and demonstrated superior efficacy versus PBO in P control in stage 5 CKD pts on dialysis with no impact on Ca levels. COL also demonstrated clinically relevant reductions from baseline in Ca x P and significantly reduced LDL-C and A1C.

**Patient and Family Engagement in Informed Decision-Making about Renal Replacement Therapy (RRT) Initiation** Johanna Sheu,[1] Patti Ephraim,[1] Raquel Greer,[1] Tanjala S. Purnell,[1] Neil R. Powe,[2] Hamid Rabb,[1] Deidra C. Crews,[1] Bernard G. Jaar,[1] L. Ebony Boulware.[1] *[1]Johns Hopkins Medical Institutions; [2]University of California San Francisco.*

Background: Patient and family engagement in informed decision-making about initiating RRT is poorly described.

Methods: To develop a culturally-sensitive intervention to improve decision-making about RRT initiation, we performed 13 focus groups (optimal size=7-10) of patients with ESRD and their family members to elicit their prior experiences with RRT decisions. Patient and family groups (held separately) were stratified by race (African American (AA) or non-African American (non-AA)) and current RRT modality. We asked groups questions to assess: a) how sick patients were when they [or their family members] first learned about patients' initial RRT modality, b) if they had enough time to choose among modalities, c) if they learned about other modalities, and d) if they understood patients' initial modality prior to initiation.

Results: Patient and family groups (N=50 and 43) had experiences with initiating hemodialysis (HD)- (7 and 7 AA; 8 and 8 non-AA), peritoneal dialysis- (9 and 7 AA; 4 and 3 non-AA), and transplant (TP)- (11 and 9 AA; 11 and 11 non-AA, respectively). Over 1,400 statements were made during group sessions. Many patients in all groups initiated RRT on HD. Patients were often very sick at the time of RRT initiation. Both patients and families felt there was "not enough time to make a decision" about what form of RRT to initiate. They also often reported they "did not know about or weren't given another option or choice" about alternative treatment options prior to initiation or felt "rushed into" HD. Many patients who had received TP reported learning about TP while on HD, during which "there was more time to make decisions". Group discussions were similar among AA and non-AA groups.

Conclusions: Sickness, lack of time, and poor knowledge of various modalities at the initiation of RRT may limit patients' ability to make informed decisions regarding treatment options. Better patient education could improve patients' access to optimal therapies, such as early transplant.

**F-PO1864**

**The Effects of Diet and Sodium Intake on Racial Differences in Plasma Renin Activity: Results from the Dietary Approaches To Stop Hypertension (DASH)-Sodium Trial** Sharon Turban,[1] Edgar R. Miller,[2] Mark Woodward,[3, 2] Lawrence J. Appel.[2] *[1]Nephrology, Johns Hopkins University, Baltimore, MD; [2]Internal Medicine and Epidemiology, Johns Hopkins University, Baltimore, MD; [3]Epidemiology and Biostatistics, University of Sydney, Australia.*

Blacks typically have lower plasma renin activity (PRA) than whites. The mechanisms for this racial difference are unknown. The lower potassium (K) intake of blacks may at least partially explain this racial difference in PRA. However, the effects of dietary K intake on PRA have been inconsistent, and data on whether changes in diet ameliorate black-white differences in PRA are sparse. We analyzed data from the DASH-Sodium (Na) randomized, controlled feeding trial (N=412) to determine if type of diet and/or sodium intake affects racial differences in PRA. Participants were randomized to either a control (1.7 g K/2100kcal/d) or DASH (4.1 g K/2100kcal/d) diet. Within each diet, participants received 3 levels of Na intake in random order for 30 days each.

Median plasma renin activity (PRA): ng/mL/hr in white and black participants on the control and DASH diets, by sodium intake

| | Intervention | | |
|---|---|---|---|
| **Control Diet** | **High Na** | **Medium Na** | **Low Na** |
| **White** | 0.58 | 0.66 | 0.98 |
| **Black** | 0.24 | 0.26 | 0.56 |
| ***p* -value*** | <0.0001 | 0.001 | 0.175 |
| | | | |
| **DASH Diet** | | | |
| **White** | 0.66 | 0.84 | 1.15 |
| **Black** | 0.36 | 0.47 | 0.60 |
| ***p* -value*** | 0.001 | 0.003 | 0.015 |

**p* -value for white-black difference, using log transformation, and adjusted for age, sex, caloric intake, baseline PRA, and clinical site

For both types of diet and at each Na level, blacks had lower PRA than whites (adjusted P value was significant in each diet-Na combination except the low Na, control diet). In both diets and in both blacks and whites, PRA increased progressively as sodium intake decreased and with the DASH diet compared to the control diet. In conclusion, racial differences in PRA are present even when individuals are on the same diets. Hence, differences in dietary intake are unlikely to be the sole cause for racial differences in PRA.

**F-PO1865**

**How Long Should We Monitor the Patients for Bleeding after Percutaneous Renal Biopsy?** Jae-Yoon Park, Seong-Woo Lee, Hajeong Lee, Hayne C. Park, Ho Seok Koo, Dong Ki Kim, Kook-Hwan Oh, Kwon Wook Joo, Yon Su Kim, Curie Ahn, Jin Suk Han, Suhnggwon Kim. *Internal Medicine, Seoul National University College of Medicine, Seoul, Korea.*

Percutaneous renal biopsy (PRB) may be complicated by serious bleeding. Overnight observation after renal biopsy is standard strategy for the safety. Although it was recently reported that outpatient observation is safe, appropriate observation time after the renal biopsy is still in debate. We evaluated prospectively the incidence, onset time and risk factors of hemorrhagic complications to determine the optimal duration of observation after PRB.

We enrolled 100 patients underwent renal biopsy for 6 months using a standard strategy. The biopsy was performed by two experienced nephrologists using biopsy gun under real-time ultrasound guidance. Serial color Doppler ultrasound was done immediately, 8 hours, 24 hours and 1 week after the PRB. Minor complication was defined as gross hematuria and/or sonographically detectable perinephric hematoma, and major complication as bleeding that needed transfusion or invasive interventions.

The 32 patients experienced hemorrhagic complications (32.0%, 10 with gross hematuria, 26 with hematoma, and 4 with both), and 1 major complication occurred 3 days after PRB. Baseline serum creatinine of the patient with major complication was 6.0 mg/dL. Gross hematuria was observed in 4 patients (40.0 %) within 8 hours after PRB, in 6 (60.0 %) between 8 and 24 hours. Hematoma was detected in 19 patients (73.1 %) within 8

hours, in 4 (15.4 %) between 8 and 24 hours, and in 3 (11.5 %) after the discharge. Serum creatinine and BMI were higher in complication group ($p < 0.05$). Number of needle passes, blood pressure, and degree of edema and proteinuria were not related to complication. In multivariate analysis, serum creatinine was the only significant risk factor of complication ($p = 0.007$). Hemorrhagic complications developed in 9 patients (28.1%) between 8 and 24 hours after PRB, all of which were minor.

The 8 hours' observation time after renal biopsy may be appropriate to the stable patients with normal creatinine. Larger scale safety study and analysis of cost-effectiveness should be made.

### F-PO1866

**The UK Registry of Rare Renal Disease (RaDaR) Enables Research Studies on a National Scale** Hugh J. Mccarthy,[1] David Ansell,[2] Charles Tomson,[3] Moin Saleem.[1] *[1]Academic Renal Unit, University of Bristol, Bristol, United Kingdom; [2]UK Renal Registry, Bristol, United Kingdom; [3]Nephrology, Southmead Hospital, Bristol, United Kingdom.*

Objectives: In 2009 all member states of the European Union agreed to improve health care in rare disease.

Political backing was mirrored by financial support from the Medical Research Council's patient-cohort-initiatives, funding the development of this registry (RaDaR).

Methods: Administrative infrastructure has been provided by the UK Renal Registry - a well established registry of all patients in the UK with end stage renal disease.

RaDaR is governed by the Renal Association and backed by the UK renal community. It is operated by a RaDaR committee. Disease Specific Working Groups (DSWG), utilizing collaborations, provide research into multiple aspects of specific diseases including diagnostic, genetic, biomarker development and therapy.

Results: Two pilot projects into MembranoProliferative GlomeruloNephritis and Steroid Resistant Nephrotic Syndrome have commenced, with recruitment expanding rapidly. Clinical datasets for the website have been developed by the DSWGs in collaboration with RaDaR. Local teams in the collaborating centres populate those datasets, including histology which will be analysed by a central pathology steering group. The information collected is owned by RaDaR and given to the DSWG in link-anonymised form. Additional data that is generated by the DSWG following analysis will be returned to RaDaR at the end of the study.

Conclusions: This project illustrates a comprehensive model for study, management and dissemination of information for rare diseases on a National basis, overcoming governance, data protection and IT hurdles in a coordinated strategy.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1867

**Quality of Evidence Informing Patients' Choice of Renal Replacement Modality (RRM)** Priscilla Auguste,[1] Raquel Greer,[1] Patti Ephraim,[1] Johanna Sheu,[1] Deidra C. Crews,[1] Tanjala S. Purnell,[1] Temitope Olufade,[1] Julio Lamprea,[1] Neil R. Powe,[1] Hamid Rabb,[1] Bernard G. Jaar,[1] L. Ebony Boulware.[1] *[1]Johns Hopkins Medical Institutions; [2]University of California, San Francisco.*

Background: Patients and their physicians are encouraged to engage in informed decision-making regarding patients' RRM choice, but the quality of evidence available to inform patients' decisions is unknown.

Methods: To develop an intervention to improve decision-making about RRM choice, we identified data from national registries and systematically reviewed studies (English-language, published after 1987) to summarize evidence on clinical outcomes with different RRMs. Using modified Grading of Recommendations Assessment, Development and Evaluation (GRADE) Working Group criteria, we assessed evidence quality ("very low" (e.g. case series), "low" (e.g. cross-sectional or pre-post observational studies), "medium" (e.g. longitudinal cohort studies or registry data), or "high" (e.g. randomized controlled trials (RCTs))) across 12 domains of outcomes previously identified by patients as important to RRM decisions.

Results: Registries provided evidence on 2 domains (8 outcomes). From 3,384 possibly relevant PubMed abstracts, 105 studies provided evidence on 10 domains (53 outcomes). (Table) There were a few (n=7) longitudinal cohort studies. Most (n=98) studies had qualitative, case-series, cross-sectional, or pre-post designs. There were no RCTs. Most (n=72) studies compared outcomes between hemodialysis (HD) versus peritoneal dialysis (PD) while fewer (n=21) compared HD versus transplant or PD versus transplant (n=3). The rigor of the design/methods/analysis was low across studies included in most domains.

Conclusion: There is little high-quality evidence to inform patients' RRM choice. Improved research is needed.

**Table.** Quality of evidence identified to inform decisions on RRM choice

| Domains of clinical outcomes relevant to decision-making | Studies (N) | Relevant Outcomes (N) | GRADE Quality Range |
|---|---|---|---|
| Mortality (e.g. 1-year, 5-year, 10-year) | Registry | 3 | Medium |
| Morbidity (e.g. infection, hospitalization) | Registry | 5 | Medium |
| Quality of Life | 15 | 4 | Very Low to Medium |
| Cognitive Function (e.g. attention and concentration) | 11 | 4 | Very Low to Low |
| Mental Health (e.g. depression and anxiety) | 20 | 6 | Low to Medium |
| Physical Function (e.g. limitations and activity level) | 20 | 6 | Very Low to Low |
| Fertility (e.g. conception, births) | 6 | 7 | Very Low |
| Sexual Function (e.g. libido, erectile dysfunction) | 17 | 13 | Very Low to Low |
| Work (e.g. employment) | 12 | 4 | Very Low to Low |
| Symptoms (e.g. pain, cramping) | 39 | 8 | Very Low to Low |
| Body Image | 9 | 2 | Very Low to Medium |
| Freedom | 6 | 1 | Very Low to Low |

### F-PO1868

**TNFα-Mediated Endocytosis of Nephrin** Magdalena Woznowski,[1] Dennis Sohn,[2] Ivo Quack,[1] Eva Koenigshausen,[1] Sebastian A. Potthoff,[1] Lars C. Rump,[1] Lorenz Sellin.[1] *[1]Department for Nephrology, University Hospital Duesseldorf, Duesseldorf, Germany; [2]Institute for Molecular Radiooncology, University Duesseldorf, Duesseldorf, Germany.*

**Introduction**

Podocytes are highly differentiated cells that form interdigitating foot processes. Podocyte damage leads to foot process retraction, disruption of the slit diaphragm and proteinuria. Human acquired glomerulopathies, such as IgA nephropathy, diabetic nephropathy, FSGS and other inflammatory glomerular diseases are associated with TNF-α elevation. Recent advances have revealed crucial roles of slit diaphragm-associated proteins, including nephrin, podocin and β-arrestin2. β-arrestin2 interaction was shown to induce nephrin endocytosis and is believed to cause thereby proteinuria. In addition, p38 MAPK is known to play a critical role in mediating podocyte injury. Therefore we investigated the influence of TNF-α on nephrin endocytosis and the involvement of p38.

**Methods**

Cells expressing nephrin and β-arrestin2 were stimulated with TNF-α. After cell lysis, co-immunoprecipitation with subsequent western blot analysis was performed. For the inhibitor studies, cells were treated with the p38 inhibitor SB202190. siRNA was used for knockdown of p38. For the endocytosis assay, cells expressing nephrin and β-arrestin2 were stimulated with TNF-α and incubated with biotin before cell lysis.

**Results**

The interaction of nephrin with β-arrestin2 is markedly enhanced through TNF–α stimulation. Incubation with SB 202190 attenuates the TNF-α mediated enhancement of the interaction between nephrin and β-arrestin2. Podocytes stimulated with TNF-α present an increased p38 phosphorylation. p38-knockdown by siRNA attenuates also the interaction of nephrin with β-arrestin2. Furthermore, p38 is shown to interact with nephrin and β-arrestin2. The most impressive finding is the TNF-α mediated enhancement of nephrin endocytosis through the interaction between nephrin and β-arrestin2.

**Conclusion**

TNF-α is shown to enhance nephrin endocytosis through increased interaction between nephrin and β-arrestin2. p38 phosphorylation is hereby of crucial importance. It is conceivable that this presents a molecular mechanism of TNF-α associated acquired proteinuria.

### F-PO1869

**Nephrin and Dynamin Share Functions in the Process of Glucose Stimulated Insulin Release** Jongmin Jeon,[1] Robier A. Aguillon Prada,[1,2] Christian Faul,[2] Jochen Reiser,[2] Camillo Ricordi,[1] Peter H. Mundel,[3] Alessia Fornoni.[1,2] *[1]Diabetes Research Institute, University of Miami Miller School of Medicine, Miami, FL; [2]Medicine/Nephrology, University of Miami Miller School of Medicine, Miami, FL; [3]Medicine, Massachusetts General Hospital, Charlestown, MA.*

We have demonstrated an important function of nephrin in glucose stimulated insulin secretion. Nephrin undergoes endocytosis upon glucose stimulation and modulates actin cytoskeleton remodeling in pancreatic beta cells. Actin mobilization is dependent on guanosine triphosphatases (GTPase) such as dynamin, which is stimulated by glucose and is functionally coupled to insulin granule exocytosis. Therefore, we tested the hypothesis that nephrin and dynamin are functionally related.

Overexpression of wild type dynamin (WTD) in MIN6 cells caused increased glucose stimulated insulin release. This positive dynamin effect on insulin secretion was prevented by the down-regulation of nephrin expression via siRNA to an extent similar to the one observed when a dominant-negative dynamin mutant (K44A) was utilized. Furthermore, dynamin regulated glucose-induced nephrin trafficking from the plasma membrane to the cytoplasm. When GFP-nephrin transfected MIN6 cells were infected with K44A, nephrin remained localized at the cell surface despite glucose or protamine sulphate stimulation, suggesting that the GTPase activity of dynamin is essential to promote nephrin relocation from the plasma membrane into the cytoplasm. On the contrary, when MIN6 cells were

infected with WTD, nephrin trafficking from the cell surface into the cell was not impaired. Despite such a functional nephrin-dynamin interaction, coimmunoprecipitation experiments did not reveal a physical interaction between both proteins.

In summary, we demonstrate that nephrin is an important downstream effector of dynamin in the process of glucose stimulated insulin release. Our findings may shed new light on the pathway responsible for the regulated targeting of vesicles to the plasma membrane in pancreatic beta cells and may allow for the identification of new therapeutic targets for the augmentation of glucose stimulated insulin secretion.

## F-PO1870

**GLEPP1 Interacts with src Family Kinases, Nephrin and Podocin** Eva Koenigshausen, Sarah Grabowski, Laura Gerbaulet, Ivo Quack, Magdalena Woznowski, Sebastian A. Potthoff, Lars C. Rump, Lorenz Sellin. *Department of Nephrology, Heinrich Heine University, University Hospital, Duesseldorf, Germany.*

**Introduction**

GLEPP1 (glomerular epithelial protein phosphatase 1) is a receptor tyrosine phosphatase expressed in the apical membrane of foot processes. GLEPP1 expression is reduced in proteinuric kidney diseases. Previously we could show that the interaction of nephrin with podocin and β-arrestin2 and endocytosis of nephrin is regulated by src family kinases. This observation led to the concept of the dynamic regulation of the glomerular slit diaphragm. Work by others implicated GLEPP1 to be a protective factor for the glomerular slit. We hypothesize a regulatory role for GLEPP1 in respect to nephrin endocytosis.

**Methods**

In our experiments, we used cells expressing GLEPP1 and nephrin, podocin, src, fyn, β-arrestin2 or paxillin. After cell lysis, co-immunoprecipitation with subsequent western blot analysis was performed. For immunofluorescence, cells expressing GLEPP1 and paxillin.GFP were fixed and permeabilized thereafter. GLEPP1 was visualized by immunofluorescence.

**Results**

GLEPP1 interacts with the slit diaphragm proteins nephrin and podocin as well as with the src family kinases src and fyn. Furthermore, GLEPP1 enhances the interaction of nephrin with podocin and reduces the interaction of nephrin with β-arrestin2. GLEPP1 expression induces cytoskeletal rearrangement and colocalizes with paxillin in focal complexes.

**Conclusion**

The integrity of the glomerular slit diaphragm is regulated by src kinase mediated tyrosine phosphorylation of the nephrin C-terminus. We assume that GLEPP1 activates src family kinases through interaction and dephosphorylation of src family kinases at their regulatory domain. Activated src family kinases consequently increase nephrin tyrosine phosphorylation at its C-terminus. Additionally, GLEPP1 seems to force cytoskeletal changes which might be of importance maintaining the delicate shape of healthy foot processes. Via this mechanism, GLEPP1 may support the integrity of the slit diaphragm and play a distinct role in protection against the development and course of glomerular proteinuric kidney disease.

## F-PO1871

**The Cell Polarity Proteins, aPKC-Par Complex, Regulate the Turnover of Nephrin To Maintain Slit Diaphragm Integrity** Daisuke Satoh,[1] Yutaka Harita,[1] Chikara Daimon,[1] Tomonori Hirose,[1] Shigeo Ohno.[1,2] *[1]Department of Molecular Biology, Graduate School of Medical Science, Yokohama City University, Yokohama, Japan; [2]Advanced Medical Research Center, Yokohama City University, Yokohama, Japan.*

The appropriate localization of nephrin, a primary component of slit diaphragm (SD), is crucial for the selective glomerular filtration. Surface expression of Nephrin has been shown to be regulated by interaction with β-arrestin2, or CIN85, or by its tyrosine phosphorylation. However, the molecular mechanisms regulating physiological turnover of nephrin remain obscure.

Previously we have reported that selective depletion of aPKCλ, a component of cell polarity regulator aPKC-Par complex, in mouse podocytes results in SD disassembly and proteinuria. Further, aPKC-Par complex binds to nephrin, and the inhibition of kinase activity of aPKC alters the solubility of nephrin and podocin. These results raise the possibility that aPKC-Par complex may regulate the turnover of nephrin.

To this end, we used the biotinylation assay system to evaluate cell-surface localization and internalization of nephrin using HCT116 cells stably expressing nephrin (HCT116-nephrin cells) or isolated glomeruli from rat. The cells were incubate at 37°C to allow endocytosis after surface biotinylation followed by sequential stripping of the remaining cell surface biotin. In this system, in addition to total amount and cell surface localization, the amount of internalized nephrin can be quantitatively evaluated. Knockdown of Par3 in HCT116-nephrin cells led to decrease of cell surface localization of nephrin. Similar results were obtained by aPKC inhibitor treatment, overexpression of kinase negative form of aPKC, or knockdown of aPKC. Src kinase inhibitors did not abrogate the effect of aPKC inhibitor, indicating that these effects were independent of its phosphorylation. Furthermore, the amount of internalized nephrin was not affected by aPKC inhibitor treatment. These results suggest that nephrin turnover cycle is regulated by the balance between exocytosis and endocytosis, and aPKC-Par complex positively regulates the balance to maintain SD integrity possibly through the exocytosis of nephrin.

## F-PO1872

**Crk1/2 Forms a Complex with Nephrin and p130Cas and Is Essential for Nephrin-Induced Cell Spreading** Britta George,[1] Rakesh Verma,[2] Abdul A. Soofi,[2] Lawrence B. Holzman.[1] *[1]Renal-Electrolyte and Hypertension Division, University of Pennsylvania, Philadelphia, PA; [2]Division of Nephrology, University of Michigan, Ann Arbor, MI.*

The slit diaphragm protein nephrin is essential for filter integrity of the kidney, transducing phosphorylation-mediated signals from the podocyte intercellular junction which regulate cytoskeletal dynamics. We previously reported that the adaptor protein Crk1/2 binds nephrin in a phosphorylation- and SH2-dependent fashion following nephrin activation. Crk1/2 is necessary for nephrin-induced lamellipodial dynamics in cultured podocytes since RNAi-mediated knockdown of Crk1/2 attenuates cell spreading. Glomeruli of mice deleted of Crk1/2 in a podocyte-specific fashion develop and age normally. However, Crk1/2 null podocytes in this model are protected from protamine sulfate injury-induced foot process spreading. Despite extensive mapping studies carried out in cell culture and *in vitro*, we were unable to identify a unique Crk binding site in nephrin that mediates nephrin-induced lamellipodial induction; this suggested that Crk1/2 interacts with nephrin both directly and indirectly. As such, we considered that Crk1/2 might alternatively function within the focal adhesion complex to mediate nephrin-induced lamellipodia formation. In support of this hypothesis, nephrin activation recruited tyrosine phosphorylated p130Cas to nephrin clusters; this required binding of the p85 subunit of pI3 kinase to nephrin and pI3 kinase activity. p130Cas recruitment occurred despite mutation of tyr residues necessary for Nephrin-Nck binding. However, Y to F mutation of these residues precluded nephrin-induced p130Cas phosphorylation suggesting that p130Cas recruitment and p130Cas tyrosine phosphorylation are mediated by independent signaling events. Consistent with these results, in developing mouse glomeruli we verified that phospho-p130Cas is present at the podocyte precursor adherens junction at all stages of development. We conclude that Crk interacts with nephrin directly through its SH2 domain as well as indirectly, through p130Cas in a pI3 kinase dependent manner, and plays an essential role in nephrin-induced lamellipodia formation.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1873

**PKCalpha and PICK1 Mediate beta-Arrestin2 Dependent Nephrin Endocytosis in Hyperglycemia** Ivo Quack,[1] Magdalena Woznowski,[1] Sebastian A. Potthoff,[1] Eva Koenigshausen,[1] Johannes Stegbauer,[1] Mario Schiffer,[2] Lars C. Rump,[1] Lorenz Sellin.[1] *[1]Department of Nephrology, Heinrich-Heine-University, Duesseldorf, Germany; [2]Department of Nephrology, Hannover Medical School, Hannover, Germany.*

Nephrin, the key molecule of the glomerular slit diaphragm, is expressed on the surface of podocytes and is critical in preventing albuminuria. In diabetes, hyperglycemia causes albuminuria and leads to loss of nephrin surface expression. Here, we report the underlying mechanism: hyperglycemia directly enhances nephrin endocytosis mediated by protein kinase C alpha. PKCalpha activity controls the rate of nephrin endocytosis via regulation of the beta-arrestin2-nephrin interaction. We identify PKCalpha and protein interacting with c kinase-1 (PICK1) as nephrin binding proteins. Hyperglycemia induces upregulation of PKCalpha and leads to the formation of a nephrin/PKCalpha/PICK1/beta-arrestin2 complex in vitro and in vivo. Beta-arrestin2 binding to the nephrin intracellular domain depends on nephrin threonine residues 1120 and 1125. PICK1 binds with its PDZ domain to nephrin amino acids 1160-1176 harboring a PDZ type III binding motif. Cellular knockdown of PKCalpha and/or PICK1 attenuates nephrin - beta-arrestin2 interaction and abrogates the amplifying effect of high glucose on nephrin endocytosis. In C57Bl/6 mice, hyperglycemia over 24 hours causes a significant increase in urinary albumin excretion supporting the concept of a rapid impact of hyperglycemia on glomerular permselectivity. In summary, the present study provides a molecular model of hyperglycemia-induced nephrin endocytosis and subsequent proteinuria and highlights PKCalpha and PICK1 as promising therapeutic targets.

**F-PO1874**

**NEPH1 Function Revisited: Role for Glomerular Development, Maintenance and Nephrin Trafficking** Tobias B. Huber. *Renal Division, University Hospital Freiburg, Freiburg, Germany.*

Podocytes form a complex 3D epithelial structure and depend on a temporally and spatially precise tuning of cellular interactions. Evolutionarily conserved Ig superfamily molecules between neighbouring podocytes interact to form the highly specialized SD that regulates interpodocyte positioning and dynamics.

To further investigate the precise function of NEPH1 within the SD we generated a conditional mouse where the transmembrane and intracellular domain was flanked by loxP sites. Sox2Cre*Neph1fl/fl mice recapitulated the described phenotype of Neph1 null mice with 95% lethality within 48h pp. EM revealed grossly disfigured secondary and aberrantly attaching primary processes correlating with a massive proteinuria on P1. In contrast, Nphs2Cre*Neph1fl/fl mice survived into adulthood. On the light and electron microscopic level the observed structural changes in the kidney were similar to the ones in the Neph1 null. These mice also showed an early onset massive proteinuria which persisted throughout their life. Histology progressed into classical FSGS which lead to uremia. The discrepancy between the Neph1 null and Nphs2Cre*Neph1fl/fl mouse might hint to an extrarenal function of NEPH1.

On the molecular level, loss of Neph1 resulted in a failure of correct SD assembly and in mis-directed Nephrin targeting as evidenced by confocal microscopy and Immuno EM.

To determine the function of neph1 in adult kidneys we generated a inducible Nphs2rtTACre line. After initiation of doxy treatment mice developed significant proteinuria and podocyte ultrastructural abnormalities indicating the critical importance of Neph1 for glomerular maintenance.

In summary we here demonstrate that NEPH1 is essential for SD assembly, foot process development and maintenance.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1875**

**Nephrin-Neph3 Bidirectional Gene Pair Is Synergistically Activated by Transcription Factors WT1 and NF-κB, and Silenced by DNA Methylation** Mervi Ristola,[1] Satu Arpiainen,[2] Moin Saleem,[3] Harry B. Holthofer,[1,2] Sanna H. Lehtonen.[1] *[1]Haartman Institute, University of Helsinki, Helsinki, Finland; [2]Dublin City University, Dublin, Ireland; [3]Academic and Children's Renal Unit, University of Bristol, Bristol, United Kingdom.*

Nephrin and Neph3 are homologous molecules expressed in the glomerular podocytes where they localize at the slit diaphragms. Nephrin, and apparently also Neph3, are crucial for podocyte function. NPHS1 and KIRREL2, encoding nephrin and Neph3, locate in human chromosome 19q13.12 in a head-to-head orientation and are separated by approximately 5-kb region constituting a bidirectional gene pair. Also mouse and rat have similar nephrin and Neph3 gene arrangement. Nephrin and Neph3 mRNAs are down-regulated and show positive correlation in human proteinuric diseases, which together with the genomic arrangement of their genes and similar protein structure and location proposes that nephrin and Neph3 genes may share key features in their regulation. In this study, we investigated if nephrin and Neph3 genes have similar mechanisms in their transcriptional regulation focusing on transcription factors WT1 and NF-κB, and DNA methylation. By overexpression studies and reporter gene assays, we show that both nephrin and Neph3 genes are activated by transcription factors WT1 and NF-κB in a synergistic manner. This cooperation was further supported by the physical interaction between WT1 and NF-κB shown by co-immunoprecipitation. Chromatin immunoprecipitation assay using cultured human podocytes demonstrated that WT1 and NF-κB bind to nephrin and Neph3 promoter. In cultured human podocytes, NF-κB activator TNF-α enhanced a time- and concentration-dependent induction of endogenous nephrin mRNA. Further, treatment of cultured podocytes and A293 cells with a demethylating agent showed that endogenous nephrin and Neph3 mRNAs are similary silenced by DNA methylation. In conclusion, these results show that nephrin and Neph3 share same mechanisms in their regulation. Both genes are synergistically activated by transcription factors WT1 and NF-κB in podocytes, and further, DNA methylation plays a role in silencing nephrin and Neph3 gene expression.

**Puromycin Aminonucleoside Induces Nuclear Translocation of IQGAP1 Protein While Decreasing Its Interactions with Slit Diaphragm Proteins in Podocytes** Claire Rigothier,[1-2] Moin Saleem,[1] Jean Ripoche,[2] Christian Combe,[2] Gavin Iain Welsh.[1] *[1]Academic Renal Unit, University of Bristol, Bristol, United Kingdom; [2]INSERM U577, Universite de Bordeaux, Bordeaux, France.*

Background

IQGAP1 is a scaffold protein that interacts with cytoskeletal proteins as well as proteins of the glomerular slit diaphragm (SD). IQGAP1 is implicated in actin cytoskeleton remodelling and in regulation of cell migration, cell adhesion, cell division and gene expression. We hypothesized that IQGAP1 is pivotal in maintaining glomerular barrier properties and podocyte cytoskeleton remodelling as observed in glomerulonephropathies (GN). We report changes in podocyte IQGAP1 subcellular localization and interaction with SD proteins upon exposure of podocytes to puromycin aminonucleoside (PAN), an inducer of experimental nephrotic syndrome.

Methods

In cultured human podocytes, a combination of Western blot (n=5) on cytoplasmic and nuclear extracts, quantitative PCR (n=3), immunoprecipitation (n=5) and immunocytolocalization (n=5) were performed to determine the subcellular localization, the transcription and interacting protein partners of IQGAP1, upon exposure to PAN.

Results

Upon exposure to PAN, IQGAP1 translocation from its usual localization on the plasma membrane to the nucleus was observed by immunocytolocalization (cytoplasm/nuclei ratio, ctl: 10.8±1.3 vs PAN: 6.6±0.5 intensity/mm2, p=0.02) and confirmed by Western blot after selective extraction (2.8±1.0 vs 1.4±0.4 intensity/mm2, p=0.03). qPCR excluded an increase of IQGAP1 transcription.

Interactions with proteins of the SD were also modified. We observed a reduction of IQGAP1 interactions with both nephrin and podocalyxin at each time of PAN exposure.

Conclusion

The alteration of IQGAP1 in PAN-induced GN may be important in the loss of the permeability of the glomerular barrier associated with this experimental model.

Also, the potential roles played by IQGAP1 in the nucleus in these conditions remain to be clarified, particularly on account of IQGAP1 implication in gene regulation. The PAN model provides a useful experimental tool to study the role of IQGAP1 in the alteration of podocyte cytoskeleton organization and remodelling as observed in GN.

**WT1-Interacting Protein (WTIP) Is Necessary for Early Mouse Development and Glomerular Filtration Barrier Function in WTIP +/- Mice** Sethu M. Madhavan, Martha Konieczkowski, John O'Toole, Bingcheng Wang, Jane H. Kim, John R. Sedor. *Medicine, MetroHealth Campus, Case Western Reserve University, Cleveland, OH.*

WT1 mutations associate with familial glomerulosclerosis, and WT1 expression is reduced in acquired glomerulosclerosis. The podocyte adherens junction protein, WTIP, a member of the ajuba LIM-domain family, translocates to the nucleus after injury and represses WT1 activity. To define Wtip function in vivo, we generated a Wtip-deficient mouse line using β-galactosidase-neomycinR (β-geo) gene trap technology. The β-geo expression vector integrated into the second intron of Wtip and sequencing after RT-PCR confirmed that Wtip exon 2 spliced in frame to β-geo. Immunoblotting with an anti-β-gal antibody showed a Mr 170 protein, the size predicted for the Wtip-β-geo fusion protein. No Wtip $^{\beta\text{-geo}/\beta\text{-geo}}$ animals were identified among live-born mice or embryos as young as E8.5 (n=300 mice). The morphology and viability of Wtip $^{\beta\text{-geo}/+}$ and wild type mice was similar. Heterozygotes up to 1 year of age did not spontaneously develop proteinuria. After LPS injection, Wtip $^{\beta\text{-geo}/+}$ mice developed statistically greater and more prolonged proteinuria compared to the wild-type littermates. To map endogenous Wtip expression pattern, we assayed X-gal staining in Wtip $^{\beta\text{-geo}/+}$ mouse embryo and adult tissues. No X-gal staining was observed in the renal vesicle, coma shaped or S-shaped stages of glomerular development. However, X-gal was seen capillary loop stage and mature glomeruli, co-localizing with synaptopodin but not PECAM-1. Wtip is also expressed in developing myocardium as early as E9.5 but not in adult heart. X-gal staining of brain, the retina, ears and lungs was identified in E14.5 and E18.5 embryos. In summary, Wtip is essential for mouse embryogenesis and is expressed in podocytes from the capillary loop stage into adulthood. Resolution of abnormal proteinuria after LPS injection is delayed in Wtip$^{\beta\text{-geo}/+}$ mice, suggesting Wtip regulates glomerular filtration barrier function.

**WT1 Interacting Protein (WTIP) Regulates Podocyte Phenotype by Cell-Cell Contact Reorganization** Jane H. Kim,[1] Martha Konieczkowski,[2] John R. Sedor.[1,2,3] *[1]Physiology and Biophysics, Case Western Reserve University, Cleveland, OH; [2]Medicine, Case Western Reserve University, Cleveland, OH; [3]Division of Nephrology, Metro Health Medical Center, Cleveland, OH.*

Wtip translocation to the nucleus after injury causes actin cytoskeletal rearrangement and glomerular filtration barrier dysfunction. To define Wtip function in slit diaphragm assembly, we generated murine podocyte lines that stably express shRNAs directed against Wtip (shWtip) or an empty vector (shEmp). Wtip transcript and protein levels decrease by 90% in shWtip cells compared to shEmp and wild type cells. Although focal adhesion kinase, vinculin and paxillin expression is equivalent in shWtip and shEmp cells, shWtip cells adhere but fail to spread normally. shWtip podocytes do not assemble actin stress fibers and focal adhesions are reduced and fail to mature. Wtip expression in shWtip cells rescues the spreading defect. As shEmp podocytes establish cell-cell contacts, Wtip localizes to the adherens junction, colocalizing with β-catenin and cadherin. Epitope-tagged Wtip coprecipitates with both cadherin and β-catenin. In contrast, shWtip cells fail to establish stable cell-cell contacts but persistently elaborate lamellipodia and filopodia. Fluorescence microscopy demonstrated disordered F-actin structures and no synaptopodin. Although primarily intracellular, some cadherin and b-catenin cluster in brightly fluorescent but irregularly distributed spots in the plasma membrane that fail to laterally expand into mature adherens junctions. Cell surface biotinylation shows diminished plasma membrane expression of cadherin, β-catenin, and α-catenin in shWtip podocytes, although all are equivalently expressed in shWtip and shEmp podocytes by immunoblotting. In a model of calcium-regulated junction assembly, cadherin-based cell-cell contacts fail to reassemble in shWtip podocytes. In conclusion, stable assembly of podocyte adherens junctions requires Wtip, suggesting in vivo Wtip functions as a molecular switch regulating podocyte phenotype through cell-cell contact remodeling.

**Activation of RhoA in Podocytes Causes Foot Process Effacement and Proteinuria in Mice** Lei Zhu, Ruihua Jiang, Lamine Aoudjit, Tomoko Takano. *Medicine, McGill University, Montreal, QC, Canada.*

Podocytes are a major component of the glomerular filtration barrier and alterations to the morphology of podocyte foot processes are associated with proteinuria. RhoA is a small GTPase that regulates the actin cytoskeleton. The aim of the current study is to investigate the role of RhoA in the alternation of podocyte morphology and function. A mouse model of tetracycline-inducible, podocyte-specific expression of the constitutively active (CA)-RhoA was developed. When these mice were treated with doxycycline (Dox) for 4 wks, CA-RhoA was expressed in podocytes and significant proteinuria developed. In contrast, vehicle-treated mice did not express CA-RhoA, nor did develop proteinuria. Electron microscopy revealed focal and segmental foot process effacement in mice treated with Dox, but not in vehicle-treated mice. The degree of foot process effacement correlated with the degree of proteinuria. Dox-induced CA-RhoA expression and proteinuria were, in most cases, reversible within 2 wks after the Dox withdrawal. However, occasional mice showed extremely high proteinuria, which persisted even after the Dox withdrawal. In these mice, light microscopy showed focal and segmental glomerulosclesosis. Glomerular fibronectin mRNA was significantly increased in mice treated with Dox, supporting that RhoA activation leads to fibronectin upregulation. Expression of other genes such as nephrin, alpha-actinin-4, WT1, synaptopodin, and laminin 1 were unchanged. Differentiated cultured mouse podocytes transfected with GFP-CA-RhoA were significantly smaller and devoid of cellular processes, as compared with those transfected with GFP or GFP-dominant negative (DN)-RhoA. Thus, activation of RhoA in podocytes results in foot process effacement and proteinuria. Activation of RhoA causes reversible foot process effacement likely via modulating the actin cytoskeleton. In addition, when the degree/duration of the RhoA activation is severe/long, it may lead to upregulation of fibronectin and irreversible glomerulosclerosis.

**Arhgap24 Controls Membrane Ruffling in Podocytes and Is a New Candidate Gene for Focal Segmental Glomerulosclerosis** Shreeram Akilesh,[1] Tobias B. Huber,[3] Michelle P. Winn,[4] Andrey S. Shaw.[2] *[1]Department of Pathology, Barnes-Jewish Hospital, St. Louis, MO; [2]Howard Hughes Medical Institute, Washington University School of Medicine, St. Louis, MO; [3]Division of Nephrology, University of Freiburg, Freiburg, Germany; [4]Division of Nephrology, Department of Medicine, Duke University, Durham, NC.*

The podocyte is the specialized epithelial cell of the kidney and is a key component of the filtration barrier. The podocyte has a complex membrane arborization that is effaced in proteinuric disease states such as focal segmental glomerulosclerosis (FSGS). We studied membrane dynamics *in vitro* and found that podocytes slow their membrane ruffling after differentiation. Since membrane dynamics are controlled by the small G-proteins Rac1 and RhoA, we examined the expression of regulators of these proteins in podocytes. We identified Arhgap24 as a GTPase activating protein (GAP) that inactivates Rac1 activity and arrests podocyte membrane ruffling. Sequencing of the *ARHGAP24* gene in patients with FSGS identified a mutation that tracks with disease in a pedigree. This mutation reduces the GAP activity of Arhgap24 *in vitro*. These findings imply that aberrant regulation of podocyte membrane dynamics, in part controlled by Arhgap24, contributes to FSGS.

**Drebrin Is a Novel Regulator of Podocyte Process Formation** Michelle N. Rheault,[1] Renee E. Koessler.[2] *[1]Pediatrics, University of MN, Minneapolis, MN; [2]Medicine, Northwestern University, Chicago, IL.*

Although they have different functions, both podocytes and neurons require the formation and maintenance of a complex arborized phenotype that is supported by the highly organized cytoskeleton. Drebrin, an actin binding protein concentrated in dendritic spines in neurons and involved in actin organization and spine elongation, is also present in podocytes. The purpose of this study was to examine the role of drebrin in the podocyte. Drebrin is present in podocytes and mesangial cells in human kidney. By confocal immunofluorescence (IF) microscopy, podocyte-specific drebrin expression was decreased in biopsies from 2 patients with minimal change nephrotic syndrome compared to controls. In cultured human podocytes, drebrin expression was induced in differentiated podocytes compared to undifferentiated podocytes and was localized to the periphery of the cell in a subcortial actin distribution. Treatment of differentiated human podocytes with 50μg/ml puromycin (PAN), a model of cytoskeletal reorganization and podocyte injury, led to a 50% reduction in drebrin protein levels after 48 hours. Drebrin localizes to adherens junctions in several cell types and podocyte slit diaphragms are known to be modified adherens junctions. Drebrin and the slit diaphragm protein, CD2AP, demonstrated co-localization in differentiated podocytes by confocal IF microscopy. They also demonstrated a specific interaction in co-immunoprecipitation studies in HEK cells suggesting that drebrin may be a novel slit diaphragm protein. To explore whether drebrin influences podocyte process formation, GFP-tagged drebrin was expressed in undifferentiated human podocytes. This caused numerous small actin and drebrin containing processes to form at the periphery of cells that did not express the classic filopodia marker fascin. Processes were not observed in cells expressing GFP alone. In conclusion, we found that podocyte drebrin protein levels are decreased in human minimal change nephrotic syndrome and a PAN culture model of cytoskeletal rearrangement in nephrotic syndrome. Drebrin may act as a novel linking protein between the slit diaphragm and actin cytoskeleton that regulates foot process structure.

**Def-6, a Novel Regulator of Small GTPases Acts Downstream of PAN and PKCλ/ι in Podocytes** Kirstin Worthmann,[1] Michael Leitges,[2] Oliver Dittrich-Breiholz,[3] Michael Kracht,[4] Hermann G. Haller,[1] Mario Schiffer.[1] *[1]Division of Nephrology, Medical School Hannover, Hannover, Germany; [2]Biotechnology Centre of Oslo, University of Oslo, Oslo, Norway; [3]Institute of Biochemistry, Medical School Hannover, Hannover, Germany; [4]Rudolf-Buchheim-Institute of Pharmakology, Justus Liebig University Giessen, Giessen, Germany.*

Background: Podocyte specific deletion of atypical PKCλ/ι in mice leads to a severe glomerular phenotype with gross proteinuria, glomerulosclerosis, atypical cell-cell junctions and mislocated slit diaphragms. This phenotype is similar to changes found in the puromycin aminonucleoside nephrosis (PAN) model in rats.

Methods and results: To test whether treatment of podocytes with PAN leads to inhibition of aPKCs we generated stable monoclonal PKCλ/ι knockout cell lines and compared these cells to podocytes stimulated for 24 hrs with PAN. We detected actin cytoskeletal rearrangements and an inbalance of the small GTPases RhoA and Rac1 in both conditions. When we compared gene expression profiles using one-color microarrays we detected several common target genes overrepresented in the PKCλ/ι KO cells and in podocytes stimulated with PAN. One of these genes is Def6, which is a known regulator of Rho-family GTPases as a GEF and cooperates with active Rac leading to morphological changes. Next, we investigated the Def-6 mRNA expression in PKCλ/ι WT and KO kidneys of different age. We could show that Def-6 mRNA expression decreases during development in the WT kidneys. In contrast, Def-6 expression levels increase in PKCλ/ι KO. During podocyte differentiation *in vitro* we detected a decrease of Def-6 expression in the WT and also in the PKCλ/ι KO cells, but interestingly the Def-6 level in the differentiated KO cells remains significantly higher similar to the Def-6 levels in the undifferentiated WT cells. Overexpression of Def-6 in podocytes resulted in an obvious phenotype with an increased number of lamellipodia and filopodia, similar to the phenotype in PKCλ/ι KO podocytes.

Conclusions: In summary, we provide evidence that Def-6 and PKCλ/ι are new downstream targets in PAN nephrosis. Dysregulation of Def-6 might be a key component of foot process effacement.

**The Role of SIRPα (SHPS-1) in Experimental Diabetic Nephropathy** Satoshi Takahashi,[#1] Keiju Hiromura,[#1] Hiroko Hamatani,[#1] Mai Kato-Tomioka,[#1] Akito Maeshima,[#1] Takashi Kuroiwa,[#1] Hiroshi Ohnishi,[#2] Takashi Matozaki,[#2] Aoki Takeo,[#3] Yoshihisa Nojima.[#1] *[1]Department of Medicine and Clinical Science, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan; [2]Laboratory of Biosignal Sciences, Institute for Molecular and Cellular Regulation, Gunma University, Maebashi, Gunma, Japan; [3]Department of Anatomy and Cell Biology, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan.*

SIRPα (SHPS-1) is a transmembrane protein that contains tyrosine phosphorylation sites in its cytoplasmic region, to which two tyrosine phosphatases, SHP1 and SHP2, are recruited in a phosphorylation-dependent manner. We previously reported that SIRPα was predominantly expressed in podocytes and that knock-in mice (C57BL/6 background) which express mutant SIRPα lacking the cytoplasmic region showed massive albuminuria by combination of uninephrectomy and adriamycin injection (ASN 2008). In this study, we sought to determine the role of SIRPα in diabetic nephropathy (DN). Type 1 DN was induced in SIRPα mutant mice (MU) and its wild type mice (WT) by streptozotocin (STZ) injection. The mean blood glucose levels between 2 to 32 weeks after STZ injection were similar in both groups (547.5±60.2 vs 528.7±63.6 mg/dL, MU vs WT). MU showed increased albuminuria compared to WT (178±33 vs 52±29 μg/day at 14 weeks; 600±168 vs 90±33 μg/day at 28 weeks; MU vs WT, $P<0.01$). Creatine clearance, measured just before sacrifice at 32 weeks, was elevated in MU compared to WT (0.78±0.11 vs 0.41±0.16 ml/min, MU vs WT, $P<0.05$), demonstrating that MU had increased glomerular hyperfiltration. Renal specimens revealed that MU had more thickened glomerular basement membrane (0.34±0.016 vs 0.27±0.034 μm, determined by electron microscopic examination, MU vs WT, $P<0.05$). Mesangial expansion was not different in both mice. These data suggested that loss of SIRPα signaling pathway enhance diabetic glomerular injury. In addition, taken together with the previous findings of adriamycin model, SIRPα signaling pathway is considered to play an important role in modulating glomerular barrier function upon podocyte injury.

**Down Regulation of SIRT1 Mediates Podocyte Apoptosis in Diabetes Mellitus** Peter Y. Chuang,[2] Yan Dai,[1] Ruijie Liu,[1] John C. He.[1,2] *[1]Medicine/Div. of Nephrology, James J. Peters VA Medical Center, Bronx, NY; [2]Medicine/Div. of Nephrology, Mount Sinai School of Medicine, New York, NY.*

Cellular events leading to podocyte loss in diabetic nephropathy are unclear. We previously found that advanced glycation endproducts (AGE) promoted podocyte apoptosis in a forkhead box O 4 (FOXO4)-dependent manner by increasing the expression of an apoptosis response gene Bim. The FOXO family of transcription factors (TF) is involved in the regulation of oxidant stress resistance, apoptosis, cell cycle inhibition, and cellular metabolism. Post-translation modification of FOXOs by phosphorylation and acetylation are essential for the regulation of their transcriptional activity. A mammalian sirtuin (SIRT1) targets FOXOs for deactylation and inhibits FOXO-induced transactivation of an apoptosis response gene, Bim, and enhances the expression of FOXO-target genes that are involved in oxidant stress resistance. In this study we tested the hypothesis that down regulation of sirtuin (SIRT1) in diabetes enhances the acetylation of FOXO4 to transactivate a pro-apoptotic, FOXO-induced gene BIM in the podocytes to promote apoptosis. We found that AGE enhanced FOXO4 binding to the Bim promoter in the podocytes by chromatin immunoprecipitation. AGE increased the acetylation of FOXO4 in cultured podocytes as determined by immunoprecipitation of endogenous FOXO4 and immunoblotting for acetylated lysine. The protein and mRNA levels of SIRT1 was reduced with AGE-treatment in podocytes. Over expression of SIRT1 using a lentiviral transduction of cultured podocytes abrogated AGE-induced apoptosis as assessed by annexin V labeling. Glomeruli isolated from diabetic db/db mice have a reduced expression of SIRT1 and increased acetylation of FOXO4. Treatment of db/db mice with a SIRT1 activator, resveratrol, attenuated glomerular Bim expression and podocyte apoptosis. This study suggest that reduced SIRT1 expression in the diabetic condition promotes FOXO4 acetylation, FOXO4-binding to the BIM promoter, BIM expression, and podocyte apoptosis.

**Role of Non-Steroid Anti-Inflammatory Drugs in Regulation of TRPC Channels in Isolated Rat Glomerulus** Daria Ilatovskaya,[1,3] Robert P. Ryan,[1] Allen W. Cowley,[1] Alexander Staruschenko.[1,2] *[1]Physiology, Medical College of Wisconsin, Milwaukee, WI; [2]Kidney Disease Center, Medical College of Wisconsin, Milwaukee, WI; [3]Institute of Cytology RAS, Saint-Petersburg, Russian Federation.*

Non-steroid anti-inflammatory drugs (NSAIDs) are major drugs used in the treatment of inflammation in a wide variety of disorders. The best-known mechanism of action of NSAIDs is the inhibition of prostaglandin synthesis secondary to their action on cyclooxygenases (COXs). NSAIDs are generally used in treatment of acute and chronic inflammation-caused conditions, particularly in brain. However, an effect of NSAIDs in the kidney and particularly in the glomerulus is not clear. Transient receptor potential canonical channels (TRPC) are cation channels that are expressed along the nephron; furthermore, there has been proposed a role for TRPC channels in renal function. TRPC6 dysfunction has also been associated with the onset of focal segmental glomerosclerosis. We have addressed here a role of NSAIDs in regulation of TRPC channels in glomeruli. Western blotting confirmed that TRPC1, 3 and 6 are highly expressed in freshly isolated glomerulus of Sprague Dawley rat kidneys. Cell-attached patch clamp analysis revealed cation channel currents with distinct biophysical TRPC properties in podocytes in isolated decapsulated rat glomerulus. SKF-96365 (10 μM), a non-selective cation channels inhibitor, rapidly and markedly decreased these currents. Diclofenac (500 μM), one of well known NSAIDs, significantly decreased TRPC channel activity. Moreover, diclofenac inhibited TRPC6 when the channel was over-expressed in CHO cells. Thus this is the first report we are aware of describing single channel properties of endogenous TRPC channels in podocytes of freshly isolated rat glomerulus. In addition we provide a novel mechanism of NSAIDs regulation of TRPC channels which might be implicated in maintaining the glomerular filtration barrier.

**TRPC5 and TRPC6 Are Antagonistic Regulators of the Podocyte Actin Cytoskeleton through Differential Coupling to Rac1 and RhoA** Dequan Tian,[1] David L. Billing,[1] Anete Rozkalne,[1] Theodora Anagnostou,[1] Johannes S. Schlondorff,[2] Anna Greka.[1] *[1]Nephrology Division, Massachusetts General Hospital and Harvard Medical School, Charlestown, MA; [2]Beth Israel Medical Center, Boston, MA.*

Dynamic regulation of the podocyte actin cytoskeleton is critical for the maintainance of the glomerular filtration barrier. Ca2+-dependent remodeling of the actin cytoskeleton is a dynamic process that drives cell migration through modulation of Rho GTPase activity. Previous work in podocytes has shown that RhoA mediates an adaptive, contractile phenotype, whereas Rac1 promotes proteinuria and progressive renal disease. Receptor-activated TRPC (Transient Receptor Potential Canonical) channels generate Ca2+ microdomains in many cell types, but antagonistic downstream pathways regulating cell migration have not been described. TRPC5 channels have been implicated in neuronal growth cone motility, and TRPC6 channel mutations have been linked to familial FSGS, but the specific mechanisms through which these channels act remain elusive.

Here we identify Angiotensin Type 1 receptor (AT1R) activated TRPC5 and TRPC6 channels as conserved antagonistic regulators of actin remodeling and cell motility in podocytes and fibroblasts. We show that TRPC5 is in a molecular complex with Rac1, whereas TRPC6 forms a molecular complex with RhoA. We further show that TRPC5-mediated Ca2+ influx induces Rac1 activation, thereby promoting cell migration. In contrast, TRPC6-mediated Ca2+ influx inhibits cell migration by increasing RhoA activity. These results suggest that under physiologic conditions, TRPC6/RhoA signaling confers a contractile phenotype, and that unopposed TRPC5 activity leads to a Rac1-mediated maladaptive migratory phenotype. In conclusion, increased TRPC5/Rac1 signaling may cause podocyte damage and proteinuria, and TRPC5 may therefore be a novel molecular target for anti-proteinuric therapies.

**F-PO1887**

**Canonical Wnt/β-Catenin Signaling Mediates TGF-β1-Driven Podocyte Injury and Proteinuria** Dan Wang, Chun-Sun Dai, Youhua Liu. *Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Podocyte dysfunction plays a causative role in the pathogenesis of proteinuria in a wide variety of primary glomerular diseases. TGF-β1, a fibrogenic cytokine that is upregulated in virtually all chronic kidney diseases, is known to induce podocyte injury, leading to defective glomerular filtration. However, how TGF-β1 causes podocyte dysfunction in vivo remains poorly understood. Here we show that canonical Wnt/β-catenin signaling plays an important role in mediating podocyte injury and proteinuria induced by TGF-β1. Incubation of mouse podocytes with TGF-β1 dramatically induced Wnt1 expression, which started as early as 1 h, reached the peak at 8 h, and sustained at least to 24 h. Several other Wnt genes including Wnt2, Wnt9a, Wnt10a, Wnt10b and Wnt11 were also induced, to a less extend, by TGF-β1. Induction of multiple Wnts by TGF-β1 resulted in marked activation of β-catenin in podocytes, as demonstrated by Western blot analysis and immunostaining. Ectopic expression of Wnt1 mimicked TGF-β1 and induced Snail expression in podocytes. In vivo, ectopic expression of constitutively active TGF-β1 via a hydrodynamic-based gene delivery approach induced Wnt1 and Snail expression in the glumeruli, which was associated with the onset of albuminuria in mice. Interestingly, simultaneous delivery of Dickkopf-1, an endogenous antagonist of Wnt/β-catenin signaling, significantly reduced TGF-β1-induced albuminuria in vivo. Taken together, these results indicate a critical role for the canonical Wnt/β-catenin signaling in mediating TGF-β1-driven podocyte injury and proteinuria.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1888**

**TGF-beta Reduces Wilms Tumor 1 Protein Expression in Podocytes In Vitro and In Vivo** Toru Sakairi, Yoshifusa Abe, Jeffrey B. Kopp. *KDS, KDB, NIDDK, Bethesda, MD.*

TGF-beta contributes to glomerulosclerosis (GS) and tubulointerstitial fibrosis. The Wilms tumor 1 protein (WT1) is a transcription factor required for normal podocyte differentiation; deletions and mutations in the WT1 gene cause syndromes associated with GS, including WAGR, Frasier and Denys-Drash. To address whether TGF-beta-induced podocyte injury might be mediated in part by altered WT1 expression, we evaluated the effect of TGF-beta1 on WT1 expression in podocytes using a human podocyte cell line (AB8/13) and Alb/TGF-beta transgenic (TG) mice, which manifest elevated plasma TGF-beta1 levels and undergo progressive GS. Following 24 hr exposure of human podocytes to TGF-beta1 (5 ng/mL), WT1 protein expression decreased as shown by Western blot and immunostaining. WT1 protein was consistently reduced with TGF-beta1, with a dose dependent effect from 0.2 ng/mL to 20 ng/mL. TGF-beta1 exposure (5 ngm/L) for 90 min reduced WT1 mRNA level, assessed by quantitative RT-PCR, 57 ± 8% ($p < 0.01$). In the presence of shRNA targeted to Smad4, WT1 mRNA was reduced with 5 ng/mL TGF-beta1 by 45±11% at eight hours compared with 80±4% in the presence of non-targeting control, suggesting a 44% abrogation of the inhibitory effect of TGF-beta1. The effect of Smad4 shRNA extended to WT1 protein as detected by Western blot. These data suggest that TGF-beta1 suppresses WT1 expression in part via a Smad dependent pathway. TG mice were studied at 1 week of age (prior to GS) and 3 weeks (early GS). By Western blot, WT1 protein expression in TG whole kidney was reduced by 23±10% ($p<0.05$) at 1 week and by 64±20% ($p<0.001$) at 3 weeks compared to wild-type mice. Immunostaining confirmed reduced WT1 expression in podocytes. WT1 mRNA expression in TG whole kidney was not altered, possibly indicating that regulation of WT1 expression in vivo differs from in vitro, or that there are species differences. In summary, TGF-beta reduced WT1 protein expression in podocytes in vitro and in vivo, at least in part via a Smad dependent pathway. These findings identify a novel pathway linking TGF-beta to podocyte injury.

**Transforming Growth Factor β1 Induced Podocyte Injury Is Partly Angiopoietin Mediated** Peter Margetts, Je Yen James Su, Anil Kapoor, Ayesha Ghayur. *Medicine, McMaster University, Hamilton, ON, Canada.*

Transforming growth factor β 1 (TGFβ1) has been demonstrated to cause injury to the glomerular filtration barrier. We used an adenovirus expressing either active TGFβ1 or green fluorescent protein (GPF), to transfect the kidneys of female Sprague Dawley rats. We

assayed for proteinuria along with tissue markers of fibrosis. We used immunohistochemistry and laser capture microdissection to study gene and protein expression in the glomeruli. In vitro, immortalized mouse podocytes were exposed to recombinant TGFβ1, angiopoietin-1 (ang1), or ang2. We blocked the TGFβ1 effects using antibodies against ang1, ang2 or the angiopoietin receptor Tie2. In the animal model, GPF co-localized with CD34 indicating that the glomerular endothelium was targeted by adenovirus. AdTGFβ1 induced significant proteinuria and podocyte effacement by EM. AdTGFβ1 treatment led to nephrinuria and downregulation of nephrin mRNA and synaptopodin protein in tissue samples. These changes were associated with in increase ang1 and ang2 expression in the glomeruli. In podocyte cell culture, TGFβ1 down regulated nephrin and synaptopodin in a dose dependent manner. Tie2 was not expressed on naïve podocytes, but its expression was induced by TGFβ1. Both ang1 and ang2 also downregulated these podocyte markers. A neutralizing anti-Tie2 antibody blocked TGFβ1 induced downregulation nephrin and synaptopodin. Antibodies against ang1 or ang2 also blocked TGFβ1 downregulation of nephrin.

We demonstrate that in vivo, TGFβ1 can lead to podocyte de-differentiation by suppressing key makers of podocyte integrity. In vitro, this TGFβ1 mediated process is suppressed by blocking angiopoietin signaling. This suggests that TGFβ1 mediated podocyte injury is partly angiopoietin mediated.

**Cathepsin L Is Transcriptionally Regulated by Dendrin and Drives Glomerular Disease Progression** Suma Yaddanapudi,[1] Mehmet M. Altintas,[2] Andreas D. Kistler,[2] Jochen Reiser.[2] *[1]Massachusetts General Hospital; [2]University of Miami Miller School of Medicine.*

Recently, a cytosolic variant of cathepsin L (CatL) has been implicated in the pathogenesis of human glomerular diseases and the LPS mouse model of proteinuria. Here, we show that cytosolic CatL is also involved in models of chronic progressive glomerular disease such as CD2AP deficient or TGF-β transgenic mice. Glomerular CatL expression in CD2AP-/- mice was normal by immunohistochemistry at the age of 1 week but increased at 3 weeks, i.e. the onset of glomerulosclerosis. Similar to the in vivo situation, conditionally immortalized podocytes from CD2AP-/- mice initially expressed low cytosolic CatL levels and normal actin cytsokeleton, but with increasing passage number, these cells undergo a phenotypic that is accompanied by the induction of high cytosolic CatL levels and cleavage of dynamin and synaptopodin along with rearrangement of the actin cytoskeleton. This phenotype could be rescued by treatment with CatL inhibitors or CatL shRNA. In both, in vivo and in vitro CD2AP-/- podocytes we found nuclear relocation of dendrin, a CD2AP-binding protein that promotes apoptosis upon nuclear import. Reporter assays in HEK cells demonstrated strong upregulation of CatL but not CatB promoter activity upon cotransfection with wild type dendrin but not with a dendrin construct devoid of the nuclear import signal. Knock down of dendrin rescued the actin phenotype of late passage CD2AP-/- podocytes and restored dynamin and synaptopodin levels. CD2AP-/- podocytes exhibit an increased susceptibility to TGF-β induced apoptosis, which was also rescued by dendrin shRNA, CatL shRNA or CatL inhibitor treatment. In line with the previous finding that TGF-β itself induces nuclear relocation of dendrin, CatL expression was also increased in TGF-β transgenic mice where it correlated with glomerular disease progression. In conclusion, we identified dendrin as a transcriptional activator of CatL. CatL not only induces acute podocyte FP effacement as shown previously, but enhances podocyte susceptibility to apoptosis and is thus involved in glomerular disease progression.

**PKCe Has Multiple Functions in Podocytes** Beina Teng, Irini Tossidou, Youying Mao, Joon-Keun Park, Hermann G. Haller, Mario Schiffer. *Nephrology, Medical School Hannover, Hannover, Germany.*

PKCε has multiple functions in podocytes

Background: Protein Kinase C (PKC) is a family of serine- and threonine protein kinases that is involved in diverse cellular functions. In recent studies it was demonstrated that the novel PKC isoform (PKCε) is a multifunctional kinase that influences a variety of cellular processes including proliferation, differentiation, apoptosis, motility, cell spreading, migration and adhesion in a wide range of cells. The role of PKCε in podocytes is still unexplored.

Methods and Results: *In vivo* in PKCε-/- mice we detected a progressive reduction of podocytes and a spontaneous glomerulosclerosis phenotype. We established immortalized cell lines for PKCε and performed migration and adhesion assays that revealed a diminished migration and adhesion of PKCε-/- podocytes. When we studied the composition of the fokal adhesion complex, we detected a strong downregulation of Integrin-β1, vinculin and Focal Adhesion Kinase (FAK) in PKCε-/- podocytes compared to PKCε+/+ podocytes. Stimulation of PKCε is required for the activation of focal adhesion components to regulate the assembly and disassembly of the focal adhesion, which influences the podocytes spreading, migration and adhesion. PKCε binds directly to actin or phosphorylates cytoskeletal proteins and plays a central role in the control of actin-cytoskeletal rearrangement by modulating multiple signalling pathways. Therefore PKCε is responsible for the extension of lamellopodia and filopodia during podocyte differentiation through turnover and actin-cytoskeletal reorganization. We performed the Actin Polymerization Assay with PKCε+/+ and deficient podocytes to see whether the deficiency of PKCε impacts the actin-polymerization in podocytes. PKCε plays also an important role in regulation of apoptosis. PKC deficiency leads to decreaded Akt and ERK1/2 activation and a prolonged apoptotic signalling after stimulation with growth factors. Moreover, PKCε is involved in Ras signalling cascade and PKCε deficiency causes arrest of cell proliferation.

Conclusion: We conclude that PKCε is an essential regulator of various cellular processes and thus is an indispensable component for normal podocyte function.

**Inhibition of MAPKAPK-2 (MK-2), a Downstream Target of p38 MAPK, Protects Podocytes from Injury** Ruma Pengal,[1] Adam Guess,[1] Shipra Agrawal,[1, 2] Rainer Benndorf,[1, 2] William E. Smoyer.[1, 2] *[1]Center for Clinical and Translational Research, The Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Department of Pediatrics, The Ohio State University, Columbus, OH.*

**Background:** The p38 mitogen activated protein kinase (MAPK) has been implicated in mediating podocyte injury in both clinical glomerulopathies and experimental models of nephrotic syndrome (NS). While targeted deletion of p38 results in prenatal death in mice, targeted deletion of one of its major downstream targets, MAPK-activated protein kinase-2 (MK-2), results in viable offspring. Based on this, we investigated the specific role of MK-2 in mediating NS-related podocyte injury.

**Methods:** We assessed the ability of MK-2 to regulate podocyte damage using C23, a novel specific inhibitor of MK-2, after exposure to puromycin aminonucleoside (PAN), a known toxic mediator of renal injury. PAN-induced injury was analyzed by measuring (i) cell viability using the MTT assay and (ii) actin cytoskeleton integrity by phalloidin staining. We also confirmed the efficacy of the MK-2 inhibitor using SDS- and isoelectric focusing followed by Western blotting to determine the degree of phosphorylation of p38 MAPK, MK-2, and the small heat shock protein Hsp25 which is a major substrate of MK-2. In addition, we measured the effect of MK-2 inhibition on the expression of Cox-2, another known mediator of podocyte injury, using qRT-PCR.

**Results:** Treatment of podocytes with C23 significantly reduced both PAN-induced cellular injury and actin filament disruption. In addition, C23 treatment also resulted in decreased MK-2 activity, as measured by phosphorylation of Hsp25. Further, qRT-PCR indicated that MK-2 inhibition led to reduced expression of Cox-2 mRNA.

**Conclusions:** These findings indicate that PAN-induced podocyte injury is mediated in part by MK-2 activation, and that MK-2 inhibition can effectively protect podocytes against injury, possibly via reduction in Cox-2 expression. We thus speculate that MK-2 inhibition may offer a more targeted therapeutic approach than p38 inhibition for podocyte protection in glomerular diseases.

**Cross-Talk between Nck1/2 and Synaptopodin Regulates Podocyte Actin Dynamics** Priyanka Rashmi,[1] Christian Faul,[2] Peter H. Mundel.[3] *[1]Graduate School, Mount Sinai School of Medicine, New York, NY; [2]Division of Nephrology, University of Miami, Miami, FL; [3]Division of Molecular Medicine, University of Miami, Miami, FL.*

Dynamic regulation of the podocyte actin cytoskeleton is paramount for proper kidney filter function and mutations affecting several podocyte proteins lead to the rearrangement of the actin cytoskeleton, disruption of the filtration barrier and renal disease. The ubiquitously expressed adapter proteins Nck1 and Nck2 modulate podocyte actin dynamics by linking phospho-nephrin to N-WASP:ARP2/3 mediated actin polymerization. Synaptopodin, another critical regulator of the podocyte actin cytoskeleton, induces stress fibers by blocking the Smurf-1 mediated ubiquitination of RhoA and suppresses Cdc42 signaling by blocking the binding of Cdc42 and Mena to IRSp53.

Here we show that in podocytes Nck1 but not Nck2 steady-state protein levels are regulated by Cbl mediated ubiquitination and subsequent proteasomal degradation. The inactivation of an evolutionarily conserved lysine residue reduces Cbl binding and proteasomal degradation of Nck1. Gene silencing of synaptopodin in podocytes reduces Nck1 but not Nck2 protein steady-state levels. Synaptopodin directly binds to Nck1 and competes with Cbl for Nck1 binding, thereby preventing its ubiquitination and subsequent proteasomal degradation. Of note, similar to synaptopodin, both Nck1 and Nck2 are targets of cathepsin L mediated proteolysis. Functionally, the overexpression of Nck1 or Nck2 in differentiated podocytes disrupts stress fibers and reduces synaptopodin levels, which can be rescued by the calcineurin inhibitor cyclosporine A or the cathepsin inhibitor E64.

Our data reveal a feedback loop whereby reciprocal control of synaptopodin and Nck1/2 steady state protein levels dynamically regulates the podocyte actin cytoskeleton. In summary, these results demonstrate a role for synaptopodin as inhibitor of Nck1 ubiquitination and proteasomal degradation. Together with the recently identified inhibition of Smurf1 mediated ubiquitination of RhoA, they reveal synaptopodin as a comprehensive inhibitor of E3 ubiquitin ligase signaling for the modulation of podocyte actin dynamics.

**Podocyte-Specific Deletion of Prohibitin-2 Leads to Progressive Proteinuria, Glomerular Sclerosis and Premature Death** Christina Ising, Sebastian Braehler, Bernhard Schermer, Thomas Benzing, Paul T. Brinkkoetter, Christine E. Kurschat. *Deparment of Nephrology, University of Cologne, Germany.*

Patients with mitochondrial disorders present with a variety of clinical symptoms including nephrotic syndrome and FSGS. The mechanisms how mitochondrial dysfunction leads to glomerular insufficiency are poorly understood. Prohibitin-1 (PHB1) and prohibitin-2 (PHB-2) are two closely related proteins that reside within the inner mitochondrial membrane. Both are essential for mitochondrial membrane stability and structure. They directly interact by forming multimeric ring complexes and stabilize each other. Here, we report a podocyte-specific prohibitin-2 knockout mouse model resembling the glomerular lesions observed in patients with mitochondrial dysfunction.

PHB-2-deficiency resulted in disorganized and swollen mitochondrial cristae in vitro. Mitochondrial membrane potential and enzymatic activities of respiratory complexes were unaffected. Depletion of PHB-2 led to decreased levels of PHB-1. The cells showed markedly reduced proliferation and an increased susceptibility to apoptotic stimuli.

PHB-2 knockout mice were born in normal mendelian ratios. At birth, glomerular development appeared to be normal. PHB-2 null mice rapidly developed significant proteinuria leading to growth retardation, massive loss of body weight and premature death. Kidney histology revealed collapsing glomerular capillaries, focal glomerulosclerosis and severe tubular atrophy with pseudostroma formation. Podocyte PHB-2 null mice did not survive longer than 5 weeks. In contrast, heterozygous floxed PHB-2;Cre positive mice showed normal kidney function.

In conclusion, the mitochondrial proteins PHB-1/-2 play an important role in glomerular function. Loss of these proteins leads to massively impaired glomerular filtration and limited survival. This knockout mouse model reflects the glomerular dysfunction observed in patients with mitochondrial disorders and provides a powerful model to further investigate the impact of mitochondrial function on glomerular biology.

**Role of CD2AP in Mitochondrial Fission and Fusion** Kumiko Moriwaki,[1] Mehmet M. Altintas,[1] Changli Wei,[1] Jing Li,[1] Hideyasu Kiyomoto,[2] Jochen Reiser.[1] *[1]Division of Nephrology and Hypertension, University of Miami, Miami, FL; [2]Division of Nephrology and Dialysis, Kagawa University, Kagawa, Japan.*

Mitochondrial dysfunction can be associated with focal segmental glomerulosclerosis (FSGS). Podocytes are target cells in FSGS and their mitochondrial regulation is not well investigated. We analyzed mitochondrial function in CD2AP knockout podocytes. Accordingly, mice lacking CD2AP or humans with CD2AP mutations develop FSGS. When we compared mitochondrial morphology of CD2AP-/- podocytes to wt podocytes, we found increased size and ballooned mitochondria that were often elongated in diseased cells similar to wt podocytes treated with puromycin, but clearly different from normal mitochondrial networks in untreated wt podocytes. We next studied mitochondrial fusion and fission, which are necessary to maintain functional integrity. In mammalian cells, fission requires dynamin-related protein 1 (DRP1) and fusion requires optic atorophy 1 (OPA1). DRP1 expression in CD2AP-/- podocytes was lower than in wt podocytes. In contrast OPA1 expression increased in CD2AP-/- podocytes. We monitored intracellular pH using 5-chloromethylfluorescein diacetate to investigate whether the alterations of mitochondrial morphology relate to its dysfunction known to affect the cytosol. Intracellular pH in CD2AP-/- podocytes was lower than in wt podocytes. To better understand the link of mitochondrial dysfunction and acidic cytosolic pH in CD2AP-/- podocytes, we analyzed expression of H+ transporters on mitochondrial membranes and found expression of SNAT3, a classical Glutamine-H+ antiporter by immnogold electron microscopy. SNAT3 expression was increased in podocytes during injury and might contribute to podocyte pH regulation. We are currently forcing expression of SNAT3 in podocytes using gene-transfer in normal and diseased mice to analyze effects on glomerular barrier function.

In summary, our data describes novel roles for CD2AP in mitochondrial morphogenesis via regulation of mitochondrial fission and fusion proteins. Mitochondrial function in podocytes is linked to podocyte cytosolic pH regulation via specific transporters such as SNAT3 to impact on the glomerular filter.

**Podocyte Specific crif1 KO Mice Show Severe Mitochondrial Deformity and Massive Albuminuria** Dae Eun Choi,[1] Jin Young Jeong,[1] Ji Yoon Jung,[1] Dong-Suk Chang,[1] Sarah Chung,[1] Yoon-Kyung Chang,[2] Ki Ryang Na,[1] Kang Wook Lee,[1] Young Tai Shin.[1] *[1]Internal Medicine, Chungnam National University Hospital, Daejeon, Korea; [2]Internal Medicine, Daejeon St Mary's Hospital, Daejeon, Korea.*

**Introduction**: Most of chronic renal diseases are associated with podocyte injury. Podocytes are important constituent of the glomerular filtration barrier. Although studies for podocyte injury using the models of diabetic glomerulonephritis (GN), drug induced GN, and hypertensive GN were done actively, there were few study of podocyte specific injury in vivo. Also, although some studies suggested mitochondrial injury of podocyte is important in progressive glomerular disease, there were few study of podocyte specific mitochondrial injury in glomerulonephritis. We made the model of podocyte specific mitochondrial injury using Cre-lox system. We studied the effects of mitochondrial injury to podocyte in vivo.

**Methods**: We made podocyte specific crif1 knockout (KO) mouse via mating C57Bl/6 background crif1-flox mouse with podocin Cre mouse. We compared control mice (crif1 (flox/flox)) to podocin specific crif1 KO mice (crif1 (Δ/Δ)). We observed metabolic finding including urine albumin, creatinine, and volume and body weight in these mice. We evaluated mouse kidney using H&E stain and electromicroscopy.

**Results**: Podocyte specific crif1 KO mice showed extensive mitochondrial swelling, broken cristae structure, and increase numbers of abnormal mitochondria in only podocyte at 5 weeks old. The levels of urine albumin/creatinine were increased markedly in crif1 (Δ/Δ) compared with crif1 (flox/flox) (45±14mg/mg vs. 1547±151mg/mg, $p<0.001$). There were no specific significant differences in body weight, urine volume, glomerular morphology in H&E stain, and the structure of foot process in electromicroscopy in both 5 weeks old mice.

**Conclusion**: podocyte specific crif1 KO mice showed severe podocyte specific mitochondrial deformity and massive albuminuria in spite of showing normal structure of foot process of podocyte.

**Angiotensin II Induces Reorganization of Actin Cytoskeleton and Myosin Light Chain in Podocytes through Rho/ROCK Signaling Pathway** Cheng Chen,[1] Wei Liang,[1] Zhilong Ren,[1] Guohua Ding,[1] Pravin C. Singhal.[2] *[1]Division of Nephrology, Renmin Hospital of Wuhan University, Wuhan, Hubei, China; [2]Department of Medicine, Long Island Jewish Medical Center, New Hyde Park, NY.*

Accumulating evidence suggests that cytoskeleton reorganization is involved in podocyte injury, finally leading to glomerulosclerosis. Rho/ROCK(Rho-associated kinases) has been demonstrated to play a crucial role in cellular cytoskeleton remodeling through serine-theronine phorsphorylation of myosin light chain phosphatase (MLCP). In the present study, we evaluated the effect of Angiotensin II (Ang II) on actin cytoskeleton and myosin light chain (MLC) in podocyte to demonstrate whether Rho/ROCK pathway is involved in this process.

Ang II was infused in Sprague-Dawley rats via subcutaneous osmotic mini-pumps (400 ng/kg/min). Animals were sacrificed at week 4. Renal morphological changes were evaluated by light and electron microscopy. Immunohistochemistry and western blot were performed to detect the expression of p-MLC and ROCKα.

Cultured podocytes(MPC5) were incubated in media containing either buffer or Ang II($10^{-7}$mol/L) with or without the Rho-kinase (ROCK) inhibitor Y-27632 for variable time periods. F-actin was stained with FITC-conjugated phalloidin. P-MLC was evaluated by immunofluorescence and western blot. Activation of Rho/ROCK was evaluated by western blot.

P-MLC was mainly expressed in the podocytes of rat glomeruli. Compared with control group, MLC phosphorylation in Ang II-infused rat was significantly increased. ROCK expression has no significant change between two animal groups. In the cultured podocytes, Ang II stimulated the expression of Rho/ROCKα while the morphology of podocyte was simultaneously changed accompanied by increased phosphorylation of MLC and redistribution of actin. Addition of Y-27632 to podocytes treated with Ang II could ameliorate F-actin cytoskeleton remodeling and the increment of p-MLC.

These results suggest that Ang II induces remodeling of podocyte cytoskeleton via MLC phosphorylation and F-actin reorganization. Rho/ROCKα signaling transduction may play a pivotal role in this process.

**Abnormal Podocyte Structure in Nestin-Deficient and Nestin/Vimentin-Deficient Mice** Amanda Murphy,[1] Paria Mohseni,[2] Hoon-Ki Sung,[2] Richard K. Leung,[1] Susan E. Quaggin,[2,3,4] Paul S. Thorner.[1,3] *[1]Division of Pathology, DPLM, Hospital for Sick Children; [2]Samuel Lunenfeld Research Institute, Mount Sinai Hospital; [3]Faculty of Medicine, University of Toronto; [4]Department of Nephrology, St. Michael's Hospital, Toronto, Canada.*

Background: The intermediate filament nestin is expressed in podocytes at all stages of development. Most cells downregulate nestin upon differentiation, but human podocytes continue to express nestin after differentiation and in glomerular disease. Animal models of glomerular injury show increased podocyte nestin expression. Assembly of nestin requires other filaments, in particular vimentin, which co-localizes with nestin in podocytes in vivo and in vitro. We hypothesize that nestin plays important roles in podocyte development, function and/or glomerular disease.

Objective: Germline nestin knockout and nestin/vimentin double knockout mice were generated and assessed renal function, morphology and ultrastructure.

Results: Progeny are viable. Nestin-deficient mice show no increase in urinary protein excretion. Kidneys appear normal by light microscopy. Compared to wild-type controls, renal podocytes in nestin -/- mice show abnormally branched, dysmorphic primary and secondary processes. Foot processes have unusual profiles, but slit diaphragms appear normal. Nestin/vimentin double knockouts show a more severe ultrastructural phenotype, with collapsed 'limp' primary and secondary processes, stubby foot processes and no intermediate filaments in the cytoplasm.

Conclusion: Nestin deficiency has a unique phenotype not typical of any human disease nor transgenic model. This is exaggerated by concomitant deficiency of vimentin. We conclude that nestin plays an important role in process formation or maintenance. Vimentin

partially compensates for nestin deficiency in podocytes, indicating some redundancy of function. Despite the abnormal podocyte morphology, there is no obvious effect on glomerular function, suggesting the branching architecture is not critical for filtration function, as long as foot processes are intact, at least under normal conditions. Whether this holds true under conditions of stress remains to be determined.

**F-PO1899**

**Podocyte-Specific Knockout of Myosin 1e Disrupts Glomerular Filtration** Mira Krendel,[1] Lawrence B. Holzman,[2] Sharon Chase.[1] *[1]Department of Cell and Developmental Biology, SUNY Upstate Medical University, Syracuse, NY; [2]Renal Electrolyte and Hypertension Division, University of Pennsylvania School of Medicine, Philadelphia, PA.*

We have previously demonstrated that knockout mice lacking an actin-dependent motor protein, myosin 1e (myo1e), develop proteinuria and effacement of podocyte foot processes (JASN, 2009, 20:86-94). In order to directly test the hypothesis that myo1e is necessary for normal podocyte functions, we have developed a new mouse strain, in which myo1e knockout is targeted to podocytes using Cre recombinase under the control of podocyte-specific NPHS2 promoter.

Immunofluorescence labeling of kidney cryosections from podocyte-specific myo1e knockout mice confirmed the loss of myo1e from podocytes. Mice lacking myo1e in podocytes developed moderate proteinuria by 8 weeks of age. The urinary albumin/creatinine ratio in podocyte-specific knockout mice was intermediate between that of control mice (normal kidney function) and myo1e-null mice (severe proteinuria). Since NPHS2 promoter becomes active only at the capillary loop stage of glomerular development, in the complete knockout myo1e may be absent from podocyte precursors at an earlier developmental stage than in the NPHS2-driven knockout and this may exacerbate glomerular abnormalities. Additionally, examination of myo1e expression pattern in podocyte-specific myo1e knockout mice revealed expression of myo1e in mesangial cells in some glomeruli, suggesting that myo1e may also be involved in mesangial cell development. In conclusion, podocyte-specific disruption of myo1e expression induces glomerular filtration defects, confirming that myo1e is required for normal podocyte activity. The timing and cell type specificity of myo1e depletion may determine the severity of kidney disease observed in myo1e-knockout mice.

**Distinct Contributions of Non-Muscle Myosin Heavy Chains IIA (Myh9) and IIB (Myh10) to Podocyte Traction and Adhesion** Joel M. Henderson,[1] Hui Chen,[1] Julie A. Tomolonis,[1] Mei Cao,[1] Martin R. Pollak.[2] *[1]Pathology, Boston University Medical Center, Boston, MA; [2]Medicine/Genetics, BIDMC/Harvard Medical School, Boston, MA.*

Purpose: Non-muscle myosin heavy chains are implicated in glomerular disease. These contractile proteins may help podocytes bolster glomerular capillary wall structure through tonic contraction. Changes which affect their function may compromise glomerular structural integrity, thereby leading to glomerular damage. The aim of this study is to characterize the functional role of non-muscle myosins in podocytes.

Methods: Myh9 and Myh10, the only myosin II heavy chain isoforms significantly expressed in cultured murine podocytes, were independently knocked down in these cells using lentiviral RNA interference. Knock down and control cells were plated on glass and polyacrylamide elastic substrates. Immunohistochemistry was performed to examine non-muscle myosin and filamentous actin distribution, and traction force microscopy was used to measure net contractile moment (an expression of inward pulling force). Blebbistatin (non-muscle myosin specific inhibitor) and lysophosphatidic acid (contractile stimulator) were applied in selected experiments.

Results: Highly efficient knockdown of Myh9 and Myh10 was achieved at the protein level using the lentiviral system. Both Myh9 and Myh10 knockdown were associated with disorganization and loss of actin stress fibers. Myh9 knock down resulted in a 52% decrease ($p=0.029$) in unstimulated traction, but only a 24% decrease in stimulated contraction (not statistically significant), relative to controls. Traction could not be measured in Myh10 knock down cells due to complete loss of adherent cells from elastic substrates. Blebbistatin almost completely abolished podocyte contractility in wild type cells.

Conclusion: Both non-muscle myosins IIA and IIB participate in cytoskeletal organization in murine podocytes, and together account for almost all traction force generation. Non-muscle myosin IIB may excede IIA in its relative contribution to stimulated traction force generation. Non-muscle myosin IIB also appears to play a unique role in podocyte adhesion.

**F-PO1901**

**Zebrafish as a Model To Study MYH9-Associated Kidney Disease** Tobias Müller,[1] Elisabeth Rumpel,[1] Susanne Hradetzky,[1] Frank Bollig,[3] Christoph Englert,[3] Andreas Greinacher,[2] Karlhans Endlich,[1] Nicole Endlich.[1] *[1]Anatomy and Cell Biology, Ernst Moritz Arndt University, Germany; [2]Immunology and Transfusion Medicine, Ernst Moritz Arndt University, Greifswald, Germany; [3]Leibniz Institute for Age Research, Fritz Lipmann Institute, Jena, Germany.*

The simplicity and the rapid development of the zebrafish pronephros together with the similarity of the glomeruli of zebrafish and mammals make the zebrafish an ideal model system for studying kidney development and function. After 48-54 h post fertilization (hpf) the zebrafish larvae start with glomerular filtration. Furthermore, zebrafish larvae are translucent during the first 96-120 hpf, which makes it possible to study the filtration processes in vivo after microinjection of fluorescently labeled dextran. Using this model we studied the influence of the heavy chain of non-muscle myosin IIA (NMMHC-IIA) on pronephros development. Three days after microinjection of morpholinos against zMyh9 into fertilized eggs we observed a phenotype in 96% of the zebrafish larvae. Beside a defect in heart development, we observed strong pericardial edema. Similar effects were observed after incubation of the larvae for 24 h with 200 µM blebbistatin, an inhibitor of non-muscle myosin II. To study the effect of zMyh9 knockdown in detail we used transgenic zebrafish larvae expressing EGFP in podocytes and tubular epithelial cells (WT1b:EGFP). Immunohistological studies revealed that zMyh9 knockdown larvae exhibited morphological changes of the glomeruli. Electron microscopy showed impaired capillarization of the glomerulus, partly thickening of the glomerular basement membrane and filopodia-like foot processes in zMyh9 morpholino injected larvae compared to control morpholino injected ones. To study the influence of zMyh9 on glomerular filtration, we injected 10 kDa Alexa-467- and 500 kDa FITC-labeled dextrans in vivo into the caudal vein of zebrafish larvae around 96 hpf. With this method we found that glomerular filtration of zMyh9 morpholino injected larvae was significantly reduced in contrast to the controls. Taken together, our results demonstrate that zMyh9 plays an essential role in glomerular development in zebrafish.

**F-PO1902**

***PAI-1*$^{-/-}$ Podocyte Resistance to Injury Is Not Overcome by Exogenous PAI-1 Suggesting Possible Intracrine PAI-1 Effects** Haichun Yang,[1] Jianyong Zhong,[2] Ji Ma,[2] Agnes B. Fogo.[1] *[1]Pathology, Vanderbilt University, Nashville, TN; [2]Pediatric Nephrology, Vanderbilt University, Nashville, TN.*

We investigated mechanisms of PAI-1 effects on podocyte injury by comparing podocytes with genetic deficiency of PAI-1 *vs.* exogenous restoration of PAI-1.

Primary podocytes were harvested from either *PAI-1*$^{-/-}$ (KO) or wild type (WT) mice, injured by puromycin aminonucleoside (PAN) and various human PAI-1 variants were added: control PAI-1, retaining native PAI-1 functions (CPAI); PAI-1 variant without VN binding but with normal proteolysis inhibition (Q123K); PAI-1 without proteolytic inhibition but with intact VN binding (T333R), and PAI-1 with reduced LRP-binding (R76E).

Endogenous PAI-1 entered cells resulting in increased PAI-1 in cell lysates. WT cells exposed to PAN had more apoptosis (by 34%) and cleaved caspase-3 (by 28%) *vs.* KO + PAN. In KO + PAN, exogenous PAI-1 with intact proteolytic inhibitory activity did not stimulate cleaved caspase-3 (CPAI 0.39±0.04, Q123K 0.26±0.04, R76E 0.46±0.10 *vs.* KO 0.57±0.08). In contrast, exogenous PAI-1 without proteolytic inhibitory activity (T333R) significantly restored caspase-3 to WT level (T333R 0.82±0.16, WT 0.79±0.07). In parallel, only T333R PAI-1 decreased Bcl-xl in PAN-injured KO cells (0.19±0.13), with no change in Bcl-xl in other groups (CPAI 0.48±0.03, Q123K 0.48±0.02, R76E 0.60±0.03). WT cells injured by PAN had decreased α-actinin 4 expression by 23.5% *vs.* KO, while none of the exogenous mutant PAI-1 variants changed the relative preservation of α-actinin 4 expression in KO podocytes injured with PAN.

Our data show that *PAI-1*$^{-/-}$ podocytes are protected from apoptosis and cytoskeletal disarray, and further, that addition of exogenous PAI-1 does not restore injury of cytoskeleton to WT levels, although apoptotic injury can be restored by adding proteolytically active PAI-1. Thus, these data suggest that endogenous and exogenous PAI-1 mediate podocyte cytoskeletal injury and apoptosis through different pathways. Endogenous PAI-1 may induce podocyte cytoskeletal injury as an intracrine peptide. Conversely, genetic deficiency of PAI-1 may protect cells against injury independent of classic PAI-1 pathways.

**F-PO1903**

**Glomerular Destabilization Causing Autonomous Podocyte Loss and Progression. Restabilization by Angiotensin II Blockade, and Monitoring by Podocyte Urine Biomarkers** Akihiro Fukuda,[1] Yuji Sato,[2] Madhusudan M. Venkatareddy,[1] Larysa T. Wickman,[1] Mahboob A. Chowdhury,[1] Su Qing Wang,[1] Jocelyn E. Wiggins,[1] Roger C. Wiggins.[1] *[1]Nephrology Division, Departments of Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Circulatoly and Body Fluid Regulation, Department of Internal Medicine, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan.*

Podocyte depletion is the major mechanism driving glomerulosclerosis. Progression is the process by which progressive glomerulosclerosis leads to End Stage Kidney Disease (ESKD). The human diphtheria toxin receptor transgenic Fischer 344 rat model of controlled podocyte loss was used to dissect the progression process. After initial podocyte injury causing > 30% loss of podocytes the glomeruli became destabilized, resulting in continued

autonomous podocyte loss over time until global podocyte depletion (ESKD). Podocyte loss was measured by WT1 positive nuclear counting, the GLEPP1 positive podocyte tuft area, and by urine podocin mRNA. Autonomous podocyte loss from glomeruli eventually resulted in global depletion of podocytes with marked glomerular and interstitial fibrosis and ectatic tubules typical of ESKD. An identical process occurred in progression initiated by Puromycin aminonucleoside in the Sprague-Dawley rat, thereby demonstrating broad applicability of the observation. Angiotensin II blockade (using a combination of enalapril and losartan administered in the drinking water) prevented autonomous podocyte loss and progression (restabilization). Discontinuing angiotensin II blockade resulted in recurrent glomerular destabilization and podocyte loss. Furthermore, blood pressure control by non-angiotensin II blockade (using a combination of hydralazine, reserpine and hydrochrolothiazide administered in the drinking water) did not prevent autonomous podocyte loss. Therefore a critical degree of initial podocyte depletion destabilizes the glomerulus such that it autonomously loses podocytes in an angiotensin II-dependent manner until glomeruli become globally depleted of podocytes (ESKD). Glomerular destabilization can be monitored non-invasively by measuring podocyte mRNAs in urine.

**F-PO1904**

**Podocyte-Specific Expression of Tamoxifen-Inducible Cre Recombinase in Mice** Hideki Yokoi,[1,2] Masato Kasahara,[1,2] Masashi Mukoyama,[1] Kiyoshi Mori,[1] Takashige Kuwabara,[1] Akira Sugawara,[1] Kazuwa Nakao.[1] *[1]Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Department of Nephrology and Blood Purification, Institute of Biomedical Research and Innovation, Kobe, Hyogo, Japan.*

Podocytes play an important role in maintaining normal glomerular function. A podocyte-specific conditional knockout technology has been established by the use of transgenic mice expressing podocyte-specific Cre recombinase to clarify the role of genes expressed in podocytes. Cre/loxP system has been used for conditional knockout mice. Although podocyte-specific conditional knockout mice are useful in investigating the role of the gene, several podocyte-specific knockout mice exhibit congenital renal abnormalities and perinatal death, which is caused by the disruption of the gene in the embryonic kidney stage. This strategy often has difficulty in elucidating the role of the gene in the diseased or postnatal kidney. Recently, efforts have been undertaken to create a temporal regulation for Cre recombination by tamoxifen or tetracycline. To introduce temporal control in genetic experiments targeting the podocyte, we constructed tamoxifen-inducible Cre-recombinase ($CreER^{T2}$) transgenic mice under the control of podocyte-specific promoter, 2.5-kb fragment of the human podocin (NPHS2) gene. Specificity and efficiency of Cre activity were examined by crossing NPHS2-$CreER^{T2}$ with the ROSA26 reporter (R26R) mouse in which a floxed-stop cassette has been placed upstream of the β-galactosidase gene. Four-week old double-mutant mice (NPHS2-$CreER^{T2}$/R26R) were intraperitoneally administered with 0.5 mg of 4-hydroxytamoxifen (4-OHT) for 3 consecutive days. NPHS2-$CreER^{T2}$/R26R treated with 4-OHT expressed β-galactosidase specifically in 85% of podocytes in glomeruli. Expression of Cre recombinase mRNA was mostly restricted in the kidney, especially in glomeruli. In conclusion, we have successfully generated podocyte-specific inducible Cre transgenic mice by tamoxifen administration. These mice allow us to disrupt genes specifically in podocytes after birth.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1905**

**Urinary Podocin: Nephrin mRNA Molar Ratio (PNMR) as a Non-Invasive Biomarker of Podocyte Stress** Larysa T. Wickman,[1] Akihiro Fukuda,[2] Madhusudan M. Venkatareddy,[2] Su Qing Wang,[2] Mahboob A. Chowdhury,[2] Jocelyn E. Wiggins,[2] David B. Kershaw,[1] Matthias Kretzler,[2] Roger C. Wiggins.[2] *[1]Pediatrics, University of Michigan, Ann Arbor, MI; [2]Internal Medicine, University of Michigan, Ann Arbor, MI.*

BACKGROUND: At the present time treatment decisions for patients with kidney disease are based on measurements of renal function which are inexact, or on repeat kidney biopsies which are invasive and carry risk. This means that therapeutic decisions are often delayed until substantial renal function has been lost. Progression to end stage kidney disease following glomerular injury is caused by persistent podocyte depletion. In rat model systems we have shown that podocyte loss can be monitored through podocyte specific urinary mRNAs (Sato et al. JASN, 2009). OBJECTIVE: To identify podocyte specific markers that can reflect changes in podocyte behavior related to progression using a combination of animal models and human urine samples from patients with glomerular diseases. METHOD: mRNAs from rat and human urine pellets and transgenic rat cortical renal tissues were extracted, reverse transcribed, and cDNAs quantitated using Q RT-PCR and cDNAs as standards. Because both Podocin and Nephrin are expressed in the same cell, the PNM ratio corrects for RNA stability, sample size, concentration, contamination from non-kidney sources, and variation in reverse transcription efficiency. RESULTS: The rates of podocyte mRNA decay for podocin and nephrin mRNAs in urine were paralleled, so that expressing data as a ratio gives reproducible values irrespective of urine collection conditions or amount of urine used. Animal data show a strong correlation between urinary and cortical PNMR, and also correlates with severity of the glomerular injury as determined histologically. Initial data from patients with various forms of glomerular diseases shows elevated levels of urinary PNMR. CONCLUSIONS: Combined animal and human data suggest that urinary PNMR reflects the progression process occurring in the glomerulus and can serve as a noninvasive biomarker of podocyte stress for use in the clinic.

**The Role of Circulating Proteases in FSGS** Jessica Harris, Gavin Iain Welsh, Moin Saleem. *Academic Renal Unit, University of Bristol, Bristol, United Kingdom.*

Focal Segmental Glomerulosclerosis (FSGS) is a steroid resistant form of nephrotic syndrome leading to end stage renal disease. The podocyte is known to be the target of injury for this disease, undergoing a dramatic change of shape and eventual loss from the glomerular basement membrane. However little is known about the external stimulus for these changes.

Here we have studied the effects of nephrotic and non-nephrotic plasma, obtained from patients with post transplant FSGS relapse, at commencement of plasma exchange and then when they are in remission, on conditionally immortalised cultured human podocytes (ciPods). In 4 consecutive patients we show that the actin associated protein VASP is phosphorylated in response to relapse plasma, with no response to remission plasma. Functionally, ciPods treated with relapse plasma show reduced adhesion compared to cells treated with remission plasma.

We investigated the role of circulating proteases in this signalling to VASP and show that inhibition of proteases in nephrotic plasma inhibits VASP phosphorylation. We show that the class of protease involved is likely to be a serine protease and, using siRNA technology, determine that plasma induced signalling is taking place via protease activated receptor 1 (PAR1).

Thus we hypothesise that excess activity of plasma proteases is involved in the pathogenesis of post transplant recurrence of FSGS, with VASP phosphorylation as a specific biomarker of disease activity.

**MDR-1 Gene Polymorphisms in Steroid Resistant Nephrotic Syndrome** Narayan Prasad. *Nephrology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, UP, India.*

**INTRODUCTION AND AIMS:**

The putative genetic regulation of MDR-1gene expression and P-gp function has not yet been clearly delineated in Nephrotic syndrome(NS) patients. We undertook this study to see the distribution of 3 most frequent MDR-1 exonic polymorphisms G3435C, G2677T (A) and C1236T in our cohort of NS cases and age and sex matched healthy children to see their usefulness as marker of steroid responsiveness.

**METHODS:** 216 children of NS and 216 healthy age, sex and ethnically matched controls were genotyped for the three exonic MDR-1 polymorphisms (G3435C, G2677T (A) and C1236T) by the PCR-RFLP technique. Genotype/allele frequencies were compared in between steroid sensitive (SSNS) and steroid resistant (SRNS) patients and between patients and healthy controls.

**RESULTS:** Of the total 216 cases of NS (mean age 11 6.6 years, 165 males), 137 were responsive and 79 resistant to steroids. The genotype frequencies were in Hardy-Weinberg equilibrium. Homozygous mutants of MDR1-C3435T (TT versus CC, $\chi^2$= 4.51, p= 0.034) and MDR1-G2677T/A (TT+AA vs GG): $\chi^2$= 4.71, p= 0.030)] were significantly high in NS patients compared to control. On comparing SRNS versus SSNS, homozygous mutant TT+AA compared to wild genotype GG was significantly higher in SRNS than SSNS patients($\chi^2$= 6.53, p= 0.011) in SNPs MDR1-G2677T/A , while other markers C3435T and C1236T were not different. On analyzing synergistic effect of 2 or 3 SNPs in combination amongst SSNS, SRNS and controls , the combination bearing mutant genotype either of C3435T or G2677T/A exhibited significantly high frequency of mutant genotypes distribution in SRNS patients. MDR-1 haplotypes did not differ significantly between SSNS and SRNS patients. On linkage disequilibrium analysis, highest LD value ($r^2$ =0.08; D'=0.35) corresponds to SNP's C3435T-C1236T. Lower LD values was found between the SNP's G2677T/A-C1236T ($r^2$ =0.007; D'=0.16) and between C3435T-G2677T/A ($r^2$ =0.005; D'=0.11).

CONCLUSIONS:

Patients carrying homozygous mutant genotype (G2677T/A (GG + GT/GA v/s TT/AA)alone or in different combinations are more prone to develop steroid resistance in north Indian NS patients.

**Novel Podocyte Protein Pdlim2 Is Differently Expressed in Human Proteinuric Diseases** Fredrik S. Dunér,[1] Jaakko Patrakka,[3] Kjell R. Hultenby,[2] Annika Wernerson.[2] *[1]Clinical Science, Intervention and Technology (CLINTEC), Karolinska Institutet, Stockholm, Sweden; [2]Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden; [3]Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden.*

The cytoskeleton of podocyte foot processes is critical for their shape and function, and mutations in several cytoskeleton-associated proteins are associated with nephrotic syndrome. Pdlim2 is a novel member of an ALP subfamily of cytosolic proteins that associate with the cytoskeleton. Our aim was to study its expression in proteinuric disease.

Materials and methods:

Biopsies from nephrotic patients fulfilling the histological criteria for focal segmental glomerulosclerosis, perihilar type (FSGS, n=4), minimal change nephropathy (MCNS, n=5) and membranous nephropathy (MN, n=5) were studied. The expression of pdlim2 in

podocytes was assessed with immunofluorescence and semiquantitative immunoelectron microscopy (immunoEM) using gold-conjugated polyclonal anti-pdlim2 antibodies. The concentration of pdlim2 was expressed as the number of gold labels per $\mu m^2$, "Au/$\mu m^2$"

Results:

Immunofluorescence showed a strong linear staining for pdlim2 protein around glomerular capillaries in the normal kidney. No positive signal was detected outside glomeruli. By immunoEM, pdlim2 was localized centrally in the cytoplasm of the podocyte foot processes, corresponding to the actin microfilaments. The labeling was significantly lower in patients with MCNS (6.4 ± 3.6 Au/$\mu m^2$) and in MN (6.7 ± 2.6 Au/$\mu m^2$), whereas in FSGS patients, it was unchanged (19.7 ± 7.9 Au/$\mu m^2$) compared to controls (19.5 ± 8.7 Au/$\mu m^2$).

Conclusion:

In the normal human kidney, the novel protein pdlim2 is exclusively expressed in podocyte foot processes, associated with the actin cytoskeleton. Its expression was lower in MN and MCNS compared to FSGS, in which pdlim2 was unchanged compared to controls. This might be of pathogenetic and diagnostic importance.

**Steroid Resistance of Nephrotic Syndrome: Glucocorticoid Receptor-β and Receptor-γ Exert Dominant Negative Effect on Gene Repression but Not on Gene Induction** Yoshinori Taniguchi. *Endocrinology, Metabolism and Nephrology, Kochi Medical School, Nankoku, Kochi, Japan.*

**Background.** Glucocorticoid has diverse biological effects through induction or repression of its target genes via glucocorticoid receptor (GR). In addition to the wild-type GR (GR-α), a variety of GR variants has been reported, and these are thought to modify glucocorticoid action. Among others, GR-β is reported be responsible for the glucocorticoid resistance frequently observed in steroid-resistant nephrotic syndrome, rheumatoid arthritis, and hematologic tumors, although the precise molecular mechanism remains unclear.

**Methods.** In this study, we examined the function of GR-β and some GR variants (GR-γ and GR-Δ313-338) on (i) trans-activation, (ii) cis-repression and (iii) trans-repression using GR-deficient BE(2)C and T84 cells *in vitro*.

**Results.** We found that GR-β, when expressed alone, completely lost the capacity of both *trans*-activation and *trans*repression on GR target genes. Interestingly, however, GR-β showed a dominant-negative effect on GR-α only for its *trans*-repressive effects on cAMP-mediated and cAMP response elementdependent genes. Furthermore, both GR-β and GR-γ had dominant-negative effects on GR-α selectively for its *trans*-repressive effects on nuclear factor-κB-mediated and inflammation-related genes. **Conclusion.** These results suggest that 1) the GR-β variant by itself has no receptor function, but 2) GR-β and GR-γ have properties to exert dominant-negative effects on the GR-α-mediated *trans*-repression, which may be responsible for the steroid resistance frequently observed in chronic inflammatory diseases including nephritic syndrome and lupus under glucocorticoid therapy.

**F-PO1910**

**ACTH (Acthar Gel) Prevents Proteinuria and Renal Injury in the Remnant Kidney: Evidence for Direct Podocyte Protection** Rujun Gong, Lance D. Dworkin. *Brown Medical School, Providence, RI.*

Evidence suggests that corticotrophin (ACTH) reduces urine protein excretion in patients with a variety of glomerular diseases, however, the mechanism of its anti-proteinuric action remains elusive. We examined rats after 5/6 nephrectomy that received Acthar (ACTH) (10 IU/kg) or vehicle (CON) every other day for 5 weeks. Compared to CON, ACTH slowed body weight gain and diminished urine protein excretion (50.78 ± 13.37 *vs* 94.20 ± 13.69 mg/d, $P = 0.046$). Compared to CON, ACTH preserved kidney function as measured by increased renal plasma flow (0.77 ± 0.15 *vs* 0.41 ± 0.05 ml/min/100g *wt*, $P = 0.04$), glomerular filtration rate (0.24 ± 0.07 *vs* 0.14 ± 0.03 ml/mim/100g *wt*, $P = 0.07$) and lower serum creatinine levels (0.19 ± 0.03 *vs* 0.52 ± 0.13 mg/dl/100g *wt*, $P = 0.037$) . Glomerulosclerosis and tubulointerstitial fibrosis revealed by Masson's trichrome staining, renal inflammation characterized by infiltration of ED-1 positive macrophages, tubular atrophy, and tubular epithelial to mesenchymal transdifferentiation marked by expression of a-smooth muscle actin were all reduced by ACTH therapy. Of note, compared to CON, ACTH had no significant effects on mean arterial pressure (151.5 ± 9.8 *vs* 169.4 ± 8.1 mmHg, $P = 0.2$) or kidney hypertrophy assessed by kidney-to-body weight ratio (0.498 ± 0.033 *vs* 0.524 ± 0.034 g/100g *wt*, $P = 0.6$). Because glucocorticoid therapy exacerbates proteinuria and glomerulosclerosis in this model, the protective effect of ACTH is also unlikely to result from steroidogenesis. Instead, we found evidence for direct podocyte protection in remnant glomeruli. This included reduction in foot process effacement (by electron microscopy), diminished podocytic apoptosis (by TUNEL staining), and lesser reductions in glomerular expression of podocyte markers including vimentin, nephrin, podocin and WT-1 (by fluorescent and peroxidase immunohistochemistry and immune blot) in ACTH treated rats. Our data suggest that ACTH reduces proteinuria and injury in this model of progressive glomerulosclerosis *via* direct podocyte protection.

**Activation of Cell Cycle in Podocytes of Developing Glomeruli** Ji Ma, Nobuaki Takagi, Taiji Matsusaka, Iekuni Ichikawa. *Pediatric Nephrology, Vanderbilt University, Nashville, TN.*

Our preliminary studies in adult transgenic mice showed that induction of Simian Virus 40 T antigen (SV40T) gene expression in podocytes by doxycycline induced cell cycle re-entry, mitosis and cell division of podocytes. However, damage in podocytes was noted as albuminuria at 1 week after doxycycline treatment, followed by decreased expression of podocyte differentiation markers and increased expression of desmin at 2 weeks, then by glomerulosclerosis at 3 weeks. These data suggest that, in podocytes of adult glomeruli, forced re-entry of cell cycle alone does not lead to increased number of differentiated podocytes. In the present study we tested the possibility that, in developing glomeruli, SV40T-expressing podocytes may differentiate into normal podocytes and enrich the population of podocytes, which will decrease the susceptibility to later glomerular damage.

Starting at birth, double transgenic mice carrying both podocin-rtTA (R) and TRE-SV40T (S) transgenes and their littermate control mice carrying only podocin-rtTA were given doxycycline continuously through the nursing mother till 3 weeks of age, when urinary albumin excretion and kidney morphology were analyzed. While there was no significant difference in kidney weight or podocyte size, mice with SV40T expression in podocytes (RS) showed increased number of podocytes by 17.6±4.3% ($P<0.01$, N=5 pairs) with parallel increase in glomerular volume. There was slightly increased urinary albumin excretion in RS mice when compared with the control R mice (RS 90.4±22.6 *vs.* R 51.3±12.3 μg/mg creatinine, n=8 for RS and 7 for R, $P=0.2$ for group-wise comparison and $P<0.05$ for pair-wise comparison).

Thus, these data indicate that podocyte population can be increased in developing mice, which, by influencing glomerular development, may increase the resistance to glomerular injury after maturation.

**Cytokine-Like Factor (CLF) Blocks the Effect of Cardiotrophin-Like Cytokine-1 (CLC-1) on Glomerular Permeability and May Point to Therapy for FSGS** Virginia J. Savin,[1] Mukut Sharma,[1] Ellen T. McCarthy,[2] Ram Sharma,[1] Jean-Francois Gauchat.[3] *[1]Medicine, MBRF, KC VA Medical Center, Kansas City, MO; [2]Kidney Institute, KU Medical Center, Kansas City, KS; [3]Pharmacology, University of Montreal, Montreal, Canada.*

A circulating substance causes recurrence of focal segmental glomerulosclerosis (FSGS) post-transplant and increases albumin permeability of isolated glomeruli ($P_{alb}$); plasma of normal humans blocks the permeability effect. We have identified cardiotrophin-like cytokine-1 (CLC1), a member of the IL6 family, as a candidate for this substance. CLC1 requires a tripartite receptor consisting of gp130, ciliary neurotrophic factor receptor (CNTFR) and leukemia inhibitory factor receptor-ß (LIFRß); podocytes express all 3 receptor components. CLC1 increases glomerular $P_{alb}$ in a dose-dependent fashion and decreases nephrin expression (RT-PCR); injection of CLC1 into rats increases urinary protein/creatinine by 3 fold. Strikingly, mAb to CLC1 prevents the increase in $P_{alb}$ by FSGS sera. CLC1 secretion requires a secretory partner, either CLF or soluble CNTFR (sCNTFR). The effect of secretory partners on activity of CLC1 is not known. To determine whether CLF alters the permeability effect of CLC1, we incubated normal rat glomeruli with CLC1 or with the complex cytokine CLC1/CLF and determined $P_{alb}$. Incubation with 0.1 ng/mL CLC1 increased $P_{alb}$ (0.45±0.04, N=3; mean ± SEM, N= # groups). Maximal effect of CLC1 occurred at concentrations of 5 ng/mL or higher ($P_{alb}$= 0.73±0.04, N=11, $p<0.001$). In contrast, CLC1/CLF complex, $10^{-3}$ to 10 ng/mL, had no effect on $P_{alb}$ (0.03±0.02, N=9). This result supports the concept that naturally occurring molecules related to CLC1 can block the its permeability effect. CLF may block CLC1 activity by binding to site III of CLC1 and interfering with interaction between CLC1 and the Ig-like domain of LIFRß. We propose that CLF may be the blocking substance of normal plasma and that CLF deficiency may increase CLC1 activity and cause glomerular injury in FSGS. In the future, CLF and similar molecules may be exploited in therapy of FSGS in humans.

**F-PO1913**

**Lack of Heparan Sulphate in Zebrafish Results in Podocyte Foot Process Effacement and Ultrastructural Changes of the Glomerular Basement Membrane** Ramzi Khalil,[1] Danielle Cohen,[1] Malgorzata Wiweger,[1] Raimond B. G. Ravelli,[2] Cristina Avramut,[2] Wietske Van der Ent,[1] Emile De Heer,[1] Jan A. Bruijn,[1] Pancras C. W. Hogendoorn,[1] Hans J. Baelde.[1] *[1]Pathology, Leiden University Medical Center, Netherlands; [2]Molecular Cell Biology, Leiden University Medical Center, Netherlands.*

Heparan sulfate (HS) proteoglycans are thought to significantly contribute to the charge selectivity of the glomerular basement membrane. Their negative charge is conveyed by covalently attached HS. Key components in the HS chain elongation are the *ext1* and *ext2* gene products encoding subunits of HS co-polymerase. The aim of this project is to determine the contribution of HS to the function and morphology of podocytes in wild type and HS-deficient zebrafish embryos.

The zebrafish (*Danio rerio H*) *dackel* (*dak*) mutant has a premature stop codon in the *ext2* gene. As the result of this mutation the truncated transcript is degraded, resulting in Ext2-deficiency in these embryos. This leads to a complete lack of HS in homozygous mutants.

Wild type larvae and homozygous *dak* mutants at 5 days post fertilization (dpf) were anesthetized, chemically fixed and embedded in Epon resin. Ultrathin sections (100nm) were cut with Leica ultramicrotome EM UC6, post stained with 7% uranyl acetate and Reynolds's lead citrate, and examined at 120kV in a FEI electron microscope (Technai 12).

The homozygous *dak* mutant showed changes in podocyte morphology, such as foot process effacement and structural changes of the glomerular basement membrane. Similar changes were previously reported in mice with a podocyte-specific *Ext1* knockout, resulting in only a partial lack of HS, whereas the homozygous *dak* mutant has a complete lack of HS. We use this zebrafish model for the morphological validation of a potentially functional model to study the contribution of HS to the glomerular charge-selective barrier. Functional studies are underway to investigate whether the HS deficiency results in the loss of glomerular perm selectivity.

**F-PO1914**

**α5 Integrin Expression and Signaling Is Downregulated in Podocytes Unable To Synthesize Heparan Sulfate Glycosaminoglycans** Kevin J. McCarthy,[1] Deborah J. McCarthy,[1] Kaitlin Marie McCarthy,[1] Shoujun Chen,[2] Yu Yamaguchi.[3] *[1]Pathology, LSU Health Sciences Center, Shreveport, LA; [2]Pathology, University of South Florida, Tampa, FL; [3]Developmental Neurobiology, Sanford-Burnham Medical Research Institute, La Jolla, CA.*

Podocytes from PEXTKO mice cannot synthesize heparan sulfate (HS) glycosaminoglycans thus their glomerular basement membranes lack significant amounts of HS. Despite the absence of HS, the animals do not develop significant proteinuria during the course of their lifetime, but their podocytes have effaced foot processes. A recent report from our laboratory showed that the HS on cell surface proteoglycans (PG) are critical determinants of podocyte adhesion and migration *in vitro* (Kidney International doi:10.1038/ki.2010.136), mediated via syndecan PGs. Microarray expression analysis of mRNAs isolated from HS+ and HS- podocytes was used to further investigate if other deficits occurred in the cell adhesion/migration pathway in HS-podocytes. The initial screen showed that compared to HS+ podocytes, the HS- cells showed a 5-fold decrease ($p<0.01$) in the expression of the α5 integrin subunit whereas α3 subunit expression was unchanged. Real time PCR assays further validated the microarray expression data. Western blot assays of cell extracts confirmed that α5 integrin subunit protein expression was downregulated to the same degree. Immunostaining of HS+ and HS- podocyte cell cultures with antibodies against α5 showed a significant decrease in the total area of the cell surface occupied by α5 integrin subunit in the HS- cells compared to HS+ cells. Immunostaining HS- cells for pFAK (phosphorylated focal adhesion kinase) showed lack of pFAK in focal adhesions compared to HS+ cells, indicating that signaling was compromised. Double label immunohistochemistry of renal tissue sections from wild-type and PEXTKO mice with antibodies against α5 integrin subunit showed a decrease in the staining intensity for α5 integrin subunit in the podocytes of the PEXTKO mice compared to control animals. These results show a previously unknown relationship between cell surface HS and the expression of specific integrin subunits in podocytes.

**F-PO1915**

**Genetic Deletion of Dendrin Delays the Onset of Proteinuria and Improves Survival of CD2AP Null Mice** Kirk N. Campbell,[1] Ritu Gupta,[1] Jaakko Patrakka,[2] Andrey S. Shaw,[3] Karl Tryggvason,[2] Peter H. Mundel.[4] *[1]Nephrology and Hypertension, University of Miami Miller School of Medicine, Miami, FL; [2]Medical Biochemistry, Karolinska Institute, Stockholm, Sweden; [3]Immunobiology, Washington University, St Louis, MO; [4]Molecular Medicine, University of Miami Miller School of Medicine, Miami, FL.*

CD2 associated protein (CD2AP) is an important component of the glomerular slit diaphragm. CD2AP null mice develop albuminuria at 2-3 weeks of age and typically die from progressive renal failure at 6-7 weeks. We previously identified dendrin as a direct binding partner of CD2AP that relocates to the nucleus under the influence of transforming growth factor beta (TGF-beta) to promote podocyte apoptosis. We also demonstrated that nuclear dendrin enhances TGF-beta induced apoptosis. Dendrin null mice are viable with no identifiable disease phenotype. Here we demonstrate that dendrin accumulates in the nuclei of podocytes in CD2AP null mice. To test the role of nuclear dendrin in CD2AP null mice we generated CD2AP/Dendrin double knockout mice.

Our results show that the deletion of dendrin in CD2AP null mice (CD2AP-/-/Dendrin-/-) delays the onset of heavy albuminuria until 6-7 weeks of age compared to 3 weeks in CD2AP null mice expressing wild type dendrin (CD2AP-/-/Dendrin+/+). CD2AP null mice that were also dendrin heterozygotes (CD2AP-/-/Dendrin+/-) had an intermediate course with heavy albuminuria developing at 4-5 weeks. Most strikingly CD2AP-/-/Dendrin-/- mice had a mean survival of 13 weeks compared to 8-9 weeks for CD2AP-/-/Dendrin+/+ mice and 9-10 weeks for CD2AP-/-/Dendrin+/- mice. In summary, the deletion of dendrin delays the onset of proteinuria and improves survival in CD2AP null mice. These findings suggest a novel mechanism where the deletion of dendrin improves renal survival in progressive chronic kidney disease.

**F-PO1916**

**Partioning Defective Par1 Polarity Protein Expression in Glomerular Development and Disease** Kimberly J. Reidy,[1] Zhong-Fang Du,[1] Jonathan M. Barasch,[6] James M. Pullman,[4] Anne Muesch,[3] Katalin Susztak.[2] *[1]Pediatrics/ Nephrology, Children's Hospital at Montefiore/ Albert Einstein College of Medicine, Bronx, NY; [2]Medicine/ Nephrology, Albert Einstein College of Medicine, Bronx, NY; [3]Developmental and Molecular Biology, Albert Einstein College of Medicine, Bronx, NY; [4]Pathology, Montefiore Medical Center, Bronx, NY; [5]Pathology, Nephrocor, Uniondale, NY; [6]Medicine/ Nephrology, Columbia University, New York, NY.*

Partioning defective (Par) proteins establish cell polarity in columnar epithelial cells and neurons by localizing to distinct cell membrane domains. Par1a/b and Par3 are expressed in mature podocytes. Recent studies have suggested a role for Par proteins in establishing podocyte structure and glomerulosclerosis: Par3 (a scaffolding protein that forms a complex with Par6/aPKC) associates with nephrin, and conditional deletion of aPKC induced glomerulosclerosis. Par1 is a serine-threonine kinase that localizes asymmetrically from Par3/Par6/aPKC. We previously identified Par1a/1b in human, mouse and rat podocytes and blockade of Par1 signaling in cultured podocytes induced altered cell shape and decreased filopodia, suggesting a role for Par1 in modulating the podocyte architecture. Par1b expression was identified in embryonic day E13 and E15 kidneys (during glomerular differentiation). We examined Par1a/1b and Par3 expression in experimental proteinuric kidney disease and identified changes in expression pattern or decreased expression of Par1a/b and Par3 in adriamycin nephropathy and puromycin aminonucleoside nephrosis. To examine the relevance to human disease, we examined expression of Par1a in human kidney biopsies of focal glomerulosclerosis (FSGS, n=10), minimal change disease (MCD, n=5) and controls (normal tissue obtained from tumor nephrectomy, n=4). Similar to our findings in experimental models of kidney disease, we identified altered expression of Par1a in FSGS and MCD. Our data suggest that Par1a/1b signaling may play a role in defining podocyte polarity and in glomerulosclerosis.

**F-PO1917**

**Chronic Kidney Disease Stage 1-3 Increases Risk of Venous Thrombosis** Gurbey Ocak,[1] Marion Verduijn,[1] Carla Y. Vossen,[1] Willem Lijfering,[1] Friedo W. Dekker,[1] Frits R. Rosendaal,[1] Ron T. Gansevoort,[2] Bakhtawar Khan Mahmoodi.[3] *[1]Dep. Clinical Epidemiology, Leiden University Medical Center, Netherlands; [2]Dep. Nephrology; [3]Dep. Hematology, University Medical Center Groningen, Netherlands.*

**Background:** End-stage renal disease has been associated with venous thromboembolism (VTE). However, the risk for VTE in chronic kidney disease (CKD) stage 1-3 has not yet been investigated. The aim of this study was to investigate whether CKD patients with stage 1-3 are at increased risk for VTE.

**Methods:** This study was conducted on participants of a population based prospective cohort study, in which renal function and albuminuria were assessed, starting in 1997-1998, and were followed for the occurrence of VTE until June 1, 2007. CKD patients were staged according to the Kidney Disease Outcomes Quality Initiative (K/DOQI) guidelines based on 24-hour urine albumin excretions and MDRD based estimated glomerular filtration rate (eGFR). Symptomatic and objectively verified VTE were considered as endpoint.

**Results:** Of the 8495 subjects, 243 had stage 1 CKD, 856 stage 2, and 491 stage 3. During a median follow-up period of 9.2 years, 128 individuals developed VTE. Age, sex, hypertension, diabetes, high sensitivity C reactive protein and body mass index adjusted hazard ratios (HRs) for CKD stage 1, 2, and 3 were respectively 2.1 (95% CI 0.9 -5.1), 1.9 (95% CI 1.1 -3.1), and 1.6 (95% CI 0.9 -2.8) relative to those without CKD. Subjects with CKD stage 3 and albuminuria (≥30 mg/day) had an adjusted HR of 3.0 (95% CI 1.4-6.4) and subjects with stage 3 without albuminuria had an adjusted HR of 1.0 (95% CI 0.4-2.4). The table shows HRs for eGFR adjusted for albuminuria and vice versa.

**Table.** Association between eGFR, albuminuria, and risk for venous thromboembolism

| | *Adjusted hazard ratios |
|---|---|
| eGFR | |
| > 90 ml/min | 1.0 (reference) |
| 60-90 ml/min | 1.2 (0.7-2.0) |
| 30-60 ml/min | 1.5 (0.7-3.1) |
| | †Adjusted hazard ratios |
| Albuminuria‡ | |
| No | 1.0 (reference) |
| Yes | 1.9 (1.3-2.8) |

eGFR indicates estimated glomerular filtration rate.
*Adjusted for age, sex, and albuminuria (continuous)
† Adjusted for age, sex, and eGFR (continuous)
‡ Albuminuria defined as urinary albumin excretion >=30 mg/d

**Conclusions:** CKD stage 1, 2, and CKD stage 3 in presence of albuminuria were risk factors for VTE. The risk for VTE seemed more related to albuminuria than to impaired eGFR.

Disclosure of Financial Relationships: nothing to disclose

**Association between Estimated Glomerular Filtration Rate, Proteinuria, and Adverse Cardiovascular Outcomes: A Longitudinal Population-Based Study** Aminu K. Bello, Brenda Hemmelgarn, Anita Lloyd, Scott Klarenbach, Matthew T. James, Braden J. Manns, Marcello Tonelli. *For Alberta Kidney Disease Network.*

Most studies of chronic kidney disease (CKD) and outcomes focus on mortality and endstage renal disease (ESRD), with limited data on other adverse outcomes. We examined the association between proteinuria, eGFR and cardiovascular (CV) events in a population-based cohort.

Of 1,526,437 subjects with at least 1 serum creatinine 920,985 (60.3%) and 102,701 (6.7%) had 1 dipstick proteinuria and 1 urine albumin-creatinine ratio (ACR) respectively. We considered time to hospitalization for 1 of 5 indications: (congestive heart failure [CHF], coronary bypass grafting [CABG] or percutaneous coronary intervention [PCI], peripheral vascular disease [PVD] and stroke/transient ischaemic attacks [CVA]).

During a median follow-up of 35 (range 0-59) months, 1,891 (0.2%) of those with dipstick proteinuria were hospitalized for PVD, 7,309 (0.8%) for PCI/CABG, 4,265 (0.5%) for CHF, and 4,692 (0.5%) for CVA. From the ACR cohort, 367 (0.4%), 2,218 (2.2%), 1,555 (1.5%), 1,157 (1.1%) had PVD, PCI/CABG, CHF and CVA respectively. In both cohorts, age-adjusted rates of CHF and CVA were increased ($p<0.001$) at lower levels of eGFR and with heavier proteinuria. While the risk of CABG/PCI and PVD increased ($p<0.001$) with heavier proteinuria, there were fewer events in subjects with lower eGFR. In fully adjusted Poisson models, compared to subjects with eGFR of 45-59 mL/min/1.73m$^2$ and no proteinuria, subjects with heavy proteinuria by dipstick and eGFR of 60mL/min/1.73m$^2$ had higher rates (events per 1000 patient years) of CABG/PCI and CVA; (1.4 [95% CI, 1.3-1.5]) vs (1.9 [95% CI, 1.6-2.3]) and 0.68 [95% CI, 0.62-0.74]) vs (1.43 [95% CI, 1.16-1.75]) respectively. Similar results were obtained in subjects with proteinuria measured by ACR.

Risks of major CV events at a given level of eGFR increased with higher levels of proteinuria. The findings extend current data on risk of mortality and ESRD, and suggest that proteinuria is of incremental prognostic value at every level of eGFR. These data support the use of proteinuria with eGFR for definition and risk stratification in CKD.

**Association of eGFR and Albuminuria with All-Cause and Cardiovascular Mortality. A Collaborative Meta-Analysis of High-Risk Population Cohorts on Behalf of the CKD Prognosis Consortium** Marije Van de Velde,[1] Kunihiro Matsushita,[2] Josef Coresh,[2] Brad C. Astor,[2] Mark Woodward,[4] Andrew S. Levey,[3] Paul E. de Jong,[1] Ron T. Gansevoort.[1] *[1]Dept. Nephrology, University Medical Center, Groningen, Netherlands; [2]Dept. Epidemiology, John Hopkins Institute, Baltimore; [3]Div. Nephrology, Tufts Medical Center, Boston; [4]George Inst. Int. Health, University of Sydney, Australia.*

Screening for chronic kidney disease (CKD) in people at high risk for CKD is recommended, but data on the independent and combined associations of eGFR and albuminuria with all-cause mortality (ACM) and cardiovascular mortality (CVM) in these populations are limited.

We performed a collaborative meta-analysis of 10 cohorts with 266,975 participants selected because of increased CKD risk, including patients with hypertension, diabetes, or a history of CV disease. Albuminuria was ascertained by albumin-to-creatinine ratio (ACR) in 6 cohorts or dipstick in 4 cohorts.

Risk for ACM was not associated with eGFR (MDRD) between 60 and 105 ml/min/1.73m$^2$, but increased at lower eGFR. Hazard ratios (HRs) (95% Confidence Intervals) at eGFR 60, 45, and 15 (versus 95) ml/min/1.73m$^2$ were 1.03 (0.81-1.33), 1.38 (1.15-1.65) and 3.11 (2.26-4.27), respectively, after adjustment for ACR and CV risk factors. Albuminuria (ACR) was associated with risk for ACM linearly without thresholds. Adjusted HRs at ACR of 10, 30 and 300 (versus 5) mg/g were 1.08 (1.01-1.16), 1.38 (1.23-1.56), and 2.16 (1.99-2.35), respectively. eGFR and albuminuria were multiplicatively associated with ACM, without evidence for interaction. Similar associations were observed for CVM, and findings in cohorts with dipstick data were generally comparable to those in ACR cohorts. The trends for increased HRs were seen for subjects above and below age 65 years, although HRs for eGFR increased more steeply in younger subjects.

In conclusion, lower eGFR and higher albuminuria are risk factors for ACM and CVM in high risk populations, independent of each other and of CV risk factors. These associations are comparable to those observed in the general population, and are consistent with the current KDOQI thresholds defining CKD.

**Development of a Risk Score for Chronic Kidney Disease in Population-Based Studies** Conall M. O'Seaghdha,[1,2] Asya Lyass,[1] Joseph Massaro,[1] Josef Coresh,[3] Brad C. Astor,[3] Caroline S. Fox.[1,2] *[1]NHLBI's Framingham Heart Study; [2]Harvard Medical School; [3]Welch Center, Johns Hopkins University.*

Background Stratification of individuals at risk for chronic kidney disease (CKD) may allow for optimization of preventive measures to reduce its incidence and complications. We aimed to develop a risk score that would estimate an individuals' absolute risk of developing CKD, and provide a tool for investigators to assess novel markers of renal risk.

Methods 2490 participants without baseline CKD from the Framingham Heart Study, who attended a baseline examination in 1995-1998 and a follow-up examination in 2005-2008, were included. CKD was defined as an estimated glomerular filtration rate (eGFR) < 60 ml/min/1.732 by the Modification of Diet in Renal Disease Study equation. Participants were assessed for the development of incident CKD after 10 years of follow-up. Stepwise logistic regression was used to identify risk factors associated with the development of CKD. Risk factors meeting the inclusion threshold were used to construct a risk score for predicting the 10-year risk of CKD. Performance characteristics of the prediction algorithm were assessed using calibration and discrimination measures. The final risk score model was externally validated in the bi-ethnic ARIC Carotid MRI Study cohort (n=1777 participants).

Results At baseline, there were 1170 men and 1320 women, with a mean age of 53 years, who were free of pre-existing CKD; 9.2% (n=229) developed CKD at follow-up. Age, diabetes, hypertension, baseline eGFR and albuminuria were associated with CKD ($p<0.05$), and were incorporated into a risk function (c-statistic 0.813). In external validation in the ARIC study, the c-statistic was 0.79 in whites (n=1353) and 0.75 for blacks (n=424).

Conclusions Risk stratification for CKD is achievable using a risk score derived from clinical factors readily accessible in primary care. The utility of this score in identifying individuals in the community at high risk of CKD warrants further investigation.

**F-PO1921**

**Contrasting Incremental Value of Estimated Glomerular Filtration Rate and Albuminuria as Independent and Additive Predictors of Cardiovascular Versus Renal Outcomes in 27,000 High Risk People** Catherine M. Clase,[1] Peggy Gao,[1] Sheldon W. Tobe,[2] Anja Grosshennig,[3] Koon K. Teo,[1] Salim Yusuf,[1] Johannes F. Mann.[3] *[1]Medicine, McMaster University, Hamilton, ON, Canada; [2]Medicine, University of Toronto, Toronto, ON, Canada; [3]Nephrology, Schwabing General Hospital, Munich, Germany.*

**Background.** Glomerular filtration rate (eGFR) and albuminuria (uACR) are independent multivariable predictors of cardiovascular outcomes but their clinical utility is unclear. Further, few studies are available on the relationship between mild abmormalities of eGFR and uACR and major renal outcomes such as dialysis.

**Objective.** To examine the additional predictive impact of eGFR and uACR on cardiovascular and renal outcomes.

**Design.** Multivariable Cox regression; risk stratification tables.

**Setting.** ONTARGET and TRANSCEND randomized trials with 5 y follow up.

**Patients.** 27,620 patients; mean age 67 years, 30% female, 37% with diabetes, 76% with cardiovascular disease.

**Measurements.** Baseline eGFR, uACR, cardiovascular (CV) risk factors.

**Results.** In adjusted analysis, both eGFR and uACR predicted the primary CV composite outcome (eg, hazard ratio [HR] 2.53, 95% confidence intervals [CI] 1.61, 3.99 for eGFR < 30 mL/min/1.73m$^2$ and very high uACR). However, risk stratification tables showed that adding information of eGFR and uACR led to no improvement in calibration, and no decrease in the proportion of patients assigned to the intermediate risk category (31% without, and 32% with renal information). In contrast, eGFR and uACR were very strong predictors of risk of chronic dialysis (eg, adjusted HR 1338, 95% CI 402 to 4456 for eGFR < 30 mL/min/1.73m$^2$ and very high uACR), and when added to traditional CV risk factors greatly improved both model calibration and risk stratification capacity (65% assigned to intermediate risk categories without renal information, decreased to 18% with renal information)

**Limitations.** Creatinine not standardized.

**Conclusions.** In patients at high vascular risk, eGFR and uACR associate with increased cardiovascular risk but add modestly to classical risk factors. Conversely, both greatly improve the prediction of renal outcomes.

**Rate of Kidney Function Decline Is Associated with Increased Risk of Death** Ziyad Al-Aly, Tarek M. Elachkar, Michael I. Rauchman. *Division of Nephrology, Saint Louis Veterans Affairs Medical Center, Saint Louis, MO.*

The effect of rate of decline of kidney function on risk of death is not well understood. Using the Department of Veterans Affairs national databases, we built a cohort of 4,171 rheumatoid arthritis patients with early stage 3 CKD (estimated glomerular filtration rate [eGFR] 45-60 ml/min) and followed them longitudinally over time to characterize predictors of disease progression and the effect of rate of kidney function decline on risk of death. After a median follow up of 2.6 years, 1604 (38%) did not experience any kidney function decline, and 426 (10%), 1,147 (28%), 994 (24%) experienced mild, moderate and severe CKD progression (defined as eGFR loss of 0-1, 1-4, >4 ml/min/yr; respectively).

Peripheral artery disease was a significant predictor of moderate CKD progression. Black race, hypertension, diabetes, cardiovascular disease, and peripheral artery disease were predictors of severe CKD progression. After a median observation period of 5.7 years, compared to patients with mild progression, patients with moderate CKD progression exhibited a trend toward increased risk of death (HR=1.10, CI=0.975-1.304), and patients with severe CKD progression had significantly increased risk of death (HR= 1.539, CI=1.298-1.824). Our results show that among patients with early stage 3 CKD, some do not experience decline in eGFR and some experience mild, moderate and severe CKD progression. The results show that there is an independent and graded association between the rate of kidney function decline and the risk of death. Incorporating the rate of decline in the definition of CKD may transform a static definition into a dynamic one that more accurately describes the disease state in an individual patient.

## F-PO1923

**Identifying Patients with Rapid Renal Decline in a Community-Based Population** William F. Clark, Jennifer J. Macnab, Jessica M. Sontrop, Louise M. Moist, Rita Suri, Marina I. Salvadori, Amit X. Garg. *University of Western Ontario.*

Background: To determine the value of simple measures of kidney impairment to detect patients with rapid renal decline (RRD) in a community-based population and in high-risk sub-populations.

Methods: Prospective cohort study of community-dwelling adults 18-87 years (2002-8, Canada). Change in eGFR was summarized using the ordinary least squares estimate of change for each participant. RRD was defined as average annual decline in eGFR >3ml/min/1.73m$^2$. The diagnostic accuracy of albustix (trace, >1g/L, >3g/L) vs. microalbuminuria (>17 mg/g if male or >25 mg/g if female) to identify a case with RRD was assessed.

Results: Of 3,371 participants, 2,560 had three eGFR measures and complete laboratory data. Median follow-up time was seven years with six serum creatinine measurements. The median change in eGFR was -0.76 ml/min/1.73m$^2$/yr; with 15.9% experiencing RRD. The incidence of RRD did not differ between males and females, and the highest rate occurred in those with baseline eGFR >90 or <30 ml/min/1.73m$^2$. The probability of identifying RRD from serial eGFR measurements was greatest following albustix >3g/L (0.41), with the lowest number needed to follow (2.4). The diagnostic accuracy of Albustix >trace was consistently better than microalbuminuria and was greatest with albustix >3g/L in those with multiple risk factors (age>60; diabetes or cardiovascular disease) with a post-test probability of 0.53 and number needed to follow of 1.9. Similar results were obtained when eGFR was calculated using the CKD-EPI equation.

Conclusions: Simple inexpensive screening tests in patients with or without risk factors will allow clinicians to follow a smaller number of patients with serial eGFR assessment in order to identify those with RRD who will potentially benefit from earlier therapeutic intervention.

## F-PO1924

**Lower Systolic BP Associated with Slower CKD Progression in the CKiD Study** Susan L. Furth,[1] Joseph T. Flynn,[2] Christopher B. Pierce,[2] Mark Mitsnefes,[2] Craig S. Wong,[2] Jeffrey M. Saland,[2] Marva M. Moxey-Mims,[2] Alison G. Abraham,[2] Bradley A. Warady.[2] *[1]Nephrology, Children's Hospital of Phila, Phila, PA; [2]Chronic Kidney Disease in Children Study, .*

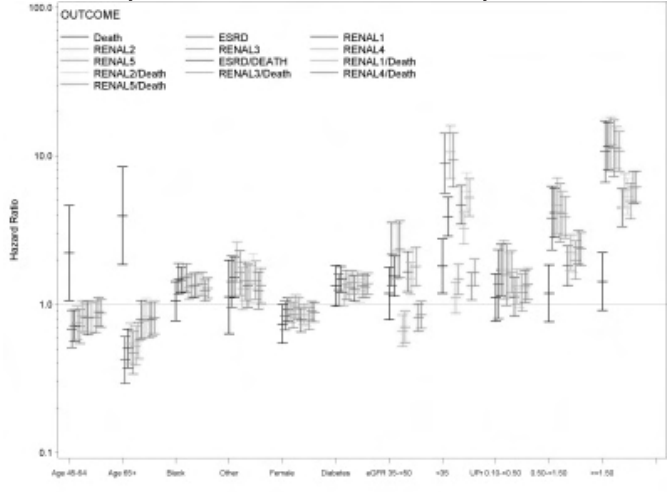
In the ESCAPE trial, subjects with mean ambulatory BP <50$^{th}$%ile had delayed CKD progression. We assessed if casual systolic (SBP) or diastolic BP (DBP)< 50%ile was associated with slower GFR decline than SBP or DBP 50- 90$^{th}$ or > 90%ile, after adjusting for age, follow-up yrs, CKD cause, baseline GFR, and presence of nephrotic proteinuria in the Chronic Kidney Disease in Children cohort study. Time-variable exposure analysis of the effect of SBP or DBP on the log-transformed annualized ratio of consecutive iohexol GFR (GFR) measures using multivariate generalized estimating equations with robust variance estimation and Cox proportional hazards models were used. 425 children, median age 11 yrs, median GFR 45 ml/min/1.73m$^2$, had BP measured at baseline, and at least one paired measure of GFR. 158 had SBP <50%ile, 175 had SBP 50 -90%ile and 92 had SBP > 90%ile. Median age (13 vs 10 vs 9 yrs) was higher in the <50%ile group (p<0.05), but median GFR (45,46,45 ml/min/1.73m$^2$), % with glomerular CKD diagnosis (23,15,24%) and nephrotic range proteinuria (11,10,12%) did not differ significantly between groups. In unadjusted analysis, after median 2.4 yrs follow-up, GFR in the SBP < 50%ile group declined at 2.3% per yr, compared to 3.5% in the 50-90%ile group, and 8.2 % in the SBP>90%ile group. In the adjusted time-variable exposure analysis, individuals with SBP<50%ile had annualized declines in GFR measurements on average 4% less than children with SBP 50th-90th%ile and similar demographic and clinical characteristics (p=0.047), while GFR decline in those with SBP>90%ile was 4% greater than in those with SBP 50-90%ile(p=ns). Point estimates for DBP were in the same direction, but not significant. In Cox proportional hazards analysis, children with SBP<50%ile had a lower risk of ESRD (initiation of dialysis or transplant) (HR 0.5, 95%CI 0.3-0.9) compared to those with SBP 50-90%ile (ref) or >90%ile (HR 1.0, 95%CI 0.6-1.7)). These data suggest that target SBP in children with CKD should be lower than the 50%ile for age, gender and height.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1925

**Failure Time Analysis of Renal Outcomes in the Chronic Renal Insufficiency Cohort (CRIC) Study** Dawei Xie, Wei Yang, Marshall M. Joffe, Valerie L. Teal, Amanda Hyre Anderson, Tom H. Greene, Harold I. Feldman. *CRIC.*

Studying the association between risk factors and renal outcomes in survival analysis is made complex by the multiple choices for renal outcome and the competing risk of death. We explored renal outcomes as ESRD alone, ESRD with 1) eGFR halving; 2) eGFR<15; 3) eGFR halving and <15; 4) eGFR drop 20, and 5) eGFR halving or drop 20. We considered 3 approaches for dealing with death; treat it as part of the outcome; a censoring event or a competing risk. We fit Cox proportional hazards models and obtained hazard ratios (HRs) for demographics and baseline characteristics adjusting for traditional risk factors. 3939 patients were included with an average of 3 years of follow-up. Rates of death, ESRD and eGFR halving were 6.9%, 10.7% and 7.0%, respectively. The associations between risk factors and renal outcomes were stable across varied definitions of renal outcomes, but were substantially different from their associations with mortality.



Risk factor associations were similar when treating death as a competing risk or censoring event.

HRs from failure time analyses

| Risk factors | | ESRD | | ESRD/eGFR halving | |
|---|---|---|---|---|---|
| | | M1[1, 2] | M2 | M1 | M2 |
| Age | 21-44 | 1 | | | |
| | 45-64 | 0.7 | 0.7 | 0.7 | 0.7 |
| | 65+ | 0.4 | 0.4 | 0.5 | 0.5 |
| Sex | Male | 1 | | | |
| | Female | 0.8 | 0.9 | 0.9 | 0.9 |
| Race | White | 1 | | | |
| | Black | 1.5 | 1.5 | 1.5 | 1.4 |
| | Other | 1.4 | 1.5 | 1.5 | 1.5 |
| Diabetes | No | 1 | | | |
| | Yes | 1.3 | 1.2 | 1.5 | 1.5 |
| Baseline eGFR | <35 | 8.9 | 8.3 | 3.9 | 3.7 |
| | 35-<50 | 2.2 | 2.1 | 1.6 | 1.5 |
| | 50+ | 1 | | | |
| Baseline 24 hour urine protein (g/day) | <0.1 | 1 | | | |
| | 0.1-<0.5 | 1.4 | 1.4 | 1.7 | 1.7 |
| | 0.5-<1.5 | 3.8 | 3.9 | 4.2 | 4.2 |
| | 1.5+ | 10.7 | 10.4 | 11.6 | 11.0 |

1. Adjusted for ABI, CVD, BMI, BP, hgb and smoking at baseline. 2. Death was treated as censoring in M1 and competing risk in M2.

Modeling ESRD or eGFR halving with death being censored is a robust approach to identify risk factors for renal progression in CRIC.

Disclosure of Financial Relationships: nothing to disclose

**Short-Term Prediction of Long-Term Renoprotective Treatment Effect: The Advantage of a Multiple Biomarker-Based Efficacy Score** Yan Miao,[1] Hiddo Jan Lambers Heerspink,[1] Hans-Henrik Parving,[2] Julia Lewis,[3] Dick De Zeeuw.[1] *[1]University Medical Center Groningen, Netherlands; [2]University Hospital Copenhagen, Denmark; [3]Vanderbilt University Medical Center.*

Efficacy on hard renal outcomes is needed for evaluation in late phase of drug development. This leads to expensive trials of long duration. Short term changes in biomarkers may be an alternative to predict the drug's renal efficacy and safety. We aimed to construct a multiple-biomarker based short-term efficacy score to predict the effect of a single drug on long-term hard renal outcomes.

Data from the merged RENAAL and IDNT trials were used (n=2661 type 2 diabetic and nephropathy). A multi-biomarker (blood pressure, uric acid, potassium, hemoglobin, and albuminuria) risk score was created using Multivariate Cox analysis in the placebo group. This score was subsequently applied to the baseline and month 6 measurements of the angiotensin receptor blocker (ARB) treatment arm to obtain the biomarker-based estimated long-term renal risk reduction. To test the validity of this estimate, the biomarker-based estimated risk reduction was compared with the actual measured long-term risk reduction on hard renal endpoints (doubling of serum creatinine or end stage renal disease).

The effect of ARB treatment on the multiple biomarker score (baseline, month 6) predicted a renal risk reduction of 20.7 %, which was remarkably equal to the actual observed risk reduction 21.0 (9.1 – 31.5) %. When single biomarker formulas were created (e.g. blood pressure) the score failed to predict the actual renal risk reduction (table).

We demonstrate the renal protective effect of an ARB (registered for blood pressure reduction) cannot be estimated from short-term BP changes alone. A multi-biomarker based efficacy score (based on 6 months changes in biomarkers) appears very accurate in predicting the long-term effect of an ARB on hard renal outcomes.

| | Predicted long-term renal risk reduction (%) using change in (single) biomarkers |
|---|---|
| ΔSystolic BP | -10.1 |
| ΔAlbuminuria | -19.8 |
| Δ Potassium | +6.7 |
| ΔHemoglobin | +5.8 |
| ΔUric Acid | -1.6 |
| | |
| ΔMultiple biomarker score | -20.7 |

Disclosure of Financial Relationships: nothing to disclose

**Association between Changes in Serum Uric Acid and Renoprotection in the RENAAL Trial** Stefan Antonius Ottenbros,[1] Hiddo Jan Lambers Heerspink,[1] Gozewijn Dirk Laverman,[1] Stephan J. L. Bakker,[1] Shahnaz Shahinfar,[2] Hans-Henrik Parving,[3] Dick De Zeeuw.[1] *[1]Clinical Pharmacology, University Medical Center Groningen, Netherlands; [2]Philadelphia Children Hospital; [3]University Hospital Copenhagen, Denmark.*

Introduction: Increased serum uric acid concentrations have been shown to be a risk factor for progressive renal function loss. Treatment with the Angiotensin Receptor Blocker losartan lowers uric acid. Whether losartan induced reductions in uric acid levels are associated with renoprotection is unclear. Therefore, the aim of this study was to elucidate the association between changes in serum uric acid during losartan therapy and renal prognosis.

Methods: A post-hoc analysis in the RENAAL trial was conducted. Patients with diabetes and nephropathy were randomized to losartan or placebo for a median follow-up of 3.4 years. Multivariate cox regression analysis was used to determine the relationship between 6 month change in SUA and renal endpoints, defined as a doubling of serum creatinine or end stage renal disease.

Results: Baseline uric acid levels of the 1513 included patients were 6.71 and 6.70 mg/dL in placebo and losartan treated subjects respectively. During the first 6 months the placebo adjusted change in SUA was - 0.16 mg/dL (95% CI - 0.26 to - 0.05; p=0.032). A total of 489 renal events occurred during follow-up. Each 1 mg/dL change in SUA during the first 6 months of treatment was associated with a 17% risk change (Hazard ratio 0.83; 95% CI 0.77 – 0.90; p<0.001) for renal endpoints. This effect was independent of other risk markers or changes in risk markers, including age, eGFR, hemoglobin, log albuminuria. The magnitude of risk reduction was similar in male and female subjects. Similar associations were observed for the individual components of the renal endpoint.

Conclusion: Losartan lowers SUA levels compared to placebo treatment in patients with type 2 diabetes and nephropathy. This change in SUA is independently associated with a lower risk for renal endpoints. These data suggest that treatments specifically focused on lowering SUE may confer additional renoprotection.

**The Relationship between Blood Pressure and the Decline in Kidney Function in Community-Based Patients with Hypertension** Rebecca Hanratty,[1] John Powers,[2] Michael Ho,[4] Michel B. Chonchol.[3] *[1]Denver Health, Denver, CO; [2]Institute for Health Research, Kaiser Permanente of Colorado, Denver, CO; [3]Division of Renal Diseases and Hypertension, University of Colorado Denver, Denver, CO; [4]Denver Veterans Affairs Medical Center, Denver, CO.*

Background Hypertension is an important cause of chronic kidney disease (CKD). Identifying risk factors for progression to CKD in patients with normal kidney function and hypertension may help target therapies to slow or prevent decline of kidney function. Our objective was to identify risk factors for development of incident CKD and decline in estimated glomerular function (eGFR) in hypertensive patients.

Methods We performed a retrospective cohort study of adult patients with hypertension. Cox proportional hazards models were used to assess the relationship between incident CKD and potential risk factors for CKD, including systolic blood pressure. General linear mixed-effects models were used to estimate the relationship between potential risk factors and rate of decline in estimated glomerular filtration rate (eGFR).

Results Of 43,564 patients meeting the inclusion criteria, 12.2% (5292 patients) developed incident CKD. Diabetes was the strongest predictor of incident CKD (HR 1.98 95% CI 1.85 to 2.11) and was associated with the greatest rate of decline in eGFR (-2.17 mL/min/year). Time weighted systolic blood pressure was associated with incident CKD with odds increasing steadily above 120 mm Hg; each 10 mm Hg increase in time weighted systolic BP was associated with a 21% increase in the risk of developing incident CKD (HR 1.21 95% CI 1.18 to 1.23).

Conclusions We found that time-weighted systolic blood pressure was associated with incident CKD and more rapid decline of kidney function, with a steady increase in odds of incident CKD above a systolic blood pressure of 120 mm Hg.

**A Comparison of Absoulte and EGFR-Indexed PCR: Implications for Clinical Trials Interpretation of Proteinuria** Timothy Ellam, Pavez Hosain, Meguid El-Nahas. *Sheffield Kidney Institute, Northern General Hospital, Sheffield, Yorkshire, United Kingdom.*

Background

Declining GFR accompanies a reduction in the functioning nephron mass across which protein leak occurs, so the index of PCR:eGFR might reflect glomerular permeability/viability changes better than absolute PCR. To investigate how indexing PCR for eGFR affects patient stratification and measures of change in proteinuria, the relationship between changes in absolute PCR and PCR:eGFR was studied.

Methods

A cohort of N=807 CKD patients with at least two measures of PCR and corresponding eGFR were studied retrospectively. Patients were categorized on the basis of baseline PCR with a threshold of 100mg/mmol (1000mg/g) as per national management guidelines. Baseline PCR:eGFR was also calculated and patients recategorized according to thresholds derived from published trial populations (i.e. the quoted evidence) where both proteinuria and GFR were reported (e.g. proteinuria of 1g/24h in a population with mean GFR 40ml/min in the MDRD study.) Percentage changes in absolute and eGFR-indexed PCR (IPCR) were also compared.

Results

At baseline, 47% of patients had PCR>100. An IPCR threshold of 1 (as for eGFR 100 and PCR 100) labelled 64% proteinuric. IPCR threshold of 2.5 (corresponding to the MDRD study cohort) labelled 50% proteinuric. Among those with more advanced renal impairment there was naturally a greater increase in proteinuria classification on the basis of IPCR vs PCR (89% vs 59% at CKD 5 and 54% vs 47% at CKD 4). In patients with preserved excretory function (CKD 1+2) a reclassification based on IPCR of 2.5 reduced the proportion labelled as proteinuric from 54% to 45%. Among patients with ≥50% GFR decline over follow up, absolute PCR increased in 35%, but IPCR increased in 91%.

Conclusions

In this CKD population the distribution of PCR and eGFR was such that the effect on patient classification of indexing PCR for eGFR was modest overall, but marked in CKD5. In the setting of a substantial decline in GFR the protein leak per unit functioning nephron mass increases almost universally even when absolute PCR does not. Changes in sclerotic glomeruli, perhaps reflecting a 'remnant nephron' effect may underlie this phenomenon.

**Predicting Kidney Disease in the Korean Population** Keunsang Kwon,[1] Sik Lee,[1] Sung Kwang Park,[1] Ju-Hyung Lee,[1] Heejung Bang,[2] Abhijit V. Kshirsagar.[3] *[1]Chonbuk National University Medical School; [2]Cornell University; [3]University of North Carolina at Chapel Hill.*

Screening algorithms, used to identify early chronic kidney disease (CKD), have been developed and validated in US populations. Their utility and applicability in foreign populations has not been examined. In the current study, we developed a CKD prediction model based on SCORED (SCreening for Occult REnal Disease) in the Korean population, known to have a growing burden of CKD. We used a cross-sectional analysis of the Korean National Health and Nutrition Examination Survey version IV-1 (KNHANES IV-

1) n=6566, year 2008, for the model development. Model validation was performed in an independent dataset combining KNHANES IV-2 (n=2921, year 2007) and Korean Genomic Epidemiologic Study (n=8548). CKD was defined as glomerular filtration rate (GFR) < 60 ml/min/1.73 m² (abbreviated MDRD equation). Female gender, anemia, hypertension, diabetes mellitus, and proteinuria were again significantly predictive of CKD. Unlike SCORED, elevated waist circumference was significantly associated with CKD, and age retained a significant, yet slightly attenuated association, while cardiovascular disease was borderline significantly associated with CKD (p=0.08). Information on peripheral vascular disease was not available in this population. The Area Under Curve (AUC) for these variables was AUC=0.83. An integer value was assigned to variables based on the strength of the odds ratio: 2 for age 50-59 years, 3 for age 60-69 and 4 for age 70 or older, and 1 for female gender, anemia, hypertension, diabetes, proteinuria, cardiovascular disease and high waist circumference. Based on the Youden index, a value of 5 or greater was used to define a high risk population [Sensitivity 74% Specificity 67% Positive Predictive Value 10%, Negative Predictive Value 98%]. This prediction algorithm, weighted towards common variables associated with CKD, may be a useful tool to identify individuals with a high likelihood of kidney disease in the Korean population. Yet, further refinement of prediction models like this one is necessary prior to their application to populations of other countries or geographic regions.

**Traditional Risk Factors Predict Renal Function Decline among Younger but Not Older CKD Patients** Sankar D. Navaneethan,[1] Susana Arrigain,[1] Welf Saupe,[3] Joseph V. Nally,[1] Jesse D. Schold.[2] *[1]Nephrology & Hypertension, Cleveland Clinic; [2]Quantitative Health Services, Cleveland Clinic; [3]eCleveland Clinic eResearch, Cleveland Clinic, Cleveland, OH.*

Purpose: Prior studies have shown African American race, diabetes, hypertension, and hyperlipidemia as risk factors for progression of chronic kidney disease (CKD). We examined whether these risk factors have differential impact on the progression of kidney disease in elderly CKD patients compared to younger CKD patients.

Methods: We examined factors associated with decline of renal function in stage 3 CKD patients (glomerular filtration rate [GFR] 30-59 ml/min/1.73m2) (n=33,756) from our institutional CKD registry. This registry included patients identified with CKD from January 2005- March 2010 based on outpatient GFR levels using CKD-EPI equation. We utilized multivariable mixed models to assess factors associated with progression of renal function over time following CKD. We utilized age >70 as a definition of older patients, which represented the median age of our study cohort.

Results: Median eGFR at baseline (time of CKD confirmation) was 51.5 ml/min/1.73 kg/m². Factors explaining progressive decline of renal function over time included older age, male gender and African American race. The effect of demographic characteristics and pre-existing comorbidities had a statistically significantly greater association with renal function decline among patients aged <70 years as compared to patients ≥70 years: males (p<0.001), African Americans (p<0.001), patients with pre-existing diabetes (p=0.003) and obesity (p=0.001). Pre-existing hyperlipidemia was less predictive of decline among older patients (p<0.001) and pre-existing hypertension did not have differential effect between age groups (p=0.39).

Conclusion: These results suggest that the impact of traditional risk factors of kidney disease progression are important among stage 3 CKD patients aged <70 years but are not clear discriminators of risk among stage 3 CKD patients ≥70 years of age. These results may have important implications for management and interventions of various risk factors of kidney disease.

## F-PO1932

**EGFR Change and Mortality Risk among Patients with Non-Dialysis Dependent CKD** Robert M. Perkins,[1] Ion D. Bucaloiu,[2] H. Lester Kirchner,[1] Nasrin Ashouian,[2] James E. Hartle,[2] Taher M. Yahya.[2] *[1]Center for Health Research, Danville, PA; [2]Nephrology/Geisinger, Danville, PA.*

**Background:** Prior estimates of the impact of rate of eGFR decline on mortality have focused on populations with normal kidney function, or have been limited by lack of information on characteristics known to influence mortality risk. **Methods:** We analyzed all adults with non-dialysis dependent CKD (NDD-CKD, eGFR 15-59 ml/min/1.73m²), stratified by tertile of rate of annualized eGFR change, at a tertiary care facility between 2004 and 2009. Independent predictors of mortality were assessed using Cox proportional hazards models incorporating demographics, comorbidities, medication use, and laboratory results. **Results:** 16,481 patients with NDD-CKD were followed for a median (IQR) of 33.6 (21.0—55.5) months. Rapid decliners across all CKD stages were more likely to be male, older, suffer from diabetes and other comorbid conditions, have proteinuria and lower serum albumin and HDL levels than those in the highest tertile of eGFR change. Death occurred more frequently in rapid decliners than in those in the highest tertile of eGFR change (116.3 vs 83.1, 176.4 vs 140.3, and 309.4 vs 241.6 deaths/1000 p-y for mild stage 3, moderate stage 3, and stage 4 CKD, respectively (p < 0.05 for all comparisons)).

Cox proportional hazard model of time to death associated with eGFR change among patients with NDD-CKD*

| | Stage 3 CKD | | Stage 4 CKD |
|---|---|---|---|
| | **Mild (baseline eGFR 45-59), n=11,222** | **Moderate (baseline eGFR 30-44), n=3,972** | **Baseline eGFR 15-29, n=830** |
| HR (95% CI), p value for death associated with eGFR decline of 1 ml/min/1.73m²/yr | 1.030 (1.026—1.034), p<0.0001 | 1.015 (1.008—1.022), p<0.0001 | 1.007 (0.994—1.020), p=0.29 |

*Model adjustments: mild and moderate stage 3 CKD = age, gender, HTN, hyperlipidemia, charlson comorbidity index, proteinuria, hemoglobin A1C, serum albumin, serum HDL; stage 4 CKD = age, smoking status, CAD, HTN, hyperlipidemia, proteinuria

**Conclusions:** Among patients with stage 3 CKD, rate of eGFR decline adds incrementally and independently to mortality risk.

## F-PO1933

**Analysis of Repeated Measures of Renal Functions in the Chronic Renal Insufficiency Cohort (CRIC) Study** Wei Yang, Marshall M. Joffe, Dawei Xie, Xin Wang, Amanda Hyre Anderson, Tom H. Greene, Harold I. Feldman. *CRIC.*

To study risk factors associated with renal progression measured as eGFR change over time, methods are needed to deal with missing eGFR due to informative dropout from ESRD or death. We fit 3 models: 1) a linear mixed effects model using only observable eGFR values; 2) a censored regression model, in which eGFR was assumed less than 10.8 ml/min/1.73m2(the average eGFR value before ESRD in USRDS) when participants developed ESRD and 3) a shared parameter model for modeling eGFR and dropout events simultaneously. There were 3939 patients with an average of 3 years of follow-up. The estimated overall eGFR slope was -1.8 ml/min/1.73m2/year. Female sex, black race, diabetes, high baseline eGFR and proteinuria were associated with faster renal progression. These relationships were stable across modeling strategies.

Estimated differences of mean change (SE) of eGFR over time (ml/min/1.73m2/year)

| Risk factors | | Linear mixed effects model[1] | Censored regression model | Shared parameter model[2] |
|---|---|---|---|---|
| Age | 21-44 | Reference | | |
| | 45-64 | 0.3 (0.2) | 0.3 (0.2) | 0.5 (0.2) |
| | 65+ | 0.2 (0.2) | 0.0 (0.3) | 0.4 (0.2) |
| Sex | Male | Reference | | |
| | Female | -0.3 (0.1) | -0.3 (0.1) | -0.2 (0.1) |
| Race | White | Reference | | |
| | Black | -0.2 (0.1) | -0.3 (0.2) | -0.3 3 (0.1) |
| | Other | -0.6 (0.2) | -0.5 (0.3) | -0.5 (0.2) |
| Diabetes | No | Reference | | |
| | Yes | -0.2 (0.1) | -0.5 (0.2) | -0.3 (0.1) |
| Baseline eGFR | <35 | 1.5 (0.2) | 1.7 (0.2) | 1.3 (0.2) |
| | 35-<50 | 0.8 (0.1) | 1.1 (0.2) | 0.9 (0.1) |
| | 50+ | Reference | | |
| Baseline 24 hr urine protein (g/day) | <0.1 | Reference | | |
| | 0.1-<0.5 | -0.6 (0.1) | -0.7 (0.2) | -0.6 (0.1) |
| | 0.5-<1.5 | -2.0 (0.2) | -1.9 (0.2) | -2.0 (0.2) |
| | 1.5+ | -4.4 (0.2) | -3.8 (0.3) | -4.3 (0.2) |

1. All models adjusted for ABI, CVD, BMI, BP, hemoglobin and smoking status at baseline. 2. Survival time assumed to follow piecewise exponential distribution.

Linear mixed effects model is appropriate for identification of risk factors for renal progression.

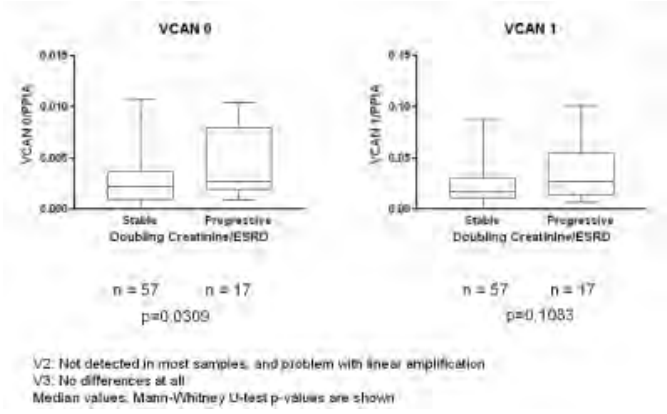
## F-PO1934

**Versican as a Novel Biomarker for Progression of Chronic Kidney Disease** Michael Rudnicki. *Nephrology and Hypertensiology, Medical University Innsbruck, Innsbruck, Austria.*

Patients with progressive chronic kidney disease are at high risk for ESRD and cardiovascular events. Prediction of progression using standard markers shows weak correlation with the clinical course and high intraindividual variation.

Using data from five published gene expression datasets we identified the proteoglycan versican (VCAN) as a marker of renal damage. Increased expression of VCAN was associated with (i) age, (ii) impaired renal function in diabetic nephropathy, (iii) progressive proteinuric nephropathies, (iv) increased histological damage scores in transplant biopsies and (v) renal graft loss.

In an independent cohort of 74 subjects with biopsy proven glomerulopathies RNA levels of VCAN isoforms V0, V1, V2 and V3 were evaluated. VCAN isoform V0, but not V1, V2 and V3 correlated significantly with doubling of serum creatinine or ESRD during a median follow up of 50 months (4-94).



V2: Not detected in most samples, and problem with linear amplification
V3: No differences at all
Median values. Mann-Whitney U-test p-values are shown

V0 and V1 correlated significantly with creatinine and proteinuria at biopsy, creatinine at follow-up, and interstitial inflammation, but not with histological diagnosis, tubular atrophy and interstitial fibrosis. V0 and V1 RNA levels predicted the course of disease significantly better than creatinine, proteinuria and the degree of histological damage. Immunohistochemical staining revealed VCAN expression mainly in the tubulointerstitial compartment. In a glomerulonephritis mouse model versican was significantly increased in nephritic mice as compared to control animals.

In summary, these data support the potential use of VCAN isoforms V0 and potentially V1 as biomarkers to predict a progressive clinical course of CKD.

## F-PO1935

**Can the Examination of the Ocular Fundus Be a Predictor of Chronic Kidney Disease?** Yoshinari Yasuda,[1] Kiyoshi Shibata,[2] Sadao Suzuki,[3] Shoichi Maruyama,[1] Enyu Imai,[1] Seiichi Matsuo.[1] *[1]Department of Nephrology/CKD Initiatives, Nagoya University Graduate School of Medicine, Nagiya, Aichi, Japan; [2]Kasugai City Health Care Center, Kasugai, Aichi, Japan; [3]Nagoya City University, Nagoya, Aichi, Japan.*

*Background:* In recent years, chronic kidney disease (CKD) has been increasingly highlighted as a risk factor for dialysis treatment and cardiovascular diseases. CKD is reported to have an association with ageing, smoking, hypertension, diabetes mellitus or hyperlipidemia. Arteriosclerosis is believed to plays an important role for CKD onset and progression, its precise mechanisms has not yet been clarified.

*Objective:* In this report, we examined the relationship between the findings in the ocular fundus (EOF), a marker for arteriosclerosis, and CKD.

*Methods:* The subjects were 3,464 men and 3,251 women, who underwent health check including the EOF in Kasugai City Medical Care Center, from 2006 to 2007. Estimated GFR (eGFR) was calculated by the Japanese eGFR equation, and cases with eGFR less than 60 mL/min/1.73m$^2$ and/or with proteinuria were diagnosed as CKD. EOF was evaluated by Keith-Wagner classification (KW) and by Scheie classification (SC). Multivariate odds ratios for CKD for abnormality of the EOF in KW and SC were calculated using logistic regression adjusted for age and sex, BMI, diabetes, hyperlipidemia and hypertension.

*Results:* By EOF examination, KW and SC abnormalities were observed in 601 (8.95%) and in 214 cases (3.19%), respectively. eGFR among patients with EOF abnormalities was significantly lower than those without. Multivariate analysis revealed that age, male, obese, hyperlipidemia and KW abnormality was significant factors for CKD.

*Multiple regression analysis of the risk factor for CKD*

| Risk factors | OR | 95%CI | p-value |
|---|---|---|---|
| Age | 1.07 | 1.06-1.08 | <0.01 |
| Male | 1.58 | 1.40-1.78 | <0.01 |
| Obese | 1.37 | 1.18-1.59 | <0.01 |
| Hypertention | 1.08 | 0.95-1.23 | 0.22 |
| Diabetes | 1.15 | 0.94-1.39 | 0.17 |
| Hyperlipidemia | 1.32 | 1.15-1.53 | <0.01 |
| KW | 1.34 | 1.07-1.67 | <0.05 |
| SC | 1.02 | 0.71-1.45 | 0.92 |

*Conclusion:* It is suggested that KW abnormality from the EOF would predict the CKD.

## F-PO1936

**Should We Redefine Classification of Chronic Kidney Disease in Elderly Population?** Arash Rashidi,[1] Ashok K. Ananthasayanan,[1] Mirela A. Dobre.[2] *[1]Internal Medicine, Fairview Hospital, A Cleveland Clinic Hospital, Cleveland, OH; [2]Internal Medicine, Huron Hospital, A Cleveland Clinic Hospital, Cleveland, OH.*

Background: According to the National Kidney Foundation, people with an estimated glomerular filtration rate (eGFR) less than 60 mL/min/1.73m2 have CKD. It is not clear if the same cut off for eGFR for CKD should be considered in all age groups. Our objective is to find whether people older than 65 years with an eGFR of 45 to 59 should be classified as CKD.

Methods. The Cardiovascular Health Study limited data base, was used to identify a cohort of patients with a baseline history of CKD (eGFR<60). Patients were categorized in three groups with eGFR more or equal to 60, between 45 to 59, and 30 to 44. Estimated GFR was derived from the calibrated creatinine level and using MDRD equation. The studied population was followed for a mean duration of 10.3 years. Total and cardiovascular mortality and cardiovascular events were compared between the different groups, using the Cox regression survival analysis. The data was adjusted based on age, race, gender, body mass index, diabetes, hypertension, coronary artery disease at baseline, lipid profile, smoking status and medications.

Results: There were 4504 subjects with an eGFR more or equal to 60 and 1212 subjects with eGFR less than 60 at baseline in which 940 people had an eGFR between 45 to 59. During the follow up period 1170 people died because of cardiovascular causes. In adjusted Cox model, there was no difference between the group with eGFR of 45 to 59 and the group with eGFR more than 60 in regards to cardiovascular events (HR=1.09; 95%CI: 0.96-1.24). The result was similar in regards to the cardiovascular mortality (HR=1.12; 95%CI: 0.97-1.30). The subjects with eGFR between 30 to 44 had significantly higher cardiovascular events and mortality (HR=1.40; 95%CI: 1.11-1.76 and HR=1.36; 95%CI: 1.06-1.74).

Conclusion: There is no significant difference in cardiovascular mortality between the elderly subjects with eGFR between 45 and 59 and eGFR more or equal to 60. Probably the cutoff point of eGFR for definition of CKD in elderly population should be different than younger population.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1937

**Chronic Kidney Disease in Octogenarians** Shani Shastri, Hocine Tighiouart, Ronit Katz, Dena E. Rifkin, Linda F. Fried, Michael Shlipak, Anne B. Newman, Mark J. Sarnak. *Tufts Medical Center.*

**Introduction:** Chronic kidney disease (CKD) is a major public health problem in older adults. However, there are limited data on the prevalence of CKD and its clinical importance in those older than 80 years. We examined the prevalence of CKD in octogenarians, and its association with cardiovascular disease (CVD) in Cardiovascular Health Study (CHS) All Stars participants.

**Methods:** Serum creatinine and cystatin C were measured in 1028 CHS All Stars participants. Kidney function was estimated using CKD-Epi creatinine and cystatin C equations that incorporated coefficients for age, gender, and race ($eGFR_{EPI}$, $eGFR_{CYS3var}$) and one variable cystatin C equation ($eGFR_{CYS1var}$). CKD was defined as estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m$^2$. Prevalent CVD was defined as a composite of coronary heart disease, heart failure or stroke. Logistic regression was used to examine the association of CKD, defined by each equation, with CVD in unadjusted and adjusted analyses.

**Results:** Mean age was 86 years, 64% were females, 86% were Caucasians, 66% had hypertension, 14% had diabetes, and 39% had prevalent CVD. Mean $eGFR_{EPI}$, $eGFR_{CYS3var}$ and $eGFR_{CYS1var}$ were 59, 62, and 70 ml/min/1.73m$^2$, respectively and 51%, 46%, and 33% of participants had CKD using the three equations. In adjusted analyses associations of CKD with CVD varied by equation (Table).

**Conclusion:** CKD is highly prevalent in octogenarians though its prevalence varied upon the equation used. The $CKD_{CYS1var}$ equation yielded the lowest prevalence but the strongest association with CVD. As there are no validated estimating equations in the elderly, estimation of kidney function based on any one equation should be interpreted with caution.

Association of CKD with CVD Based on eGFR Equations Using Serum Creatinine and Cystatin C

## F-PO1938

**Risk Factors for ESRD among African American Adults in the Community: A Genetic Epidemiology Network of Arteriopathy (GENOA) Study** LaTonya J. Hickson,[1] Andrew D. Rule,[1] Kenneth R. Butler,[2] Gary L. Schwartz,[1] Tom Mosley,[2] Stephen T. Turner.[1] *[1]Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [2]Geriatrics, University of Mississippi, Jackson, MS.*

Background: African Americans have an increased risk for the development of end stage renal disease (ESRD).

Aim: To determine the incidence of ESRD and its primary risk factors in predominately hypertensive African American adults in the community

Methods: The GENOA cohort includes African American (Af-Am) sibships from Jackson MS with two or more adult members having hypertension. The cohort was assessed from 1996 to 1999 with a medical questionnaire, physical examination, and a blood sample. The risk of subsequent ESRD was assessed using the USRDS database with censoring at death.

Results: Of the 1846 Af-Am adults, 69% were females, 72% had hypertension, 23% had diabetes, mean (±SD) age was 58±10 years, and estimated glomerular filtration rate 85±21 mL/min/1.73 m$^2$. After 9.7±1.3 years of follow up, 48 (2.6%) developed ESRD. The listed cause of ESRD was diabetes in 34 (71%), unspecified/missing in 13 (27%), and multiple myeloma in 1 (2%). MYH9, non-muscle myosin IIA heavy chain, genotype (rs5756130) was available for 1525 participants. Allele frequency was 88%. Baseline characteristics adjusted for age and sex that predicted ESRD were **MYH9** genotype (HR 3.5, CI 1.0-11.8, p=0.02), **hypertension** (HR 12.9, CI 1.8-95.5, p=0.01), and **diabetes** (HR 24.2, CI 9.3-62.7, p<.0001). In a multivariate model, diabetes remained the strongest risk factor (HR 19.4, CI 7.5-50.5, p<.0001), see Table.

Multivariable-adjusted hazard ratios for incident ESRD

| Predictors | HR | 95% CI | P value |
|---|---|---|---|
| Age | 1.0 | 0.7-1.5 | 0.92 |
| Male | 2.0 | 1.0-3.9 | 0.05 |
| Diabetes | 19.4 | 7.5-50.5 | <.0001 |
| Hypertension | 5.6 | 0.7-43 | 0.10 |
| MYH9 genotype | 3.5 | 1.1-11.1 | 0.04 |

HR: Hazard Ratio, CI Confidence Interval

Conclusion: After a decade of follow-up, 2.6% of these predominately hypertensive African American adults in the community developed ESRD. While those with diabetes were at highest risk of ESRD, MYH9 genotype made an additional contribution to the prediction of ESRD.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1939

**Apolipoprotein E and Kidney Function Decline in Older Adults** Rebecca Kurnik Seshasai,[1] Ronit Katz,[2] Ian H. de Boer,[2] David Siscovick,[2] Michael Shlipak,[3] Dena E. Rifkin,[4] Mark J. Sarnak.[1] *[1]Tufts Medical Center, Boston, MA; [2]University of Washington, Seattle, WA; [3]San Francisco VA Medical Center, San Francisco, CA; [4]University of California San Diego.*

Chronic kidney disease is a public health problem that mostly affects older adults. Although studies in middle-aged adults have suggested that the apo ε4 is associated with slower progression of kidney disease and the apo ε2 allele with more rapid progression of kidney disease, there are limited data in older adults.

We evaluated 4,015 participants from the Cardiovascular Health Study (CHS), a cohort of adults aged >65. An established genotype score (JAMA 2005) was determined for each individual: ε2 /ε2 (+2), ε2/ ε3 (+1) ε2/ ε4 (0), ε3/ ε3 (0), ε3/ ε4 (-1), ε4/ ε4 (-2). In cross sectional analysis, we evaluated the association of CKD (eGFR cystatin <60 ml/min/1.73m2) with genotype score in unadjusted and adjusted logistic regression. In longitudinal analysis we evaluated the association of the genotype score with rapid kidney function decline, defined by eGFR cystatin C decline >3ml/min/1.73m$^2$/year.

Mean age was 72 years, 40% were men, 13% black and 14% had diabetes. Mean baseline eGFRcys was 80 ml/min/1.73 m$^2$. The predominant genotypes were ε3/ ε3 (60.6%), ε3/ ε4 (20.6%) and ε2/ ε3 (13.6%). 12.4% had CKD at baseline and 24.9% had rapid progression over a median follow up of 6.8 years. There was no association between apoE genotype score and CKD in cross-sectional analysis or longitudinal analysis (Table).

Conclusions: Apo E allelic frequency does not appear to be a major determinant of prevalent CKD or declining kidney function in older adults.

Association of Genotype Score with Prevalent CKD and with Rapid Kidney Function Decline

| | Cross Sectional (OR per unit increase in genotype score) | | Longitudinal (OR per unit increase in genotype score) | |
|---|---|---|---|---|
| Unadjusted | 1.05 (0.93, 1.18) | 0.44 | 0.99 (0.88, 1.10) | 0.83 |
| Adjusted* | 0.98 (0.85, 1.12) | 0.73 | 0.96 (0.86, 1.08) | 0.52 |

* Adjusted for age, gender, race, DM, SBP, DBP, antihypertensive medications, BMI, prevalent CHD, LDL, HDL, triglycerides and lipid lowering medications.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1940

**Chronic Kidney Disease Japan Cohort (CKD-JAC) Study** Enyu Imai,[1] Seiichi Matsuo,[1] Hirofumi Makino,[2] Tsuyoshi Watanabe,[3] Kosaku Nitta,[4] Tadao Akizawa,[5] Satoshi Iimuro,[6] Yasuo Ohashi,[6] Akira Hishida.[7] *[1]Nagoya University; [2]Okayama University; [3]Fukushima Medical University; [4]Tokyo Women's Medical University; [5]Showa University; [6]University of Tokyo; [7]Fujinomiya Munichipal Hospital.*

Prevalence of chronic kidney disease (CKD) is estimated to 13.3 million in Japan, but the patient characteristics during the predialysis period (CKD stage 3-5) are not well studied. We established the Chronic Kidney Disease Japan Cohort (CKD-JAC) to study the incidence of CVD, end stage renal disease (ESRD), and all-cause mortality in pre-dialysis patients treated by nephrologists for 4 years. The inclusion criteria were 1) Japanese and Asian patients living in Japan; 2) age 20-75 years; and 3) estimated GFR (eGFR) of 10-59 ml/min/1.73 m$^2$. We analyzed 2977 participants for baseline characteristics. Mean eGFR was 28.6±11.8ml/min/1.73m$^2$ and mean albuminuria was 976±1340 mg/g Cr. In our study, 91.9% of the participants had hypertension, but it was well-controlled (131/76 mmHg). ACE inhibitors and ARBs were used by most of the participants. The number of participants with eGFR >45ml/min/1.73m$^2$, 45 to 30 ml/min/1.73m$^2$, 30 to 15 ml/min/1.73m$^2$, and <15 ml/min/1.73m$^2$ were 304, 1037, 1160, and 476, respectively. Less than 15% of participants had a history of ischemic heart disease, and 11.5% had a history of stroke. Heart failure and arteriosclerosis obliterance were present in 3.9% and 2.9% of patients, respectively. Comorbidity of cardiovascular diseases was more prevalent in proportion to declining eGFR. Indicators of arteriosclerosis, higher pulse wave velocity (PWV), and high pulse pressure were associated with declinig eGFR, diabetes and particularly with diabetic nephropathy. Patients due to glomerulonephritis seemed to be at low risk for atherosclerosis and also to show lower levels of hypertension. In conclusion, the difference between causative diseases is associated with different comorbidity and level of arteriosclerosis. Future analysis of the cohort will clarify whether the incidence of ESRD and CVD will differ among causative diseases.

## F-PO1941

**Development and Validation of an Electronic Health Record-Based Chronic Kidney Disease Registry** Sankar D. Navaneethan,[1] Stacey Jolly,[2] Jesse D. Schold,[3] Susana Arrigain,[3] Welf Saupe,[4] John W. Sharp,[3] James F. Simon,[1] Martin J. Schreiber,[1] Anil K. Jain,[2,4] Joseph V. Nally.[1] *[1]Nephrology and Hypertension, Cleveland Clinic; [2]Medicine Institute, Cleveland Clinic; [3]Quantitative Health Sciences, Cleveland Clinic; [4]eCleveland Clinic eResearch, Cleveland Clinic.*

**Objectives:** Chronic Kidney Disease (CKD) is increasing and outcomes related research from diverse health care settings are needed to target appropriate efforts and interventions. We developed an Electronic Health Record (EHR) based CKD registry at the Cleveland Clinic and validated its contents.

**Methods:** Patients who had at least one face-to-face outpatient encounter with a Cleveland Clinic health care provider and a) had two estimated glomerular filtration rate (eGFR) values <60 ml/min/1.73m$^2$ more than 90 days apart as of January 1, 2005 and/or b) patients with International Classification of Diseases (ICD-9) codes for kidney disease were included.

**Results:** Our registry includes 57,276 patients (53,399 patients with two eGFR <60 ml/min/1.73m$^2$ and an additional 3,877 patients who met the ICD-9 code criteria) as of March 2010. Mean age was 69.5 ±13.4 years with 55% females and 12% African Americans. Medicare is the primary insurer for over half of the study cohort. The kappa statistics to assess the extent of agreement between the administrative dataset derived from the EHR and actual EHR chart review showed substantial agreement (≥ 0.80) for all conditions except coronary artery disease and hypertension which had moderate agreement (<0.60).

| Condition | Kappa statistic | Sensitivity | Specificity | Positive predictive value | Negative predictive value |
|---|---|---|---|---|---|
| Diabetic nephropathy | 0.75 | 85% | 90% | 90% | 85% |
| Glomerulonephritis | 0.85 | 95% | 90% | 90% | 85% |
| Polycystic kidney disease | 0.90 | 100% | 90% | 90% | 100% |
| Diabetes | 0.90 | 91% | 100% | 100% | 90% |
| Hypertension | 0.45 | 65% | 90% | 95% | 50% |
| Hyperlipidemia | 0.85 | 95% | 90% | 90% | 95% |
| Coronary artery disease | 0.60 | 80% | 80% | 80% | 80% |
| Congestive heart failure | 0.85 | 87% | 100% | 100% | 85% |
| Cerebrovascular disease | 0.90 | 95% | 95% | 95% | 95% |

**Conclusions:** Development of EHR based CKD registry is feasible in a large health system and the comorbid conditions included in the registry are reliable. Apart from research purposes, such a registry would help to improve the quality of care delivered to CKD patients and complement the ongoing nationwide efforts to develop a CKD surveillance project.

**Multiple Admissions for Suspicion of Acute Coronary Syndrome: Effect of Kidney Function** Claudine T. Jurkovitz,[1] Xin Xu,[1] James R. Bowen,[1] Angela J. Disabatino,[2] Michael Stillabower,[2] William S. Weintraub.[1,2] *[1]Center for Outcomes Research, Christiana Care Health System, Newark, DE; [2]Division of Cardiology, Christiana Care Health System, Newark, DE.*

***Background.*** Chronic kidney disease (CKD) is a well known risk factor for cardiovascular disease. Whether patients with CKD are more likely to be admitted multiple times for suspicion of acute coronary syndrome (ACS) is unclear. ***Methods.*** We studied the likelihood of emergency department readmission in all patients for whom Troponin T (cTn) was measured between 2004 and 2010 at a large regional health care institution. A total of 83959 patients had complete records for cTn, serum creatinine, and demographic variables. Estimated glomerular filtration rate (GFR) was stratified as follows: GFR≥60, 30-59, 15-29, <15 mL/min/1.73m$^2$. CKD was defined as GFR<60. The maximum cTn achieved was stratified into cTn≥0.03, 0.04-0.3, > 0.3 ηg/mL. Logistic regression was used to estimate the association between one or more readmissions (dependent variable) and CKD stages after adjusting for age, race, sex, and cTn. ***Results.*** Readmissions involved 34.5% of the patients. Among those, 16.8% had only 1 readmission and 17.7% had 2 or more. CKD was present

in 24.7% (n=20754) of the study population. The population characteristics are described in the table. Compared to patients with normal kidney function (GFR≥60), patients with CKD were more likely to be readmitted (Odds ratio (OR), 95% Confidence Interval), OR = 1.32 (1.27-1.38) for those with GFR 30-59, OR=1.40 (1.30-1.51) for those with GFR 15-29 and OR=1.64 (1.48-1.81) for those with GFR <15. ***Conclusion.*** The decision-making process regarding the evaluation and treatment of CKD patients suspected of ACS should take into account the high likelihood of readmissions for these patients.

Characteristics of the population

| | All | GFR<60 | GFR≥60 | p |
|---|---|---|---|---|
| >1 readmission (%) | 34.5 | 45.9 | 30.8 | <0.0001 |
| Age≥ 65 (%) | 40.8 | 72.5 | 30.4 | <0.0001 |
| Male (%) | 47.3 | 42.4 | 48.9 | <0.0001 |
| White (%) | 71.4 | 79.0 | 68.8 | <0.0001 |
| Black (%) | 23.9 | 18.4 | 25.7 | |
| cTn>0.3 (%) | 4.0 | 6.7 | 3.2 | <0.0001 |

Disclosure of Financial Relationships: nothing to disclose

## F-PO1943

**Incidence of End-Stage Renal Disease among Type 2 Diabetes Patients – A Nationwide Register-Based Cohort Study** Patrik Finne,[1] Marjo Helena Kervinen,[2] Carola Gronhagen-Riska,[3] Reijo Sund.[4] *[1]Finnish Registry for Kidney Diseases, Helsinki, Finland; [2]Department of Internal Medicine, Kuopio University Hospital, Kuopio, Finland; [3]Division of Nephrology, Helsinki University Central Hospital, Helsinki, Finland; [4]National Institute for Health and Welfare, Helsinki, Finland.*

Background

Incidence of type 2 diabetes has increased rapidly due to increase in sedentary life-style and improved detection of the disease. Type 2 diabetes is the most common cause of end-stage renal disease (ESRD) in most industrialized countries. Type 2 diabetes patients' risk of developing ESRD has not previously been estimated in nationwide cohorts.

Material and methods

Finland has 5.3 million inhabitants. Through linkage of several national healthcare registers (hospital diagnoses from registers of National Institute for Health and Welfare, drug prescriptions and reimbursements from the registers of The Social Insurance Institution of Finland) we identified 332,340 patients aged 40 years or older with a first registration of type 2 diabetes in 1988 to 2007. Statistics Finland provided information on patients' deaths. Time of initiation of renal replacement therapy (RRT) was obtained from the Finnish Registry of Kidney Diseases which contains data on all RRT patients in Finland. ESRD was defined as initiation of RRT.

Results

By the end of 2007, 2,048,474 patient-years were accrued, during which 941 type 2 diabetes patients developed ESRD and 105,625 died. Overall, the incidence rate of ESRD was 46 per 100,000 person-years and all-cause mortality rate was 5156 per 100,000 person-years. Incidence rate of ESRD was 51–55 per 100,000 person-years in those aged 40–69 years at time of diagnosis of type 2 diabetes. In those diagnosed at age 70–79 years the rate was 32 and in older patients it was 8 per 100,000 person-years. Mortality rate was 1531 deaths per 100,000 person-years in 40–49-year-olds and 8377 in 70–79-year-olds. Men had higher risk of ESRD than women (incidence rate ratio 2.2, 95% CI 1.9–2.5) and this did not change with adjustment for age.

Conclusions

Although type 2 diabetes is a common cause of ESRD, type 2 diabetes patients' risk of ESRD is minimal and much smaller than their risk of death.

**Predictors of Decline in Renal Function in Older Adults: Results from the Einstein Aging Study (EAS)** Jennifer Yi-Chun Lai,[1] Mindy Katz,[2] Andrzej Galecki,[3] Richard B. Lipton,[2] Markus Bitzer.[1] *[1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Neurology, Einstein, Bronx, NY; [3]Institute of Gerontology, University of Michigan, Ann Arbor, MI.*

Background: Decreased kidney function (DKF) in older adults harbors increased morbidity and mortality, but risk factors for rapid decline of renal function are not established. Therefore, we examined rates and predictors of estimated glomerular filtration rate (eGFR) decline in a sub-study of the EAS, a systematically-recruited prospective cohort of community-dwelling adults. Method: eGFR decline rate was determined in 161 subjects based on early serum creatinine measurements and MDRD formula using mixed effect modeling. Average eGFR (AeGFR, ml/min/1.73m2) was calculated for each subject across the observation period. Multivariate linear and logistic regression analyses were used to identify factors associated with more rapid eGFR decline. For latter the sample was dichotomized into those with high versus lower GFR decline. Albuminuria was determined by dipstick analysis. Results: Mean age of all subjects was 81 years (70-96 years; 96 female, 65 male). The AeGFR was 64 in males and 66 in females; the difference was statistically not significant. The average loss of renal function was -2.2% and -3.3% per year in male and female subjects, respectively. In multivariate linear analysis with GFR % decline as outcome, subjects of female gender (β= -0.93, P value <0.0001) and higher AeGFR (β= -0.02, P value <0.0001) were more likely to have more rapid GFR decline. Similar findings were obtained using multivariate logistic analysis predicting high eGFR decline for female subjects and subjects with higher AeGFR (OR>999, P value <0.0001; OR=1.1, P value=0.006, respectively). No association of eGFR decline with albuminuria was detected. Conclusions: Female gender and higher AeGFR are independent risk factors for more rapid eGFR decline in subjects in the EAS, but albuminuria is not associated with eGFR decline. This suggests that other risk factors for rapid loss of eGFR exist in older adults compared with younger adults. We are expanding the sample size to further test our findings.

## F-PO1945

**Association of Estimated Glomerular Filtration Rate and Albuminuria with Mortality and End-Stage Renal Disease: A Collaborative Meta-Analysis of Kidney Disease Cohorts** Brad C. Astor,[1] Kunihiro Matsushita,[1] Ron T. Gansevoort,[2] M. van der Velde,[2] Mark Woodward,[4] Andrew S. Levey,[3] Paul E. de Jong,[2] Josef Coresh.[1] *[1]Department of Epidemiology, Johns Hopkins University, Baltimore; [2]Department of Nephrology, University Medical Center, Groningen, Netherlands; [3]Division of Nephrology, Tufts Medical Center, Boston; [4]George Inst. Int. Health, University of Sydney, Australia.*

Limited data are available on the independent associations of estimated glomerular filtration rate (eGFR) and albuminuria with mortality and end stage renal disease (ESRD) among individuals with chronic kidney disease (CKD). We conducted a collaborative meta-analysis of 21,688 participants selected for CKD from 13 cohorts.

A total of 4,374 deaths occurred in the 10 studies from which information on mortality was captured. A total of 4,128 ESRD events occurred in the 12 studies from which such information was captured. After adjustment for potential confounders and albuminuria, a 15 mL/min/1.73m$^2$ lower eGFR below 45 mL/min/1.73 m2 was significantly associated with mortality (pooled hazard ratio [HR] 1.47 [95% CI: 1.22-1.79]), and ESRD (pooled HR 6.24 [95% CI: 4.84-8.05]). There was significant heterogeneity between studies for both HR estimates. After adjustment for risk factors and eGFR, an eight-fold higher albumin:creatinine ratio (ACR) or protein:creatinine ratio (PCR) was significantly associated with mortality (pooled HR 1.40 [95% CI: 1.27-1.55]), without evidence of significant heterogeneity. An eight-fold higher ACR or PCR was also strongly associated with ESRD (pooled HR 3.04 [95% CI: 2.27-4.08]), with significant heterogeneity between HR estimates.

Lower eGFR and more severe albuminuria independently predict mortality and ESRD among individuals selected for CKD. The associations are stronger for ESRD than for mortality. The observed associations are consistent with CKD classification based on eGFR stages, and suggest that albuminuria provides additional prognostic information among individuals with CKD.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1946

**Pregnancy as the First Occasion for CKD Diagnosis** Rossella Attini,[1] Arianna Pagano,[1] Valentina Consiglio,[2] Pietro Gaglioti,[1] Tullia Todros,[1] Giorgina B. Piccoli.[2] *[1]Materno-Fetal Unit, Department of Obstetrics, ASO Universitaria OIRM-S.Anna, University of Torino, Italy; [2]Struttura Semplice Nefrologia Department of Clinical and Biological Sciences, ASO Universitaria San Luigi Gonzaga, University of Torino, Italy.*

Background

CKD and pregnancy share a complex relationship. Outside of pregnancy, CKD is frequently asymptomatic, and often diagnosed only if specifically searched for. Pregnancy may be the first occasion for diagnosis of CKD, as blood and urine tests are rarely performed in asymptomatic patients.

Aim of the study was to evaluate the prevalence and the main clinical features of CKD diagnosed during pregnancy in a Materno-Foetal unit and Outpatient facility dedicated to pregnant CKD patients.

Methods

Prospective analysis of CKD cases referred to the Unit, January 2000– June 2010. Start of observation: referral to the unit. End of observation: 1 month after delivery. All diagnosed were posed and reviewed by the same nephrology gynaecology team.

Results

Over 189 pregnancies, 68 patients had a diagnosis of kidney disease during pregnancy: in 38 the clinical history was silent, while in 30 a previous diagnosis was not considered as relevant (Single kidney, acute pyelonephritis with kidney scars). Excluding 8 cases with acute pyelonephritis, CKD was diagnosed in 60 new patients.

The diagnosed were glomerular diseases in 12/60 patients (2 dropped from follow-up; 7 underwent a renal biopsy: IgA nephropathy in 4, membranous nephropathy in 3); in 6 cases CKD stage 4-5 was diagnosed. The main diagnostic clue was either a small for gestational age baby or alteration in biochemical tests during pregnancy. Interstitial nephropathy or urological anomalies or previous acute pyelonephritis were diagnosed in 34/60 cases, and persistent urinary anomalies in 9/60 cases; the remaining 5/60 patients had other diagnoses.

At referral median age was 30 years; 57 were Caucasians; referral occurred late (52% in the second and 17% in the third trimester), median creatinine 0.79 mg/dl (0.3-4.9 mg/dl) , median proteinuria 0.66 g/24 hours (0-7.8).

Conclusions

Pregnancy may be an occasion for early diagnosis of CKD. The awareness of this condition may be precious tool for ensuring woman's health.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1947**

**The Impact of Moderate Chronic Kidney Disease (CKD) on All Cause Mortality, Cardiovascular (CV) Mortality, and Defibrillation in Patients with Implantable Cardioverter Defibrillators (ICD) for Sudden Cardiac Arrest (SCA) Prevention** Sejan B. Patel, Eric W. Raasch, Patrick H. Pun, John Paul Middleton. *Division of Nephrology, Duke University Medical Center, Durham, NC.*

Patients with end stage renal disease (ESRD) have an inordinate risk for SCA, but compared to those without ESRD, they have reduced survival despite presence of an ICD for SCA prevention. Less is known about patients with CKD. We evaluated the impact of CKD on all cause mortality, CV mortality, and ICD shocks in patients with an ICD for SCA prevention.

We performed a retrospective study of subjects who received a de novo ICD between 2002 and 2004 in our institution. We defined CKD as an estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73m2. The primary outcome was time to all cause and cardiovascular (CV) death. The secondary outcome was time to ICD shock.

Of 102 subjects, 46 subjects had CKD (45%). Subjects with CKD were older (age 70±10 vs. 60±15 years, p<0.001) and had lower left ventricular (LV) ejection fraction (27±13% vs. 35±18%, p<0.05) than those without CKD. There was no difference in comorbidities. Subjects with CKD had 12 all cause and 6 CV deaths and those without CKD had 3 all cause and 3 CV deaths over a mean period of 14.5±6.5 months associated with a 12-month survival of 84% with CKD vs. 98% without CKD (p<0.01) and 12-month CV survival of 88% with CKD vs. 98% without CKD (p=0.20). Subjects with CKD had 12 ICD shocks and those without CKD had 14 ICD shocks over a mean period of 5.9±4.5 months associated with a 6-month survival from ICD shock of 78% with CKD vs. 74% without CKD (p=0.60). Cox regression adjusting for demographics, comorbidities, and LV ejection fraction showed that an increase in eGFR by 1 mL/min was associated with a 3.4% hazard reduction for all cause death (HR 0.966, 95%CI 0.938-0.995, p<0.05).

Patients with CKD have reduced survival despite presence of an ICD for SCA prevention. No difference in CV death and ICD shock suggests that mechanisms of death other than SCA may limit ICD effectiveness in this population. Clinicians should consider competing non-cardiovascular causes of death in assessing benefit and risks of an ICD in this population.

**Nationwide Outcomes of Patients with Chronic Kidney Disease Undergoing Coronary Artery Bypass Surgery** Ankit Sakhuja, Abhishek Deshmukh, Nilay Kumar, Rahul S. Nanchal, Aaron T. Dall, Gagan Kumar. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

**Background:**

Chronic kidney disease (CKD) has been associated with adverse outcomes after coronary artery bypass grafting (CABG). However data from a national perspective are limited. We sought to investigate outcomes of patients with CKD undergoing CABG with a focus on development of acute kidney injury (AKI) and the need for dialysis.

**Methods**

Retrospective analysis was performed using National Inpatient Sample from the year 2007. All adult patients (age 18 years or more) with discharge diagnosis of CKD and the procedure CABG were identified using appropriate ICD-9-CM codes. Patients with end stage renal disease were excluded. The primary outcomes measured were frequency of AKI, need for dialysis, all cause in hospital mortality, length-of-stay, total charges and disposition of the patients. Pearson correlation and Chi square were used to compare the variables for unadjusted analysis and logistic regression was used to obtain adjusted odds ratios. $\alpha$ was set at 0.05.

**Results**

There were an estimated 212,237 patients undergoing CABG in 2007of which, 8.3% had CKD. After multivariate logistic regression and controlling for demographic factors and co-morbid conditions, the CKD patients were more likely (OR 8.5; 95%CI 7.7-9.4) to develop AKI and require dialysis. Patients with CKD developing AKI and requiring dialysis had significantly higher in-hospital mortality (OR 3.92; 95%CI 2.21-6.94) when compared to those who did not require dialysis.

Length of stay was 3.1 days longer (95%CI 2.8-3.4) and charges were $27,440 higher (95%CI $23,502-$31,337) in CKD patients when compared to those with normal kidney function.

The CKD patients were discharged to long term care, significantly more than those with normal renal function (31% vs. 16%)

**Conclusion**

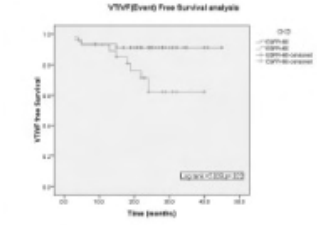
In patients undergoing CABG, CKD predicts higher in-hospital mortality and increased frequency of AKI, including need for dialysis. CKD predicts longer length of stay, higher incurred charges and discharges to long term care facilities.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1949**

**Moderate Chronic Kidney Disease Is an Independent Risk Factor for Malignant Ventricular Arrhythmias in Chronic Heart Failure Patients with Primary Prevention Cardiac Resynchronization Therapy-Defibrillator (CRT-D) Devices** Sanjeev Kumar,[1] Girish Babu,[2] A. Gopalamurugan,[2] Anthony Chow,[2] Pierre Lambiase,[2] Oliver Segal.[2] *[1]Department of Nephrology, Royal Free Hospital, United Kingdom; [2]The Heart Hospital, University College London Hospitals, United Kingdom.*

Chronic kidney disease (CKD) in the context of chronic heart failure (CHF) occurs frequently and is associated with increased mortality. We sought to determine whether baseline CKD is associated with increased incidence of malignant ventricular arrhythmias (sustained ventricular tachycardia/fibrillation;VT/VF) in CHF patients. A retrospective analysis of prospectively collected data for all CHF patients with no previous history of VT/VF implanted with primary prevention CRT-D devices between Jan'04 and Nov'08. VT/VF incidence was analyzed by device follow-up records from stored electrograms. The cohort was divided into 2 groups, G1 and G2 with MDRD eGFR < 60 and eGFR > 60 mls/min per 1.73m2 respectively. 117 patients met the inclusion criteria and there were 54(46%) in G1 and 63(54%) in G2. The mean eGFR in CKD group (G1) was 44±9 mls/min. The two groups were similar with respect to age, follow-up duration (mean 2 years) , baseline left ventricular ejection fraction (LVEF), NYHA class and anti-arrhythmic drugs. Significantly greater proportion of VT/VF occurred in G1 when compared to G2 (31% vs 12%, G1vs.G2; p< 0.05). Kaplan Meier survival analysis revealed significantly lower event-free survival in G1 (p<0.01). Multivariate analysis revealed eGFR<60 ml/min per 1.73m2 (HR 3.7, p<0.05) and LVEF (HR 0.9, p<0.05) as independent risk factor for sustained VT/VF. CONCLUSION: Even moderate CKD is a strong independent risk factor for malignant ventricular arrhythmia in HF patients with no previous history of VT or VF.



Disclosure of Financial Relationships: nothing to disclose

**F-PO1950**

**The Impact of Renal Dysfunction on Overall Mortality in Cancer Patients** Sun Young Na, Jiyoon Sung, Wookyung Chung, Hyun Hee Lee, Sejoong Kim, Jae Hyun Chang, Ji Yong Jung. *Department of Internal Medicine, Gachon University of Medicine and Science, Incheon, Republic of Korea.*

**Background**

Patients with renal dysfunction are at increased risk for cardiovascular and all-cause mortality. The effects of renal dysfunction on the risk of death with malignant disease are uncertain. The aim of this study is to determine the association between estimated glomerular filtration rate (eGFR) and overall mortality in cancer patients.

**Methods**

In this retrospective study, we identified 8226 cancer patients with one or more in and outpatient serum creatinine measurements from January 1, 2000 to December 31, 2004. Patients were followed up to December 31, 2008. We estimated glomerular filtration rate (eGFR) using the abbreviated Modification of Diet in Renal Disease (MDRD) equation. Renal dysfunction was defined as an eGFR of less than 60ml/min/1.73m$^2$. Cox's proportional hazards models adjusted for age, gender, diabetes mellitus, hypertension, proteinuria, serum hemoglobin and albumin level.

**Results**

The mean age of the patients was 56.3 years, and the proportion of male patients was 50.7%. The cancer types were included kidney and urinary tract cancer in 312 (3.8%), other solid organ cancer in 7621 (92.6%), and hematologic malignancy in 293 (3.6%) patients. A total of 1054 (12.8%) patients had renal dysfunction (baseline eGFR less than 60ml/min/1.73m$^2$). Lower eGFR was associated with increased risk of death in cancer patients. The adjusted hazard ratios were 1.17 with an eGFR of 30 to 59 ml/min/1.73m$^2$ (95% confidence interval 1.04 to 1.31, $p$=0.01), 2.22 with an eGFR of less than 30ml/min/1.73m$^2$ (95% confidence interval 1.76 to 2.80, $p$<0.001), compared to patients who had eGFR more than 60ml/min/1.73m$^2$.

**Conclusions**

The prevalence rate of renal dysfunction was 12.8% in cancer patients and higher than 4.7% of general population. The risk of death with cancer was greater at lower eGFRs. This association may contribute to excess mortality in cancer patients with renal dysfunction. Therefore, nephrologists should be aware of renal dysfunction as a predictor of mortality and should make efforts to preserve renal function in cancer patients.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1951**

**Use of Renin-Angiotensin System Blocking Agents and Retarded Progression of End-Stage Renal Failure: A Retrospective Study** Akira Fujiwara,[1] Nobuhito Hirawa,[2] Gen Yasuda,[2] Satoshi Umemura.[1] *[1]Department of Medical Science and Cardiorenal Medicine, Yokohama City University School of Medicine, Yokohama, Japan; [2]Division of Nephrology and Hypertension, Yokohama City University Medical Center, Yokohama, Japan.*

Since angiotensin II receptor antagonists have been available around 2000, many studies have revealed their effects in retarding the deterioration of renal function. However, before these trials, physicians were reluctant to use renin-angiotensin system blocking agents (RASBA) in end-stage renal failure, because of the risk of renal function deterioration and hyperkalemia. In the present retrospective cohort study, we reviewed the records of uremic patients before initiation of dialysis therapy to evaluate whether RASBA changed the natural course of renal function deterioration.

**Methods.** Between 1990 and 2010, 274 patients were followed from 3 to 5 years before dialysis therapy. The patients were categorized into 4 groups: diabetic and non-diabetic, and 1990s and 2000s. The slope of the reciprocal of the serum creatinine levels versus time (1/Cr), an index of the rate of renal failure progression, was evaluated.

**Results**. Ninety-one percents of patients in the 2000s diabetic group (n=52, men/women 33/19, mean age 74±5 years) received RASBA, compared with 4% in the 1990s diabetic group (n=55, men/women 40/15, mean age 71±5 years). The 1/Cr was 0.11±0.05 dL/min/month in the 2000s diabetic group, which was lower than 0.15±0.08 dL/min/month in the 1990s diabetic group, showing retardation of progression of renal impairment. Meanwhile, there was no difference in 1/Cr (0.07±0.04 vs. 0.08±0.04 dL/min/month) between the non-diabetic 1990s (n=100, men/women 71/29, mean age 73±6 years) and 2000s groups (n=67, men/women 33/34, mean age 75±15 years), although the proportion of patients receiving RASBA was higher in the 2000s non-diabetic group (92%) than that in the 1990s non-diabetic group (4%).

**Conclusion**. Our study suggests that increasing use of RASBA is associated with retarded deterioration of renal failure caused by diabetes, whereas the use of these agents is not associated with a clear retardation in renal failure progression in non-diabetic uremic patients.

**F-PO1952**

**Improvement in GFR in Patients with Chronic Kidney Disease** Lise Weis,[1,3] Marie Metzger,[2] Benedicte Stengel,[2] Emmanuel Letavernier,[1,3] Marc C. Froissart,[4] Jean-Philippe Haymann,[1,3] Jean-Jacques Boffa.[1,3] *[1]U 702, INSERM, Paris, France; [2]U 780, INSERM, Paris, France; [3]Hopital Tenon, APHP, Paris, France; [4]Hopital Georges Pompidou, APHP, Paris, France.*

Renal function decline in chronic kidney disease (CKD) patients is considered ineluctable. We report patients with CKD whose GFR improved.

We studied 406 patients from the Nephrotest cohort who underwent at least 3 mGFR measures by $^{51}$Cr-EDTA clearance, over at least 2 year-follow up. Patients were assigned as having improved *vs* declined mGFR, on the basis of visual examination of mGFR slopes by 4 independent nephrologists who further reached consensus about discrepancies. We compared patients with improved mGFR first with those with moderate mGFR decline of 0 to -2ml/min/1.73m$^2$/yr, then with those with declined mGFR, on number of achieved nephroprotection targets: systolic and diastolic blood pressure,<130 and <80 mm Hg, U-albumin/creatinin ratio<30 mg/mmol, diabetes control and RAS blocker use. We identified 63 patients (15.5%) with improved mGFR over time. Their mean mGFR slope was 2.8 ± 2.2 ml/min/1.73m$^2$/yr *vs* -3.0±3.0 for the 332 patients with mGFR decline and -0.6± 1.1 for the 144 with moderate decline. They had various nephropathies except diabetic and polycystic kidney disease. As compared to the 332 with declining mGFR, those who improved did not differ in age, sex and cardiovascular history, but their baseline mGFR was higher, 42.3 vs 39.7±13.2 ml/mn/1.73 m$^2$, they had less often 2 or more metabolic complications, 30% vs 48%, and higher number of achieved targets, 3.7±0.9 vs 3.3±0.8. After adjusting for baseline mGFR, the OR (95%CI) for improved mGFR significantly increased 1.7 (1.2-2.3) with each increase of achieved target unit. However, when compared to patients with moderate mGFR decline, the adjusted OR was no longer significant, 1.3 (0.9-1.9).

This is the first description of a rather large cohort of CKD patients whose mGFR improved over time, including a fourth with severe CKD. This study revealed that nephroprotection alone may not explain this evolution, suggesting the existence of other factors. Our data suggest the reversal of renal fibrosis in human pathology, as previously described in experimental models.

**F-PO1953**

**The Impact of Moderate Chronic Kidney Disease (CKD) on Survival in Patients with Implantable Cardioverter Defibrillators (ICD) for Primary and Secondary Sudden Cardiac Arrest (SCA) Prevention** Sejan B. Patel, Eric W. Raasch, Patrick H. Pun, John Paul Middleton. *Division of Nephrology, Duke University Medical Center, Durham, NC.*

Patients with CKD have an inordinate risk for SCA. While an ICD attenuates the risk of SCA in the general population, it is not evident whether patients with CKD have similar benefit. We evaluated the impact of CKD on survival in patients with an ICD for SCA prevention.

We performed a retrospective study of subjects who received a de novo ICD between 1997 and 2009 in our institution. We defined CKD as an estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73m2. The primary outcome was time to all cause death.

Of 400 subjects, 201 subjects had CKD (50%). Subjects with CKD were older and had more comorbidities than those without CKD (age 68±11 vs. 58±13 years, coronary artery disease 80% vs. 67%, diabetes mellitus 36% vs. 27%, hypertension 94% vs. 83%, left ventricular (LV) ejection 27±10% vs. 32±13%, p<0.01). Subjects with CKD had a eGFR 43±13 mL/min and those without CKD had a eGFR 80±19 mL/min. There was no difference in primary and secondary prevention indications for an ICD among subjects with and without CKD (primary 81% vs. 73%, secondary 19% vs. 27%, NS). There were 135 deaths during a mean period of 4.6±2.7 years. The primary prevention cohort was associated with a 5-year survival of 61% with CKD vs. 88% without CKD (p<0.001). The secondary prevention cohort was associated with a 5-year survival of 61% with CKD vs. 77% without CKD (p<0.05). Cox regression adjusting for demographics, comorbidities, LV ejection fraction, and ICD indication showed that an increase in eGFR by 1 mL/min was associated with 1.1% hazard reduction in death (HR 0.989, 95%CI 0.979-0.999, p<0.05).

Patients with CKD have reduced survival despite presence of an ICD for primary and secondary SCA prevention. Effectiveness of an ICD may be limited by mechanisms of death other than SCA that are significant in this population.

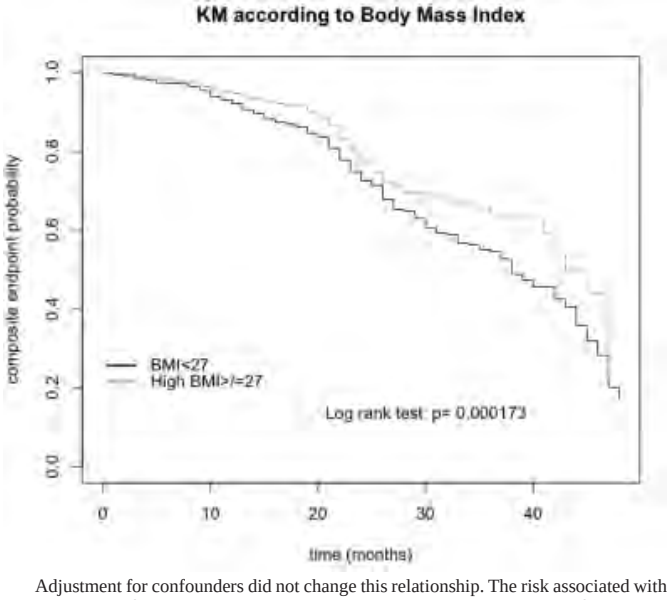
**Chronic Kidney Disease Progression and Mortality in Moderate Kidney Dysfunction According to Body Mass Index** Antonio Bellasi, Marcora Mandreoli, Antonio Santoro. *On Behalf of the PIRP Study Group, Policlinico S.Orsola-Malpighi, Italy.*

In the general population the excess of weight represents a strong risk factor for End Stage Renal Disease (ESRD) and all-cause mortality. Conversely, in dialysis patients a high Body Mass Index (BMI) is inversely related to overall mortality. This study sought to investigate the impact of BMI on the risk of the composite endpoint of dialysis inception or all-cause mortality in a large cohort of Chronic Kidney Disease (CKD) patients not on dialysis.

We utilized the patient's records from the "Prevenzione Insufficienza Renale Progressiva" (PIRP) database, a large project sponsored by the Emilia-Romagna Institute of Health, aimed at optimizing CKD patients care. Survival analyses estimated the relationship between BMI at baseline and outcomes.

A total of 4174 patients with CKD 3-5 (male 65,7%; mean age 73,3 (1.2) yrs; diabetes 30,5%) patients registered in the PIRP database between year 2004 and 2007 were identified. The median eGFR (MDRD4) and BMI were 29 ml/min/1.73m$^2$ [IQ: 21-37] and 26 Kg/m$^2$ [IQ: 24-29], respectively. The mean follow-up was 14.5 (10.7) months. An inverse relationship between BMI and the risk of commencing dialysis or dying was noted. Indeed, a moderate overweight was linked with a better survival (long-rank test: p<0.001).



Adjustment for confounders did not change this relationship. The risk associated with a BMI ≥27 Kg/m$^2$ was 38% lower than that associated with a BMI <27 Kg/m$^2$ (HR 0.62, 95% IC: 0.40-0.95; p=0.03).

In summary, as documented in dialysis patients the presence of CKD modify the prognostic significance of traditional CV risk factors. Indeed, a moderate overweight probably due to a better nutritional status, is associated with a better prognosis. Finally, this results further underlie the need of a dedicated nutritional approach in elderly with moderate chronic kidney dysfunction

**Epidemiology and Risk Fcators of Chronic Kidney Disease in Sichuan Province** Li Wang. *Department of Nephrology, Sichuan Provincial Hospital, Chengdu, Sichuan, China.*

Objective: To investigate the epidemiology and its risk factors of chronic kidney diseaes.Method:3024 people older than 18 years in chengdu (represent urban area and Guanghan (represent rural area)were enrolled by cluster random sampling.This reseach included a questionnaire , physical exminations and laboratory examinations CKD was diagnosed by decreased eGFR(<60ml/min/1.73m$^2$) or presentation of microalbuminuria, macroalbuminuria, proteinuria or hematuria. .**Results:***1.Prevalence of CKD in Sichuan province*: The overall prevalence and age-and-sex-standardized prevalence of CKD in Sichuan was 19.1% and 16.48% respectively. The prevalence of hematuria, albuminuria, proteinuria and decreased eGFR was 7.2%, 11.4%, 1.4% and 2.9%; and the standardized prevalence was 6.74%, 9.49%, 1.11% and 2.34%, respectively. Prevalence of CKD, hematuria, microalbuminuria and macroalbuminuria were 15.1%, 11.2%, 12.4% and 1.1% in female , and everyone was lower in male population with the corresponding prevalence of 6.2%, 3.3%, 8.4% and 1.0%(p<0.001). Prevalence of CKD in Chengdu was lower than in Guanghan(10.4% vs 19.1%, p<0.001). And prevalence of hematuria, proteinuria, albuminuria and decreased eGFR was also lower in Chengdu than in Guanghan(p<0.001). Prevalence of CKD and microalbuminuria increased with age. In different age groups(18~39, 40~49, 50~59, 60~69, 70~95), the prevalence of CKD was 11.6%, 16.8%, 19.9%, 27.4% and 41.3% respectively. The awareness rate of CKD was 7.9%. The logistic regression analysis showed that hypertension(OR =1.933, 95.0%CI: 1.506-2.482), diabetes(OR=4.528, 95.0%CI: 3.239-6.329), hyperuricemia(OR=1.644, 95.0%CI: 1.233-2.192) and history of reral disease(OR=1.682, 95.0%CI: 1.137-2.487) was risk factors of CKD. And male(OR=0.496, 95.0%CI: 0.379-0.648), high degree of education(OR=0.839, 95.0%CI: 0.738-0.955), and high income(OR=0. 804, 95.0%CI: 0.727-0.889) was negative associated with CKD.Conclusion:The prevalence of CKD in Sichuan province is relatively high in China with a higher prevalence in rural population than in urban population. Female gender, hypertension, hyperuricemia, diabetes, past history of renal disease, low degree of education and low income are risk factors of CKD.

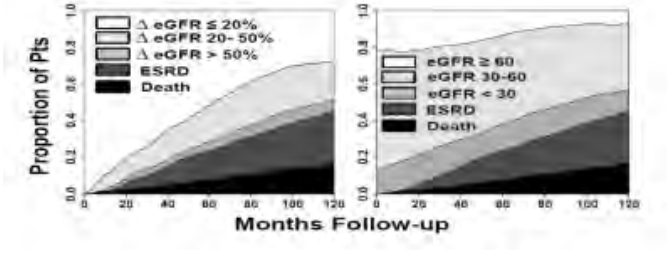
**Multistate Representations of the Evolution of Cohorts with Chronic Kidney Disease (CKD)** Bo Hu,[1] Liang Li,[1] Lawrence J. Appel,[2] Brad C. Astor,[2] Julia Lewis,[3] Michael S. Lipkowitz,[4] Robert D. Toto,[5] Xuelei Wang,[6] Jackson T. Wright,[6] Tom H. Greene.[7] *[1]Cleveland Clinic; [2]Johns Hopkins; [3]Vanderbilt; [4]MSSM; [5]UTSW; [6]CWRU; [7]Utah.*

**Introduction** Longitudinal analyses of CKD progression often use as outcome the mean slope of estimated GFR (eGFR) or time to a designated event (eGFR level or ESRD). These approaches use limited portions of available data, restricting statistical power and clinical insight, and are susceptible to informative censoring bias. The time-to-event approach emphasizes patients at greatest risk for adverse events and is not well suited to assessment of favorable outcomes. We show alternative representations of evolution of CKD cohorts that avoid these problems by jointly incorporating information from clinical events **and** eGFR.

**Methods** We propose a hybrid multistate method which applies competing risk methods to estimate cumulative incidence of ESRD and death in conjunction with non-parametric regression analysis for change in eGFR.

**Results** Multistate representations of the evolution of the cohort of 1094 African American Study of Kidney Disease (AASK) pts over 10 yrs are in 2 panels showing proportion of pts with ESRD and death with additional states defined by change in eGFR from baseline (left) or absolute level (right). After 10 yrs, an estimated 17% of patients died, 29% had ESRD, 6% had 50% eGFR decline w/o ESRD, 21% had 20% - 50% eGFR decline. The remaining 28% had stable function (10-yr eGFR ≥ 80% of initial eGFR).



**Conclusion** The proposed multistate approach avoids bias from informative censoring by death and/or ESRD and accounts for the full spectrum of negative and positive outcomes ranging from death to stable function. The method extends to states jointly defined by eGFR and other markers such as protein excretion and can be adapted to increase power for treatment comparisons.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1957**

**Impaired Fasting Glucose Is Associated with Renal Hyperfiltration in the General Population – Results from the Renal Iohexol-Clearance Survey in Tromsø 6 (RENIS-T6)** Toralf Melsom,[1.2] Ulla Dorte Mathisen,[1.2] Trond G. Jenssen,[2] Marit D. Solbu,[1.2] Bjorn Odvar Eriksen.[1.2] *[1]University Hospital of North Norway; [2]University of Tromsø, Norway.*

**Background**: Approximately 30% of the adult U.S. population have impaired fasting glucose (IFG), which is associated with increased prevalence of chronic kidney disease. Elevated glomerular filtration rate (GFR), or hyperfiltration (HF), has been proposed as an underlying mechanism for renal injury in diabetes and obesity. The purpose of this study was to assess whether impaired fasting glucose (IFG) or insulin resistance were associated with HF in the general middle-aged population.

**Method**: From the 6$^{th}$ Tromsø study, we investigated 1627 individuals from the general population between 50 to 62 years without self-reported diabetes, cardiovascular disease or kidney disease. GFR was measured by single sample iohexol-clearance. 34 persons with GFR< 60 ml/min/1,73m$^2$ and 20 with fasting glucose ≥ 126 mg/d were excluded. Insulin resistance was estimated by using the Homeostasis Model Assessment (HOMA-IR). We defined HF as GFR above the 90 percentile, adjusted for sex, age, weight and height. Multiple logistic regression was performed with HF (yes/no) as the dependent variable and fasting glucose, fasting insulin, HOMA-IR and IFG (yes/no) as independent variables in different models.

**Results**: IFG was present in 33 % of males and 15% of females.

Table 1. Adjusted odds ratio (OR) for hyperfiltration

| | OR | 95% CI |
|---|---|---|
| Model 1: | | |
| Glucose, per mmol/L | 1.87 | 1.31 to 2.69 |
| | | |
| Model 2: | | |
| IFG (yes/no) | 1.77 | 1.21 to 2.58 |
| | | |
| Model 3: | | |
| Insulin, per µU/ml | 1.03 | 0.99 to 1.06 |
| | | |
| Model 4: | | |
| HOMA-IR, per mU x mmol/L² | 1.13 | 1.01 to 1.27 |
| | | |
| Model 5: | | |
| HOMA-IR, per mU x mmol/L² | 1.05 | 0.93 to 1.20 |
| Glucose, per mmol/L | 1.77 | 1.20 to 2.61 |

All models were adjusted for age, gender, weight, height, smoking status, diastolic blood pressure and the use of inhibitors of the renin-angiotensin system.

**Conclusion**: Fasting serum glucose and IFG but not fasting insulin levels, were associated with HF. This indicates a similar mechanism for HF in prediabetes and diabetes. IFG could be one of the causes of renal injury in the general population.

Disclosure of Financial Relationships: nothing to disclose

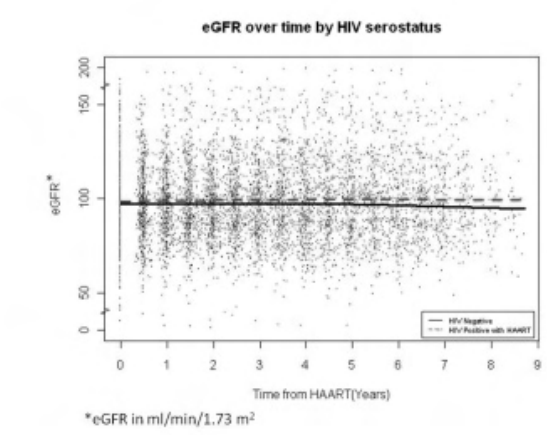
**F-PO1958**

**Antiretroviral-Treated HIV-Infected Women Have Kidney Function Trajectories Similar to HIV-Uninfected Women** Michelle M. Estrella,[1] Alison G. Abraham,[1] Yuezhou Jing,[1] Rulan S. Parekh,[2] Phyllis Tien,[3] Kathryn Anastos,[4] Mardge H. Cohen,[5] Jack A. Dehovitz,[6] Lynda A. Szczech,[7] Stephen J. Gange.[1] *[1]Johns Hopkins University; [2]University of Toronto; [3]University of California, San Francisco; [4]Montefiore Medical Center; [5]Stroger Hospital; [6]SUNY Downstate Medical Center; [7]Duke University.*

To determine whether HIV infection in the context of highly active antiretroviral therapy (HAART) was associated with faster kidney function decline, we compared estimated glomerular filtration rates (eGFR) between HIV-infected and uninfected women comparable at baseline on known risk factors for kidney disease. Using data from 3766 women in the Women's Interagency HIV Study, we identified 127 HIV-infected women who were matched at HAART initiation to 493 HIV-uninfected women on calendar time, age, and kidney disease risk factors (systolic blood pressure ±20 mm Hg, total cholesterol ±20 mg/dl, hepatitis C status, and diabetes; see Table). We used linear mixed models to examine the difference in annual eGFR decline by HIV status. The effect of HIV disease severity was assessed by stratifying eGFR slope by time-varying CD4$^+$ cell count in HIV-infected women. Baseline mean eGFRs were similar between HIV-infected and uninfected women (HIV$^+$=98 vs HIV$^-$=97 ml/min/1.73 m$^2$). We found no significant difference in eGFR slope by HIV status ($ß_{HIV+}$=-0.08 vs $ß_{HIV-}$=0.18, P=0.13), though the mean difference by 7 years was marginally significant (P=0.06). No trend was noted in eGFR decline by CD4$^+$ cell count. Our results suggest that HAART-treated HIV-infected women with a mean age of 39 years at baseline experience a similar eGFR trajectory as those of HIV-uninfected women.

Table. Baseline characteristics

| Characteristic | Mean | |
|---|---|---|
| | HIV+ | HIV- |
| Age, y | 39 | 39 |
| Systolic BP, mm Hg | 115 | 116 |
| Total cholesterol, mg/dl | 182 | 182 |
| Hepatitis C infected, % | 29 | 29 |
| Diabetic, % | 16 | 16 |



Disclosure of Financial Relationships: nothing to disclose

**Serum Uric Acid Predicts End Stage Renal Disease and Mortality in Chronic Kidney Disease Patients in Southern Taiwan** Chi-Chih Hung, Shang-Jyh Hwang. *Division of Nephrology, Department of Internal Medicine, Kaohsiung, Taiwan.*

Background: Serum uric acid (UA) is a risk factor for cardiovascular disease in general population. However, whether UA is a risk factor for end stage renal disease (ESRD) is controvertial. Taiwan has high incidence of both hyperuricemia and ESRD. We would thus hypothesize that UA is a risk factor for ESRD in chronic kidney disease (CKD) patients.

Method: From 2002.11.11 to 2008.12.31, 3272 patients joined the integrated CKD care cohort study in Kaohsiung Medical University Affiliated Hospitals. All biochemical data within 3 months of the enrollment were averaged. Renal outcome and survival were followed till 2009.12.31. Chi-square test, t-test, Kaplan-Meier survival analysis and multivariate cox regression analysis were used and p value less than 0.05 was considered as significant.

Results: UA level increased significantly from CKD stage 1 to 5 ($p<0.05$, compared with CKD stage 1). In the multivariate linear regression, UA correlated with male gender, use of anti-hyperuricemic drug, phosphate, proteinuria and GFR ($p<0.01$). The patients were thus divided by UA level quartiles as UA1 to UA4 (from low to high UA level). The UA4 group had higher percentage of DM, hypertension, cardiovascular disease, and use of anti-hyperuricemic drug than the other groups (all $p<0.05$). Also the UA4 group had lower glomerular filtration rate (GFR), lower albumin, lower hematocrit, higher body mass index and higher phosphate than the other groups (all $p<0.05$). Kaplan-Meier survival analysis showed lower renal survival rate in UA4 group compared with all other three groups ($p<0.05$). The 5 year renal survival is 78% and 55% in UA1 and UA4 group, respectively. The mortality was different only between UA1 and UA4 groups with 93% and 82% 5 year survival rate, respectively. In the multivariate cox regression analysis, albumin, UA groups, male, proteinuria, and GFR were risk factors for ESRD. In the multivariate cox regression analysis, higher C-reactive protein, lower GFR, UA groups and lower albumin were risk factors for all-cause mortality.

Conclusion: Serum UA level at the time of enrollment predicts ESRD and mortality in CKD patients in Southern Taiwan.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1961**

**Illicit Drug Use and Chronic Kidney Disease: Findings from the National Health and Nutrition Examination Survey** Arjun Das,[1] Lydia Bazzano,[2] James P. Lash,[1] Sanjeev Akkina.[1] *[1]Nephrology, University of Illinois at Chicago, Chicago, IL; [2]Epidemiology, Tulane University, New Orleans, LA.*

Studies have reported a possible link between illicit drug use and chronic kidney disease (CKD). The purpose of this study was to examine this relationship in a nationally representative sample.

**Methods:** We performed a cross-sectional analysis of data from the National Health and Nutrition Examination Survey 1999 – 2004. The sample included 8270 participants between the ages of 20 - 59 years who completed a survey regarding use of illicit drugs. CKD was defined as an MDRD estimated glomerular filtration rate (eGFR) ≤60 mL/min/1.73m$^2$ or the presence of microalbuminuria (>20mg/g). We compared non-drug users to those who used any illicit drugs (apart from marijuana) and to those who used IV drugs. Using logistic regression models, we estimated odds ratios for CKD by type of illicit drug use adjusted for age, gender, race (white vs. non-white) and diabetes (DM).

**Results:** We found that drug users had similar mean eGFR (106.0 ± 0.8 vs. 106.6 ± 0.7 ml/min/1.73m$^2$, p = 0.51) and albumin/creatinine ratio (23.5 ± 4.6 vs. 21.7 ± 2.5 mg/gm, p = 0.73) as compared to non-drug users. The unadjusted risk for CKD was lower in the drug user group but this difference became insignificant after adjustment (see table). Similarly, IV drug users did not differ from non-drug users in terms of eGFR (105.7 ± 2.9 vs. 106.6 ± 0.7 ml/min/1.73m$^2$, p = 0.74) and albumin/creatinine ratio (45.9 ± 23.6 vs. 21.7 ± 2.5 mg/gm, p = 0.32). The risk of CKD was also not significantly different among the two groups (see table).

**Table: Risk of CKD in Drug users and IV Drug users versus Non-Drug users**

| | Model Attributes | OR (95% CI) | p - value |
|---|---|---|---|
| **Illicit drug use** | *Unadjusted* | 0.739 (0.590-0.926) | 0.0086 |
| | Multivariate Adjusted* | 0.829 (0.657-1.046) | 0.1133 |
| **IV drug use** | *Unadjusted* | 0.644 (0.317-1.308) | 0.2235 |
| | Multivariate Adjusted* | 0.655 (0.309-1.389) | 0.2699 |

* Age, gender, race and DM

**Conclusion:** In a representative sample of the U.S. population, we did not find an association between illicit drug use and CKD.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1962**

**Oral Paricalcitol Effects from Hyperparathiroidism Treatment to Renoprotection Role in Patients with Chronic Kidney Disease (CKD) Stages 3-5nd** Secundino Cigarran,[1] Francisco Coronel,[2] Montserrat Pousa,[1] Ignacio Docal.[3] *[1]Nephrology, Hospital Da Costa, Burela, Lugo, Spain; [2]Nephrology, Hospital Clinico Universitario San Carlos, Madrid, Spain; [3]Radiology, Hospital Da Costa, Burela, Lugo, Spain.*

The new understanding of vitamin D endocrine/intracrine system alters the view of renal disease and its treatment.Vit D analogs are expanding because of its role on inflammation and fibrosis related to renin-angiotensin-aldosterone axis (RAAS) in which is important as renoprotective effect. The aim of this study is to assess the effect of oral paricalcitol on PTH and on Proteinuria in CKD stage 3-5ND patients with 25D and 1,25 D normal levels on 6 months of follow up. 42 patients, were followed during 6 months, mean age 70.34± 12.4 yr, 34.2% female, 34% diabetic, estimated glomerular filtration rate (GFR-MDRD): 33.93±13.0 ml/min. Inclusion criteria were Vitamin 25D &1,25D in normal range and PTHi >150 pg/ml. Paracalcitol 1µ/daily p.o. was added to treatment. The primary end point was to compare change in PTHi levels and secondary, the effect in mean spot urinary albumin / creatinine ratio between baseline measurement and the last of the study evaluation. Parameters analyzed at start and every 3 months there were: PTHi, serum calcium, serum phosphorous, phosphorous fractional excretion, GFR, and urine spot albumin/creatinine ratio.

t-paired analysis

| Variable | Baseline | 6 months | P |
|---|---|---|---|
| GFR (ml/min) | 33.9±13.2 | 24.9±13.8 | .003 |
| Serum Albumin (gr/dl) | 4.25±.24 | 4.23±.35 | NS |
| Serum Phosphorous(mg/dl) | 3.7±.52 | 3.96±1.01 | .032 |
| Serum Calcium (mg/dl) | 9.17±.52 | 9.19±.73 | .005 |
| CaxP (mg2/dl2) | 34.12±9.09 | 36.40±11.1 | .006 |
| PTHi (pg/ml) | 259.93±134.92 | 124±15 | .000 |
| 25D Vitamin (ng/ml) | 46±9.3 | 49±4.2 | NS |
| 1,25D Vitamin (pg/ml) | 33.0±10 | 36.86±13.4 | NS |
| Urinary spot Albumin/creatinine (mg/gr crea) | 1044.51±1786.7 | 408.57±793.26 | .030 |

NS Not significance

There were not serious adverse events.

Paricalcitol resulted in significant reduction of PTHi, significant increase of calcium and phosphorous and significant reduction in urinary albumin/creatinine ratio showing a renoprotective action.GFR reduction could be RAAS effect.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1963**

**Impacts of rHuEPO Treatment on Progression of CKD and on Mortality and Hospitalization during 1 Year after HD Onset in Japan** Tadao Akizawa.[1,2] *[1]Department of Nephrology, Showa University School of Medicine, Tokyo, Japan; [2]On Behalf of JET Study Group.*

Background and Objective: There are a few evidences with respect to the clinical significance of anemia treatment in CKD patients with recombinant human erythropoietin (EPO). We retrospectively evaluated the effects of EPO treatment on progression of CKD and prognosis after onset of HD in the sub-cohort (3,286 patients) of the ongoing multicenter, prospective JET study in Japan.

Method: The effect on time to renal failure of EPO treatment during the non-dialysis period was estimated using the inverse probability weighted (IPW) analysis to adjust for time-dependent confounding. The weights used in IPW analysis were calculated using the logistic model, which included baseline confounders and time-dependent variables : hemoglobin (Hb) and serum creatinine (sCre). The cumulative proportion (Kaplan-Meier method) without death, evaluated in 3,280 patients, excluded 6 patients with no data on first EPO treatment after HD.

Results: During the non-dialysis periods, 69.3% of CKD patients were treated with EPO at the mean Hb level of 8.73 g/dL. The effect of covariates on the motivation to start EPO treatment were significant in some parameters of Hb, sCre, age, diabetes, cardiac insufficiency, hyperlipidemia and hypertension. The adjusted Hazard Ratio of HD introduction by EPO treatment was 0.65 (0.54-0.78; $p<0.0001$). Compared to non-EPO treatment group, in EPO treatment group, the cumulative proportion without death was significantly higher, with 98.59%, 97.10% and 95.36% at 3, 6 and 12 months after onset of HD, respectively, and the risk of death during 12 months was also lower (HR 0.598; 0.419-0.853; $p=0.005$). Likewise, patients treated with EPO had lower risk of hospitalization/death (HR 0.887; 0.790-0.995; $p=0.041$).

Conclusion: This retrospective research strongly suggests that EPO treatment during non-dialysis in CKD patients has preventive effects not only on the progression of CKD but also on mortality and hospitalization after onset of HD.

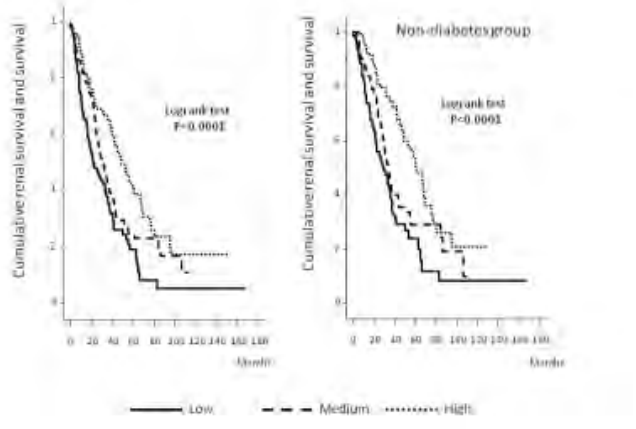
**Association between Body Mass Index (BMI) and Renal Outcome in Predialysis Chronic Kidney Disease** Daijo Inaguma. *Nephrology, Nagoya Daini Red Cross Hospital, Nagoya, Aichi, Japan.*

[Introduction] It is claimed that the higher the BMI values of maintenance dialysis patients are, the more likely their life expectancy is to be favorable, but there have been hardly any reports in regard to the predialysis period. [Purpose] The purpose of this study was to investigate the association between BMI and both renal outcome and life expectancy in predialysis chronic kidney disease. [Subjects] The subjects were 455 patients with chronic kidney disease who presented to the nephrology department during the period between January 1995 and December 2008 and whose BMI was recorded. There were 143 women, and the subjects' mean age was 65.9 ± 12.8 years. Their estimated GFR was 17.4 ± 8.6 ml/min/1.73 m². [Methods] This was a retrospective observational study. The patients were divided into 3 groups according to their BMI values at the first presentation: low-BMI group (14.3-21.2), medium-BMI group (21.3-24.2), and high-BMI group (24.3-35.1), and the endpoint was renal death or death. [Results] The observation period (median) was 20.0 months, and during the observation period 233 patients were started on dialysis and 15 patients died. According to the Kaplan-Meier survival curves the low-BMI group had the poorest outcome (Log-rank test, $P < 0.0001$), especially limited to non diabetes group.



The results of a multivariate analysis using the Cox proportional hazard model showed that BMI was a factor associated with outcome even after adjusting for age, sex, presence or absence of diabetes, albumin values, hemoglobin concentrations, and whether the patient was treated with a renin-angiotensin inhibitor (95% CI 0.890-0.974, HR = 0.931, $P = 0.021$). [Discussion] The results suggested that nutritional status deteriorates as chronic kidney disease progresses, probably influencing the rate of progression of renal dysfunction and life expectancy.

**Genetic Investigation of JunD Mediated Activation Networks in Primary Rat Macrophages** Richard P. Hull,[1] Santosh S. Atanur,[1] Jacques Behmoaras,[2,3] Zelpha D'Souza,[1] Jennifer Smith,[3] Charles D. Pusey,[3] H. Terence Cook,[2,3] Timothy J. Aitman.[1] *[1]MRC CSC, Imperial College; [2]CCIR, Imperial College; [3]Renal Medicine, Imperial College, London.*

Activated macrophages are major cellular mediators of injury in proliferative and crescentic glomerulonephritis (Crgn). Our previous work on a rat model of Crgn identified a genetically determined macrophage activation phenotype associated with Crgn susceptibility. Using congenic, linkage and microarray studies we found that the AP-1 transcription factor JunD was a primary determinant of macrophage activation in the Crgn-susceptible WKY rat. *Jund* is markedly overexpressed in WKY compared to Crgn-resistant Lewis bone marrow derived macrophages (BMDMs) and, using *Jund* congenic strains, we demonstrated *Jund* dependant control of IL10 expression. *Jund* knockdown in WKY BMDMs led to a decrease in Fc receptor-mediated macrophage activation. Our current work aims to identify genome-wide JunD mediated macrophage activation networks in the WKY rat and to understand the genetic determinants of JunD-mediated overactivity in WKY BMDMs.

We have performed chromatin immunoprecipitation combined with high throughput sequencing (ChIP-Seq) in BMDMs from WKY and *Jund* congenic strains to give a genome wide profile of JunD binding. Our preliminary analysis has identified differential binding between basal and LPS stimulated WKY BMDMs with 65-67% of peaks in each condition located in intergenic regions and 25% located within introns. 52% of intragenic peaks were found within 20 kilobases (kb) of a transcriptional start site (TSS) suggesting preferential JunD binding to enhancer regions. Gene ontology analysis of peaks located ±20kb from a TSS is consistent with a role for JunD as a mediator of macrophage activity enriching, for example, for processes such as intracellular signaling cascades ($P=2.5x10^{-9}$) in basal BMDMs. We have now performed comparative microarray experiments in WKY, Lewis and *Jund* congenic BMDMs and by integrating these gene expression data sets with the ChIP-Seq data sets, we aim to identify the key genes in networks through which JunD mediates macrophage overactivity and novel targets through which to modulate macrophage activation.

**Developmental Tissue-Specific Expression of the Prorenin Receptor** Renfang Song, Graeme James Preston, Ihor V. Yosypiv. *Pediatrics, Tulane School of Medicine, New Orleans, LA.*

The prorenin receptor [(P)RR] has two major roles: 1) Mediate specific intracellular effects of prorenin and renin and 2) Enhance their enzymatic activity on the plasma membrane. In this study, we examined (P)RR gene and protein expression during mouse organogenesis. (P)RR mRNA and protein levels were determined in the brain, kidney, lung and heart of CD1 mice on embryonic (E) days E12.5-18.5 and postnatal (P) days P1, P10 and P60 (adult) by quantitative RT-PCR and Western blot analysis, respectively. Cellular distribution of the (P)RR protein and mRNA in the metanephros was mapped by immunohistochemistry and *in situ* hybridization (ISH), respectively. RT-PCR demonstrated that brain, kidney and lung (P)RR mRNA levels increase progressively during gestation, peak on P10 and decline in adulthood. In contrast, (P)RR protein levels were high during early gestation and decreased with maturation. In the heart, (P)RR mRNA and protein contents remain stable during gestation to subsequently decline on P10 and P60. The (P)RR protein is weakly expressed in the developing metanephros in inner tubular structures as early as on E14.5. On E16.5 and E18.5, (P)RR is present in the ureteric bud (UB) epithelia followed by glomerular mesangium. On P1 and P10, (P)RR is most abundant on the luminal aspect of collecting ducts followed by proximal tubules and mesangium. This expression pattern persists into adulthood. ISH revealed weak diffuse presence of (P)RR mRNA in the inner mesenchyme and UBs on E13.5. A significant increase in the intensity of (P)RR mRNA expression throughout the kidney was observed on E14.5. These results demonstrate that (P)RR gene and protein expression is developmentally regulated in a tissue-specific manner. During early metanephric development, (P)RR mRNA is broadly distributed in the mesenchyme and UB epithelia. (P)RR protein expression in the kidney is spatially restricted to UBs/collecting ducts followed by glomerular mesangium and tubules. The enrichment of (P)RR in UB-derived collecting ducts and glomeruli suggests a novel function for the (P)RR in the regulation of nephron and renal collecting system development.

**Establishment of a Rapid and Simple Protein Enrichment Method in Clinical Proteomics Study: Enrichment of Proteins by Nitrocellulose Membrane** Xuejiao Liu,[1] Lulu Jia,[2] Mingxi Li,[1] Bixia Gao,[1] Xiaohong Fan,[1] Xuemei Li,[1] Youhe Gao,[2] Xue-Wang Li.[1] *[1]Nephrology, Dept Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences,Peking Union Medical College, Beijing, China; [2]Perking Union Medical College, Beijing, China.*

**Objective:** To establish a rapid and simple protein enrichment method by nitrocellulose (NC) membrane and compare it with acetone precipitation (AP). **Methods:** The morning urine samples of fourteen healthy donors (7M/7F, 20-30 year old) were collected. Twelve samples (6M/6F) were pooled together. The urinary proteins of pooled, single male and female samples were enriched by AP overnight, NC membrane for 30, 60 and 90 minutes respectively. The concentration of protein was measured by Bradford method, and the differences of protein bands between AP, NC membrane enrichment (30, 60 and 90 min) was evaluated using 1D-SDS-PAGE electrophoresis. The proteins of pooled sample enriched by AP (Group A) and NC membrane for 90 minutes (Group B) were identified by LC-MS/MS (Thermo,LTQ Velos). **Results**: The proteins were enriched by NC membrane rapidly. (figure1) The amounts of proteins enriched by AP were higher than that by NC membrane in pooled, male and female samples. The amount of proteins enriched by NC membrane was increased with the enriching time in pooled, male and female samples. The NC membrane method selectively reduced the amount of albumins.(figure1)The number of proteins identified by LC-MS/MS in group B was more than that in group A.**Conclusion:** A rapid and simple protein enrichment method was established. This new method enriched less urinary albumin which diminishes the suppression of albumin on low-abundant proteins in the urine and may be used in biomarkers discovery studies. Further research is needed to evaluate the profile of proteins and the significance of this new method in clinical proteomics study.

Figure 1

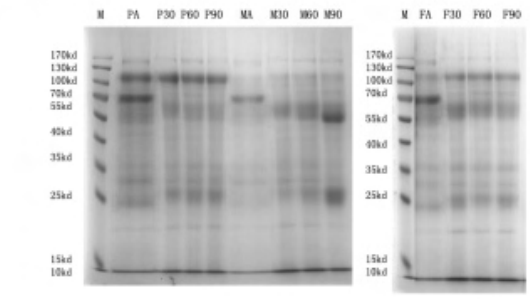

Figure 1: Proteins enriched by AP and NC membrane. (M):marker, (PA): the pooled protein precipitated by acetone, (P30-P90):the pooled protein enriched by NC membrane for 30-90 minutes. (MA): male proteins precipitated by acetone, (M30-90): male proteins enriched by NC membrane for 30-90 minutes. (FA):Female proteins precipitated by acetone. (F30-90): Female proteins enriched by NC membrane for 30-90 minutes.

**Isolation of Whole Glomeruli from a Needle Biopsy Sample of a Patient with Glomerulonephritis** Kenichiro Koitabashi,[1,2] Takashi Yasuda,[2] Kenjiro Kimura.[2] *[1]Clinical Proteomics and Molecular Medicine, St. Marianna University Graduate School of Medicine, Kawasaki, Japan; [2]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan.*

*Background:* Renal biopsy samples are important not only for the diagnosis of glomerulonephritis, but also for the investigation of its pathogenesis. However, it remains difficult to biochemically analyze proteins extracted solely from the glomeruli of the needle biopsy samples. To overcome this difficulty, we established a simple but reliable method, named as "micro-sieving," to isolate whole glomeruli from a single needle biopsy sample of a patient with glomerulonephritis.

*Method:* We isolated glomeruli from each of four renal needle biopsy samples by the micro-sieving and from each of the two surgically resected kidneys by a conventional sieving method. In the micro-sieving, the biopsy sample was sieved the 180 μm mesh, then the sieved fraction was sieved again on the 75 μm mesh. The glomeruli were recovered on the 75 μm mesh. The number of the isolated glomeruli was counted by microscopy. This procedure took about one hour. The glomerular proteins (2.5 μg) extracted by the micro-sieving and the conventional sieving were compared by 2-dimensional electrophoresis (2-DE).

*Result:* The glomeruli isolated from the biopsy samples showed no obvious destruction. On average, 55 glomeruli were isolated from a single renal biopsy and 23 μg proteins were extracted from the glomeruli. Further, we successfully obtained clear 2-DE images of the glomerular proteins from a single biopsy sample. The 2-DE images were very similar to that by the conventional sieving method.Conclusion: The "micro-sieving" can be used widely as a fundamental technique to analyze glomeruli in renal needle biopsy samples.

**Alternative Splicing of a Comprehensive ESRP-Regulated Network Contributes an Extensive Additional Layer of Complexity to the Global Changes in Gene Expression That Occur during the Epithelial Mesenchymal Transition (EMT)** Russ P. Carstens. *University of Pennsylvania School of Medicine.*

The Epithelial Mesenchymal Transition (EMT) is a critical process during the development and has also been implicated in tissue fibrosis and tumor metastasis. Furthermore, the reverse process of Mesenchymal Epithelial Transition (MET) is also crucial for development, as shown during renal organogenesis. Changes in the transcriptional profile of epithelial cells that undergo the EMT have been well studied, including the downregulation of E-cadherin and upregulation of vimentin. However, the extent to which changes in splicing contribute an additional layer of gene regulation that impacts the EMT has not been systematically investigated. Alternative splicing achieves coordinated changes in gene expression and generates protein isoforms with differential and often opposing activities. In a genome-wide cell-based screen we recently discovered Epithelial Splicing Regulatory Proteins 1 and 2 (ESRP1 and ESRP2) as essential regulators of transcripts that switch splicing during the Epithelial to Mesenchymal Transition (EMT), including genes with important roles in the EMT. The ESRPs are transcriptionally inactivated during the EMT and direct knockdown of ESRP expression promotes the EMT indicating that they are crucial components of an epithelial-specific gene signature. Using splicing sensitive microarrays and massively parallel high throughput sequencing (RNA-seq) we uncovered a global ESRP-regulated splicing network defined by hundreds of transcripts that switch splicing during the EMT. These ESRP-regulated transcripts encode numerous proteins associated with the EMT, regulation of the actin cytoskeleton, cell-cell adhesion, cell polarity, and cell migration. Our results strongly suggest that the definition of this ESRP-regulated splicing regulatory network defines protein interaction networks and isoform-dependent functional properties of numerous proteins that underlie the EMT. These studies thus highlight the importance of coordinated changes in alternative splicing, in addition to changes in transcription, to promote dynamic changes in proteomic complexity during the EMT.

**RNA-Seq Analysis of TGFβ-Induced Gene Expression in Tubular Epithelial Cells Identifies Novel Low-Copy Number Transcripts and Correlation with Differentially Expressed Genes in Renal Biopsy Material** Eoin P. Brennan,[1] Melissa Morine,[2] David Walsh,[1] Derek P. Brazil,[1] Catherine Godson,[1] Finian Martin,[1] The Genie Consortium.[1] *[1]UCD Diabetes Research Centre, Conway Institute, University College Dublin, Dublin, Ireland; [2]Nutrigenomics Research Group, Conway Institute, University College Dublin, Dublin, Ireland.*

TGF-β1 is implicated in disease progression in diabetic nephropathy (DN). We have assessed the global transcriptional profile in cultured proximal tubule epithelial cells (HK-2) stimulated with TGF-β1 (10 ng/ml, 48h) using 'next generation' sequencing (RNA-seq). We identified 624 differentially expressed genes (304 upregulated, 320 downregulated; p≤0.05), and network analysis indicated upregulation of key pathways including TGF-β1 signalling, extracellular matrix (ECM)-receptor interaction and focal adhesion. Differential expression of six representative genes was validated by qRT-PCR. Of particular note, was the induction by TGF-β1 of expression of transcripts of all 7 chorionic gonadotropin/LH beta chain genes in a locus on chromosome 19q13.3. We noted a shared motif which contained a HNF1α/Tcf transcription factor binding element in the proximal promoters of all 7 genes. This may identify the path by which TGF-β1 is acting in this context. Comparison of the RNA-Seq analysis with microarray [Affymetrix HGU133A] analysis of an identical TGF-β1 cell treatment showed 103 genes were detected as differentially expressed in both analyses and an additional 109 genes ('low expressors'; <100 transcript reads) were detected as differentially expressed by RNA-Seq only. Preliminary analysis of the differentially expressed gene cohort detected by RNA-seq and microarray analysis with genes selectively expressed in biopsies from patients with DN [Affymetrix HGU133A microarray analysis; Schmid H et al.,2006] identified a shared subset of 65 transcripts, thereby detecting a TGF-β1-driven pro-fibrotic 'finger-print' in the DN-biopsy transcriptome. RNA-seq therefore achieves a more sensitive and comprehensive transcriptomic analysis that will facilitate our improved understanding of the molecular events that underpin DN progression including integration with GWAS-derived data.

**Genome-Wide Microarray Coupled with ChIP-Seq Identify the Wnt Signaling Pathway as a Major p53 Target in the Developing Kidney** Zubaida R. Saifudeen, Meera Harshad Velankar, Nathaniel J. D. Mclaughlin, Jiao Liu, Samir S. El-Dahr. *Pediatrics, Tulane University, New Orleans, LA.*

p53 regulates expression of cell cycle, apoptosis, differentiation and senescence pathway genes. We recently described a requirement for p53 function in kidney development. Interestingly, $p53^{-/-}$ kidneys have fewer nephrons than wild-type littermates. Early in development, $p53^{-/-}$ metanephroi exhibit an atypical large cap mesenchyme suggesting a defect in conversion of mesenchyme to epithelial progenitors. To identify pathways directly regulated by p53, genome-wide microarray coupled with ChIP-Seq was done on E15.5 metanephroi of $p53^{+/+}$ and $p53^{-/-}$ littermates (n=3/group). 3627/44000 (~8%) mapped genes showed significant differential expression ($p<0.05$). 40% (1422/3627) of these are potential direct targets of p53 as they have at least one p53 binding site, discovered by p53 ChIP-seq. In addition to known p53-target genes (cancer, cell cycle, DNA damage, metabolism), pathway analysis identified many renal developmental regulators (Osr1, HNF1b, Pax2, Pax8, Fgf8) and signaling pathways (Wnt, Bmp, FGF, Notch) as p53-targets. Importantly, p53 is enriched *in vivo* at genes of several members of the Wnt signaling pathway that are differentially expressed in $p53^{-/-}$ kidneys, including Fzd4, Fzd7, LRP1/6, Dvl2, Gsk3β, Csnk1g1 and cyclin D1 suggesting these Wnt pathway members as primary targets for p53 regulation in the developing kidney. Using a TCF-reporter, we show p53 potently represses β-catenin transcriptional activity in metanephric mesenchyme cells, associated with reduced β-catenin levels. P53 repression of TCF-reporter activity was maintained in the presence of LiCl, a GSK3β inhibitor, implying p53 acts downstream of the β-catenin destruction complex. siRNA-mediated knockdown of p53 up-regulates Axin2, a Wnt responsive gene. This study demonstrates that p53 regulates nephrogenesis via multiple mechanisms, including direct transcriptional effects on the Wnt signaling pathway. Our data suggest aberrant Wnt signaling in the mesenchymal cap cells in the absence of p53 as a possible mechanism for the defect in differentiation of the cap mesenchmye to nephron progenitors.

**Uncovering Genes and Regulatory Pathways Related to Urinary Albumin Excretion Using Linkage Analysis and Genetical Genomics in Mice** Rachael S. Hageman, Magalie S. Leduc, Christina R. Caputo, Shirng-Wern Tsaih, Gary Churchill, Ron Korstanje. *The Jackson Laboratory, Bar Harbor, ME.*

Identifying the genes underlying quantitative trait loci (QTL) for disease has proven difficult, mainly due to the low resolution of the approach and the complex genetics involved. However, recent advances in bioinformatics and the availability of genetic resources now make it possible to narrow the genetic intervals and test candidate genes. In addition to

identifying the causative genes, defining the pathways that are affected by these QTL is of major importance as it can give us insight into the disease process and provide evidence to support candidate genes. In this study we mapped three significant and one suggestive QTL on Chromosomes (Chrs) 1, 4, 15, and 17, respectively, for increased albumin excretion (measured as albumin-to-creatinine ratio) in a cross between the MRL/MpJ and SM/J mouse inbred strains. By combining data from several sources and by utilizing gene expression data, we identified Tlr12 as a likely candidate for the Chr 4 QTL. Through the mapping of 33,881 transcripts measured by microarray on kidney RNA from each of the 173 male F2 animals, we identified several downstream pathways associated with these QTL. Among these were the glycan degradation, leukocyte migration, and antigen presenting pathways. We demonstrate that by combining data from multiple sources, we can identify not only genes that are likely to be causal candidates for QTL, but also the pathways through which these genes act to alter phenotypes. This combined approach provides valuable insights into the causes and consequences of renal disease.

**Systems Approach Identify HIPK2 as a Critical Regulator of Kidney Tubulointerstitial Fibrosis** Yuanmeng Jin,[1] Yifei Zhong,[1] John C. He.[1,2] *[1]Medicine/Nephrology, Mount Sinai School of Medicine, New York, NY; [2]Medicine/Nephrology, James J. Peters VA Medical Center, Bronx, NY.*

Tubulointerstitial fibrosis is a common pathway leading to the progression of kidney disease for which there are limited treatment options. We describe an integrated computational/experimental approach to identify upstream protein kinases that regulate gene expression changes in kidneys of HIV-1 transgenic mice (Tg26), a model for HIV-associated nephropathy (HIVAN) where significant tubulointerstitial injury is present. With this approach we identified that the homeo-domain interacting protein kinase 2 (HIPK2), a previously unrecognized kinase for kidney disease, is a highly expressed kinase in the renal tubulointerstitium of Tg26 as well as in patients with HIVAN or with other kidney diseases. HIPK2 mediates transforming growth factor-β-induced Smad3 phosphorylation and expression of epithelial-mesenchymal transdifferentiation markers in renal tubular epithelial cells. Knockout of HIPK2 attenuated tubulointerstitial fibrosis in kidneys of mice with unilateral ureteral obstruction, a well-established model for renal fibrosis. We conclude that HIPK2 is a critical regulator of kidney fibrosis and a potential target for anti-fibrosis therapy.

**Application of Laser Capture Microscopy (LCM) and Proteomic Tissue Analysis To Characterize Fibronectin Glomerulopathy (FNG)** Anjali A. Satoskar,[1] John P. Shapiro,[2] Cherri N. Bott,[1] Gyongyi Nadasdy,[1] Michael A. Freitas,[2] Lee A. Hebert,[3] Tibor Nadasdy,[1] Brad H. Rovin.[3] *[1]Pathology, Ohio State University, Columbus, OH; [2]Molecular Virology Immunology Medical Genetics, Ohio State University, Columbus, OH; [3]Nephrology, Ohio State University, Columbus, OH.*

FNG is a rare familial glomerulopathy characterized by proteinuria, progressive renal dysfunction, and pathologically by lobular glomerular enlargement, obliteration of capillary loops and mesangial deposition of acellular finely granular/fibrillary material. Although these deposits were shown to stain for fibronectin, staining can be weak and inconsistent. It was therefore postulated that other proteins may contribute to these deposits. To address this question and to demonstrate the utility of LCM and proteomic analysis for studying glomerular diseases, we examined renal biopsy material from two affected members of a known FGN family. Snap frozen renal biopsy tissue was sectioned, fixed in ethanol and stained. LCM was used to collect glomeruli by dissecting around the Bowman's capsules. For comparison, glomeruli were collected from baseline allograft biopsies (n=3), diabetic nephropathy (DN) (n=2), and lupus nephritis (LN) (n=5) biopsies. Glomeruli were digested with trypsin and a proteomic profile obtained using liquid chromatography-tandem mass spectrometry. Compared to normal, DN, and LN glomeruli, FNG glomeruli showed a significantly greater content of fibronectin isoforms 1, 3, 4, 5, 8, fibulin-1 and 5, and transthyretin. Several proteins were down-regulated in FNG glomeruli including vimentin, laminin, HSP70, podocin and synaptopodin (also decreased in DM and LN glomeruli). The interstitium of FNG biopsies uniquely showed an increased content of apolipoprotein-A1, A4, and serpin. This study demonstrates that LCM followed by tissue proteomics is a promising technique to identify unique proteins in kidney compartments. This will be useful in dissecting the pathogenesis of glomerular diseases. The data suggest that fibulin-1 and 5 may play a role in FNG. Several basement membrane and podocyte proteins were under-represented in FNG. This may account for the proteinuria seen in FNG.

**Using Gene Knock-Outs and Transposon Based Transgenics in Sensititized Rat Strains To Study Genes Nominated by Human GWAS for Renal Disease** Howard J. Jacob,[1,2] Rebecca R. Schilling,[1] Jozef Lazar,[1,3] Carol Patricia Moreno Quinn.[1] *[1]Physiology & Human and Molecular Genetics Center, Medical College of Wisconsin, Milwaukee, WI; [2]Pediatrics, Medical College of Wisconsin, Milwaukee, WI; [3]Dermatology & Human and Molecular Genetics Center, Medical College of Wisconsin, Milwaukee, WI.*

Genome Wide Association Studies (GWAS) and other types of genetic studies in humans have nominated genes contributing to hypertension and associated renal disease. Functional studies must now be undertaken for these genes. The rat is the dominant model for the physiological assessment of the cardiovascular system, but has lacked the ability to target genes. Using zinc finger nucleases (ZFN), which takes a fraction of the time of ES cell technology, we have knocked out (KOed) 45 genes in 9 months. An additional 55 genes will be KOed over the next 15 months. As there is interplay between hypertension and renal disease, we are knocking the genes out on the hypertensive backgrounds of SS and FHH rats. For select genes we also use transgenic rats generated using the *Sleeping Beauty* transposon system to over expressing a gene of interest.

Twelve renal genes are currently under evaluation. As an example, we have studied *Rab38* a gene responsible for a quantitative trait locus for hypertension-associated renal failure and a host of other traits associated with protein trafficking using both transgenic rescue and site directed gene KO. In the FHH rat, *Rab38* is responsible for the coat color, eye color, platelet storage pool deficit and proteinuria. We completely rescued all 5 classes of phenotypes with addition of a transposon carrying the wild-type *Rab38*. To validate the utility of the ZFN for functional studies, we also knocked out the *Rab38* gene in a consomic strain (FHH.BN1), which all the wild type phenotypes. The KO completely replicated the disease phenotypes proving both the gene and methodology. Data from the phenotyping of other renal strains will come online before the meeting and will also be presented.

**RNA-Seq Defined Glomerular Cell-Lineage Enriched Transcipts in Human Glomerular Disease** Jeffrey B. Hodgin,[1] Felix H. Eichinger,[2] Courtenay M. Vining,[2] Ann Randolph,[2] Preethi Sankaranarayanan,[2] Simon C. Satchell,[3] Moin Saleem,[3] Matthias Kretzler.[2] *[1]Pathology, University of Michigan; [2]Nephrology, University of Michigan, Ann Arbor; [3]University of Bristol, United Kingdom.*

To perform their specialized functions, glomerular endothelial, epithelial and mesangial cells have developed unique structural and molecular components. For a comprehensive survey of cell lineage-enriched transcripts, deep-sequencing (RNA-Seq) was employed on conditionally immortalized human endothelial and podocyte cell lines and microdissected glomeruli. Transcript abundance was determined using Affymetrix U133plus and RNA-Seq with 30 million reads per experiment(Illumina Genome Analyzer), yielding an average expression correlation of 0.80 for transcripts detected on both platforms. On NGS, a total of 17441 transcripts were detected above noise for podocytes, 17305 for endothelial cells, and filtered against 18244 transcripts in glomeruli to confirm in vivo expression. Cell lineage enrichment was defined by the absolute difference in normalized expression exceeded by 2 standard deviations across all transcripts and yielded 449 podocyte and 283 endothelial transcripts. The podocyte-enriched transcripts were interrogated for protein-protein interactions and the resulting networks analyzed for shared transcriptional responses using promoter models (Genomatix ModelInspector). Comparative promoter analysis defined a model containing transcription factor matrices V$ZBPF and V$EGRF (including WT1) in THRB, CAMK2B, COL4A4, MATN2. Among the 656 human genes containing the promoter model, 264 were present on Affymetrix HGU133A microarrays and investigated for their ability to classify expression profiles from 34 patients with glomerular diseases. These could also segregate glomerular transcriptional profiles of MGN from FSGS. Functional analysis of this gene set revealed significant overrepresentation of the Wnt canonical pathway and PI3K signaling events. Identifying novel cell-lineage enriched transcripts in the glomerular context will allow better definition of the unique molecular pathways essential for the glomerular ultrafiltration barrier and it's failure in disease.

**F-PO1977**

**Common Peptide Motifs Binding HLA-DQ in Caucasian and Japanese Idiopathic Membranous Nephropathy Patients** Satoru Ogahara, Yasuhiro Abe, Kenji Ito, Maho Watanabe, Takao Saito. *DIvision of Nephrology and Rheumatology, Department of Internal Medicine, Fukuoka University, Fukuoka, Japan.*

Thirty Japanese adult patients with idiopathic membranous nephropathy (IMN) and 238 Japanese normal controls were analysed for HLA-DRB, DQA1 and DQB1 gene polymorphism using second exon amplification and sequence-specific oligonucleotides. A highly significant increased frequency of the DRB1*15:01 (0.80 vs 0.15, OR 23.2, $p = 2.8 \times 10^{-15}$), DRB5*01:01 (0.80 vs 0.15, 23.2, $2.8 \times 10^{-15}$), DQA1*01:02 (0.87 vs 0.26, 18.6, $1.1 \times 10^{-10}$) and DQB1*06:02 (0.80 vs 0.13, 25.8, $2.2 \times 10^{-16}$) alleles were found in Japanese IMN patients. Caucasoid patients with IMN have been reported to be associated with a HLA-DRB1*03:01, DQA1*05:01 and DQB1*02:01(Vaughan et al., 1995). It was interesting to note that a HLA-DR15 subtype in Japanese and that of HLA-DR3 in Caucasoid were associated with susceptibility to IMN. HLA-DR3 was very rare in Japanese. Thus, no disease associated with these antigens has been reported in Japanese. We thought that

HLA molecule primarily contribute to autoimmune disease by binding peptides that were presented to antigen-HLA molecule specific T-cell receptors in a context that results in the loss of tolerance to self-antigens. We evaluated the presentation of peptide motifs on HLA-DR and DQ associated with both ethnic IMN in comparison to other HLA-DR or DQ using SYFPEITHI algorithm (www.syfpeithi.de) to predict the binding peptide to specific HLA molecules. Common amino acid residues were found within pocket 1 (A, F, W, Y, I, L or V), pocket 4 (L, V or I), pocket 6 (P or A), pocket 7 (D or E) pocket 9 (I, L or V) between HLA-DQ2 (DQA1*05:01-DQB1*0201) associated with Caucasoid IMN and HLA-DQ6 (DQA*01:02-DQB1*06:02) with Japanese IMN. There was no common peptide motif in HLA-DR associated with IMN. M-type phospholipase A2 receptor (PLA2R) have been proposed to be target antigen in IMN (Beck LH et al., 2009). We predicted that PLA2R(24-32, AAALTPERL) was one of the antigenic peptide binding HLA-DQ molecules using protein-BLAST. To seek a putative antigenic peptide might be important for achieving a understanding of disease pathogenesis and designing antigen-specific therapy.

**F-PO1978**

**Homozygosity Mapping of Recessive Disease Genes for Steroid-Sensitive Nephrotic Syndrome** Xuewen Song,[1] Pingzhao Hu,[2] Ning He,[1] Andrew D. Paterson,[2] York P. Pei.[1] *[1]Divisions of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada; [2]Genetics and Genome Biology, Hospital for Sick Children, Toronto, ON, Canada.*

Recent studies of familial steroid-sensitive (SS-) nephrotic syndrome (NS) due to minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) suggest that these disorders may be underpinned by mutations of rare recessive genes (JASN 12:374-8, 2001; 14:1897-900, 2003). Homozygosity mapping is a powerful approach for mapping rare recessive disease genes in inbred families and has been recently extended to outbred populations. We completed a genome-wide homozygosity scan in 30 patients (Caucasian, n=21; Chinese, n=3; Native Indian, n=3; South Asian, n=2; Japanese, n=1) with SS-MCD/FSGS by using the Illumina Human CNV 370-Quad arrays. All patients except three Native Indians were unrelated. Using the software PLINK, we calculated the inbreeding coefficient F and found cryptic relatedness in the parents of 8 patients (F > 0.03). We catalogued all runs of homozygosity (ROHs) > 1Mb in individual patients and found a total of 284 tracts in 21 Caucasian patients and 42 tracts, in 3 Chinese patients. Using the ethnic-specific database from the HapMap reference populations for comparison, we identified 21 unique ROH tracts shared by > two Caucasian patients and 4 unique ROH tracts shared by > two Chinese patients. Among the Caucasian study patients, six shared a ROH on Chr. 5, five shared a ROH on Chr. 7 and two unique ROH tracts on Chr. 11, and 4 shared a ROH on Chr. 22, and none of these tracts were seen in 60 Caucasian control subjects. Of interest we found only two ROH tracts on Chr. 1 and 12 shared by all three affected cases from a Native Indian family. Genome-wide ROH scan with an expanded number of patients with familial and sporadic SS-MCD/FSGS and ethnicity-specific control subjects from HapMap3 database is currently in progress. Our preliminary study suggests homozygosity mapping is a promising approach for discovering recessive disease genes for SS-MCD/FSGS.

**Genome-Wide Analysis of DNA Methylation in Monocytes and Naïve T Helper Cells in Minimal Change Nephrotic Syndrome Patients between Relapse and Remission** Yasuko Kobayashi. *Pediatrics, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan.*

DNA methylation in the promoter region of a gene is associated with transcriptional inactivation, while demethylation contributes to the activation. Changes in the DNA methylation lead to differences in gene expression and influence disease development. Minimal change nephrotic syndrome (MCNS) is a major cause of nephrotic syndrome in children and has been shown to involve immunological disturbance. Since one of the most characteristic features of the disease is relapse, the pathogenesis might be in part due to epigenetic changes such as DNA methylation. However little is known about epigenetic changes in MCNS. To know if the epigenetics is underlying MCNS, we investigate genome-wide DNA methylation in monocytes and naïve T helper cells between pediatric MCNS patients in relapse and remission.

We performed Microarray-based Integrated Analysis of Methylation by Isoschizomers; HpaII/MspI (MIAMI) method which provides high throughput global analysis of DNA methylation with 18,014 sites in the vicinity of genes in monocytes (n = 6) and naïve T cells (n = 4) isolated from the peripheral blood of the MCNS patients during both relapse and remission, and from healthy controls (n = 5). The results were confirmed by bisulfite-pyrosequencing analysis. We found three loci (GATA2, PBX4 and NYX ) less methylated in relapse compared with remission in naïve T cells from the same MCNS patients, when the data were analyzed with standard threshold. The loci were less methylated in relapse compared with controls either. We found no significant difference in monocytes between relapse and remission.

Consequently, this study demonstrates that DNA methylation patterns change from remission to relapse of MCNS and that the change is cell-type specific. We are currently studying what brings this difference in DNA methylation and how it could be linked to pathogenesis of relapse of MCNS.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1980**

**Genome-Wide Analysis of the Change of DNA Methylation in Naïve T Helper Cells in Minimal Change Nephrotic Syndrome** Yasuko Kobayashi. *Pediatrics, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan.*

An increasing body of evidence indicates that epigenetic modifications including DNA methylation play critical roles in development of diseases. Minimal change nephrotic syndrome (MCNS) has been associated with immunological disturbances such as T cell dysfunction, but its pathogenesis is not fully understood. To know if DNA methylation states are involved in pathogenesis of MCNS, we have analyzed genome-wide DNA methylation in naïve T cells.

We performed a genome-wide profiling assay called Microarray-based Integrated Analysis of Methylation by Isoschizomers; HpaII/MspI (MIAMI) at 18,328 sites in the vicinity of genes in naïve T cells using three sets of comparison between: 1) relapse vs. controls (CompA), 2) remission vs. controls (CompB) and 3) relapse vs. remission of MCNS (CompC). Naïve T cells were extracted from peripheral blood of the patients (n = 4) both during relapse and remission, and from healthy controls (n = 5).

The number of detected genes are shown in Table1. We found a larger number of genes changing in methylation in CompA and B than CompC (analyzed with lower threshold), suggesting DNA methylation in T cells play roles in MCNS. There were many co-occurrent genes between each comparison (Figure1). Intriguingly, 93.5% genes in CompA except co-occurrent ones with CompB were less methylated. Gene ontology(GO) analysis in CompA revealed that most of the GO categories of which false discovery rate were under 0.1 shows the close interaction between regulation of biological processes leading to control of gene expression and protein modifications.

The genome wide approach we have performed here for DNA methylation in T cells will provide further insights into our understanding of pathogenesis of MCNS.

Number of the genes detected more or less methylated

| | More Methylated Gene | Less Methylated Gene |
|---|---|---|
| CompA | 60 | 139 |
| CompB | 94 | 42 |
| CompC | 4 | 56 |

**Urine Peptide Profiling by MALDI-TOF Mass Spectrometry Can Distinguish FSGS from Four Common Glomerulopathies** Michael G. Janech,[1,2] Elizabeth G. Favre,[2] Benjamin Neely,[2] Jonas S. Almeida,[3] John M. Arthur.[1,2] *[1]Research Service, Dept. Veterans' Affairs, Charleston, SC; [2]Medicine, Medical University of South Carolina, Charleston, SC; [3]Bioinformatics and Computational Biology, Univ. of Texas, MD Anderson Cancer Center, Houston, TX.*

Clinical presentation of patients with focal segmental glomerulosclerosis (FSGS) is similar to patients with other glomerulopathies (GN). Renal biopsy provides a definitive diagnosis, but is contraindicated for some patients and carries risk for bleeding. Previous reports suggest low molecular weight polypeptides have diagnostic value as non-invasive markers for the classification of glomerular disease. We investigated the potential for urine peptides as diagnostic classifiers of FSGS relative to four common GNs (membranous, MPGN, minimal change, IgA). Urine was collected from 41 patients [biopsy-proven FSGS=18; biopsy proven other GN=23]. Peptides were isolated from equivalent volumes using two different resins [strata-x or graphite]. Spectra were collected using MALDI-TOF, aligned and background subtracted. Peak areas were normalized to total ion current(TIC) or an internal standard(IS). Few differences between FSGS and other GNs were detected by parametric statistics. Peaks at 3459, 3387, 3283, and 2569 were 3-4 fold higher in the FSGS group compared to minimal change using graphite; whereas peak 2360 was 4 fold higher in the minimal change group compared to FSGS using strata-x resin. A non-

parametric support vector machine was trained to classify patients. Receiver operator characteristic(ROC) curves were used to estimate model performance to classify FSGS patients. For each model, between 16 and 28 peptides were utilized as classifiers. Area under the ROC curve(AUC) to predict FSGS with strata-x resin was 0.99 for TIC and 0.92 for IS normalized data. AUC for peptides isolated by graphite was 0.99 for TIC and 0.97 for IS normalized data. Regardless of isolation or normalization method, modeling MALDI-TOF data by support vector machine classified FSGS from other GNs with high specificity and sensitivity. If validated, analysis of urine peptides is a promising alternative to renal biopsy to diagnose FSGS.

**Expression of TSPAN8, a Susceptible Gene for IgA Nephropathy in Human Renal Tissues** Takashi Hirukawa,[1] Qiong Wu,[1] Sanae Saka,[2] Nobuhito Hirawa,[2] Masayuki Endoh,[1] Taiji Matsusaka,[1] Takatoshi Kakuta,[1] Masafumi Fukagawa,[1] Satoshi Umemura,[2] Hidetoshi Inoko,[3] Iekuni Ichikawa.[3] *[1]Division of Nephrology, Endocrinology and Metabolism, Department of Internal Medicine, Tokai University School of Medicine, Isehara, Japan; [2]Department of Medical Science and Cardiorenal Medicine, Yokohama City University, Japan; [3]Department of Molecular Life Science and Molecular Medicine, Tokai University School of Medicine.*

Through a large-scale genome-wide association study using 23,000 microsatellite markers, we have found that TSPAN8, encoding tetraspanin-8, is a candidate susceptible gene for the onset of IgA nephropathy (IgAN), the most common form of primary glomerulonephritis. Tetraspanin-8 is a cell surface glycoprotein of unknown function and suggested to be involved in angiogenesis of colon cancer. In the present study, we analyzed the expression of tetraspanin-8 in human renal tissues with various kidney diseases.

We performed immunohistochemical examination using polyclonal rabbit anti-human tetraspanin-8 in renal biopsy samples [20 IgAN, 5 ANCA associated nephropathy (ANCA), 5 interstitial nephritis (IN), and 5 normal].

Tetraspanin-8 was occasionally expressed on renal tubular epithelial cells. Analysis in serial sections revealed that tetraspanin-8 was co-expressed with cytokeratin 7 (84.6%), aquaporin 2 (49.0%), and aquaporin 1 (14.0%), thus indicating that it was predominantly expressed in distal and collecting tubules. In IgAN, on average, 2.38±1.21% of tubule cross sections contained tetraspanin-8 positive cells. This percentage was not significantly different from those in ANCA (3.80±1.19) or IN (2.84±1.42), but tended to be higher than that in normal (0.50±0.48). Analysis of clinical data at biopsy revealed that tubule tetraspnin-8 positivity was negatively correlated with eGFR (correlation coefficient -.659, $p < 0.001$). In addition to tubular cells, approximately 70% of vascular smooth muscle cells of the interlobular artery intensely expressed tetraspanin-8, uniformly in all samples.

These findings indicate that renal injury causing decline in eGFR, irrespective of nature of disease, enhances expression of tetraspanin-8 in tubule cells.

**TRPC6 Polymorphisms in Membranous Nephropathy** Julia M. Hofstra,[1] Marieke Coenen,[2] Tom Nijenhuis,[1,3] Jeroen Schoots,[2] Mascha M. V. A. P. Schijvenaars,[2] Jo H. M. Berden,[1] Joost G. Hoenderop,[3] Johan Van der Vlag,[1] Rene J. Bindels,[3] Nine V. Knoers,[2] Jack F. Wetzels.[1] *[1]Nephrology; [2]Antropogenetics; [3]Physiology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.*

BACKGROUND: Mutations in the transient receptor potential channel TRPC6 cause autosomal dominant focal segmental glomerular sclerosis (FSGS). TRPC6 expression is up-regulated in renal biopsies of patients with idiopathic membranous glomerulopathy (iMN). Hence, we hypothesized that genetic variants (single nucleotide polymorphisms (SNPs)) in TRPC6 might confer susceptibility to development or progression of iMN.

METHODS AND RESULTS: Genomic DNA was isolated from blood samples of 101 iMN patients and 292 controls. In the patient cohort 13 SNPs were identified, using direct sequencing of the TRPC6 gene. Clinical outcome in patients was determined (remission n=26, renal failure n = 47, persistent proteinuria n= 28, follow-up median 80 months [range 51-166]). The 13 identified SNPs showed no correlation with remission nor renal failure.

Five SNPs were selected, based on frequency and possible functionality, for genotyping in controls. No statistically significant differences in genotypes nor allele frequencies between patients and controls were observed for the 4 SNPs genotyped hitherto.

Genotype of 5 selected SNP's in iMN patients and controls

| | Patients (n=101) | Controls (n=292) | p-value* |
|---|---|---|---|
| **C1-10C>A** | | | 0.31 |
| CC | 95.0% | 97.5% | |
| CA | 5.0% | 2.5% | |
| **rs3802829** | | | 0.65 |
| CC | 82.2% | 85.7% | |
| CT | 16.8% | 13.4% | |
| TT | 1.0% | 0.8% | |
| **rs36111323** | | | 0.07 |
| GG | 67.3% | 77.9% | |
| GA | 32.7% | 21.3% | |
| AA | 0% | 0.7% | |
| **rs12366144** | genotyping in progress | | |
| **rs12805398** | | | 0.11 |
| CC | 68.0% | 77.7% | |
| CT | 31.0% | 21.6% | |
| TT | 1.0% | 0.7% | |

* Fischer exact test

CONCLUSION: TRPC6 polymorphisms do not seem to play a role in clinical outcome in our iMN cohort. One SNP (rs36111323) showed a tendency to higher minor allele frequency in patients compared to controls. However, this suggestive finding needs to be replicated in a larger, independent patient cohort.

**An Integrative Genomics Approach to HIV Associated Nephropathy** Roel Sterken,[1] Murim Choi,[2] Natalia Papeta,[1] Paul E. Klotman,[3] Vivette D. D'Agati,[1] Richard P. Lifton,[2] Ali G. Gharavi.[1] *[1]Columbia University Medical Center, New York, NY; [2]Yale University School of Medicine, New Haven, CT; [3]Mount Sinai School of Medicine, New York, NY.*

Introduction: The goal of this project is to identify a transcriptional network of risk attributable genes to HIV associated nephropathy (HIVAN). HIVAN is a complication of HIV infection characterized by dedifferentiation and depletion of glomerular podocytes and collapsing glomerulopathy.

Method: The HIV transgenic mouse model TgFVB develops significant HIVAN in 80% of mice. We integrated phenotype, genotype and gene expression data in a TgFVB×B6 mouse cross segregating for HIVAN, and performed genome-wide quantitative trait locus analysis of both disease and gene expression (called "eQTL mapping") to identify mediators of HIVAN.

Results: 141 (TgFVB×B6) F2 mice were phenotyped, genotyped for ~1,400 SNPs and whole genome expression data for 33,881 transcripts was collected. Linkage mapping of HIVAN identified two major HIVAN QTL on Chr. 13 (HIVAN2, LOD = 3.77) and Chr. 4 (HIVAN3, LOD = 3.65), accounting resp. for 10% and 7% of the variance in HIVAN. Linkage analysis identified 9,818 expression QTL (eQTL) with LOD score above 3.0 ($P < 0.0001$). 2,438 eQTL had a LOD peak within 20Mb of their genome location (cis-QTL), while 8,062 genes had a LOD peak beyond 20Mb (trans-eQTL). 513 eQTL linked to HIVAN2 and 335 eQTL linked to HIVAN3, several of which are known podocyte expressed genes, such as Nphs2, Podxl, Vegfa, Stat3 and Pkd2. To identify eQTLs causal to HIVAN, we fitted HIVAN regulated eQTLs to a conditional causality model. We found 88 and 48 trans-eQTLs for HIVAN2 and HIVAN3 resp., that fitted a causal model. Pathway analysis indicated overrepresentation of interferon pathways ($P < 1.36$ e-5) and Tcf21 regulated cell differentiation pathways ($P < 3.06$ e 7). In addition we found 12 cis-eQTLs located on the HIVAN2 locus and 4 cis-eQTLs on HIVAN3, making these eQTLs prime candidate genes to be the HIVAN QTL itself.

Conclusion: We identified candidate mediators to HIVAN using an integrated eQTL approach. Identifying regulatory networks underlying HIVAN can help provide insight into the pathogenesis of HIVAN and kidney disease in general.

**Urinary Biomarkers To Distinguish Class IV from Class V Lupus Nephritis** Michael R. Bennett, Michiko Suzuki, Shannen Nelson, Joshua David Pendl, Hermine Brunner, Prasad Devarajan. *Cincinnati Children's Hospital.*

Up to 80% of children with systemic lupus erythematosus (cSLE) have lupus nephritis (LN). The ISN/RPS Morphologic Classification of LN reports on histological features that differentiate forms of LN, such as Diffuse Proliferative Class IV and Membranous Class V lesions. Kidney biopsies are the choice for diagnosing LN, but are impractical to accurately assess the course of LN in clinical practice.

We set out to discover non-invasive urinary biomarkers that can discriminate LN subtypes using 4 independent proteomic techniques.

We used 2 dimensional gel electrophoresis (2-DGE), NMR based metabonomics, surface-enhanced laser desorption/ionization time of flight MS (SELDI), and liquid chromatography tandem ms (LC MS/MS2) to investigate novel biomarkers that could distinguish Class IV vs. Class V LN. Urine samples from children with Class IV (n=6) and (pure) Class V LN (n=7) collected within 60 days of kidney biopsy and those of controls with focal segmental glomerulosclerosis (n=4) were tested. Samples were normalized for total protein (2-DGE and LC-MS/MS2) or urine creatinine (NMR and SELDI). Using 2-DGE and MALDI-TOF-MS/MS, we found albumin fragments (25kDa) and α1-B glycoprotein (A1BG, 60kDa) significantly over-expressed in class IV vs. class V LN. Using SELDI, we identified Alpha-1 Antitrypsin (A1AT). This protein was significantly ($p < 0.01$; AUC 0.90) over-expressed in Class V vs Class IV LN and FSGS controls. Principal component analysis of NMR metabonomics spectra suggests decreased levels of citrate and increased levels of taurine in Class V when compared to Class IV patients, while LC-MS/MS2 uncovered the most differences between the groups. Among proteins upregulated in Class V LN were apolipoprotein D, lipocalin-like prostaglandin D synthetase, ITIH4, Caspase 10, uromodulin and CD14. Those most upregulated in Class IV LN were vitamin D binding protein, ceruloplasmin, hemopexin, A1BG and orosomucoid. A1AT has been linked to SLE flares and hemopexin is associated with glomerular disease.

The validation of these novel non-invasive biomarkers that can distinguish LN subtypes would greatly aid in diagnosing and monitoring treatment in LN.

**Identification of Shared Transcriptional Networks of Diabetic Glomerulopathy in Man and Mouse** Jeffrey B. Hodgin,[1] Viji Nair,[2] Hongyu Zhang,[2] Ann Randolph,[2] Raymond C. Harris,[3] Robert G. Nelson,[4] Frank C. Brosius,[2] Matthias Kretzler.[2] *[1]Pathology, University of Michigan; [2]Nephrology, University of Michigan, Ann Arbor, MI; [3]Medicine, Vanderbilt University, Nashville, TN; [4]Epidemiology and Clinical Research Branch, NIDDK, Phoenix, AZ.*

Though mouse models of diabetic nephropathy have been quite useful, none reliably mimics human disease. This has made it challenging to identify specific factors that cause or predict diabetic glomerulopathy (DG). Therefore, we wished to define where mouse models faithfully recapitulate human DG on a functional level using a cross-species comparison to identify shared transcriptional networks. Transcriptional networks for diabetic humans and three AMDCC mouse models were generated using glomerular mRNA, Affymetrix microarrays, transcriptional pathway mapping, and promoter modeling tools. The human transcriptional network was derived from albuminuric (>30 mg/g Alb/Cr) versus nonalbuminuric (<30 mg/g Alb/Cr) Pima Indians, a cohort with early DG. Mouse transcriptional networks were derived from streptozotocin treated DBA/2 mice, db/db C57BLKS mice, and eNOS-deficient db/db C57BLKS mice, each versus control. Integrating the gene expression alterations with biological knowledge resulted in complex networks of 1000s of genes linked by multiple co-citations and promoter binding sites (Genomatix Bibliosphere). TALE (Tool for Approximate Large Graph Matching, University of Michigan) was used to align the human and mouse transcriptional networks to derive three conserved network structures for each human-mouse comparison, comprised of approximately 100 nodes representing key hubs of conserved regulatory events. Shared gene nodes were found in all three networks, many of them reflecting established pathogenetic mechanisms of diabetic complications including JAK-STAT and VEGFR signaling pathways. Shared top biological processes included endothelial cell differentiation, angiogenesis, and phospolipase C activity. This approach can guide the selection of disease pathways in mouse models that are the most relevant to the human disease process and identify new pathways that are excellent targets for future study.

**Prediction of Diabetic Nephropathy by Urine Metabolomic Profiling** Robert G. Nelson,[1] Robert C. Williams,[1] Robert L. Hanson,[1] William Knowler,[1] Frank J. Gonzalez,[2] Andrew Patterson.[2] *[1]NIDDK, Phoenix, AZ; [2]NCI, Bethesda, MD.*

We performed a global, unbiased urine metabolomic screen to identify candidate biomarkers of diabetic kidney disease in 68 Pima Indians with type 2 diabetes. In a nested case-control study, 34 cases were matched for age, sex, and duration of diabetes with 34 controls. All participants had normal urinary albumin excretion (albumin/creatinine ratio (ACR) <30 mg/g) at baseline; cases progressed to diabetic nephropathy, defined by macroalbuminuria (ACR≥300 mg/g), during 10 years of follow-up, whereas controls remained normoalbuminuric during the same period. Baseline urine samples stored at -20°C were profiled using ultra-performance liquid chromatography coupled with quadrupole time-of-flight mass spectrometry operating in either electrospray ionization (ESI) positive or negative mode. The urine samples contained 21,041 features (13,809 ESI+, 7,232 ESI-) in which at least 17 cases had different relative concentrations than their matched controls. Fisher's permutation test was used to test the statistical significance of the difference in relative concentration of these candidate biomarkers between cases and controls; the false discovery rate procedure was used to adjust for multiple comparisons. The analysis identified 66 biomarkers with p-values $<10^{-3}$, corresponding to a false discovery rate of 56.2%. These biomarkers are now being structurally identified by co-chromatography and tandem mass spectrometry comparison with authentic standards; the first to be identified, ranked 32 on the list of top putative biomarkers, was indoxyl sulfate ($p=5.6x10^{-4}$) , a protein-bound endogenous uremic toxin excreted in the proximal tubule that increases tubulointerstitial fibrosis and glomerulosclerosis by increasing the expression of transforming growth factor-β1. The relative concentration of this toxin was higher in cases than in controls (3.1 vs. 1.8). Structural identification of the other metabolites continues and may provide new insights into mechanisms of diabetic kidney disease and a means of identifying those at risk before they can be identified by conventional clinical tests.

**Global MicroRNA Gene Profiling in Autosomal Dominant Polycystic Kidney Disease (ADPKD)** Xuewen Song, Ning He, Kairong Wang, York P. Pei. *Divisions of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada.*

MicroRNAs (miRNAs) play an important role in regulating gene expression in health and disease. Previously, we have shown that aberrant activation of gene pathways and transcriptional networks were associated with human PKD1 renal cysts (Hum Mol Genet 18: 2328-2343, 2009). In the current study, we examined the global expression of miRNAs and related their changes to the expression of genes/gene pathway in human PKD1 renal cysts of different size, minimally cystic tissue from six PKD1 human polycystic kidneys, as well as normal renal cortical samples. We identified 158 differentially regulated miRNAs (Up: 59; Down: 99) using a false discovery rate (FDR) of 0.1%. Among these miRNAs, 76 were located in 23 genomic clusters. Within each of 19 genomic clusters, all differentially expressed miRNAs were changed in one direction, suggesting co-expression of these miRNAs. Pathway analysis of miRNA-predicted target genes suggested some miRNA families may regulate gene pathways associated with renal cyst growth in ADPKD. For example, down-regulation of miR-424/503 were associated with increased expression of pathway components for G1-S cell cycle progression (e.g. CDC25A, CDK6, CCND1, CCDN2, CCND3, CCNE1 and E2F3), mTOR signalling (IGF1, IGF1R, PIK3R1, AKT3, RICTOR, EIF4E, EIF4B, RAF1 and VEGFA); and miR-301a may promote EMT by targeting transcriptional factors ZEB1 and ZEB2 as well as TGF β pathway components (e.g. TGFBR2, BMPR2, ACVR1, SMAD5). By integrating dysregulated miRNAs and our previously reported dysregulated mRNAs, we also found a inverse correlation between expression of these miRNAs and most of their predicted target genes. Taken together, our results indicate that a unique panel of miRNAs is associated with renal cyst growth in ADPKD. Targeting these specific miRNAs may provide a novel approach in the treatment of ADPKD.

**F-PO1989**

**Computational Prediction of MicroRNA Targets in ADPKD** Priyanka Pandey, Shan Qin, Jacqueline Ho, Jordan A. Kreidberg. *Division of Nephrology, Children's Hospital Boston, Harvard Medical School, Boston, MA.*

microRNAs (miRNAs) have emerged as a new area of interest in renal development and pathology. They are a class of several hundred short non-coding RNAs that have been implicated in a wide spectrum of biological processes and their expression levels have been found to be increased or decreased in several disease processes including kidney cancer, diabetic nephropathy and polycystic kidney disease. Autosomal dominant polycystic kidney disease (ADPKD) is a relatively common genetic kidney disease characterized by the formation of cysts throughout the kidney parenchyma. In the vast majority of cases, this disease is caused by mutations in PKD1 or PKD2. Although the involvement of several genes and transcriptional networks, as well as miRNAs has been previously shown in PKD, specific miRNA:mRNA pairings that affect the initiation and progression of cyst formation remain to be identified. Kidneys of Pkd1-/- embryos develop a rapidly progressive cystic disease during embryogenesis. We first performed gene expression profiling using embryonic kidneys of wild type and Pkd1-/- embryos, to identify genes whose expression were highly mis-regulated in Pkd1-/- embryonic kidneys. By using computational approaches (TargetScan, miRanda, microT and miRDB), we then predicted miRNAs that were suggested to target these mRNAs, and selected a set of candidate miRNAs for further study suggested by at least two of four prediction tools. Differential expression of 9 candidate miRNAs and 17 potential target mRNAs was then confirmed by qRT-PCR. These studies predicted 14 candidate interactions that will be subject to experimental validation. Gene Ontology and gene set enrichment analysis identified overrepresented signaling pathways between Pkd1 mutant and wild-type kidneys, including calcium, Wnt, Notch, TGF-β, MAPK and VEGF signaling. Our results suggest a possible role of miRNAs in specific signal transduction pathways mis-regulated in ADPKD.

**Endocytosis of α-Galactosidase A in Human Podocytes in Fabry Disease Is Mediated by Different Receptors** Thaneas Prabakaran,[1] Rikke Nielsen,[1] Jakob V. Larsen,[1] Moin Saleem,[3] Claus Munck Petersen,[1] Pierre J. Verroust,[4] Erik I. Christensen.[1] *[1]Department of Anatomy and Department of Medical Biochemistry, Aarhus University, Aarhus, Denmark; [2]Department P and Department of Medical Endocrinology, Rigshospitalet, Copenhagen, Denmark; [3]Children's Renal Unit and Academic Renal Unit, University of Bristol, Southmead Hospital, Bristol, United Kingdom; [4]UMRS 592, Institut de la Vision, Paris, France.*

Background: Injury and loss of glomerular podocytes are leading factors of glomerular disease and renal failure. Podocyte repair is therefore an important therapeutic target. In Fabry disease, podocyte injury is caused by the progressive intracellular accumulation of glycosphingolipid in form of globotriaosylceramide (GL-3). Aim: To determine how recombinant α-galactosidase A (α-Gal A) (agalsidase beta; Fabrazyme®) designed for enzyme replacement therapy in Fabry disease is taken up by human podocytes in the renal glomeruli. Methods: The uptake of α-Gal A in podocytes was investigated using affinity chromatography, immunochemistry, laser capture microdissection, RT-PCR and Western blotting analyses. Results: This study identifies three endocytic receptors, mannose 6-phosphate receptor (M6PR), megalin, and sortilin, with drug delivery capabilities in human podocytes. All receptors are localized on the surface membrane of podocytes indicating their endocytic capabilities. The receptors mediate the uptake and lysosomal targeting of recombinant α-Gal A. Conclusions: These findings highlight the importance of receptor-mediated endocytosis as a key mechanism to maintain podocyte integrity by delivering α-Gal A to lysosomes for degradation of GL-3 deposits. The present study provides the rationale for the renal effect of treatment with α-Gal A and identifies potential pathways for future non-carbohydrate based drug delivery to the kidney podocyte and other tissues.

**Analysis of the Foetal Urinary Proteome Predicts Postnatal Renal Outcome of Posterior Urethral Valves (PUV)** Julie Klein,[1] Chrystelle Lacroix,[2] Françoise Muller,[3] Benjamin Breuil,[1] Justyna Siwy,[4] Harald Mischak,[4] Flavio Bandin,[1,5] Bernard Monsarrat,[2] Jean-Loup Bascands,[1] Stéphane Decramer,[1,5] Joost Schanstra.[1] *[1]U858, Inserm, Toulouse, France; [2]IPBS, CNRS, Toulouse, France; [3]Nephrologie Pediatrique, Hôpital Robert Debré AP-HP, Paris, France; [4]Mosaiques Diagnostics & Therapeutics AG, Hannover, Germany; [5]Paediatric Nephrology, Hôpital des Enfants, Toulouse, France.*

Posterior urethral valves (PUV) are rare diseases associated with a wide spectrum of outcomes ranging from prenatal death with terminal renal failure to survival with normal renal function. *In utero* the most severe cases can be easily identified based on severe oligohydramnios or sonographic evidence of bilateral renal dysplasia with microcystic hyperechogenic kidneys and absence of corticomedullary differentiation. For the less severely affected patients, the long term outcome is nearly impossible to predict. We hypothesise that foetal urine (FU) contains biomarkers that allow assessing the severity of renal lesions *in utero* and subsequent prediction of postnatal renal outcome.

The FU proteome was analysed by capillary electrophoresis coupled to mass-spectrometry (CE-MS). In addition, parallel LC-MS/MS analysis of a number of FU samples yielded peptide sequence data allowing calibration of the CE-MS data and therefore patient comparison.

We have compared the FU proteome of 20 foetuses with PUV leading to normal-acceptable renal function up to at least the age of two years (*controls*) with that of 18 foetuses with PUV leading to termination of pregnancy due to non-functional kidneys (*cases*). This lead to the identification of 30 FU biomarkers that classified with 100% sensitivity and specificity this training set.

These 30 biomarkers were validated in an independent blinded cohort of 22 PUV patients (7 terminations of pregnancy + 7 neonatal deaths (*cases*) and 8 patients with good postnatal function (*controls*)), predicting the post-natal outcome with 93% sensitivity, 100% specificity and an AUC=0,973. Three of the 30 biomarkers were identified as collagen fragments.

These data strongly suggest that the analysis of the FU proteome allows predicting post-natal renal outcome of posterior urethral valves.

**Identification and Functions of microRNAs in the Developing and Adult Mouse Kidney** Vishal Patel, Sachin S. Hajarnis, Donovan Huynh, Ryan Hunter, Darren Williams, Rajiv Parmar, Peter Igarashi. *Internal Medicine-Nephrology, UT Southwestern Medical Center, Dallas, TX.*

MicroRNAs (miRNAs) are short, non-coding RNAs that inhibit mRNA translation and promote mRNA degradation. miRNAs play critical roles in embryonic development and tissue homeostasis in the heart, lung, and blood vessels, but their roles in the kidney are poorly understood. We performed microarray analysis of 707 known mature miRNAs in the adult and immature mouse kidney. Analysis of kidneys at different ages from postnatal day (P) 2 ,P7, P14, P21, and P35 revealed stage-dependent expression of 114 miRNAs. 60 miRNAs were highly expressed in the immature kidney and down-regulated in the adult, whereas 54 miRNAs showed a reciprocal pattern of expression. To examine the functions of miRNAs in the kidney, we generated mutant mice that lack Dicer, an enzyme required for miRNA biogenesis, specifically in renal epithelial cells. Approximately 70% of neonatal *Dicer* mutant mice developed hydroureter and hydronephrosis. A subset of neonatal *Dicer* mutant mice also developed kidney cysts. *Dicer* mutant mice that survived to adulthood developed interstitial fibrosis and de-differentiation of tubular and parietal epithelial cells. Tamoxifen-inducible, kidney-specific inactivation of *Dicer* in adult mice resulted in increased interstitial fibrosis and tubular epithelial de-differentiation. Target prediction analysis revealed that the 3'UTRs of mRNAs encoding tumor suppressors contained binding sites for miRNAs that were enriched in the developing kidney. Conversely, miRNAs that were enriched in the adult kidney targeted oncogenes and genes involved in the prevention of epithelial-to-mesenchymal transition and fibrosis. Taken together, these studies show that distinct subpopulations of miRNAs are expressed in the developing and adult kidney. Expression of miRNAs in renal epithelial cells is essential for both kidney development and the prevention of renal fibrosis. miRNAs represent novel therapeutic targets for the treatment of kidney diseases, such as PKD and renal fibrosis.

**F-PO1993**

**Renal Gene Expression Profile in Radiation Nephropathy** Marek Lenarczyk,[2] John E. Moulder,[2] Brian L. Fish,[2] Martin Hessner,[3] Eric P. Cohen.[1] *[1]Medicine, Medical College of Wisconsin, Milwaukee, WI; [2]Radiation Oncology, Medical College of Wisconsin, Milwaukee, WI; [3]Pediatrics, Medical College of Wisconsin, Milwaukee, WI.*

Oxidative stress may play a significant role in kidney disease. But neither protein nor lipid oxidative stress (OS) were found in radiation nephropathy (Rad Res 171:164, 2009), in which chronic OS is said to occur. We therefore tested for OS using a genome-wide expression array, with attention to the latent period before physiologically-significant renal damage. WAG/RijCmcr male rats were divided into experimental and age-matched control groups (6 per group). At age 2 months rats underwent 10 Gy total body irradiation (TBI) , followed by a syngeneic bone marrow transplant. Controls were sham-treated. Half of the irradiated and control animals were placed on captopril 500 mg/L in their drinking water at 2 days after TBI and thereafter.

Animal groups according to day post-TBI and CAP treatment

| | 1 day | 21 days |
|---|---|---|
| 0 Gy, no drug | x | x |
| 0 Gy, captopril | | x |
| 10 Gy, no drug | x | x |
| 10 Gy, captopril | | x |

x denotes gene array testing

Differentially expressed genes were defined as those having greater than a 2-fold change and a false discovery rate<0.01. We identified 41, 50, and 6, differentially expressed genes for group comparison between 1d 10 Gy vs. 1d 0 Gy, 21d 10Gy vs. 21d 0 Gy, and 21d 10Gy with CAP vs. 21d 10 Gy no CAP, respectively.Comparison between 21d 10Gy+CAP vs. 21d 10Gy identified 4 down-regulated (Ucp1 uncoupling protein 1, Slco4a1-solute carrier organic anion transporter family, Grem2 -gremlin 2, Eif4g2-eukaryotic translation initiation factor 4) and 2 up-regulated (Gadd45g-growth arrest and DNA-damage-inducible, Ren-renin) transcripts. Up-regulation of renin is expected with use of captopril and confirms drug delivery to the rats. Gadd45g enables DNA repair. The down-regulation of eIF4G2 could affect the translation of laminin, which would be a mechanism for the benefit of captopril in this model. None of the 97 annotated genes are associated with oxidative stress, which suggests that persistent oxidative stress does not occur in radiation nephropathy.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1994**

**Proteomics Reveals Potential Biomarkers of Chronic Kidney Disease in Patients after Hematopoietic Cell Transplantation** Sangeeta R. Hingorani,[1,2] Qing Zhang,[2] Jacob Kennedy,[2] Hong Wang,[2] Samir Hanash.[2] *[1]Pediatrics, University of Washington/Seattle Children's Hospital, Seattle, WA; [2]Clinical Research, Fred Hutchinson Cancer Research Center, Seattle, WA.*

Chronic kidney disease (CKD) is a cause of morbidity and mortality within the first year after hematopoietic cell transplant (HCT). We studied 18 patients with CKD (defined as a GFR <60 ml/min/1.73m$^2$ at 1 year post HCT) and 18 age and gender-matched control patients without CKD. Urine samples were collected between 0800-1000 hours on day 100 after transplant (prior to development of CKD). Pooled samples were created using equal amounts of protein. The pooled urinary proteins were separated by SDS-PAGE, and digested with trypsin. Acquired mass spec data from LTQ-Orbitrap was automatically processed by the CPAS pipeline. Identified peptides were validated through PeptideProphet and inferred into proteins via ProteinProphet. Tandem mass spectra were searched against the human IPI database. For each protein identified, the number of MS/MS events was normalized and the G-test was performed. The calculated G-value was used to assess whether the protein was differentially expressed.

We identified 609 unique proteins in the urine at day 100 post-HCT; 435 in cases and 516 in controls. Fifty-nine proteins were expressed only in cases at day 100 and undetectable in controls; candidate biomarkers are listed in Table 1. These proteins were chosen based on a p-value of <0.05, their presence in 2 or 3 runs and biologic plausibility. These proteins are involved in inflammatory responses, dermatologic diseases, and cell adhesion, signaling and migration.

Candidate biomarkers of CKD post-HCT

| Gene | Description |
|---|---|
| ANXA2 | Annexin a2 |
| ANXA3 | Annexin a3 |
| ANXA5 | Annexin a5 |
| C3 | Complement C3 precursor |
| FLG | Filaggrin |
| IL-10RB | Interleukin-10 receptor beta chain precursor |
| IVL | Involucrin |
| PLAU | Urokinase-type plasminogen activator |
| RDX | Radixin |
| S100A8 | Calgranulin a |
| TAGLN2 | Transgelin-2 |

Further work is needed to replicate our findings in a larger number of patients and to determine if these proteins are expressed in the kidney using EIA to measure proteins in the urine and immunohistochemistry of autopsy or biopsy specimens.

**F-PO1995**

**Upregulation of Inflammatory Mediators in End-Stage Renal Disease as Measured Via Biochip Array Technology** Vinod K. Bansal,[1] Rachael Davis,[2] Evangelos Litinas,[2] Debra Hoppensteadt,[2] Evangelos Litinas.[2] *[1]Department of Nephrology, Loyola University Medical Center, Maywood, IL; [2]Department of Pathology, Loyola University Medical Center, Maywood, IL.*

End-Stage Renal Disease (ESRD) is a complex syndrome in which systemic vascular pathophysiologic changes contribute to adverse cardiovascular and cerebrovascular manifestations. Given that inflammatory and hemostatic aberrations contribute to the overall pathogenesis of the syndrome, the purpose of this study is to profile several inflammatory mediators in order to better understand their role in the underlying mechanism of vascular changes in ESRD. Plasma samples from 49 patients with ESRD were collected prior to maintenance hemodialysis sessions. A group of 56 normal individuals, both male and female, was included as control. Cerebral Array II chips were used in the Randox® system to simultaneously measure Neuron Specific Enolase (NSE), Neutrophil Gelatinase-associated Lipocalin (NGAL), Soluble Tumor Necrosis Factor Receptor I (TNFRI), D-Dimer (DD), Thrombomodulin (TM), and C-reactive protein (CRP). The Randox® technology utilizes

multiple discrete test regions of immobilized antibody to simultaneously quantify multiple markers from a single patient plasma sample. As compared to the normals, all of the markers studied showed an upregulation in patients with ESRD. Most notably, TNFRI showed a 19.8 fold increase in patients with ESRD (mean 7.8 ± 2.8 ng/ml, range 0.8 to 13.7) compared to the control (mean 0.4 ± 0.2, range 0.1 to 1.0). TM was increased 5.2 fold (mean 6.5 ± 2.6, range 0.7 to 14.1) compared to control (mean 1.2 ± 0.4, range 0.6 to 2.3). Also, NGAL showed a 4.6 fold increase (mean 1390 ± 257, range 406 to 1729), compared to control (mean 299 ± 99, range 115 to 603), and CRP a 4.2 fold increase (mean 5.7 ± 4.2 ug/ml, range 0.6 to 13.2) compared to control (mean 1.4 ± 1.7, range 0.2 to 11.4). DD and NSE were also increased 3.0 and 1.8 fold respectively. These studies show that inflammatory markers such as TNFRI, NGAL and NSE are upregulated in ESRD. The marked increase in TM and TNFRI is highly suggestive of endothelial damage in this syndrome.

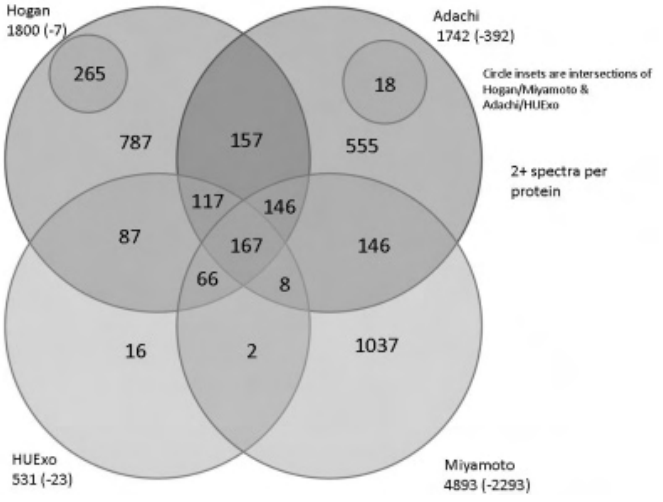
**In-Depth Proteomic Analysis of Podocin-Rich Exosomes in Human Urine** Marie C. Hogan,[1] Roman Zenka,[2] Kenneth L. Johnson,[2] Cristine Charlesworth,[2] Peter C. Harris,[1] H. Robert Bergen,[2] Christopher James Ward.[1] *[1]Nephrology, Mayo; [2]Proteomics Center, Mayo Clinic, Rochester, MN.*

Ready isolation of glomerular proteins would be of great significance for identifying diagnostic & prognostic markers of glomerular disease. To isolate such proteins we performed a comprehensive proteomic study of pooled urines containing the podocin exosome subfraction using modifications to prior protocols (Hogan et al JASN 2009). **Methods:** Fresh urine from 14 subjects (seven with normal renal function & no microalbuminuria (age 28±3.3yrs) & nine ADPKD individuals (27.7± 6.2yrs)) were used for exosome isolation by centrifugation on 5-30% sucrose ($D_2O$). 30ug protein (pooled podocin rich fraction) of each individual was separated with 1D PAGE (to isolate 10 slice sections from high to low Mw). Slices were trypsinized, eluted & analyzed by quantitative MS/ MS. Elucidator® compared relative peptide M/Z intensities. ID mapping to Uniprot facilitated comparison of our proteome with urine, glomerular & existing exosome proteomes. **Results:** Of a confident set of 1792 proteins identified (≥2 peptides), 594 are shared with the glomerular proteome but 1476 were not. 1039 are involved in cellular process.



Ribonucleotide & purine nucleotide binding proteins were overrepresented. Podocyte disease related proteins, podocin, podocalixyn, podocalixyn-like protein, ACTN4, CD2AP & MYH9 were present. **Conclusions:** Our data substantially expands the number of urine exosome proteins identified to date. Exosome of podocyte origin are shed in urine in individuals without proteinuria & can be isolated for label free MS. As these vesicles are enriched in membrane & intracellular proteins of glomerular origin, this offers the prospect of their use for biomarkers in glomerular diseases. Our future studies will concentrate on simplifying extraction methods & studies in albuminuric patients with glomerulopathies.

## F-PO1997

**Outcomes as a Function of Donor Type from a Phase III Study of Belatacept vs Cyclosporine in Kidney Transplantation (BENEFIT-EXT)** Sander Florman,[1] Antoine Durrbach,[2] Christian Larsen,[3] Jose Medina-Pestana,[4] Yves Vanrenterghem,[5] Flavio Vincenti,[6] Alan Block,[7] Pushkal Garg,[7] J. Brian Copley,[7] Tao Duan,[7] Josep Grinyo.[8] *[1]Mount Sinai Med Cntr; [2]Bicetre Hosp; [3]Emory Univ; [4]Hosp do Rim; [5]Univ Hosp Leuven; [6]UCSF; [7]BMS; [8]Univ Hosp Bellvitge.*

**Purpose:** To assess 2-yr outcomes of belatacept vs cyclosporine (CsA) in adults receiving extended-criteria donor (ECD) kidney transplants as a function of donor type.

**Methods:** BENEFT-EXT is a 3-yr, randomized, Phase III study of belatacept in adults receiving ECD kidney transplants. Pts were randomized 1:1:1 to receive a more intensive (MI) or less intensive (LI) regimen of belatacept or CsA; all pts received basiliximab induction, MMF, and corticosteroids. Randomized and treated patients met protocol-specified ECD criteria of donor age>60, UNOS EC, CIT≥24 hrs and/or DCD. Yr 2 outcomes included composite patient/graft survival, measured GFR (mGFR), calculated GFR (cGFR) and protocol-defined acute rejection (AR).

**Results:** 543 pts composed the ITT population; 384 and 55 pts received UNOS ECD and DCD kidneys, respectively. Similar AR rates were observed in pts regardless of donor type. Patient/graft survival with belatacept was comparable to CsA across the ITT, UNOS ECD, and DCD populations. Outcomes in recipients of protocol-defined ECD kidneys are consistent with recipients of UNOS ECD kidneys. Belatacept pts demonstrated better GFR compared with CsA in ITT and UNOS ECD.

Outcomes as a Function of Donor Type at Yr 2

| | Patient/Graft Survival, % | mean, mGFR, mL/min | mean, cGFR, mL/min | AR, % |
|---|---|---|---|---|
| ITT: MI (n=184) | 83 | 52 | 44 | 17 |
| ITT: LI (n=175) | 84 | 50 | 43 | 18 |
| ITT: CsA (n=184) | 83 | 45 | 35 | 15 |
| UNOS ECD: MI (n=129) | 81 | 48 | 40 | 19 |
| UNOS ECD: LI (n=122) | 82 | 46 | 40 | 21 |
| UNOS ECD: CsA (n=133) | 81 | 41 | 31 | 15 |
| DCD: MI (n=18) | 83 | 56 | 50 | 11 |
| DCD: LI (n=19) | 100 | 42 | 56 | 21 |
| DCD: CsA (n=18) | 72 | 46 | 36 | 17 |

**Conclusions:** Belatacept demonstrated better renal function, comparable patient/graft survival and comparable AR compared to CsA in ECD kidney recipients irrespective of donor type at Yr 2. The outcomes among donor types were consistent with the overall ITT population.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1998

**Genetic Differences in Native Americans Affects Tacrolimus Dosing after Kidney Transplant** Harini A. Chakkera,[1] Anita Grover,[2] Jason K. Bodner,[1] Senaida Behmen,[1] Raymond L. Heilman,[1] Kunam Sudhakar Reddy,[1] Adyr A. Moss,[1] Khaled Hamawi,[1] Lynda A. Frassetto.[2] *[1]Mayo Clinic AZ; [2]UCSF.*

**Background:** Tacrolimus (FK) pharmacokinetics (PK) is influenced by enzymes cytochrome P450 (CYP) 3A4 and 5, and the transporters P-glycoprotein -MDR1, MRP1 and BCRP. Racial differences are seen in SNPs encoding these transporters and enzymes. Genetic variabilities among Native Americans (**NA**) have not been studied but clinically NA require lower FK to achieve therapeutic levels.

**Methods:** 12-hour PK studies and SNPs for CYP3A4 (*1, *1B) & 5 (*1, *3), MDR1 (C1236T, G2677T, C3435T), MRP1 (G1299T) and BCRP (G34A, C376T) performed on 24 NAs with kidney tx on stable dose FK. PK estimated using NONMEM and fit to a two compartment model using an empirical Bayesian approach. Genotyping using TaqMan. Genetic, PK and demographic correlations assessed.

**Results:** Mean age: 51±13 yr, 70% male, 15 were Navajo. Average NA FK dose was 0.03±0.02 mg/kg/day. Literature averages 0.2-0.25mg/kg/day for AA and 0.05-0.1 mg/kg/day for Chinese. Genotype frequencies (table 1).

| Gene | NA % (WT/HT/HZ) | AA % (WT/HT/HZ)* | As % (WT/HT/HZ)* |
|---|---|---|---|
| CYP3A5*1/*1, *1/*3, *3/*3 | 0.00/0.12/0.88 | 0.4-0.7/0.05-0.15/0.3-0.45 | 0-0.1/0.45-0.5/0.455-0.5 |
| MDR1 C1236T | 0.25/0.58/0.17 | 0.87/0.13/0 | 0.1/0.45/0.45 |
| MDR1 G2677T | 0.57/0.19/0.24 | 0.85/0.15/0 | 0.13/0.29/0.47 |
| MDR1 C3435T | 0.25/0.65/0.10 | 0.86/0.14/0 | 0.3/0.4/0.3 |

WT=wild type; HT=heterozygote; HZ=homozygous; AA = African Americans; As = Asians. *population frequency - http://www.ncbi.nlm.nih.gov/snp;

Significant interactions in the entire cohort include: *G2677T* and absorption rate (p=0.01), CYP3A5 and intercompartmental clearance (p=0.01) and steady-state distribution volume (p=0.03), and among Navajo only, between *G2677T* and absorption rate (p=0.01).

**Conclusion:** Native Americans have lower drug clearance and often have CYP3A5*3 genotype and MDR variants. Compared to WT, variants have lower FK absorption and metabolism, thus NA require less FK to achieve trough levels.

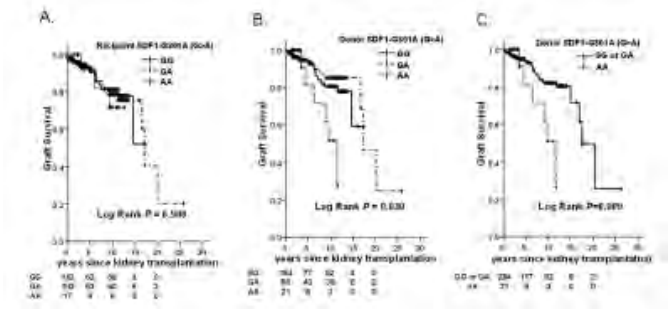
## F-PO1999

**Genetic Predisposition of Donors Affects the Allograft Outcome in Kidney Transplantation; Stromal-Derived Factor-1 Polymorphism** Jung Pyo Lee,[1] Seung Hee Yang,[1] Shin-Young Ahn,[2] Jae-Yoon Park,[2] Kwon Wook Joo,[2] Dong Ki Kim,[2] Yon Su Kim.[2] *[1]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background and method; Genetic predisposition may be an important aspect to discern impending responses after transplantation. In this study, we evaluated the role of the genetic predisposition of SDF1 at the 3' untranslated region (G801A) on renal allograft outcomes. A total of 263 pairs of recipients and donors were enrolled.

Results; SDF1 was differentially expressed in renal tissues with acute rejection according to genetic variations of donors showing higher expressions in the grafts from GG donors. Biopsy-proven acute rejection (BPAR) within 1 year and long-term graft survival were traced. Despite similar allele frequencies between donors and recipients, A allele from donors, not from recipients, has a protective effect on the development of BPAR (p=0.037). Adjustment for multiple covariates did not affect this result (OR 0.49, 95% C.I 0.26–0.91, $P$ = 0.023). However, patients who received AA homozygote grafts showed poor graft survival compared to recipients from GG or GA donors ($P$ =0.009).



This association was significant after adjusting for several risk factors (hazard ratio 3.14; 95% C.I = 1.19-8.29; *P* = 0.021). The allelic variation of recipients, however, was not associated with BPAR and graft loss.

Conclusion; A donor-derived genetic polymorphism of SDF1 has influenced the graft outcome. Thus, the genetic predisposition of donor should be carefully considered in transplantation.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2000**

**Access to the Waiting List and Renal Transplantation within Europe** Vianda S. Stel,[1] Reinhard Kramar,[2] Torbjorn Leivestad,[3] Keith Simpson,[4] Jacqueline Smits,[5] Kitty J. Jager.[1] *[1]ERA-EDTA Registry, Netherlands; [2]Austrian Dialysis and Transplant Registry, Austria; [3]Norwegian Renal Registry, Norway; [4]Scottish Renal Registry, United Kingdom; [5]Eurotransplant International Foundation, Netherlands.*

The aim of the study is to examine 1) access to the kidney transplant waiting list (WL) and 2) access to renal transplantation for those who are waitlisted. We focus on time trends, international differences and patient subgroups.

Of the incident RRT patients from 1995 to 2007 in the ERA-EDTA Registry database, the date on the WL from 1995 to 2005 was available for Austria (AT) and The Netherlands (NL) (from Eurotransplant), Norway (NO) (Scandiatransplant) and Scotland (UKs) (Scottish Renal Registry). Patients receiving a transplant without waitlisting were put on the WL for 1 day.

From 1995 to 2007 the incidence of RRT per million age related population (pmarp) was highest in AT, and increased slightly in patients <65 years (AT:77-80; NO:53-61; NL:58-61, UKs:64-68 pmarp) and importantly in patients ≥65 years (AT:287-520; NO:216-399; NL:277-415, UKs:223-298 pmarp). The number of transplants performed pmp increased over time (AT:38-48, NO:43-55, NL:31-51, UKs:27-36 pmp), with the highest number of deceased donors in AT (41 pmp in 2007), and of living donors in NO until 2006 (17 pmp) and in NL in 2007 (23 pmp).

Of the patients starting RRT from 1995 to 2003 at age <65 years, the proportion of patients waitlisted within 2 years was 52, 78, 57 and 52% in AT, NO, NL and UKs respectively. In patients ≥65 years it was 24% in NO and 6% in the other countries. In NO, 92% of waitlisted RRT patients <65 years were transplanted within 4 years after the start of RRT whereas this was less in AT (73%), NL and UKs (both 65%). In patients ≥65 years it was 71% (AT), 77% (NO), 52% (NL) and 36% (UKs). There was no gender difference, and no clear trend in access to WL and transplantation for those who were waitlisted.

In conclusion, in contrast to the other countries, Norway transplanted virtually all waitlisted patients <65 years and most patients ≥65 years within 4 years. This may be due to their relatively high number of (live donor) kidney transplants and a lower RRT incidence.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2001**

**Depressed Kidney Function in Kidney Donors Causes Significant Endothelial Dysfunction without Cardiovascular Risks** Masahiko Yazawa,[1] Ryo Kido,[2] Takashi Yasuda,[1] Yugo Shibagaki,[1] Kenjiro Kimura.[1] *[1]Center for Kidney Diseases, St. Marianna University Hospital, Kawasaki, Kanagawa, Japan; [2]Department of Epidemiology and Healthcare Research, Kyoto University, Kyoto, Japan.*

[Purpose] Living kidney donors (LKDs) who were proved to be free from CVD risks by pretransplant evaluation are theretically good models of depressed kidney function without CVD risk factors. In order to elucidate the role of kidney function per se in the pathogenesis of CVD in CKD, we evaluated vascular function in LKDs compared to general CKD patients (CKDs).

[Methods] Twenty-eight prevalent LKDs were compared to the same number of CKDs who were matched with age, sex and estimated GFR. Same number of healthy control volunteers were also studied as reference. Flow mediated dilatation (FMD), as a maker of endothelial function, ankle brachial index (ABI) and pulse wave velocity (PWV) as markers for arteriosclerosis were measured and compared between LKDs and CKDs. Urine nitric oxide (NOx) excretion was measured as another maker of endothelial function. We also tried to clarify factors that affect results of FMD using multiple regression analysis.

[Results] The median age were 62.5 and 53.5 years old, median eGFR were 49.4 and 50.0 ml/min/1.73m$^2$, in LKDs and CKDs, respectively. LKDs had lower prevalence of hypertension, use of the RAS inhibitors and smoking. Their ABI and PWV were better than those of the CKDs (1.18 vs. 1.13 and 1383 vs. 1571, respectively, P<0.05 for both markers). On the other hand, FMD was equally low in the LKDs and CKDs (median 3.3% vs. 3.4% P=0.56). The LKDs had higher prevalence of severe endothelial dysfunction expressed as FMD less than 2.0% (35.7% vs. 17.6%, P=0.13). The median Urine NOx excretion in LKDs was 109.2 μmol/ mmolcr, which was much less than that of healthy controls. The multiple regression analysis showed that the presence of hypertension (p<0.001), LKDs (p=0.03) and age (p<0.001) were significantly correlated with low FMD.

[Conclusion] Endothelial function in living kidney donors was at most as low as CKD patients, which suggests depressed kidney function per se causes endothelial dysfunction without CVD risk factors.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2002**

**What Happens to Patients Returning to Dialysis after Renal Transplant Failure? An Analysis of UK Renal Registry Data** Lynsey Helen Webb,[1] Anna Casula,[1] Charles Tomson,[2] Chris Maggs,[1,3] David Ansell,[1] Yoav Ben-Shlomo.[4] *[1]UK Renal Registry, Bristol, United Kingdom; [2]Richard Bright Renal Unit, Southmead Hospital, Bristol, United Kingdom; [3]University of Hull, Hull, Yorkshire, United Kingdom; [4]Department of Social Medicine, University of Bristol, Bristol, United Kingdom.*

**Background:** Around 22,000 patients in the UK have functioning renal transplants, 3% of which fail each year. Patients with established renal failure who undergo successful transplantation have better quality of life and longer survival compared to those patients remaining on dialysis. This study is the first large UK study examining survival following transplant failure.

**Methods:** Using the UK Renal Registry database, two cohorts were identified. The control cohort comprised patients commencing haemodialysis (HD) or peritoneal dialysis (PD) as an initial form of renal replacement therapy (RRT) between 01/01/2000-30/09/2008, who were wait-listed for transplantation within 2 years of starting RRT. The case cohort were patients commencing HD or PD after failure of a first transplant between 01/01/2000-30/09/2008. Patients were followed until death, loss to follow up or the 31/12/2008, and were censored from the relevant cohort if transplanted. Hazard ratios (HR) and Kaplan-Meier survival were calculated. Cox regression modelling was performed, adjusting for age, gender, ethnicity and diabetic status.

**Results:** The study cohort consisted of 11,280 controls and 3,417 cases. The adjusted HR for death within 90 days of starting dialysis post-graft failure was 5.4 (95%CI 3.5-8.4) compared to the control group. The adjusted HR for death in the 1st year was 4.5 (95%CI 3.3-6.0) which steadily fell to a HR 1.2 (95%CI 0.3-1.6) at >5 years post-graft failure.

**Conclusions:** In keeping with previous North American work, return to dialysis following graft loss is associated with significant mortality, most pronounced in the 1st year after transplant failure. Patients commencing dialysis after graft failure do significantly worse than "fit" (i.e. suitable for transplantation) patients starting dialysis as initial RRT. Further investigation of the patient- and centre-level causes of this increased mortality risk is required.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2003**

**Impact of State Living Donor Policies on Rates of Living Kidney Donation** Caroline E. Jennette,[1] James Bradley Layton.[1,2] *[1]UNC Kidney Center, NC; [2]Gillings School of Global Public Health, NC.*

Kidney transplantation is limited by the number of organs available. Since 2004, efforts have been made on a state level to increase opportunities for transplantation through a tax deduction/credit to reimburse living donors for non-medical expenses related to donation. It is unclear whether policy enactment has influenced living kidney (LK) donation.

**Methods**: States with enacted bills (N=15) were compared to states without (N= 30). States without LK donor information were excluded (n=5), as was the District of Columbia. Average changes per year in the number of LK donations, LK donation rate per 10,000 population, and proportion of all kidney donations made by living donors were considered from 2001 to 2009 using mixed models for repeated measures. States with enacted laws promoting LK donation were considered for the years on and after the law's passing and compared to states without enacted laws. Models were adjusted for the proportion of the state population on dialysis. Donation and dialysis numbers were obtained from the United States Renal Data System and the Organ Procurement & Transplantation Network. Population sizes were obtained from census estimates.

**Results:** Bill enactment did not have a significant effect on the percentage of LK donors nor on the increase of total LK donors. Rates of LK donation increased in all states, but enacted states had a significantly lower rate of increase. Enacted states tended to have higher LK donor rates in the years before policy enactment, but this was not statistically significant.

LK Donation in Enacted vs. Non-Enacted States

| Average per year changes | Enacted States | Non-Enacted States | P Value |
|---|---|---|---|
| Proportion of kidneys from living donors | -1.21% | -1.11% | 0.8 |
| Number of LK donors | 19.13 | 17.11 | 0.9 |
| LK donor rate per year per 10,000 pop | 0.015 | 0.030 | <0.0001 |

**Conclusion:** State enactment of policies to reimburse LK donors for expenses has not significantly increased LK donation. Further research is needed to understand and improve upon methods of policy implementation and educational outreach related to financial reimbursement for living organ donation.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2004**

**Gender-Matching in Renal Transplant Allograft Allocation – Does Mismatch Matter?** G. Junge, Alexander Karpov, H. Schwende, C. Cornu-Artis. *Novartis Pharma AG.*

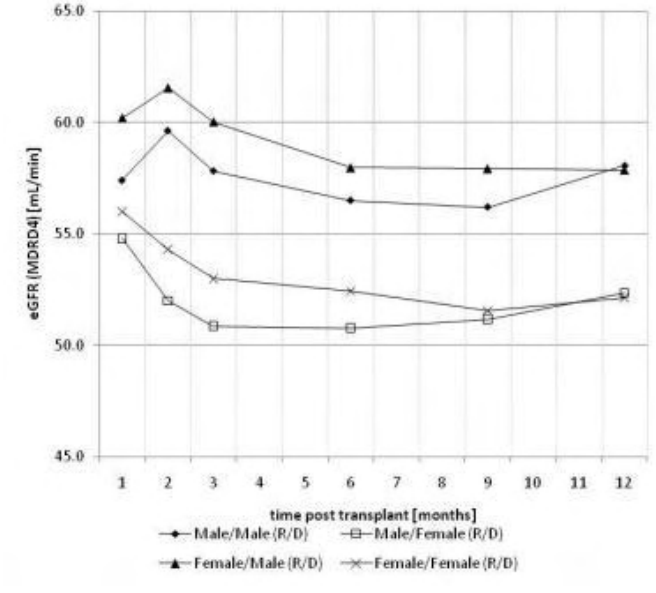
Long-term renal function (RFct) is dependent on a multitude of recipient-related and a few definable donor-related factors that represent the quality of the renal parenchyma being transplanted. However, the effect of donor/recipient gender mismatch on evolution of RFct is rather poorly delineated.

**Method**

RFct at M12 was assessed in 807 KTx recipients from Study A2309, a randomized, open-label, non-inferiority trial comparing TDM-everolimus with reduced CsA vs MPA with standard dose CsA. A2309 demonstrated non-inferiority at M12 which allowed looking at pooled data, neglecting the impact of the immunosuppressive regimen (non significant in univariate RFA). Recipient age, gender, race, BMI, graft type, PRA, donor age, race and gender were tested in univariate/multivariate risk factor analysis (RFA) of RFct(SCR) at M12.

**Results**

Male(M) donor organs showed 5.7 mL/min higher eGFR at M12 compared to female(F) allografts (Fig 1). Lowest change in eGFR (-0.7 mL/min) from M1-12 was observed in the M/M recipient/donor combination and highest in F/F (-4.1 mL/min). SCR-change from M1-3, M6 and M12 will be presented. The univariate RFA of SCR at M12 revealed statistical significance for younger recipient age (p=0.017), F-gender (p<0.001), Afro-American (AA) race (p=0.022), higher BMI (p=0.025), deceased donor allograft (p=0.023), and older donor age (p<0.001) which all remained significant in the multivariate RFA.



**Conclusion**

Male allografts showed higher eGFR at M12 compared to female grafts with highest eGFR measured in the M/M constellation (58.1 mL/min). Highest eGFR decline from M1-12 was observed in F/F recipient/donor situation with max change in SCR (+11.1 µmol/L). Significant RF of SCR were older donor- and younger recipient age, female gender, AA-race, higher BMI and allografts of deceased donors. The two different immunosuppressive regimens did not appear to influence RFct differently.

**F-PO2005**

**Medical Tourism: Organ Trafficking and Kidney Transplantation** Snezana H. Mijovic-Das. *Nephrology Division, Albany Medical College, Albany, NY.*

Despite great success of kidney transplantation there is a fair amount of frustration because of inability to provide enough kidneys to address the need for a rapidly growing population of patients with ESRD. In the USA 65 000 patients are on the waiting list and 3000 of them die yearly while being on such a list.

Because of this sad reality organ sale from commercial living donors (CLDs) or vendors has now become evident. According to WHO's estimates, 5-10% of nearly 70, 000 kidneys transplanted annually are obtained by organ trafficking. Patients with enough resources may travel from one country to another to purchase a kidney mainly from a poor person for an amount between $1000 and $5000, while brokers take from wealthy recipients between $100, 000 and $200, 000. China, India, Pakistan, Egypt, Brazil, The Philippines, Moldavia, Romania and Colombia are known to be "hot spots" for organ trafficking, well known to encourage the sale of organs to the tourist recipients from the client countries.

Selling and buying of organs should be prohibited. Organs should be donated only freely and without monetary reward. The entire international community should support the global fight against organ trafficking and illicit medical tourism. The alternative programs must be developed to make more organs available and to provide a good care of donors, their needs and social benefits. Engaging governments to make laws on transplantation and Ministry of Health to control the transplant practices is essential to improve the global situation of Organ Trafficking/Transplant Tourism. The alliance with international professional organizations such as International Society of Nephrology and other societies, all working with WHO to influence health authorities at World Health Assembly to fight the organ Trafficking and Medical Tourism, is a must.

However, the prohibition of selling and buying organs should not affect reimbursement to donors for documented costs including loss of income or expenses related to cost of recovering and medical expenses incurred for post- discharge care.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2006**

**Association of Race and Insurance Type with Discussion of Transplant Options at Dialysis Initiation** Kirsten L. Johansen,[1,3] Rebecca H. Zhang,[2,3] Yijian Huang,[2,3] Nancy G. Kutner.[2,3] *[1]UCSF; [2]Emory; [3]USRDS Rehab/QOL SSC.*

Black pts are wait listed for kidney transplant (txp) within the first year of dialysis less often than White pts. We hypothesized that there would be differences in rates of early txp discussion based on race and insurance. Adults starting dialysis in 2005-2008 who were not on the wait list were studied (n=317,434). Demographic, clinical, and insurance information was taken from USRDS files, along with whether txp options had been discussed and reasons for not discussing. Logistic regression was performed within age strata with txp discussion as the outcome.

Logistic regression of being informed by age

| | | OR (95% CI) by age | | | |
|---|---|---|---|---|---|
| Variable | 18-34 | 35-49 | 50-64 | 65-79 | 80+ |

Txp was less likely to be discussed with Black pts age 18-34 but more likely to be discussed with those 50-79. Non-private insurance was associated with lower odds of discussion in all but the 80+ age group. When we examined reasons, Black pts were more likely not to have been assessed in the youngest age group, and the same was true for every category of non-private insurance in all age groups except 80+. Pts with private insurance are more likely to have txp discussed with them at the time of dialysis initiation. Even after adjustment for insurance, younger Black pts - but not older Black pts - have lower odds of being informed about txp options.

**The Impact of Living Versus Deceased Kidney Donation on Renal Allograft Loss Due to Recurrence of Common Glomerular Diseases** Phuong-Chi T. Pham,[1] Phuong-Thu T. Pham.[2] *[1]Nephrology Division, UCLA-Olive View Medical Center, Sylmar, CA; [2]Kidney and Pancreas Transplantation, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Recurrence of the primary kidney disease in renal allografts may reflect a persistent environmental factor or systemic condition associated with the recipient, an intrinsic inheritable kidney abnormality, or a combination of these factors. We propose that allograft loss due to recurrence of the primary kidney disease may be highest in recipients of kidneys from closely related relatives where intrinsic kidney abnormalities play a key role in recurrence and lowest in recipients of deceased donors. In conditions where environmental or recipient systemic factors play a key role in disease recurrence, minimal, if any, difference in the rates of allograft loss due to disease recurrence should be observed between deceased and living related renal transplantation. In the current study, we review the OPTN/UNOS database for the difference in Kaplan Meier rates of renal allograft loss due to disease recurrence between deceased donors and living donors, the latter further stratified by haplotype match. Primary kidney transplants performed during 1988-2003 (as of February 5, 2010) with the native renal diagnoses of diabetes mellitus (DM), IgA nephropathy (IgAN), membranous glomerulonephropathy (MGN), membranoproliferative glomerulonephropathy (MPGN), lupus nephritis (LN), and focal segmental glomerulonephropathy (FSGS) were included.

There were negligible differences in the rates of allograft loss due to disease recurrence between deceased and living renal transplantation for all aforementioned glomerulonephropathies over a 10 year follow-up. There was a trend for worse allograft loss with higher number of haplotype match in DM, IgAN, and FSGS. Most interestingly, increasing haplotype match was associated with significantly lower rates of allograft loss due to reccurence for LN (4.3 vs 2.7 vs 0.5% for zero (n=187), 1 (n=602), and 2 (n=192) haplotype match, respectively). Further studies and analyses to elucidate contributing factors for these differences are needed.

**Long-Term Compensation of Renal Function after Donor Nephrectomy Is Not Affected by Donor Factors** Dong Jin Joo, Kyu Ha Huh, Beom Seok Kim, Yu Seun Kim. *Yonsei University, Transplantation Center, Seoul, Korea.*

***Background:*** We retrospectively evaluated the factors that influence the compensatory ability of the remaining kidney after nephrectomy in donors for kidney transplantation.

***Patient and Methods:*** Follow-up renal function data of 396 donors (46.2%) were available from 857 living kidney donors from January 1999 to December 2007 at Yonsei University, Severance Hospital, Korea. The renal function was expressed as estimated glomerular filtration rate (e-GFR) was calculated by Modification of Diet in Renal Disease (MDRD) formula. Post-nephrectomy renal function was expressed as relative renal function (post-nephrectomy e-GFR ratio versus pre-nephrectomy e-GFR,%). ***Results:*** Two cases (0.05%) of renal failure resulted during 26.0±24.2 months of follow-up. The mean e-GFR decreased to 62.0±13.1 ml/min immediately after nephrectomy from 93.2±18.5 ml/min at pre-nephrectomy. Donors with high body mass index (BMI) and male sex showed a greater decrement of renal function at the immediate post-nephrectomy period (within 7 days). The long-term follow-up relative renal function significantly increased by post-nephrectomy duration. The slope of relationship between the relative e-GFR and post-nephrectomy duration was 0.176 (y=67.022+0.176*x, $R^2$=0.103, $p$<0.0001). It indicates that the estimated e-GFR increased 2.11± 3.12% of its initial e-GFR per post-nephrectomy year. Unlike the immediate post-nephrectomy change of renal function, the long-term renal function was not affected by donor factors such as age, gender and BMI. The compensation of renal function persisted after nephrectomy regardless of donor factors in univariate and multivariate linear regression analysis.

**Utility of Estimated Glomerular Filtration Rate in Live Kidney Donation** Soo Kun Lim, Kok Peng Ng, Li Ping Tan, Chew Ming Wong, Tee Chau Keng, Yip-Boon Chong, Wai Yew Kong. *Renal Unit, Department of Medicine, University Malaya Medical Centre, Kuala Lumpur, Malaysia.*

**Introduction:** Creatinine-based prediction equations have been widely used to estimate glomerular filtration rate (GFR). However, these formulas have not been validated to be used in certain group of patients, including previous kidney donors. **Objectives:** To compare the utility of GFR estimating formulae based upon creatinine and cystatin-C in assessing residual renal function after living donor nephrectomy. **Methods:** A cross-sectional study that included live kidney donors who had their nephrectomy at least 6 months before. Demographic and transplant data were collected and laboratory investigations including renal profile, cystatin-C were done. Residual kidney function was assessed using Cr-51 EDTA method. The estimated GFR (eGFR) was calculated using Cockroft-Gault formula, modified 4-variable Modification of Diet in renal Disease (MDRD) formula and cystatin C-based formula (Dade Behring Calibration). **Results:** There were a total of 38 kidney donors in this study. The median age was 52.0±10.5 years and 66% were females. Most of the donors were Chinese (76%) followed by Indians (13%) and Malay (11%). The duration of kidney donation ranged from 8 to 227 months with mean of 81.7 months. Mean serum creatinine was 96µmol/L and mean GFR was 82ml/min/1.73m$^2$. Thirty five donors (92%) have GFR of 60ml/min/1.73m$^2$ and above. Estimated GFR (eGFR) of 60ml/min/1.73m$^2$ and above was only present in 61% and 66% of the donors using MDRD and Cockroft-Gault formula respectively. Using cystatin C-based formula, the mean eGFR was 94ml/min/1.73m$^2$ and 92% have GFR of 60ml/min/1.73m$^2$ and above. Cystatin C-based formula overestimated GFR by at least 20% in almost half of the donors (47.4%). **Conclusion:** Our preliminary results showed that eGFR using creatinine-based formula is not validated in live kidney donors. Estimated GFR using MDRD and Cockroft-Gault formulas tend to underestimate the GFR. Cystatin C-based formula correlates better with GFR but can significantly overestimate the GFR in almost half of the donors. Further study is needed to validate the use of cystatin C in estimating GFR in this patient population.

**Accepting Kidneys from Older Living Donors: Impact on Transplant Recipient Outcomes** Ann Young,[1,2] Joseph Kim,[3] Mark Speechley,[2] Anjie Huang,[4] G. V. Ramesh Prasad,[3] Greg A. Knoll,[5] Darin Treleaven,[6] Michael Diamant,[1,2] Amit X. Garg.[1,2] *[1]Division of Nephrology, University of Western Ontario, Canada; [2]Department of Epidemiology and Biostatistics, University of Western Ontario, Canada; [3]Division of Nephrology, University of Toronto, Canada; [4]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; [5]Division of Nephrology, University of Ottawa, Canada; [6]Division of Nephrology, McMaster University, Canada.*

Background: Due to increasing demand for kidney transplant, selection criteria for living kidney donors have been relaxed. Older individuals are now accepted. Age-associated changes in renal morphology and function may affect transplant survival.

Methods: This retrospective cohort study examined outcomes of kidney recipients whose donors were: Older-living (≥60 years), younger-living (<60 years), and deceased standard criteria (SCD). Transplants occurred from 01/2000 to 03/2008 in Ontario, Canada. The study used Canadian health administrative data, supplemented by original medical records. The primary outcome was time to death or graft loss.
