**TH-FC001**

**De Novo Acute Kidney Injury (AKI) and Acute-on-Chronic AKI Share Similarly Poor Long-Term Survival** Michael Heung,[1] Vahakn B. Shahinian,[1] Elizabeth Hedgeman,[1] Chi-Yuan Hsu,[2] Neil R. Powe,[2] Paul W. Eggers,[3] Desmond Williams,[4] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of California San Francisco, San Francisco, CA; [3]National Institutes of Health, Bethesda, MD; [4]Centers for Disease Control and Prevention, Atlanta, GA.*

Chronic kidney disease (CKD) is a known risk factor for AKI, but comparative outcomes of acute-on-chronic AKI vs. de novo AKI are not well characterized. We sought to describe the risk for AKI in patients with and without pre-existing CKD, and to compare their long-term mortality.

A 5% sample of the national U.S. Veterans Affairs database for 2005 was analyzed for hospitalizations of ≥2 days. Patients with AKI (AKIN criteria) were categorized into those with prior CKD (60mL/min>eGFR>10mL/min) or no prior CKD. Survival was assessed up to 3 years post-admission with time-dependent Cox regression.

Incidence of AKI was 7.9% among the 16343 hospitalizations and was higher among those with prior CKD than those without (22.1% vs. 6.1%, p<0.0001). Mean age of patients with AKI was 68 years, 97.5% were male and 31.7% had pre-existing CKD; mean length of stay was 14.6 days. The overall 3-year mortality of this AKI cohort was 38.3% vs. 13.9% in those without AKI. While crude 3-year mortality was significantly higher in AKI patients with prior CKD versus those without CKD (44.3% vs. 35.6%, p<0.01), adjusted Cox regression suggested increasing survival risk over time for those with prior CKD (Table 1).

While past studies have focused on short-term or intensive care outcomes, we provide insight into long-term outcomes following AKI. Trends were toward higher short-term mortality with de novo AKI but higher long-term mortality in the acute-on-chronic group. Overall, de novo AKI and acute-on-chronic AKI share higher long-term mortality, emphasizing the need for improved AKI prevention, especially in those with CKD.

Table 1: Time-Dependent Mortality in AKI Patients by Prior CKD Status[a]

| Time Period (from hospital admission) | Hazard Ratio (Prior CKD vs. No-CKD) | 95% CI | P-value |
|---|---|---|---|
| 0-1096 days (proportionality test)[b] | - | - | 0.04 |
| 0-30 days | 0.72 | 0.49, 1.06 | 0.10 |
| 30-90 days | 0.88 | 0.59, 1.32 | 0.54 |
| >90 days | 1.18 | 0.95, 1.46 | 0.13 |

[a]Adjusted for age, sex, race/ethnicity, diabetes and hypertension status.
[b]Due to violation of proportional hazards assumption for prior CKD we included time-dependent covariates to model the varying hazard ratios over time.

**Long-Term Influence of Prior Chronic Kidney Disease on Post-Operative Patients with Acute Kidney Injury in the Surgical Intensive Care Unit: The 5 Year NSARF Experience** Hung-Bin Tsai,[1,2] Vincent Wu.[3] *[1]Department of Internal Medicine, Buddhist Dalin Tzu Chi General Hospital, Chiayi, Taiwan; [2]School of Medicine, Tzu Chi University, Hualian, Taiwan; [3]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan.*

**Background.** Prior chronic kidney disease (CKD) is among the most potent predictors of acute kidney injury (AKI) following major surgery. The long term influence after acute on CKD (ACKD) in the critical setting is poorly studied. This study was to examine whether critical patients with ACKD experience different disease courses and outcomes than merely AKI or patients with chronic dialysis. **Method.** This non-concurrent prospective, multi-center, observational study enrolled 10,903 patients admitted after major operations since 2003 to 2009 and a total of 9524 patients survived to hospital discharge. CKD was defined according to estimated glomerular filtration rate (eGFR) ≤ 45 mL/ min/ 1.73m^2 .AKI were stratified according to the maximal RIFLE classification. The baseline sCr was the data obtained at hospital discharge from the previous admission, or the nadir creatinine value during the hospital course. **Result.** During the index admission, 1379 patients expired, 4393 (46.6%) of them survived to hospital discharge had an episode of AKI: 2434 (25.8%) RIFLE-R, 979 (10.4%) RIFLE-I, 745 (7.9%) RIFLE-F and 235 (2.5%) AKI patients had prior CKD. The Cox proportional hazard model showed ACKD patients had worse long term survival (HR, 4.00; 95% CI, 3.20-5.15) than patients without prior CKD. Hazard ratio (HR) for death increased with the severity of AKI: RIFLE-f (HR, 2.96), RIFLE-I (HR, 2.42) and RIFLE-R, (HR, 1.61) then the counter part. After a median follow–up of 3.89 years, the incidence of long-term dialysis were 0.17 versus 22.4 per 100 person–years among patients without CKD and with CKD, corresponding to an adjusted HR of 19.4 (95% CI, 8.2-45.8) and 56.2 (95% CI, 26.7-118.5). **Conclusion.** The patients with prior CKD were at higher risk for long term mortality and dialysis dependence after major surgery. ACKD patients with partial renal recovery during hospitalization were associated with an increased risk of death and long term dialysis.

**TH-FC003**

**Acute Kidney Injury (AKI) Episodes as a Time-Dependent Predictor of Progression of Chronic Kidney Disease (CKD) in Diabetes Mellitus (DM)** Charuhas V. Thakar,[1,2] Annette Christianson,[2] Jonathan Himmelfarb,[3] Anthony Leonard.[2] *[1]University of Cincinnati, Cincinnati, OH; [2]Cincinnati VA, Cincinnati, OH; [3]University of Washington, Seattle, WA.*

Studies of long-term outcomes in AKI have examined the impact of a single event of AKI. We assessed the effects of AKI episodes during multiple hospitalizations as predictors of advanced CKD in a cohort of diabetics.

4,082 patients with DM, seeking longitudinal care within a VA healthcare system between 1999 - 04 were followed until 07. Primary outcome was Stage IV CKD [outpatient glomerular filtration rate (GFR) of < 30 ml/min/1.73m2]. Excluded were patients with < 3 outpatient creatinine (Cr) values (n, 278), and with baseline GFR of < 30 (n, 125), leaving 3,679 for analysis. Baseline demographics (age, gender, race), and co-morbidity information (initial diagnosis of hypertension, obesity, ischemic heart disease, congestive heart failure, peripheral vascular disease, and proteinuria) was extracted. AKI during hospitalization was defined as 0.3 mg/dl or 1.5 times increase in Cr relative to baseline. Cox-survival models examined the effect of first inpatient AKI episode vs no AKI, and up to 3 AKI episodes as time-dependent covariates, on Stage IV CKD. Covariates included demographics, baseline Cr, and time-dependent co-morbid diagnoses.

The sample was 97% male, median age was 62 yrs, and mean baseline GFR was 81 ml/min/1.73m2. Median follow-up was 62 months. 1,822 (49%) patients required >/= 1 hospitalization. 530/1,822 (29%) patients experienced at least one AKI episode during the study;30% of those experienced >/= 2 AKI episodes. Frequency of Stage IV CKD was 13% in those never hospitalized, 10% in those hospitalized but no AKI, and 23% in hospitalized with AKI (p < 0.0001). In multivariable cox-proportional hazards models, first inpatient AKI vs. no AKI was a time-dependent risk factor for Stage IV CKD [hazard ratio (hr), 3.6, 95% CI, 2.8, 4.6]; each AKI episode doubled that risk (hr, 2.0; 95% CI, 1.8, 2.3).

AKI increases risk of advanced CKD in diabetics, independent of co-morbidities in a time-dependent analysis; there is a dose-response effect associated with the number of AKI episodes.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC004**

**Predicting Which Patients Who Survive an Episode of AKI Will Progress to CKD: Validation of a Risk Score** Lakhmir S. Chawla,[1] Richard Amdur,[2] Carlos E. Palant,[2] Paul L. Kimmel.[1] *[1]Division of Renal Diseases, George Washington University, Washington, DC; [2]Research and Medical Service, Veterans Affairs Medical Center, Washington, DC.*

Intro: Patients who survive an episode of AKI are at high risk for progressing to advanced stages of CKD. Up to 20% of patients with an inpatient diagnosis of ATN progress to CKD4 or higher within 24 months. We hypothesized that if patients who survive AKI that are at highest risk for progression to CKD can be identified, opportunities to intervene might be realized.

Methods: We assessed all patients in the VA healthcare system who were admitted with a primary diagnosis indicating AKI (ARF or ATN ICD9 codes 584.xx) from 10-1-99 to 12-31-05. In the exploratory phase, we used logistic regression to test three multivariate prediction models for progression to CKD4. In the confirmatory study phase, we validated the models in all VA patients admitted for MI or pneumonia during the same time frame (CON).

Results: There were 5358 patients in the AKI population. 13.6% entered CKD4 post-admission. Full model with stepwise entry: This model was significant (p<.0001) and good predictive accuracy (ROC curve = 0.82). Simple model: Predictors tested included age, mean-albumin-during, mean-SC-during, and time at risk. This model was significant (p<.0001) and good predictive accuracy (ROC curve = 0.81) User-friendly model: Predictors entered included age, time at risk, pre-eGFR, mean-albumin, and RIFLE score. This model was significant (p<.0001), and acceptable predictive accuracy (ROC curve = 0.77). User friendly model validation- When the AKI-derived user-friendly model was tested in CON subjects, it was significant (p<.0001), and had moderate effect size (R2 = .12) and good predictive accuracy ( ROC = 0.82). Using a cut-point of -2.0, the model had sensitivity 0.76, specificity 0.63, and OR = 5.21 for those with positive compared to negative risk.

Conclusions: We developed 3 models to identify AKI survivors at high risk for progression to advanced CKD. Such tools can allow for identification of patients who should receive additional follow-up and candidates for interventional clinical trials.

**CKD, ESRD and Death after Reversible Acute Kidney Injury in Patients with Normal Baseline Renal Function** Ion D. Bucaloiu,[1] H. Lester Kirchner,[2] Evan Norfolk,[1] James E. Hartle,[1] Robert M. Perkins.[1] *[1]Nephrology, Geisinger Medical Center, Danville, PA; [2]Biostatistics and Data Core, Center for Health Research, Danville, PA.*

**Background:** Acute kidney injury (AKI) accelerates established CKD. The long term risks of de-novo CKD, ESRD, and death after reversible AKI in patients with normal baseline kidney function are unknown. **Methods:** All adult discharges with normal baseline

renal function from a tertiary medical center between January 2004 and December 2007 were identified and followed for outcomes through December 2009. The exposure of interest was reversible (to baseline eGFR) hospital-associated AKI. Patients with and without AKI were compared for the outcomes of CKD stages 3, 4, 5 and death, after propensity-score matching, using a marginal Cox proportional hazards model. **Results:** Of 21,373 eligible patients, 2,633 sustained a reversible AKI episode. Of these, 2,571 were successfully matched with up to 3 controls (n = 6,403). Median (IQR) follow up was 39.3 (28.3-50.6) months. The incident rate ratios (95%CI) of stage 3, 4, and 5 CKD, as well as death, were significantly higher in the AKI vs. non-AKI group [2.86 (2.66-3.07), 4.85 (4.08-5.76), 7.67 (5.14-11.46), 2.26 (2.05-2.49), respectively].

Adjusted long term risk of de novo stages 3, 4, and 5 CKD and death after AKI and subsequent renal recovery, among patients with normal pre-hospitalization renal function*

| Outcome | HR (95% CI) |
|---|---|
| Stage 3 CKD | 2.70 (2.52, 2.91)† |
| Stage 4 CKD | 4.80 (4.04, 5.70)† |
| Stage 5 CKD | 7.82 (5.19, 11.78)† |
| Death | 2.14 (1.94, 2.36)† |

*Model adjusted for baseline eGFR, Charlson Co-Morbidity Index, coronary artery disease, and procedure code for echocardiogram. † p < 0.0001.

**Conclusion:** A single, reversible AKI event in patients with normal baseline kidney function independently confers mortality risk, and associates with the development of CKD and ESRD.

## TH-FC006

**Comparison of Urinary L-FABP with NGAL and IL-18 in an Adult Heterogeneous ICU Population** Kent Doi,[1] Kousuke Negishi,[1] Tomoko Ishii,[1] Toshiro Fujita,[1] Takehiro Matsubara,[1] Naoki Yahagi,[1] Takeshi Sugaya,[2] Eisei Noiri.[1] *[1]University of Tokyo; [2]CMIC Co., Ltd.*

Acute kidney injury (AKI) significantly worsens the outcomes of critically ill patients. Biomarkers that detect AKI early and reflect the severity will be useful to improve the outcomes. Although several new AKI biomarkers have been reported, evaluation in heterogeneous disease-oriented populations is necessary to confirm their reliability before transition to clinical use. Three hundred thirty nine adult critically ill patients who admitted to a mixed intensive care unit (ICU) were prospectively studied. Five urinary biomarkers including L-type fatty acid-binding protein (L-FABP), neutrophil gelatinase-associated lipocalin (NGAL), IL-18, N-acetyl-β-D-glucosaminidase (NAG), and albumin were measured at ICU admission. One hundred thirty one patients (38.6%) were diagnosed as AKI by the RIFLE criteria. Urinary L-FABP could detect AKI better than the other biomarkers [the area under the receiver operating characteristic curves, AUC-ROC, for L-FABP 0.748 (95%CI 0.691–0.798), NGAL 0.695 (0.634–0.750), IL-18 0.686 (0.623–0.743), NAG 0.621 (0.558–0.680), albumin 0.687 (0.626–0.741)]. Urinary L-FABP was also able to predict later onset AKI after ICU admission. Moreover, L-FABP, NGAL, and IL-18 were able to predict 14-day mortality better than serum creatinine (sCr) [AUC-ROC for L-FABP 0.896 (0.835–0.937), NGAL 0.827 (0.688–0.912), IL-18 0.826 (0.679–0.914), sCr 0.733 (0.614–0.826)]. Multiple logistic regression analysis revealed only urinary L-FABP was associated with 14-day mortality, although urinary NGAL also showed virtually the same tendency without reaching statistical significance ($p = 0.0507$) . Combination of urinary L-FABP and NGAL achieved the highest sensitivity and specificity for mortality prediction [AUC-ROC 0.903 (0.847–0.940)]. This is the first study to compare new urinary biomarkers of L-FABP, NGAL, and IL-18 directly for AKI detection and prediction with a cohort of heterogeneous patients in a mixed ICU. Our data indicate urinary L-FABP can contribute to development of new AKI diagnostic tools in critical care.

## TH-FC007

**Comparative Analysis of Urinary Biomarkers in the Diagnosis of Acute Kidney Injury and the Prediction of Renal Replacement and Mortality at the Time of Admission to the Hospital. A Multicenter-International Study** Thomas L. Nickolas,[1] Kai M. Schmidt-Ott,[2,4,5] Pietro A. Canetta,[1] Omar H. Maarouf,[3] Meghan E. Sise,[1] Catherine Forster,[1] David Sola-Del Valle,[1] Eugenia Singer,[4,5] Saban Elitok,[5] Antje Elger,[4] Ralph Kettritz,[4,5] Friedrich C. Luft,[4,5] Jonathan M. Barasch.[1] *[1]Columbia University; [2]Max Delbruck Center for Molecular Medicine; [3]Staten Island University Hospital; [4]Charite'-Universitatmedizin; [5]Helios Clinics Berlin.*

NGAL, Kim-1, IL-18 and L-FABP are released by renal tubules in response to acute kidney injury (AKI) and along with Cystatin C have been shown in small studies to respond to stimuli (ischemia, sepsis, nephrotoxicity) which generally induce AKI. We have conducted the largest, prospective, multicenter study to date to discern the prognostic significance of urinary biomarkers. The study comprised 1677 patients entering Emergency Departments in the United States and in Germany, including 53% female, 9.5% black and 18% Caribbean Hispanics. Diagnostic adjudication, performed by a panel of nephrologists was certain or likely in 1212 patients (72.3%). AKI was found in 94 patients (7.7%), Prerenal Azotemia in 252 patients (20.8%), Stable Chronic Kidney Disease in 150 patients (12.4%), and Normal kidney function in 716 patients (59.1%). AUC-ROC for the prediction of AKI was highest for NGAL (0.81; CI 0.76-0.86) followed by Kim-1 (0.71; CI 0.65-0.76)**, LFABP (0.71; CI 0.65-0.76) ***, IL-18 (0.63; CI 0.57-0.70)***, and Cystatin C (0.65; 0.58 - 0.72)***, (** p 0.001; *** p 0.0001 vs. NGAL). Additionally, the median values of NGAL were nearly 8 fold higher in AKI than in Prerenal Azotemia, but the other biomarkers were elevated 2 or less. NGAL, Kim-1, and LFABP independently predicted a poor clinical outcome in the subsequent week in the hospital prognosticating dialysis initiation and/or mortality, when corrected for age, gender, ethnicity, comorbidities, and serum creatinine. These data show that upon presentation to hospital, urinary biomarkers have both individual and combined value in both the prediction of AKI and a poor outcome in hospital, NGAL being the most highly dynamic and discriminatory for AKI.

Disclosure of Financial Relationships: Consultancy: Abbott DiagnosticsResearch Funding: Abbott Diagnostics: A study of NGAL in the Emergency Room; Patent: Columbia University has licensed NGAL to Abbott and Biosite.

## TH-FC008

**Cystatin C: A Superior Filtration Marker for Pre-Operative Acute Kidney Injury Risk Stratification – The TRIBE-AKI Consortium** Michael Shlipak,[1] Amit X. Garg,[2] Steven G. Coca,[3,4] Jay L. Koyner,[5] Zhu Wang,[3,4] Heather Thiessen Philbrook,[2] Uptal D. Patel,[6] Prasad Devarajan,[7] Chirag R. Parikh.[3,4] *[1]SFVA; UCSF, San Francisco, CA; [2]University of Western Ontario; [3]Yale University, New Haven, CT; [4]VA CT HealthCare System, New Haven, CT; [5]University of Chicago, Chicago, IL; [6]Duke University, Durham, NC; [7]University of Cincinnati, Cincinnati, OH.*

Acute kidney injury (AKI) following cardiac surgery is associated with poor outcomes, but is challenging to predict from clinical information. The TRIBE-AKI Consortium prospectively enrolled a cohort of adults undergoing cardiac surgery at 6 academic centers during 2007-2009. All participants were at high risk for AKI, defined by one or more of the following: emergency surgery, baseline creatinine (Cr)>2 mg/dL, left ventricular dysfunction, age>70, diabetes, concomitant bypass and valve surgery, or repeat revascularization surgery. Pre-operative serum Cr was measured by each hospital's clinical lab, and eGFR was estimated by the CKD-EPI equation. Cystatin C (CysC) was measured from frozen sera by nephelometry (Siemens). Each kidney predictor was categorized as Low (quintiles 1-2), Medium (quintiles 3-4), and High (quintile 5). The outcome was AKI by AKIN Stage 1 or higher (≥0.3mg/dL or 50% rise in Cr). Analyses were adjusted for characteristics used for pre-operative risk stratification by the Society of Thoracic Surgeons. The 1,147 participants with pre-operative Cr and CysC levels had average age of 71±10, Cr 1.1±0.3, eGFR 74±9, and CysC 0.93±0.32. 407 (36%) participants developed AKI during hospitalization. CysC categories had the strongest and most linear associations with AKI. Adjusted odds ratios (95% CI) were 1.9 (1.4-2.5) for Medium and 4.4 (3.0-6.4) for High CysC, compared with 1.2 (0.9-1.6) and 2.0 (1.4-2.8) for Cr categories, and 1.0 (0.7-1.3) and 1.7 (1.2-2.4) for eGFR categories, respectively. After adjustment for clinical predictors, the c-statistic to predict AKI was 0.62 without kidney markers, 0.64 with Cr, 0.63 with eGFR, and 0.68 with CysC. In conclusion, CysC appears to offer substantial improvement over Cr and eGFR as a pre-operative marker to forecast the risk of AKI after cardiac surgery.

## TH-FC009

**Mobilization of Vascular Progenitors and Recovery of Renal Function in Humans with Acute Kidney Injury** Yuan Chung, Yuhua Li, Rhian Touyz, Lionel G. Filion, Lauralyn Mcintyre, David Allan, Kevin D. Burns. *Medicine, The Ottawa Hospital, OHRI, University of Ottawa, Ottawa, ON, Canada.*

**Background:** Endothelial-like vascular progenitor cells (VPCs) are blood-derived angiogenic precursors that may facilitate vascular repair following ischemic injury. We determined if acute kidney injury (AKI) in humans is associated with mobilization of peripheral blood VPCs, and if VPC levels correlate with renal recovery. **Methods:** After obtaining informed consent, blood samples were drawn from 30 patients admitted to the intensive care unit, at times 0, 1, 3, 7 and 14 days after diagnosis of AKI using the RIFLE criteria. VPC levels were determined by cell cluster-forming assay and cell populations enriched for angiogenic precursors were enumerated by flow cytometry. **Results:** 30 patients were enrolled (16 males, mean age 62.4 yrs) with the following RIFLE categories of AKI at time 0: Risk (n=5), Injury (n=11) and Failure (n=14). Most admissions to intensive care were due to sepsis (n=19), and 20 patients had pneumonia or others causes of respiratory failure. A significant time-dependent increase in VPC clusters was observed over 14 days following AKI in the overall cohort. Greater mobilization of VPCs was observed at 14 days in patients with more severe AKI (I and F categories at enrollment) compared with patients presenting with Risk (p=0.043) as demonstrated by increases in VPC clusters and proportion of circulating CD34+,CD133+,VEGFR2+ angiogenic precursors. In patients with improvement in renal function, there was a significantly greater mobilization of VPC clusters, compared to patients who experienced stable or worsening RIFLE scores (p<0.03). Greater VPC mobilization was also observed in patients with improvement in Sequential Organ Failure Assessment (SOFA) scores during the study period (p=0.046). **Conclusion:** Time-dependent increases in circulating VPCs occur in patients with AKI. Greater mobilization of VPCs is associated with global improvement and recovery of renal function, suggesting a potential biological role for VPCs in repair of kidney injury in humans.

**TH-FC010**

**Duration of Injury and Baseline Renal Function Define Biomarker Performance in Acute Kidney Injury** Zoltan H. Endre,[1] John W. Pickering,[1] Robert J. Walker,[2] Prasad Devarajan,[3] Charles L. Edelstein,[4] Joseph V. Bonventre.[5] *[1]Department of Medicine, University of Otago Christchurch, Christchurch, New Zealand; [2]Department of Medicine and Surgery, University of Otago, Dunedin, New Zealand; [3]Department of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Centre, Cincinnati, OH; [4]Division of Nephrology, University of Colorado, Denver, CO; [5]Renal Division, Department of Medicine, Brigham and Women's Hospital, Boston, MA.*

Background

Biomarker performance in acute kidney injury (AKI) is usually based on populations homogeneous with respect to time and type of renal insult. We investigated urinary biomarkers in a high-risk heterogeneous population.

Methods

In a prospective observational study six urinary biomarkers in 529 patients admitted to two general intensive care units, we compared diagnostic and predictive performance of urinary γ-glutamyltranspeptidase (GGT), alkaline phosphatase (AP), neutrophil-gelatinase-associated-lipocalin (NGAL), Cystatin C (CysC), Kidney Injury Molecule-1 (KIM-1) and Interleukin-18 (IL-18). Biomarker concentrations were compared using the area under the receiver operator characteristic curve (AUC) for diagnosis or prediction of AKI, dialysis or death. Performance was reassessed after stratification according to pre-admission (baseline) renal function (eGFR) and time after renal insult.

Results

On entry, all biomarkers except KIM-1 predicted death at 7 days (0.61<AUC<0.69). Without stratification, no biomarker had an AUC above 0.7 in diagnosis or prediction of AKI; NGAL, CysC and IL18 predicted dialysis with AUC>0.7. AKI was detected in patients with eGFR<60 ml/min by GGT, CysC, NGAL and IL18 with an AUC≥0.85, but only between 12 and 36 hrs after insult; with eGFR≥60ml/min, GGT detected AKI with AUC ≥0.73, IL18, with AUC≥0.63, and AP with AUC≥0.62, for up to 12 hours following insult. NGAL, with AUC≥0.68, CysC, with AUC≥0.65, and KIM1, with AUC≥0.62, detected AKI for up to 36 hours.

Conclusions

All biomarkers predicted death and dialysis. For detection of AKI in a heterogeneous population, urinary biomarker performance is critically dependent on both timing and baseline function before renal insult.

**Paneth Cell Activation after Acute Kidney Injury Causes Liver and Intestine Injury and Systemic Inflammation in Mice** Sang Won Park,[1] Mihwa Kim,[1] Kevin M. Brown,[1] Vivette D. D'Agati,[2] H. Thomas Lee.[1] *[1]Anesthesiology, Columbia University, New York, NY; [2]Pathology, Columbia University, New York, NY.*

Patients with acute kidney injury (AKI) frequently suffer from extra-renal organ dysfunction and systemic inflammation. These extra-renal complications from AKI are the leading causes of mortality in the intensive care unit. We aimed to determine the mechanisms of ischemic and non-ischemic AKI induced systemic complications. C57BL/6 mice were subjected to sham surgery, 20 min renal ischemia or unilateral nephrectomy. Both ischemic (ALT=201±22 U/l, N=6, p<0.01) and non-ischemic AKI (ALT=154±17 U/l, N=6, p<0.01) caused significant hepatic injury compared to sham-operated mice (ALT=53±6 U/l, N=6) in 5 hrs. The rises in plasma ALT correlated with focused peri-portal hepatocyte necrosis, vacuolization, neutrophil infiltration and pro-inflammatory mRNA upregulation. Plasma levels of TNF-α and IL-17A were also significantly elevated 5 hrs after ischemic (TNF-α=21.8±1.5 pg/ml, N=4, P<0.01; IL-17A=98.8±10.0 pg/ml, N=4, p<0.01) or non-ischemic AKI (TNF-α=20.5±2.9 pg/ml, N=4, p<0.01; IL-17A=103.7±12.0 pg/ml, N=4, P<0.01) compared to sham-operated mice (TNF-α=3.4±1.5 pg/ml, N=4; IL-17A=0.0±0.0 pg/ml, N=4). Neutralization or genetic deletion of TNF-α or IL-17A prevented AKI induced hepatic and intestine injury. Small intestine histology after AKI showed massive epithelial necrosis and apoptosis as well as profound endothelial apoptosis. Remarkable hyperplasia and degranulation of Paneth cells were observed. Laser capture microdissection demonstrated increased mRNAs for TNF-α and IL-17A in Paneth cells of mice subjected to AKI. Finally, wild type mice treated with dithizone to deplete Paneth cells or Paneth cell deficient (*Sox9$^{flox/flox}$;VilCre*) mice were protected against hepatic and intestine injury after ischemic or non-ischemic AKI. Taken together, we propose that Paneth cell activation/degranulation after AKI produces hepatic damage and systemic inflammation via cytokine induction and intestinal barrier dysfunction. Modulating Paneth cell dysregulation may have important therapeutic implications in reducing systemic complications arising from AKI.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC012**

**Proximal Tubular Epithelial Cell Specific Deletion of Netrin-1 Receptor UNC5B in Mice Exacerbate Ischemia Reperfusion Injury of the Kidney** Ganesan Ramesh,[1] Sutip Navankasattusas,[2] Dean Y. Li,[2] Weiwei Wang.[1] *[1]Medicine, Penn State University College of Medicine, Hershey, PA; [2]Medicine, University of Utah, Salt Lake City, UT.*

The axon guidance molecules netrin-1 was shown to regulate inflammation and apoptosis during ischemia reperfusion injury of the kidney. However, the receptor through which netrin-1 suppresses tubular epithelial cell apoptosis was unknown. Kidney proximal tubular epithelial cells are known to express specific netrin-1 receptor called UNC5B in the apical surface of the tubules. To determine whether netrin-1 mediates its protective effect against ischemia reperfusion injury of the kidney through UNC5B, we have generated a proximal tubular epithelial cell specific UNC5B knockout in mice using cre-lox technology. To enhance cre pentrance for floxed-UNC5B gene deletion, UNC5B-flox mice were mated with UNC5B heterozygous knockout mice to create UNC5B–/Flox mice. Deletion of UNC5B was confirmed by genomic PCR and immunohistochemical staining for UNC5B in kidney cortex. Tissue specific knockout mice and their littermate control mice without cre were subjected to 26 minutes or 22 minutes of ischemia followed by 72 h of reperfusion. Kidney function was monitored by measuring BUN and creatinine. Both heterozygous UNC5B knockout mice and tissue specific homozygous knockout mice are highly susceptible to kidney injury and did not survive beyond 24 h after reperfusion as compared to WT control mice. However, when these mice are subjected to mild 22 minutes of ischemia, heterozygous knockout (UNC5B–/Flox) mice without cre did not show any increase in serum creatinine where as proximal tubule specific knockout mice (UNC5B–/flox/GGT-cre) showed a dramatic increase in kidney injury as shown by increase in serum creatinine ( 0.81±0.2 vs. 0.15±0.02, p<0.001, 24h). These results suggest that netrin-1 receptor UNC5B plays critical role in tubular epithelial cell survival and deletion of UNC5B gene in mice exacerbate kidney injury.

**Deletion of VHL in the Thick Ascending Limb Protects from Ischemic Acute Kidney Injury** Gunnar Schley,[1] Bernd Klanke,[1] Kai-Uwe Eckardt,[1] Patrick Maxwell,[2] Carsten Willam.[1] *[1]Nephrology and Hypertension, University of Erlangen-Nuremberg, Erlangen, Germany; [2]Division of Medicine, University College London, London, United Kingdom.*

Ischemia is a central pathophysiological factor in the development of acute kidney injury (AKI). In murine models of AKI, like in ischemia/reperfusion experiments, tubular ischemic necrosis and activation of the hypoxia-inducible factors (HIF) occur in particular in the outer medulla of the kidney involving the proximal tubule and the thick ascending limb of Henle's loop (TAL). In this study we investigated the effects of genetic HIF induction in the TAL in ischemia/reperfusion experiments.

To target the TAL the Tamm-Horsfall protein (THP) promoter was used to drive Cre recombinase expression in transgenic mice which were then crossed with mice carrying floxed von Hippel-Lindau (VHL) gene. Ischemic AKI was induced by clamping both renal pedicles for 25 min, with 3 days of reperfusion afterwards.

TAL specific knockout of the VHL gene led to stable expression of HIF1alpha. No further HIF induction was seen in other organs and no erythrocytosis was noted. HIF1 accumulation in the TAL was associated with cellular target gene induction (e. g. Glucose transporter-1). Renal morphology and functional parameters were not different at control conditions. Clamping of the renal pedicles led to profound ischemic injury in the outer medulla. Compared to wildtype mice, VHL deletion in the TAL functionally (creatinine: sham 0,08±0,01 vs. wt 0,78±0,12 vs. ko 0,32±,03 mg/dl, p=0.003; urea: sham 48,10±3,69 vs. wt 470,86±66,53 vs. ko 185,30±21,68 mg/dl, p=0,001) and morphologically protected mice from ischemic AKI. Although VHL has several biological functions, the protective effect of VHL knockout is presumably HIF-dependent and might be mediated by HIF target genes. Our findings underscore the role of the TAL in the pathophysiology of AKI.

**TH-FC014**

**Cystathionine-γ-lyase Is an Endogenous Modulator of Oxidative Stress** Eelke M. Bos,[1,2,3] Henrike Jekel,[1] Pauline M. Snijder,[1,2] Guangdong Yang,[3] Henri G. D. Leuvenink,[2] Harry Van Goor,[1] Rui Wang.[3] *[1]Department of Pathology and Medical Biology, University Medical Center Groningen, University of Groningen, Netherlands; [2]Department of Surgery, University Medical Center Groningen, University of Groningen, Netherlands; [3]Cardiovascular Research Lab, Lakehead University, Thunder Bay, ON, Canada.*

Cystathionine-γ-lyase (CSE) is the main $H_2S$-producing enzyme in the mammalian cardiovascular system. Exogenous $H_2S$ treatment is highly beneficial in renal ischemia/reperfusion injury (IRI). Here, we investigated whether endogenous $H_2S$-production is protective against IRI, and if overexpression of CSE reduces mitochondrial ROS production.

Male C57BL/6 wildtype (WT) or $CSE^{-/-}$ were subjected to 30 min of bilateral renal ischemia. After 24h kidneys and plasma were collected. Renal $H_2S$-production rate in untreated WT and $CSE^{-/-}$ mice was measured using the Zn-trap method. HEK293 cells were transfected with pIRES2-EGFP-CSE plasmid to overexpress CSE. Mitochondrial superoxide production or or cytoplasmatic ROS level were measured using MitoSOX probe or dihydroethidine (DHE), respectively.

Renal IRI caused considerable mortality in $CSE^{-/-}$ mice, while WT mice showed no deaths post reperfusion (64% vs. 100% survival). Tubular necrotic area in the renal cortex of $CSE^{-/-}$ animals was 60% higher than that of WT ($p<0.01$). This coincides with a 91% reduced renal production of $H_2S$ in $CSE^{-/-}$ mice ($p<0.01$). In-vitro results showed that NaHS (a donor of $H_2S$) concentration-dependently reduced Antymicin A-induced mitochondrial superoxide production with a significant reduction at 10 μM (61%, $p<0.01$), max reduction at 1 mM (83%, $p<0.01$). Cytoplasmatic ROS levels were significantly reduced by NaHS at 10 μM (44%, $p<0.05$) with a max reduction at 1 mM (95%, $p<0.001$)). CSE overexpression in HEK293 cells significantly reduced the increase in MitoSOX (75%) and DHE (49%) fluorescence after Antimycin treatment when compared with mock-transfected cells ($p<0.01$).

It is concluded that endogenous $H_2S$-production by CSE plays a beneficial role in the response to renal IRI. This role is mediated in part by the antioxidant effect of $H_2S$, involving the reduction of ROS levels in both cytosol and mitochondria.

**TH-FC015**

**Absence or Blockade of SR-BI/II and CD36 Receptors Improves Sepsis Survival and Acute Kidney Injury in Mice** Asada Leelahavanichkul, Alexander V. Bocharov, Roger Kurlander, Irina Baranova, Tatyana G. Vishnyakova, Xuzhen Hu, Kent Doi, Gyorgy Csako, Robert A. Star, Thomas L. Eggerman, Peter S. Yuen. *NIDDK, NIH, Bethesda, MD.*

Class B scavenger receptors bind/internalize oxidized LDL, apoptotic cells, and bacteria, which initiates pro-inflammatory cell signaling. A synthetic SR-B antagonist, L-37pA, reduced bacterial uptake and bacteria-induced cytokine secretion. Therefore, we tested L-37pA in a cecal ligation puncture (CLP) mouse sepsis model. L-37pA reduced organ damage, including serum LDH, and improved kidney and liver function (lower creatinine/BUN/ tubule damage, AST/ALT, respectively). Serum IL-6, TNF-α and IL-10 levels were also diminished by L-37pA, indicating reduced systemic inflammation. In contrast to typical anti-inflammatory agents, L-37pA increased peritoneal granulocyte counts and modestly reduced peritoneal bacterial load. These complementary actions improved the survival rate from 6% to 27%. Mice deficient in either SR-BI/II or CD36, were further protected from CLP-induced sepsis. In both knockout strains, 2- to 3- fold less systemic inflammation and organ damage were accompanied by an 8-fold increase of peritoneal granulocyte accumulation and a ~50-fold reduction of peritoneal bacterial counts, relative to CLP in wild-type mice. CD36-deficient mice survival was 58% vs 17% in control mice. SR-BI/II- deficient mice, which showed mineralocorticoid and glucocorticoid deficiency due to defective HDL uptake, demonstrated almost 50% survival vs 5% in steroid-compensated experiments. Cultured granulocytes, deficient in either SR-BI/II or CD36, had reduced cytokine response to exogenous bacteria and lived longer (more resistant to bacteria induced cell death). Our data indicate that L-37pA promotes local peritoneal granulocyte accumulation, bacterial killing, and inhibits systemic inflammation. These results demonstrate that targeting class B scavenger receptors are anti-inflammatory and indirectly anti-bacterial, without being immunosuppressive.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC016**

**Dendritic Cell (DC) Deficiency of Sphingosine 1-Phosphate Receptor 3 ($S1P_3R$) Attenuates Natural Killer T (NKT) Cell Activation and Kidney Ischemia-Reperfusion Injury (IRI)** Amandeep Bajwa, Liping Huang, Li Li, Mark D. Okusa. *Medicine and the Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA.*

Sphingosine 1-phosphate (S1P), a sphingolipid that is the natural ligand for a family of five G-protein coupled receptors ($S1P_{1\text{-}5}Rs$), regulates cell survival, differentiation, cytoskeletal rearrangements, angiogenesis, calcium regulation, and lymphocyte circulation. $S1P_3Rs$ on vascular endothelial and epithelial cells have been linked to enhanced vascular and epithelial permeability, respectively, and dendritic cell (DC) $S1P_3R$ deficiency protects mice from lethal sepsis. Previous work has demonstrated that kidney IRI is dependent on the DC activation of NKT-mediated production of interferon gamma (IFN-γ). We hypothesized that DC $S1P_3Rs$ are involved in mediating DC-NKT interaction in kidney IRI. Both kidney pedicles were clamped in C57BL/6 mice for 26 min and then released for 24 hrs. FACS, ELISA, H&E staining and plasma creatinine (mg/dL) measurement were performed. WT mice injected with alpha-galactosylceramide (αGalCer; 10μg/mouse) had significantly higher levels of plasma IFN-γ (81.1%, $p<0.05$) at 6 and (95%, $p<0.05$) at 24h compared to $S1P_3KO$ mice. We next transferred WT or $S1P_3KO$ DCs loaded with aGalCer (DC-αGalCer) into WT mice and performed kidney IRI. Mice reconstituted with WT DC-αGalCer had more kidney IRI with higher plasma creatinine (57.1%, $p<0.01$), neutrophil infiltration (84.5%, $p<0.001$), NKT infiltration (61.9%, $p<0.001$) compared to mice reconstituted with $S1P_3KO$ DC-αGalCer. Additionally, mice reconstituted with WT DC-αGalCer prior to kidney IR had had significantly higher mRNA levels of proinflammatory cytokines (TNFα, IL-12p40, IL-1β, IL-6) and chemokines (CXCL1,2,5) compared to $S1P_3KO$ DC-αGalCer reconstituted mice. We conclude that absence of DC $S1P_3Rs$ attenuates NKT cell activation, neutrophil infiltration and proinflammatory cytokine production in response to kidney IRI. Thus the development of $S1P_3$ antagonists may lead to novel therapeutic approach for the prevention and treatment of kidney IRI.

**TH-FC017**

**CD4 T Cells and CXCL1 in Cisplatin-Induced Acute Kidney Injury** Ali Akcay, Kultigin Turkmen, Quocan Nguyen, Zhibin He, Sarah Faubel, Alkesh Jani, Charles L. Edelstein. *Univ of Colorado Denver.*

We have previously demonstrated that neither neutrophil depletion nor macrophage depletion is protective in cisplatin-induced acute kidney injury (Cis-AKI). Thus we further investigated CD4 T cells in Cis-AKI. The aim of the study was to determine the role of CD4 T cells and CD4 T cell cytokines like CXCL1 (also known as IL-8 or KC) in Cis-AKI. Mice were injected with Cis 25 mg/kg and sacrificed on days 1, 2 and 3. BUN and serum creatinine (SCr) were elevated on Day 3. Flow cytometry for CD4 T cells was performed on single cell extracts of kidney. CD45+ (common leukocyte antigen) gated events were analyzed for expression of CD3 and CD4. The increase in CD4+ cells in Cis-AKI was not seen in CD4 -/- mice. Both CD4 T cell depletion with GK 1.5 antibody (10 mg/kg IP on day 7, 3 and 0 before Cis) and CD4 T cell -/- mice were protective against Cis-AKI. SCr was 1.5 in wild type (WT) mice+Cis and 0.9 in CD4 -/- mice+Cis ($P<0.05$, n=20). SCr (mg/dL) was 2.1 in Cis+vehicle and 0.9 in Cis+GK1.5 ($P<0.05$, n=6). CD4 T cells are known to produce CXCL1. CXCL1 (pg/mg) in whole kidney was 1.4 in vehicle and 15 on day 1, 61 on day 2 and 72 on day 3 (all $P<0.01$ *vs.* vehicle, n=4). The increase in CXCL1 in Cis-AKI was decreased in CD4 T cell -/- mice demonstrating that CD4 T cells result in an increase of CXCL1 in Cis-AKI. CXCL1 (pg/mg) in whole kidney was 98 in WT mice+Cis and 21 in CD4 -/- mice+Cis ($P<0.001$, n=5). To determine whether CXCL1 is a mediator of Cis-AKI, CXCR2 -/- that lack the CXCL1 receptor were studied. CXCR1 -/- mice were protected against C-AKI. SCr was 2.6 in WT mice+Cis and 0.8 in CXCR1 -/- mice+Cis ($P<0.01$, n=10). In summary, in Cis-AKI: 1) CD4 T cell depletion is protective, 2) CXCL1 is increased in kidney, 3) CXCL1 is decreased in CD4 -/- mice, 4) inhibition of the action of CXCL1 in CXCR1 -/- mice is protective. In conclusion, the injurious effect of IL-8 from CD4 T cells merits further study in Cis-AKI.

**NGAL Reporter Mouse Illuminates Tubular Cell Stressors In Vivo** Neal A. Paragas,[1] Andong Qiu,[1] Jonathan M. Barasch.[1] *[1]Medicine, Columbia University, New York, NY; [2]; [3].*

We generated a difusion reporter knockin mouse, Ngal-Luc2/mC, under the control of the NGAL promoter. The NGAL-Luc2/mC knockin mouse was constructed by fusing luciferase (Luc2) and mCherry (mC) genes by overlap PCR and this product was inserted immediately 3' of the NGAL promoter using Bac recombineering. Unilateral IR (30 minutes) was performed on the right or left kidney of the NGAL-Luc2/mC reporter mouse while the contralateral kidney was left undisturbed as an internal control. NGAL expression was measured by both NGAL-Luc2 and NGAL-mC activities. NGAL expression was specific to the damaged kidney and was found to be dependent on the dose of ischemia, namely, NGAL-Luc2 activity rose as much as 40 fold after a 30min dose of ischemia, but only 10 fold after 15min of ischemia, whereas the contralateral kidney did not express the reporter. NGAL-Luc2 expression appeared within 3 hours of insult and conversely extinguished by 24 hours. NGAL-Luc2 activity correlated in timing and intensity with the appearance and concentration of urinary NGAL. Similar data were obtained in a bilateral IR model, sepsis model, and cisplatin nephrotoxic model. Using in situ hybridization as well as mCherry fluorescence, we show NGAL expression was expressed in the TALH and α Intercalated Cells of the Collecting Ducts. Cells extracted from NGAL Reporter Kidneys responded to nephrotoxins (cisplatin, cobalt and LPS) and bacterial products, and were modulated by novel Nf-κβ inhibitors. In contrast to these studies, simple volume depletion sufficient to increase serum Na and reduce body weight did not induce NGAL-Luc2 expression. In sum, in a living animal, Ngal-Luc2/mC revealed rapid expression, dose dependence, reversibility and kidney specificity during stressed conditions. Furthermore, we show that kidney NGAL directly correlates with uNGAL confirming reports that kidney epithelia secrete uNGAL. Additionally, primary cultures of adult kidney cells reveal that NGAL expression is mediated by Nf-κβ. Ngal-Luc2/mC mice and primary cell lines will permit the study of signaling pathways that trigger massive NGAL expression resulting in its utility as a biomarker of kidney epithelial stress.

**siRNA Against P53 Minimizes Recurrent AKI and Prevents Development and Exacerbation of CKD** Swetlana Boldin-Adamsky,[1] Silvia B. Campos-Bilderback,[2] Ruben M. Sandoval,[2] Elena Feinstein,[1] Bruce A. Molitoris.[2] *[1]Quark Pharmaceutical, Ness Ziona, Israel; [2]Dept. of Medicine/Division of Nephrology, Indiana University, Indianapolis, IN.*

Recent evidence from experimental and clinical investigations indicates repeated AKI episodes trigger CKD and accelerate its progression. Thus, prevention of AKI may minimize CKD development and reduce its progression to ESRD. As we have previously shown that siRNA against P53 (siP53) minimized ischemia/reperfusion AKI, we assessed whether its use during repeated AKI would limit CKD progression. First, we tested whether siP53 was capable of preventing CKD development caused by recurrent AKI. Male SD rats underwent 5 recurrent (at monthly interval) 45 min bilateral renal pedicle clamp followed by i.v. injection of siP53. As expected, each consecutive AKI cycle resulted in higher SCr levels in untreated rats but not in siP53 treated rats. Ten days after the fifth AKI, untreated AKI rats displayed lower 24 hr GFR ($p<0.01$) and more advanced proteinuria and histological signs of CKD than siP53-treated ($p< 0.01$). We next investigated the efficacy of siP53 in minimizing AKI exacerbation of CKD with pre-existing CKD. CKD was induced in SD rats

by unilateral nephrectomy, followed by 3-4 bimonthly cycles of AKI with rats on high salt diet. When CKD was confirmed (high SCr, proteinuria and low GFR), rats were subjected to AKI (40 min clamp) followed by treatment with either control siRNA or siP53. Dynamics of post-AKI changes of SCr indicated treatment with siP53 markedly attenuated AKI and lead to a rapid return of increased SCr levels to baseline. In contrast, SCr levels in control siRNA treated CKD rats reached 2-fold higher levels of SCr as a result of AKI and SCr remained elevated for at least one week. Histopathological evaluation showed less signs of both AKI and CKD in siP53-treated rats($p< 0.01$). Finally, we observed by two-photon in vivo imaging that Cy-3 siRNA uptake by proximal tubule cells was not impaired in CKD rats, but the cellular siRNA half-life was prolonged with CKD progression.

Thus, siP53 is efficacious with recurrent use in AKI, and prevents the development of CKD and progression of CKD in a proteinuric CKD model.

**TH-FC020**

**Sestrin2 Is Up-Regulated and Causes Autophagy of Renal Tubular Cells in the Acute Kidney Injury In Vitro and In Vivo** Masayuki Ishihara. *Endocrinology, Metabolism and Nephrology, Kochi Medical School, Japan.*

Autophagy is one of the systems which protects life from stresses. We reported autophagy occurred in mice AKI model before. Recently it was reported sestrin2(sesn2) induce osteosarcoma cells to autophagy. Autophagy is thought to play an important role for preventing AKI from stresses. However, little is known about the role of sesn2 in AKI.

The purpose of this study is to understand the roles of sesn2 in autophagy in renal tubular cells, and the regulation of sesn2 in AKI. To clarify the significance of sesn2 in AKI, we used a rat I/R AKI model in vivo and cultured renal tubular cells as an in vitro model. We observed sesn2 expression in the time course of a rat AKI model by Western blot analysis. We also evaluated sesn2 expression by immunostaining in vivo. To elucidate the regulation of sesn2, we evaluated the expression of sesn2 in MCT cells under H2O2 and hypoxia conditions by RT-PCR and Western blot analyses. Furthermore, to examine sesn2 regulates autophagy or not, we established MCT cells which stably transfected with LC3-GFP as a marker of autophagy. Using this cell line, we detect autophagy as a GFP-positive-autophagosome.

In Western blot analysis, sesn2 expressed significantly in AKI model in 3-12 hours after I/R. The peak time of sesn2 expression was 6 hours. In immunohistological examination, sesn2 expressed in the proximal tubule cells. Sesn2 gene and protein expressed strongly in the stress condition of MCT cells. Overexpression of sesn2 induces autophagy in MCT cells. In this study, we showed sesn2 expression increased in the stresses in vitro and in the AKI model in vivo. Increments of sesn2 expression caused autophagy in renal tubular cells. These results indicate the up-regulated sesn2 induces damaged tubular cells to autophagy, and play a role in the pathophysiology in AKI.

**Genome-Wide RNAi Screen Identifies a Role for the Proteasome and the MAPK Pathway in Metazoan Phosphate Sensing** Clemens Bergwitz,[1] Sumi Sinha,[1] Charles Derobertis,[1] Hway Helen Chen,[1] Meghana M. Kulkarni,[2] Michael Schnall-Levin,[3] Harald Jueppner,[1] Stephanie Mohr,[2] Bonnie Berger,[3] Norbert Perrimon.[2] *[1]Endocrine Unit and Dept. of Pediatrics, MGH, Boston, MA; [2]Dept. of Genetics, HMS/HMI, Boston, MA; [3]CSAIL, MIT, Cambridge, MA.*

Traditional sequence homology-based database searches to find metazoan orthologs of the bacterial and yeast phosphate sensors have been unsuccessful. We performed a genome-wide RNAi screen using the Drosophila hemocyte-like cell line S2R+ with phosphate-induced activation of MAPK as a readout. Members of the canonical MAPK pathway were among a set of 124 genes identified in the screen and subsequently validated with independent RNAi reagents. Using inhibitors of the MAPK and Akt pathways in S2R+ and murine C2C12 cells, we confirmed that activation of the canonical MAPK pathway in response to phosphate is evolutionarily conserved. However, our results also indicate that the MAPK pathway may not be specific for phosphate; rather, its activation by phosphate may reflect cross-talk between the insulin- and phosphate-sensing pathways. We, therefore, re-screened all 124 genes with insulin as a stimulus and identified 69 genes for which insulin-induced MAPK signaling was unaffected. Six of these phosphate-specific genes encode for regulatory subunits of the 26S proteasome. This finding was validated using the proteasomal inhibitor MG132, which blocks phosphate-induced activation of MAPK in S2R+ cells, as well as in the murine bone marrow ST2 stromal cells and rat osteosarcoma UMR106 cells. MG132, furthermore, reduces phosphate-induced expression of osteopontin in ST2 and UMR106 cells, a gene well-known to be regulated by phosphate. Proteasomal activity has been demonstrated to regulate gene expression via degradation of cytoplasmic inhibitors resulting in the activation of transcription factors, or via the select degradation of various transcription factors. Identification of the phosphate-related target(s) of the proteasome will therefore be important to understanding how phosphate activates MAPK and regulates osteopontin gene expression.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC022**

**Characterization of Phosphate Metabolism in NaPi-IIb Conditional Knock-Out Mice** Yasuhiro Ichida,[1] Hiroko Segawa,[2] Otoya Ueda,[1] Mami Kakefuda,[1] Naoshi Horiba,[1] Etsuyo Hanabusa,[2] Naoko A. Wada,[1] Takanori Tachibe,[1] Yosuke Kawase,[1] Kumiko Koguchi,[1] Ichiro Kaneko,[2] Shoji Kuwahara,[2] Sawako Tatsumi,[2] Hirotake Takai,[1] Shuichi Ohtomo,[1] Kou-Ichi Jishage,[1] Naoshi Fukushima,[1] Ken-Ichi Miyamoto.[2] *[1]Chugai Pharmaceutical Co., Ltd., Gotemba, Shizuoka, Japan; [2]Tokushima University, Tokushima, Japan.*

Elevated plasma phosphate (Pi) is a major risk factor associated with the increased cardiovascular morbidity and mortality of dialysis patients. Plasma Pi is regulated by dietary Pi intake in small intestine and secretion from kidney. Dietary Pi is efficiently absorbed (60-70%) through the small intestine by both active and passive mechanisms. Although active transport of Pi is mediated primarily via the type IIb Na/Pi cotransporter (Slc34a2/NaPi-IIb), the contribution ratio of active transport is not clear. To analyse the role of NaPi-IIb *in vivo*, we have generated *NaPi-IIb* gene knockout mice. At the last ASN meeting we reported that intestinal Pi absorption was decreased in *NaPi-IIb*$^{+/-}$ mice. This time, we generated *NaPi-IIb* conditional KO mice with a tamoxifen-inducible Cre-loxP system. After induction of *NaPi-IIb* gene disruption, *NaPi-IIb*$^{flox/-}$ mice were indistinguishable from wild-type mice littermates with respect to size, body weight, and behavior. However not only urinary Pi excretion but also plasma Pi concentration was significantly decreased in *NaPi-IIb*$^{flox/-}$ mice compared with wild-type mice. *NaPi-IIb*$^{flox/-}$ mice also exhibited significant low plasma FGF23 levels and high plasma $1,25(OH)_2D_3$ levels. Intestinal $Na^+$-dependent Pi uptake was significantly decreased in *NaPi-IIb*$^{flox/-}$ mice compared with wild-type mice. The present study indicates that the active Pi transport (NaPi-IIb) system of the small intestine plays an important role to regulate Pi absorption, and NaPi-IIb should be a potential drug target of hyperphosphateima.

**TH-FC023**

**Conditional Knock-Out of the Calcium-Sensing Receptor in Mouse Kidney** Hakan R. Toka,[1] Martin R. Pollak.[2] *[1]Nephrology, Brigham and Women's Hospital, Boston, MA; [2]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

High urinary calcium excretion is a major risk factor for the development of kidney stones. Rare gain-of-function mutations in the Calcium-sensing receptor (CaSR) can lead to high urinary calcium excretion. Furthermore, population studies suggest a role for CaSR variants in explaining human variation in renal calcium excretion. The CaSR was reported to be expressed along the entire nephron including proximal tubule, thick ascending limb and distal nephron. However the exact localization and function of CaSR in these various parts of the nephron, and its role in regulating calcium excretion are poorly understood.

A conditional CaSR KO mouse for targeted inactivation of exon 3 was generated. Germline knock-out mice showed increased embryonic lethality. Viable animals displayed failure-to-thrive with hypercalcemia and severe osteomalacia recapitulating the phenotype of neonatal severe hyperparathyroidism (NSHPT) in humans. These results confirm that deletion of exon 3 leads to complete loss of CaSR function.

A nephron-specific knock-out of CaSR was studied by crossing conditional exon3-less CaSR mouse with animals expressing Cre under the Six2 promoter. Homozygous exon3-floxed Six2Cre mice were viable without apparent phenotype. Six2Cre is expressed in the metanephric mesenchyme during kidney development and therefore targets renal tubular epithelial cells in the entire nephron except the collecting duct. RT-PCR and Western blotting showed absent CaSR protein in whole kidney of floxed Six2Cre mice. Baseline serum and urine Calcium levels as well as PTH data showed no difference between experimental and control mice. There was also no difference in serum Calcium levels when kidney-specific CaSR KO mice were challenged with increased dietary Calcium intake. These results suggest that renal expression of CaSR is not required for maintaining calcium homeostasis under basal conditions. Future experiments will address the importance of renal CaSR under conditions of dietary calcium load, PTH infusion, vitamin D loading, and phosphate depletion.

**Tissue Transglutaminase Inhibits TRPV5-Dependent Calcium Transport in a N-Glycosylation-Dependent Manner** Sandor Boros, Henrik Dimke, Rene J. Bindels, Joost G. Hoenderop. *Department of Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Tissue transglutaminase (tTG) is a multifunctional $Ca^{2+}$-dependent enzyme, catalyzing the covalent crosslinking of proteins. Recent studies have shown that the transient receptor potential vanilloid (TRPV) family of cation channels can contribute to the activity of tTG in keratinocytes and hence skin barrier formation. In the kidney, where active transcellular $Ca^{2+}$ transport via TRPV5 predominates, the potential effect of tTG remains untested. TRPV5 is regulated by a multitude of factors, many (such as klotho or tissue kallikrein) secreted into the urine, acting from the extracellular side. tTG was detected in mouse urine and in the apical medium of polarized cultures of rabbit connecting tubule and cortical collecting duct (CNT/CCD) cells. Importantly, patch clamp experiments revealed that extracellular application of tTG significantly reduced TRPV5 activity in human embryonic kidney (HEK 293) cells transiently expressing the channel. Similarly, a strong inhibition of transepithelial $Ca^{2+}$ transport was observed after apical application of purified tTG to polarized rabbit CNT/CCD cells. tTG promoted the aggregation of the plasma membrane-associated fraction of

TRPV5. Using (whole cell) patch clamp, we observed a clear reduction in the pore size after tTG treatment, indicating distinct structural changes in TRPV5 upon crosslinking by tTG. As N-linked glycosylation of TRPV5 is a key step in the extracellular regulation of channel function, we determined the effect of tTG in the N-glycosylation-deficient TRPV5 mutant. In the absence of N-linked glycosylation, the TRPV5 channel was insensitive to tTG treatment. Taken together, these observations suggest that tTG is a novel extracellular enzyme inhibiting the activity of TRPV5 via catalyzing covalent heterotetramer formation. The inhibition of TRPV5 occurs in an N-glycosylation-dependent manner, signifying a common final pathway by which different extracellular factors regulate the activity of the channel.

### TH-FC025

**Adaptations in Renal and Intestinal Phosphate Handling in the Rodent Roux-en-Y Gastric Bypass Model** Joanne Marks,[1] Marco Bueter,[2] Havovi Chichger,[1] Carel W. Le Roux,[2] Edward S. Debnam,[1] Robert J. Unwin.[1] *[1]Neuroscience, Physiology and Pharmology, University College London, London, United Kingdom; [2]Investigative Medicine, Imperial College London, London, United Kingdom.*

Recent studies have shown that phosphate (Pi) absorption by the small intestine (SI) rapidly induces changes in renal Pi reabsorption. Acute administration of a high Pi diet to rats previously maintained on a low Pi diet increases duodenal, but not jejunal, brush boarder membrane (BBM) Pi uptake and NaPi-IIb protein levels; this adaptation is associated with transient postprandial hyperphosphatemia and reduced renal BBM Pi uptake and NaPi-IIa protein expression (1). Additionally, infusion of a duodenal mucosal homogenate evokes a rapid increase in renal Pi excretion (2). The current study used the Roux-en-Y gastric bypass (RYGB) model, in which the duodenum is 'bypassed', to investigate further the gut-renal axis controlling Pi homeostasis.

RYGB or sham surgery was performed on male Wister rats according to the protocol of Bueter *et al* (3). After 16 weeks, the kidneys and segments corresponding to the duodenum (biliopancreatic limb), jejunum (alimentary limb) and ileum (common limb) were harvested for determination of Pi transporter mRNA and protein levels. RYGB resulted in a significant increase in NaPi-IIb mRNA expression in the alimentary limb (sham: 0.88±0.54 vs. RYGB: 6.78±2.17 ^^Ct, P<0.05). Interestingly, PiT1 and PiT2 mRNA expression was increased in the common limb (PiT1: sham: 2.1±0.8 vs. RYGB: 4.8±3.5 and PiT2: sham: 4.5±1.5 vs. RYGB: 21.6±9.5 ^^Ct, P<0.05). In keeping with previous findings, up-regulation of NaPi-IIb in the alimentary limb had no effect on renal NaPi-IIa or NaPi-IIc mRNA or protein levels, and it did not affect serum Pi concentration.

These findings suggest that the RYGB model may be a useful tool in defining the functional role and adaptation of different segments of the small intestine in response to dietary Pi changes, and more specifically, in exploring the mechanisms of cross-talk between the SI and kidney in controlling Pi homeostasis.

**Mechanisms of Apical Membrane Trafficking of Sodium Phosphate Cotransporters** Eleanor D. Lederer,[1,2] Syed J. Khundmiri,[2] Francesca Pribble,[2] Silvia Mercedes Uriarte,[2] Kenneth R. McLeish.[1,2] *[1]Medical Service, Robley Rex VA Medical Center, Louisville, KY; [2]Medicine, University of Louisville, Louisville, KY.*

Regulation of phosphate homeostasis is a function of the brush border membrane (BBM) expression of type IIa sodium phosphate cotransporters (Npt2a) in proximal renal tubule cells; however, the mechanisms for BBM trafficking and insertion of Npt2a are unknown. We recently found that NHERF1 deficient proximal tubule cells exhibit impaired BBM trafficking in association with a decrease in Munc-18 expression. Based on these findings, we hypothesize that Npt2a exocytosis occurs through a vesicle trafficking pathway involving SNARE (Soluble NSF Attachment Protein Receptors) protein interactions. We stimulated Npt2a forward trafficking by treating opossum kidney (OK) cells with low phosphate medium after Npt2a depletion by pretreatment with either PTH (100 nM, 6h) or high phosphate medium (24h). We examined the effect of actin depolymerization agents (Colchicine and Cytochalasin D), a dynein inhibitor (EHNA), and a SNAP23 TAT fusion peptide which inhibits SNARE protein interactions on low phosphate-stimulated Npt2a BBM expression by Western blot, confocal microscopy, and radiolabeled phosphate uptake. Pretreatment with PTH or high phosphate decreased the expression of Npt2a by 40% while subsequent treatment with low phosphate medium for 24 hours restored the BBM expression of Npt2a to control levels. The addition of actin depolymerization agents, EHNA, or the SNAP23 TAT fusion peptide in the presence of low phosphate medium blunted the increase in BBM expression of Npt2a stimulated by low phosphate medium treatment by 60%, 50%, and 60% respectively as determined by Western blot. Confocal imaging and phosphate transport confirmed the inhibition of low phosphate-stimulated Npt2a exocytosis by all three classes of inhibitors. Western blot identified the presence of SNARE proteins syntaxin 2 and 4, VAMP2, and SNAP 25 in OK cells. We conclude that exocytosis of Npt2a stimulated by low phosphate occurs through trafficking of Npt2a-containing vesicles through a pathway involving actin polymerization, dynein motor, and SNARE protein interactions.

**TRPV6 Is Downregulated by OCRL, a Protein Associated with Oculocerebrorenal Syndrome of Lowe and Dent Disease** Guojin Wu, Wei Zhang, Tao Na, Haiyan Jing, Ji-Bin Peng. *Nephrology Research and Training Center, Division of Nephrology, Department of Medicine, University of Alabama at Birmingham, Birmingham, AL.*

Oculocerebrorenal syndrome of Lowe (OCRL) gene product is a phosphatidyl inositol 4,5-bisphosphate [PI(4,5)$P_2$] 5-phosphatase, and mutations of OCRL cause Lowe syndrome and Dent disease, both of which are frequently associated with hypercalciuria. Transient Receptor Potential, Vanilloid subfamily, subtype 6 (TRPV6), is an intestinal epithelial calcium (Ca) channel mediating active Ca absorption. Hyperabsorption of Ca was found in patients of Dent disease with increased Ca excretion. In this study, we tested whether TRPV6 is regulated by OCRL and if so, to what extent it is altered by Dent-causing OCRL mutations using *Xenopus* oocyte expression system. Co-expression of OCRL decreased TRPV6-mediated Ca uptake in a dose-dependent manner. The decrease in Ca uptake was associated with lowered TRPV6 protein abundance. The PI(4,5)$P_2$ 5-phosphatase domain of OCRL alone was sufficient to downregulate TRPV6, whereas other domains alone had little effect. Deletion of RhoGAP domain in OCRL further increased the inhibitory effect of OCRL on TRPV6, and mutations that disrupt interactions between OCRL and Rab proteins, including S564P and G664D, attenuated it. Thus, the PI(4,5)$P_2$ 5-phosphatase domain is essential to the inhibitory effect of OCRL on TRPV6, and the RhoGAP and Rab binding domains are also involved in this regulation. To assess whether the regulation of TRPV6 by OCRL is impaired under Dent disease condition, the effects of 7 OCRL Dent-causing mutants on TRPV6 were evaluated. All the Dent-causing mutants of OCRL tested, including F243S, I274T, R318C, Y479C, R493W and D523N in the phosphatase domain and E737D in the RhoGAP domain, exhibited decreased ability (ranging from 0 to 80% compared to wild-type) to inhibit TRPV6. In conclusion, OCRL downregulates TRPV6 and the disruption of this regulation by Dent-causing mutations in OCRL may lead to increased intestinal Ca absorption and in turn, hypercalciuria.

### TH-FC028

**Regulation of the Epithelial Calcium Channel TRPV5 by Sex Hormones** Yu-Juei Hsu,[1,2] Shih-Che Hsu,[2] Joost G. Hoenderop,[2] Rene J. Bindels.[2] *[1]Division of Nephrology, Tri-Service General Hospital, Taipei, Taiwan; [2]Physiology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.*

Sex hormones play a key role in sex differentiation and development, as well as in the regulation of skeletal growth and maturation. Long-term female sex hormone estrogen and male sex hormone androgen deficiency resulted in a negative $Ca^{2+}$ balance and osteoporosis among elderly women and men, respectively. Studies have reported gender differences in urinary $Ca^{2+}$ excretion, showing a greater urinary $Ca^{2+}$ loss in males than in females. However, the molecular mechanisms underlying different renal $Ca^{2+}$ handling by sex hormones remain unexplored. To determine whether sex hormones affect active $Ca^{2+}$ reabsorption by regulating the $Ca^{2+}$ transport proteins Transient Receptor Potential Vanilloid-subtype 5 (TRPV5) and calbindin-D28K, the castrated mice model was used to investigate the regulation of TRPV5 and calbindin-D28K by sex hormones. Male mice, compared to females, had a higher urinary $Ca^{2+}$ excretion accompanied by reduced renal $Ca^{2+}$ transporter expression. Androgen deficient bilaterally orchidectomized (ORX) mice excreted less $Ca^{2+}$ in their urine than sham-operated controls. ORX-induced hypocalciuria was normalized after testosterone replacement. Consistently, androgen deficiency resulted in augmentation of both renal mRNA and protein abundance of TRPV5 and calbindin-D28K, which in turn was suppressed by testosterone treatment. Moreover, there is no significant difference in serum 1,25$(OH)_2D_3$ levels between controls, ORX mice, and testosterone-supplemented ORX mice. In contrast, supplementation with 17β-estradiol to ovariectomized (OVX) rats normalized renal mRNA levels of TRPV5 and calbindin-D28K and increased the protein abundance of TRPV5. This was confirmed in 25-hydroxyvitamin $D_3$ 1-1α-hydroxylase-knockout mice where 17β-estradiol replacement therapy enhanced renal expression of TRPV5, leading to the normalization of serum $Ca^{2+}$ levels. In conclusion, we demonstrated that sex differences in renal $Ca^{2+}$ reabsorption, which are mediated by the inhibitory effects of androgen and the stimulatory effects of estrogen on TRPV5-mediated renal $Ca^{2+}$ transport in a 1,25$(OH)_2D_3$-independent manner.

Disclosure of Financial Relationships: nothing to disclose

### TH-FC029

**Regulation of Intestinal and Renal NaPi Transporters by Liver X Receptor** Yupanqui A. Caldas,[1,2] Michael A. Cortázar,[1,3] Hector Giral-Arnal,[1] Victor Sorribas,[2] Judith Blaine,[1] Kayo Okamura,[1] Moshe Levi.[1] *[1]University of Colorado Denver, Aurora, CO; [2]Universidad de Zaragoza, Zaragoza, Spain; [3]Universidad del Valle, Cali, Colombia.*

The Liver X Receptor (LXR) agonists have shown to modulate the lipid composition of different tissues including the vascular tissue, the intestine, the liver and the kidney through modulation of the ATP-binding cassette transporters A1 (ABCA1) and G1 (ABCG1), which mediate reverse cholesterol transport. The effects of LXR agonists on phosphate transporters however are not known. Phosphate homeostasis is regulated by the intestinal and renal sodium-phosphate (NaPi) transporters that are expressed in the brush border membrane (BBM) of these organs. Recent studies indicate that hyperphosphatemia presumably mediated through upregulation of the NaPi transporters play an important role in cardiovascular disease. We used both an in vitro and in vivo system to study the effect of the LXR agonists on intestinal and renal NaPi transporters. C57BL/6 mice fed

chronically with either of the LXR agonists TO901317 and DMHCA show marked and significant reductions in the abundance of renal BBM NaPi transport proteins: 57% for NaPi-2a, 40% for NaPi-2c, and 30% for PiT-2, as well as intestinal BBM NaPi transporter: 66% for NaPi-2b. The decrease of the expression of these NaPi cotransporter proteins was correlated with significant decreases in the activity of 32Pi uptake, 63% in the ileum and 20% in the kidney BBM. Even more significant, serum Pi levels were decreased by 40% while Pi urine excretion was increased by 30%. After incubation for 24 hours with TO901317 and DMHCA the same effect was also observed in opossum kidney cells (OK: a cell culture model of the renal proximal tubule) where NaPi4 protein abundance (the main type II NaPi transporter in OK cells) was reduced by 55% and Pi transport by 49%. In this cell line we have demonstrated increased nuclear expression of the endogenous LXR receptor, and several of the target genes, following treatment with the LXR agonists. Our studies therefore document a novel role for the LXR agonists in modulation of intestinal and renal NaPi transporters and serum Pi levels.

## TH-FC030

**Phosphate Homeostasis in Osteocyte-Ablated Mice** Sawako Tatsumi, Seiichi Yamaguchi, Tatsuya Kamatani, Yuji Shiozaki, Kengo Nomura, Yukiko Saito, Shinsuke Kido, Hiroko Segawa, Ken-Ichi Miyamoto. *Molecular Nutrition, The University of Tokushima Graduate School, Tokushima, Japan.*

Recent studies have shown that alterations in osteocytes metabolism occur in very early stages of chronic renal disease (CKD) and likely mediate altered bone and mineral metabolism in patients with even very mild degree of renal dysfunction. The fibroblast growth factor 23 (FGF23) and dentin matrix protein 1 (DMP1) genetic mutations cause phosphorous (Pi) metabolic disorders. FGF23 and DMP1 are made primarily in osteocytes. These are suggesting that the osteocyte plays the total systemic Pi regulation. In a previous study, we have established a transgenic mouse model, based on the diphtheria toxin (DT) receptor-mediated cell knockout (TRECK) system, in which inducible and specific ablation of osteocytes is achieved in vivo (Tatsumi S et al. Cell Metab 2007). Within 48 hours of DT administration, more than 70% the osteocytes were killed. "Osteocyte-ablated" mice exhibited excessive bone resorption, impaired mineralization and adipose tissue proliferation in marrow space, all of which are hallmarks of the ageing skeleton. To analysis the role of osteocyte in Pi homeostasis, we investigated renal Pi handling in the osteocyte-ablate mice. Plasma Pi and calcium concentration were not changed in the ablated mice. Plasma FGF23 levels were significantly decreased and plasma PTH levels were not changed in the ablated mice. Urinary Pi excretion was markedly increased and renal sodium dependent Pi cotransporter NaPi-IIa and NaPi-IIc protein levels were significantly decreased in the ablated mice. Thus, the osteocyte-ablated mice show increased renal Pi excretion. We will discuss the mechanisms of hyperphosphaturia in the osteocyte-ablated mice.

**Hemodialysis in Pregnant Women with ESRD (PW-ESRD) a Tertiary Care Hospital Experience** Miguel Angel González Alfaro,[1] Enrique Rojas-Campos,[2] Benjamin Gomez-Navarro.[1] *[1]Nephrology, Hospital de Especialidades, CMNO, IMSS, Guadalajara, Jalisco, Mexico; [2]Medical Research Unit in Renal Diseases, Hospital de Especialidades, CMNO, IMSS, Guadalajara, Jalisco, Mexico.*

INTRODUCTION. There is low information regarding maternal and perinatal outcomes in Pregnant women with ESRD. We report the experience of PW-ESRD in a tertiary care hospital in the west of Mexico. METHODS. 45 pregnant women who were on HD from Jan-2006 to Dec-2009. They receive a 20-Hrs standard weekly HD (5 sessions), all conceptions were before ESRD diagnosis. RESULTS. Age 26±7 yrs; gestational age at start HD 13±6wks. All neonatal deaths require Neonatal ICU (N-ICU). Main maternal-perinatal results are shown in table.

Maternal and Neonatal Outcomes

| Variable | N=45 |
|---|---|
| Hypertension during pregnancy N (%) | 32 (71) |
| Uncontrolled hypertension | 80 % |
| Pre-eclamsia/Eclamsia N (%) | 10 (23)/4 (9) |
| Antihypertensive treatment N (%) | 35 (78) |
| Antihypertensive drugs N (min-max) | 3±1.5 (1-7) |
| Neurological complications N (%) | 5 (11) |
| Polyhidramnios N (%) | 13 (29) |
| Newborn variables | |
| Gestational age (Wks) | 28±8 |
| Weight at birth (Grams) | 1,750±634 |
| Live/neonatal death (ND)/abortion N (%) | 33(73) / 4(9) / 8(18) |
| Apgar 1/5 minutes | |
| Live | 8±1 / 9±1 |
| ND | 5±1 / 8±1 |
| Weight at birth Live/ND (grams) | 1930 / 1128* |
| Neonatal-ICU N (%) | 32 (71) |
| N-ICU Live / ND | 85%/100% |
| Diagnosis to N-ICU Live/ ND N (%) | |
| Respiratory distress | 12 (43)/4 (100)* |
| Ictericia | 16 (57) / 0 |

*p<0.05

CONCLUSION: This is one of the largest reports regarding outcome in pregnant with ESRD. The majority of patients develop and had uncontrolled hypertension, they receive 3 antihypertensive drugs. Living newborns had higher weight, higher apgar and require less frequently N-ICU.

Disclosure of Financial Relationships: nothing to disclose

## TH-FC032

**Greater Dialysate Endotoxin Level Asociated with Increased Mortality of Hemodialysis Patients in Japan** Takeshi Hasegawa,[1, 2] Shigeru Nakai,[2] Ikuto Masakane,[2] Kunitoshi Iseki,[2] Yoshiharu Tsubakihara.[2] *[1]Division of Nephrology, Showa University Fujigaoka Hospital, Yokohama, Japan; [2]Comittee of Renal Data Registry, The Japanese Society for Dialysis Therapy, Tokyo, Japan.*

**INTRODUCTION AND AIMS:** The Japanese Society for Dialysis Therapy (JSDT) has advocated the strictest standards for dialysate. The aim of this study was to evaluate the impact of water quality by dialysate endotoxin (ET) level on mortality of hemodialysis (HD) patients in Japan.

**METHODS:** We analyzed 135,814 patients on HD (at the end of 2006: on HD > one year, three times HD per week, during 2007: no changing facilities and modalities) from a nationwide annual survey of the Japan Renal Data Registry (JRDR) by the JSDT. Main exposure to be tested was ET level (EU/ml) reported by 2,942 facilities at the end of 2006 (categorized into 5groups: <0.001, 0.001 to 0.01, 0.01 to 0.05, 0.05 to 0.1, and 0.1<). Logistic regression analysis was employed to estimate the relative risk (RR) of all cause death during 2007, adjusted for age, gender, time on end-stage renal disease (ESRD), diabetes mellitus, Kt/V, normal protein catabolic rate (nPCR) , treatment time, serum albumin, and hemoglobin. Other outcome of interest was odds ratio (OR) of ET level higher than the limit level (0.05EU/ml) of the JSDT standards by attach rates of ET filter.

**RESULTS:** 92.2% of HD patients followed the limit of ET level in Japan (<0.05EU/ml). There were no significant differences in patient characteristics among groups by ET level. Patients who were exposed to greater ET level (0.1EU/ml<) displayed a 26% increased risk of all-cause death compared to those who with lower ET level (<0.01 EU/ml). Wide variation was seen across facilities in attach rate of ET filter (0 to 97.9%). Higher attach rates of ET filter associated with lower odds of exceeding the limit of ET level in Japan (<0.05EU/ml) .

**CONCLUSIONS:** These results suggested that greater ET level was related to increased risk of all-cause death in Japanese HD patients and that higher attach rates of ET filter decreased the likelihood of ET level greater than the limit advocated by the JSDT. Correcting this modifiable water management practice may improve outcomes of HD patients in Japan.

Disclosure of Financial Relationships: nothing to disclose

## TH-FC033

**Accelerated Coronary Artery Calcification and Hyperparathyroidism in Hemodialysis Patients Receiving Low Calcium Dialysate** Soo Jin Kim, Youngki Lee, Ji Eun Oh, Young Rim Song, Sung Gyun Kim, Ja-Ryong Koo, Jung-Woo Noh. *Department of Internal Medicine, Hallym Kidney Research Institute, College of Medicine, Hallym University, Seoul, Korea.*

Background: Coronary artery calcification (CAC) has been shown to be a significant predictor of cardiovascular mortality and morbidity in hemodialysis (HD) patients. Some concern regarding the calcium loading is raised as an inducer of CAC. We hypothesized that lowering of dialysate calcium levels would result in decreased the progression rate of CAC with compared to that of standard calcium dialysate.

Methods: Seventy-six HD patients were randomized to receive low calcium dialysate (LCD; 1.25 mmol/L, n=36) or continue on standard calcium dialysate (SCD; 1.5 mmol/L, n=40) for 12 months. The 64-slice multidetector computed tomography was performed at entry into the study and again at 12 months to calculate coronary artery calcium scores (CACS). Biochemical data were evaluated every 3 months.

Results: Baseline demographic or clinical characteristics were not different between two groups. Serum calcium, phosphorus and calcium x phosphorus product at baseline, 3, 6, 9, 12 month were similar in both group. However, intact-PTH levels of LCD group showed an increase at 3 month and maintained higher thereafter. At 12 month, the CACS significantly increased in LCD group and not at all in SCD group (LCD: median 64.1 at baseline *vs* 328.9 at 12 months, *P*=0.001, SCD: median 40.1 *vs* 199.7, *P*=0.9, between group *P*=0.03). There was no difference in doses of a calcium-based phosphate binder and the frequency of intradialytic hypotension between two treatments.

Conclusions: Use of LCD appears to be associated with more progression of CAC than use of SCD. While the exact mechanisms accounting for this result cannot be ascertained, increased serum PTH levels in LCD group might have influenced on the progression of CAC. However, a larger study should be undertaken to confirm these results.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC034**

**Tolerance to Hemodialysis in Insulin-Requiring Diabetic Patients: A Prospective Randomized, Cross-Over Multicenter Study between Bicarbonate Dialysis (BD) and Blood Volume Controlled Acetate-Free Biofiltration (BVC-AFB) (THIRD Study)** Antonio Santoro,[1] Ezio Movilli,[2] Elena Mancini,[1] Giovanni Cancarini.[2] *[1]O.U. Nephrology, Dialysis, Hypertension, Policlinico S.Orsola-Malpighi, Bologna, Italy; [2]O.U. of Nephrology, A.O. Spedali Civili & University, Brescia, Italy.*

To investigate a possible better tolerance to dialysis for the fragile diabetic (D) patient, eliminating acetate in the dialysate bath (AFB) and using an automatic blood volume control (BVC), we evaluated cardiovascular stability and frequency of intradialysis symptoms in a prospective,randomized,cross-over study,comparing conventional BD to BVC-AFB.

55 insulin-requiring D patients took part in the study (72% male, 28% female;68±8 years, dialysis vintage 36±15 months): 68% of them completed it (30% dropout). Each patient was treated for 3 months with BD, then for 3 months with BVC-AFB. Primary end point was the frequency of dialysis complicated by hypotensive events (systolic blood pressure value(SBP)<90mmHg, or drop of SBP>25mmHg from the predialysis value and requiring therapy). Frequency of sessions requiring nurse call/intervenction were accounted. Sessions with hypotensive events and nurse calls were analyzed by crosstabs and Chi$^2$, while the ΔSBP by ANOVA. Dialysis treatments were comparable as time lenght, weight loss, electrolyte content of the bath.BVC-AFB treatments have an 2,3±0,3 (L/h) infusion flow rate. Not all the hypotensive events required therapies or nurses inteventions. A significant reduction of ΔBP was observed.

Table1

| | BD | BVC-AFB | p |
|---|---|---|---|
| Symptomatic dialysis | 11,0% | 5,1% | p<0,01 |
| Dialysis with acute hypotension | 19,5% | 14,1% | p<0,01 |
| ΔSBP lying (mmHg) | -7,5 ± 0,6 | -0,8 ± 0,6 | p<0,01 |
| ΔHR lying (bpm) | +2,3 ± 0,3 | +0,6 ± 0,3 | p<0,01 |
| Dialysis sessions with nursing call/intervention | 17,5% | 5,4% | p<0,01 |

Main results as frequency, or M ±SEM

The BVC-AFB association seems to improve the cardiovascular response to dialysis treatment in D patients.We observed a reduction in hypotensions frequency, in ΔBP and an increase in call-free sessions. Besides, the BVC-AFB combination seems to increase the nurse time saving.

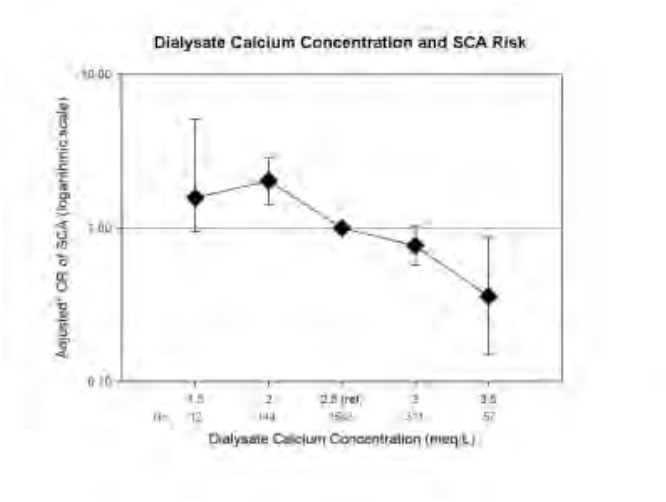
**TH-FC035**

**Sudden Cardiac Arrest Risk Associated with Low Calcium Dialysate in Hemodialysis Patients** Patrick H. Pun, Ruediger W. Lehrich, John Paul Middleton. *Nephrology, Duke University, Durham, NC.*

The optimal dialysate calcium (Ca) concentration to maintain normal mineralization and reduce risk of cardiovascular events is in debate. KDOQI guidelines suggest that the dialysate Ca concentration should be lowered to 2.5 mEq/L among patients receiving oral Ca to avoid potential risks of vascular and soft tissue calcification. However, arrhythmias may be more likely to occur with lower dialysate Ca secondary to worsening of QT prolongation. We sought to examine the influence of low dialysate Ca on the risk of witnessed sudden cardiac arrest (SCA) within dialysis clinics.

We previously designed a case control study from among 43,200 US Davita hemodialysis patients between 2002-2005. 502 patients who experienced a witnessed SCA were compared with 1632 randomly selected age and dialysis-vintage-matched controls. We examined baseline clinical and dialysis characteristics including last prescribed dialysate Ca concentration and concurrent prescription of medications associated with QT prolongation. Adjusted risk of SCA was modeled using logistic regression techniques.

82% (N=1699) of patients received dialysate Ca <=2.5 meq/L at the time of event (cases) or index date (controls). After adjusting for differences in demographics, comorbidity, serum Ca levels and other baseline differences, use of dialysate Ca<=2.5 meq/L was independently associated with risk of SCA (adjusted OR 1.5, CI 1.1-2.1). Concurrent exposure to QT prolonging medications (OR 2.23, 95% CI 1.42-3.49) and low potassium dialysate (OR 2.9, 95% CI 1.9-4.3) conferred additional risk.



Lowering of dialysate Ca concentration is associated with an increased risk of SCA. Our study suggests that inherent or acquired cardiac conduction disturbances and coincident medication exposures should be considered in addition to Ca absorption and bone turnover in determining the optimal dialysate Ca prescription.

Disclosure of Financial Relationships: Research Funding: Satellite Health Care, Davita Clinical Research; Scientific Advisor: Genzyme.

**TH-FC036**

**Dialysate Na Prescription in Patients Undergoing Conventional HD: A Stealthy Foe?** Jair Munoz Mendoza,[1,2] Sumi Sun,[2] Sheila Doss,[2] Glenn M. Chertow,[1] John E. Moran,[1,2] Brigitte Schiller.[1,2] *[1]Department of Nephrology, Stanford University, Palo Alto, CA; [2]Department of Research, Satellite Healthcare, Mountain View, CA.*

Fluid control is critical in patients with end stage renal disease (ESRD). While higher dietary sodium (Na) intake is associated with higher interdialytic weight gain (IDWG), the role of dialysate Na concentration on IDWG is less well understood. We conducted a cross-sectional study of 1084 stable, anuric hemodialysis (HD) patients to assess the relations among pre-dialysis plasma Na, dialysate Na prescription, IDWG, blood pressure (BP), and thirst. The Na gradient was calculated by subtracting plasma Na drawn prior to the first HD of the week from the dialysate Na prescription. IDWG and pre-HD BP were averaged over the previous six treatments. Self-reported degree of thirst was studied in a subset of 432 patients.

The dialysate Na prescription varied with a median dialysate Na of 140 mEq/L (range 133 to 149). 52% of patients were dialyzed at Na=140, 36% with Na >140, only 12% at Na <140 mEq/L. The mean Na gradient was 4.6, (range -7 to 24). Only one-third of patients were dialyzed with a gradient ≤ 2 mEq/L.

IDWG was higher in the dialysate Na >140 mEq/L group compared to Na=140 mEq/L (2.99 vs. 2.64 Kg) ($p<0.05$). However, there was no difference in pre-HD MAP between these two groups ($p>0.05$). Patients with a Na gradient >6 mEq/L gained on average 700 mL more per session than patients with a Na gradient ≤ 2 mEq/L ($p<0.0001$).

IDWG was estimated as 70 mL higher per each mEq/L increase in Na gradient ($p<0.0001$). Self-reported thirst was directly, albeit weakly correlated with Na gradient ($r=0.11$, $p=0.02$). Intradialytic hypotension was not significantly related to the dialysate Na concentrations ($p=0.54$) or Na gradient ($p=0.91$).

There are statistically significant and clinically meaningful associations among the dialysate Na prescription, Na gradient, and IDWG in stable HD patients. Insufficient attention to Na dialysate prescription may be an unrecognized contributor to increased IDWG in HD patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC037**

**Heparin-Grafted Dialysis Membrane Permits Minimal Systemic Anticoagulation and a Lower Anti Xa Level at Treatment End** Michele Kessler,[1] Thanh Cao Huu,[1] Alberto Gutierrez,[2] Marie-Jeanne Coudert-Krier,[3] Jan T. Kielstein,[4] Concetta Gangemi,[5] Roula Galland,[6] Françoise Moussion-Schott.[7] *[1]CHU, Nancy, France; [2]Karolinska Hospital, Stockholm, Sweden; [3]ALTIR, Nancy, France; [4]Medical School, Hanover, Germany; [5]OCM Borgo Trento, Verona, Italy; [6]Clinique St Exupery, Toulouse, France.*

**INTRODUCTION AND AIMS:** A new Hepran (H) dialysis membrane that has unfractionated heparin (UFH) grafted to its surface was evaluated for the possibility to reduce the systemic anticoagulation during hemodialysis (HD) and the resulting change in anti Xa activity at treatment end.

**METHODS:** In a prospective multicenter clinical study in stable HD patients (n=41), the H membrane was first used with the previous heparin (hep) dose followed by a stepwise weekly reduction of hep dose. Heparin reduction was stopped when two or more treatments in a week showed very early signs of clotting (circuit pressures, signs of clot formation, quality of rinse-back using a visual scale).

**RESULTS:** Regardless of the type of hep used, with the H membrane, the hep dose was reduced from 68±17 to 38±14 IU/kg for 29 patients lowering antiXa at treatment end from 0.45±0.26 to 0.22±0.11 IU/ml (p<0.001) (51% reduction).The reduction of the usual hep dose (64±14 to 35±12 IU/kg for LMWH and 81±18 to 45±13 IU/kg for UFH) resulted in an antiXa level at treatment end of 0.25 ± 0.11 IU/ml for LMWH and 0.14 ± 0.07 IU/ml for UFH-treated patients. Failure to further decrease hep dose was related to signs of clotting in blood lines (56%), in dialyzer (10%), or both (33% of treatments). For 12 patients (1 LMWH ,11 UFH patients) for whom hep dose reduction was not possible (usual hep dose 76±21 IU/kg), usual AntiXa level at treatment end was 0.23 ± 0.08 IU/ml. **CONCLUSIONS:** When using the H membrane significant reduction of pre-study hep dose and post-HD anti Xa level was possible in regular HD patients. Different responses in LMWH and UFH groups may relate to different ways of hep administration and patient profiles. Our data indicate that a heparin-grafted membrane can be beneficial for HD patients who require low anti Xa activity at the end of treatment to reduce bleeding risk and possibly other heparin side effects

Disclosure of Financial Relationships: nothing to disclose

## TH-FC038

**Increasing Dialysate Flow Rate in Dialyzers with Enhanced Dialysate Flow Distribution Does Not Increase the Delivered Dose of Dialysis in Terms of $Kt/V_{urea}$** Richard A. Ward,[1] John W. Idoux,[2] Rosemary Ouseph,[1] Thomas A. Depner,[3] Thomas A. Golper.[2] *[1]Medicine, University of Louisville, Louisville, KY; [2]Medicine, Vanderbilt University, Nashville, TN; [3]Medicine, University of California Davis, Sacramento, CA.*

Previous in vitro and clinical studies showed that the urea mass transfer - area coefficient ($K_oA$) increased with increasing dialysate flow rate. This observation led to increased dialysate flow rates in an attempt to maximize the delivered dose of dialysis ($Kt/V_{urea}$) during a given treatment. Recently, we showed that urea $K_oA$ was independent of dialysate flow rate in the range 500 - 800 mL/min for dialyzers incorporating features to enhance dialysate flow distribution. This finding suggested the hypothesis that increasing the dialysate flow rate with such dialyzers will not significantly increase delivered $Kt/V_{urea}$. To test this hypothesis, we performed a multi-center randomized clinical trial of dialysate flow rates, 600 mL/min (A) and 800 mL/min (B), in 28 patients using an ABAB or BABA sequence. All other aspects of the dialysis prescription, including treatment time (223 ± 33 min), blood flow rate (435 ± 23 mL/min), and dialyzer (Revaclear or Revaclear MAX), were kept constant for a given patient. Delivered $Kt/V_{urea}$ was determined as single-pool (Kt/Vsp) and equilibrated (eKt/V) $Kt/V_{urea}$ from pre- and post-dialysis plasma urea concentrations according to Daugirdas and as ionic Kt/V from serial measurements of ionic dialysance made throughout each treatment. The three measures of $Kt/V_{urea}$ are shown in the table for the two dialysate flow rates.

| Dialysate Flow Rate | Kt/Vsp | eKt/V | ionic Kt/V |
|---|---|---|---|
| 600 mL/min | 1.67 ± 0.04 | 1.39 ± 0.03 | 1.44 ± 0.04 |
| 800 mL/min | 1.65 ± 0.04 | 1.38 ± 0.03 | 1.48 ± 0.04 |

Data presented as mean ± SE for n = 28

By analysis of variance, there was no significant difference between the two dialysate flow rates in any of the three measures of $Kt/V_{urea}$ ($p > 0.284$). These data suggest that increasing the dialysate flow rate beyond 600 mL/min for these dialyzers offers no benefit in terms of delivered $Kt/V_{urea}$.

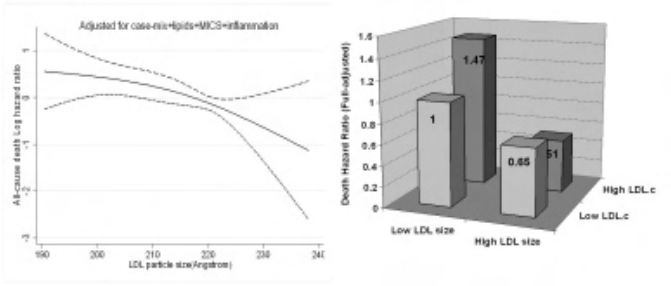
**Novel LDL Particle Diameter Measurement by Ion Mobility Predicts Mortality in Maintenance Hemodialysis Patients** Nazanin Noori,[1] Csaba P. Kovesdy,[2] Michael Caulfield,[3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]Nephrology, Salem VA, Salem, VA; [3]Quest Diagnostics, Irvine, CA.*

**Background:** It is not clear whether different aspects of LDL-cholesterol other than its conventionally measured concentration are associated with mortality in maintenance hemodialysis (MHD) patients. We hypothesized that the LDL particle diameter, measured by novel ion mobility method, may be a better outcome predictor. **Methods:** We examined the survival predictability LDL particle diameters using Cox proportional hazard regression in 235 MHD patients who were followed for up to 6 years (2001-07) and performed incremental levels of multivariate adjustment for case-mix (age, gender, race, diabetes, dialysis vintage , Charlson comorbidity score and Kt/V), malnutrition-inflammation complex syndrome (albumin, creatinine, phosphorus, calcium, ferritin, hemoglobin, nPNA [nPCR]; and body mass index).and additional inflammatory markers (CRP, IL-6, and TNFα).**Results:** The highest quartile of LDL particle diameter (compared to the lowest quartile) was associated with a 54% greater survival (see spline figure): Death hazard ratio (95% confidence interval) was 0.46 (0.21-0.98). Lower mortality persisted with higher LDL diameter (above median) when combined with either high or low total LDL concentration (see bar diagram).



**Conclusions:** Larger LDL particles appear associated with greater survival in MHD patients independent of LDL concentration or other confounders. Use of LDL subfraction morphology in risk-stratification of dialysis pts warrants additional studies.

## TH-FC040

**Sleep-Disordered Breathing Is a Novel Risk Factor for Cardiovascular Events and Mortality in Hemodialysis Patients** Takahiro Masuda,[1,2] Mitsunobu Murata,[3] Sumiko Honma,[1] Yoshitaka Iwazu,[2] Nobuhiro Sasaki,[1,2] Manabu Ogura,[2] Akira Onishi,[2] Yasuhiro Ando,[2] Shigeaki Muto,[2] Kazuomi Kario,[3] Eiji Kusano,[2] Yasushi Asano.[1] *[1]Department of Nephrology, Koga Red Cross Hospital, Koga, Ibaraki, Japan; [2]Division of Nephrology, Department of Medicine, Jichi Medical University, Shimotsuke, Tochigi, Japan; [3]Division of Cardiovascular Medicine, Deparment of Medicine, Jichi Medical University, Shimotsuke, Tochigi, Japan.*

Sleep-disordered breathing (SDB), characterized by repetitive apnea and hypopnea during sleep, is a risk factor for cardiovascular events in the general population. However, the links between SDB and cardiovascular events in hemodialysis (HD) patients remains unclear. We followed the clinical outcome of 94 HD patients, who underwent overnight pulse oximetry on dialysis day. The SDB group was defined as 3% oxygen desaturation index (3%ODI) over 5 events per hour, and the others were the normal group. Forty-four patients (46.8%) were classified into the SDB group. Body mass index (BMI), diabetes mellitus, 3%ODI and Epworth Sleepness Scale, a questionnaire about daytime sleepiness were significantly higher; and duration of dialysis, Kt/V, normalized protein catabolism rate (nPCR) and hemoglobin were lower in the SDB group than in the normal group. During a median 55 months follow-up, Kaplan-Meier analysis revealed that the SDB group had significantly higher cardiovascular events and all-cause mortality than the normal group. Age, cardiothoracic ratio, serum albumin and 3%ODI were predictors of cardiovascular events and all-cause mortality at univariate Cox regression analysis. After adjustment for age, gender, BMI, duration of dialysis, diabetes mellitus, Kt/V, nPCR, cardiothorac ratio, systolic blood pressure, hemoglobin, serum albumin and total cholesterol, SDB is an independent predictor of increased cardiovascular events (hazard ratio 2.93; 95% confidence interval [CI], 1.13-7.61; *P*=0.027) and all-cause mortality (hazard ratio 3.73; 95% CI, 1.03-13.54; *P*=0.045).These results indicate that SDB is a novel risk factor for cardiovascular events and mortality in HD patients. Effective and earlier treatment for these patients is needed to improve clinical outcome.

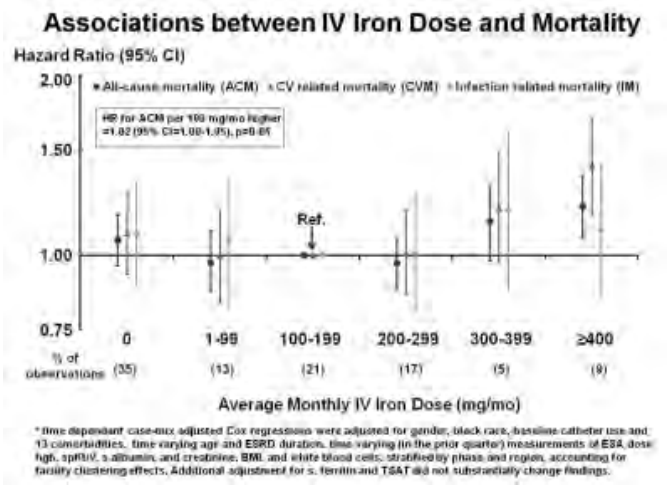
## TH-FC041

**Association of Intravenous Iron (ivFe) Dosing with Mortality: Findings from the DOPPS** George R. Bailie,[1] Lin Tong,[2] Yun Li,[3] Nancy A. Mason,[3] Ronald L. Pisoni,[2] David A. Goodkin,[2] Francesco Locatelli,[4] Mark R. Marshall,[5] Masaaki Inaba,[6] Bruce M. Robinson.[2,3] *[1]Albany College of Pharm. & Health Sci.; [2]Arbor Research; [3]Univ. of Michigan; [4]Ospedale A. Manzoni; [5]Middlemore Hosp.; [6]Osaka City Univ. Grad. Sch. of Med.*

Previous studies found equivocal associations between ivFe and clinical outcomes but did not compare countries. We examined associations between ivFe dosing and mortality using international Dialysis Outcomes and Practice Patterns Study (DOPPS) data.

IvFe data were collected from 2002 to 2008 for 20,445 HD pts in 584 facilities in US, Jap, Australia, Can, NZ and 7 European countries. Using time dependent, case-mix adjusted Cox regression, we examined associations of longitudinal ivFe use with all-cause (ACM), cardiovascular (CVM), and infection-related (IM) mortality for 4-month ivFe dose categories (expressed as average dose/mo). Instrumental variable analysis (using facility as the instrument) was also performed due to potential for confounding of pt-level ivFe dosing by indication.

In the 1st 4-mo after study enrollment, % receiving ivFe ≥400 mg/mo varied from 0.7% (Jap) to 21% (Swed). Compared to pts receiving ivFe 100-199 mg/mo, pts with average dose ivFe ≥400 mg/mo had 21% higher risk of ACM, 41% higher risk of CVM, and no elevation of IM risk (Figure). Higher total ivFe dose over 1 year was associated with increased risk of ACM (HR per 100 mg/mo higher =1.05 [95% CI=1.01-1.09], p=0.02). Instrumental variable analysis yielded consistent findings (elevated mortality risk at average monthly ivFe ≥400 mg, p=0.02 for ACM and 0.007 for CVM).



IvFe dosing varies across HD facilities and countries. Higher ivFe doses (above 300 or 400 mg/mo) are associated with higher ACM and CVM. Differences by region, ivFe agent, and use of regular maintenance doses compared with intermittent repletion, require evaluation.

### TH-FC042

**The Beneficial Effect of Dual Renin-Angiotensin System (RAS) Blockage Against Peritoneal Membrane Dysfunction in CAPD Patients: A Randomized Controlled Study** Talerngsak Kanjanabuch,[1,2] Wassawon Wontanatawatot,[1] Piyatida Chuengsaman,[3] Pisut Katavetin,[1] Somchai Eiam-Ong.[1] *[1]Chulalongkorn University, Thailand; [2]Kidney&Metabolic Disorders Research Center, Thailand; [3]Banphaeo Hospital, Thailand.*

To investigated the protective effect of RAS blockades over peritoneal membrane dysfunction in CAPD patients.

**Patients&Methods:** A stratified randomized controlled single-blinded study was conducted in 93 hypertensive (HT) & naïve CAPD patients. There were 3 groups of patients: 1) ACEI (enalapril 40 mg/day,N=31), ACEI+ARB (40mg-daily enalapril+50mg-daily losartan,N=31), and Placebo (N=31). The dosage of anti-HT agents in all groups were titrated to achieve the target BP≤130/80 mmHg. Peritoneal equilibration test with 3.86%G solution, 24-hr dialysate protein, 8-hr dialysate CA125, residual renal function (RRF), and dialysis adequacy were examined at the beginning and 6-month periods.

**Results:** 69 patients had completed study. Half of patients in all groups had diabetes. No differences were observed in baseline demographics, including peritoneal membrane parameters. The mean arterial BP level after treatment was not different among groups and throughout the study period. There were significant improving of these parameters in the ACEI and ACEI+ARB groups when comparing with the Placebo: D/D0 glucose (0.45±0.05 *vs.* 0.36±0.05 *vs.* 0.31±0.04, $p$=0.03), 24-hr net UF (1,114.6±497.7 *vs.* 855.7±357.0 *vs.* 690.0±289.4 ml., $p$=0.01), 24-hr dialysate protein loss (3.5±0.4 *vs.* 4.5±0.4 *vs.* 5.3±0.4 gm, $p$<0.01), serum albumin (3.7±0.4 *vs.* 3.8±0.4 *vs.* 3.2±0.5 gm/dl, $p$<0.01), dialysate CA125 appearance rate (63.5±54.5 *vs.* 76.7±64.9 *vs.* 37.1±19.2 U/min, $p$<0.01). Adding ARB to ACEI showed further increments of serum albumin and dialysate CA125 appearance rate compared to single RAS blockage. Although adequacy and $D/P_{Cr}$ were no significant differences at 6 mo among 3 groups, there were trend to improvement in both treatment groups. RAS blockades did not yield in serious adverse effects including hyperkalemia.

**Conclusions:** Blocking of RAS significantly increased UF and preserve peritoneal membrane function CAPD patients. RAAS Blockage should be selected as a first-line anti-HT agent in CAPD patients.

Disclosure of Financial Relationships: nothing to disclose

### TH-FC043

**Has the Probability of Death on Peritoneal Dialysis Been Overestimated? The Importance of Competing Risks in Survival Analysis** Jean-Baptiste Beuscart,[1,2] Dominique C. Pagniez,[2] Celia Lessore,[2] Luc Frimat,[3] Alain Duhamel.[1] *[1]Biostatistics, EA2694, UDSL, Lille, France; [2]Nephrology, CHU Lille, France; [3]Nephrology, EA 4003, CHU Nancy, France.*

Background: The Kaplan-Meier method may be suboptimal in survival analysis on peritoneal dialysis (PD). This method considers one event only, usually death. Transfer to haemodialysis (HD) and renal transplantation are not taken into account, although these events alter the probability of death and hinder its observation in PD. It has been shown in other fields of medicine that the competing risks method was more appropriate in such situations.

Methods: All consecutive incident patients starting PD in our center between 1992 and 2008 were enrolled in this study. Cumulative incidence was estimated for death during PD, transfer to HD, and renal transplantation, using both the Kaplan-Meier and the competing risks methods.

Results: At five years, of 383 patients included, 107 (28%) had died during PD treatment, 109 (28%) had been transferred to HD, and 91 (24%) had underwent renal transplantation. The Kaplan Meier method systematically overestimated the probabilities of these events: the estimated risks at five years were 50% for death, 59% for transfer to HD, and 39% for renal transplantation.

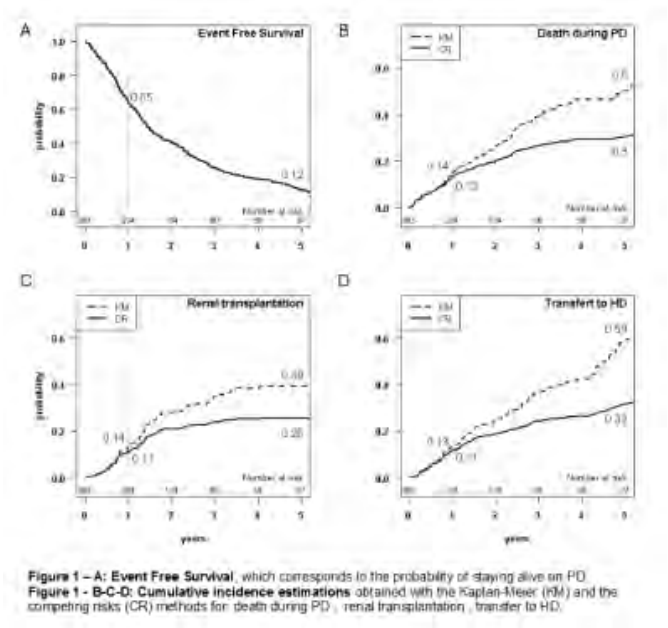

**Figure 1 – A: Event Free Survival**, which corresponds to the probability of staying alive on PD.
**Figure 1 - B-C-D: Cumulative incidence estimations** obtained with the Kaplan-Meier (KM) and the competing risks (CR) methods for: death during PD , renal transplantation , transfer to HD.

The sum of these three probabilities exceeded 100% at five years, which means that patients are expected to experience more than one event, which is impossible. With the competing risks method, the estimated probabilities for death during PD, transfer to HD and renal transplantation were 30%, 32% and 26% at five years, respectively. The sum of probabilities estimated with this method never exceeded 100% at any times.

Conclusion: The competing risks method appears to be a more appropriate and reliable way than the Kaplan Meier method to estimate the probability of events in PD.

### TH-FC044

**Higher eGFR at Dialysis Initiation Is Associated with Increased Mortality** William F. Clark,[1] Yingbo Na,[2] Steven J. Rosansky,[3] Jessica M. Sontrop,[1] Jennifer J. Macnab,[1] Richard J. Glassock,[4] Paul W. Eggers,[5] Kirby L. Jackson,[3] Louise M. Moist.[1] *[1]University of Western Ontario; [2]Canadian Institute of Health Information; [3]University of South Carolina; [4]UCLA; [5]National Institute of Diabetes and Digestive and Kidney Diseases.*

Background: Recent studies report a trend towards earlier dialysis initiation [at higher levels of glomerular filtration rate (GFR)], and an association between early initiation and increased mortality. Here, we examine trends in hemodialysis initiation within Canada, and compare the mortality risk between early and late dialysis initiators.

Methods: The analytic cohort included 25,901 incident hemodialysis patients >18 years from the Canadian Organ Replacement Registry (2001-7). Early dialysis initiation was defined as estimated GFR >10.5 mL/min/1.73m$^2$. Time-dependant proportional hazards Cox models were fitted to compare the risk for mortality between early and late dialysis initiators.

Results: From 2001-7, mean eGFR at dialysis initiation increased from 9.3 (+/-5.2) to 10.2 (+/-7.1) (p<0.001) and the proportion of early starts rose from 28% [95% confidence interval (CI): 27%-30%] to 36% (95% CI: 34%-37%). Mean eGFR among early vs. late starts was 15.5 (+/-7.7) and 7.1 (+/-2.0), respectively. The unadjusted hazard ratio (HR) for mortality in early vs. late starts was 1.48 (95% CI: 1.43-1.54), which decreased to 1.18 (95% CI: 1.13-1.23) after adjusting for demographics, comorbidities, serum albumin, vascular access and transplant status. The mortality differential between early and late initiators per 1000 patient-years narrowed after one year of follow-up, but never crossed and began widening after 24-months of follow-up; differences were significant at 6, 12, 30 and 36 months.

Conclusion: In Canada, patients are initiating hemodialysis at increasingly higher levels of eGFR. A higher eGFR at dialysis initiation is associated with an increased risk for mortality that is not fully explained by differences in baseline characteristics.

**TH-FC045**

**Weekend Admissions Predict Higher Mortality in Patients with End Stage Renal Disease** Ankit Sakhuja, Nilay Kumar, Rahul S. Nanchal, Aaron T. Dall, Gagan Kumar. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

**INTRODUCTION:**
End stage renal disease (ESRD) is common medical condition affecting an increasing number Americans. Patients are commonly admitted with acute care issues like infection or electrolyte disturbances. There are limitations to hemodialysis services and manpower on weekends. Poor outcomes on weekends for acute medical conditions have been described in acute renal failure. We hypothesize that weekend admissions are associated with higher mortality and fewer hemodialysis procedures compared to weekdays.

**METHODS:**
Retrospective case control design was utilized to analyze the Nationwide Inpatient Sample from year 2007. Adult patients (age ≥ 18 years) with ESRD admitted on weekdays formed the controls and patients admitted on weekends formed the cases. Primary outcomes measured were all cause in-hospital mortality and use of hemodialysis on weekends. Pearson correlation and Chi square were used to compare the variables for unadjusted analysis and logistic regression was used to obtain adjusted odds ratios. α was set at 0.05.

**RESULTS:**
Of the 836,550 estimated admissions with ESRD, 19.7% were admitted on a weekend. Patients admitted on a weekend had significantly higher mortality (7.6% vs. 6.6%) than those admitted on a weekday. After adjusting for age, sex, race, patient's co-morbidities and hospital characteristics, the mortality was found to be significantly higher on the weekend (OR 1.17, 95%CI 1.11-1.24). The time to dialysis was 0.29 days longer (95%CI 0.21-0.36) on weekends.

**CONCLUSIONS:**This nationwide inpatient observational study holds up the inference that weekend admissions of ESRD patients have significantly increased mortality over weekday admissions. Other factors that affect this 'weekend phenomena' warrant further studies.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC046**

**The Effect of Hemodiafiltration on Quality of Life in a Randomized Controlled Trial (CONTRAST Study)** Albert H. Mazairac,[1] G. Ardine De Wit,[2] E. Lars Penne,[1,3] Neelke C. Van Der Weerd,[1,3] Claire H. Den Hoedt,[1,4] Muriel Grooteman,[3] Marinus A. Van Den Dorpel,[4] Pieter M. Ter Wee,[3] Michiel Bots,[2] Peter J. Blankestijn.[1] *[1]UMCU, Utrecht, Netherlands; [2]JULIUS, Utrecht, Netherlands; [3]VUmc, Amsterdam, Netherlands; [4]Maasstad Hospital, Rotterdam, Netherlands.*

**Background:** It is unclear if hemodiafiltration (HDF) leads to a preferable health status as compared to hemodialysis (HD). The overall results of small randomized trials or observational studies are indecisive.

**Aim:** To assess the effect of HDF on quality of life (QOL) as compared to HD in a cohort of chronic dialysis patients.

**Methods:** We performed a 24 month analysis in 312 patients from the CONvective TRAnsport Study (CONTRAST; NCT00205556), an ongoing randomized controlled trial on the effect of online HDF versus continuation of low-flux HD on all-cause mortality. QOL was assessed with the KDQOL-SF. This questionnaire provides data for a physical (PCS) and mental (MCS) composite score, and describes kidney disease-specific QOL in 12 domains.

**Results:** Over 24 months time, the PCS and MCS declined in HD patients (ΔPCS: -3.0 points, 95% CI -5.0 to -1.0, p=0.001; ΔMCS: -2.3 points, 95% CI -4.5 to -0.1, p=0.043), but not in HDF (ΔPCS: -0.9 points, 95% CI -2.8 to 1.0, p=0.827; ΔMCS: -0.4 points, 95% CI -2.2 to 1.4, p=1.00). As both domains were somewhat better at baseline in HD patients, this did not lead to statistical significant differences in generic QOL between HD and HDF (PCS: p=0.07; MCS: p=0.09). Kidney disease-specific QOL domains did not vary between both dialysis modalities over 24 months. There was a strong decline in patient satisfaction in both HD (-11.1, 95% CI -16.1 to -6.1, p<0.001) and HDF patients (-10, 95% CI -16.8 to -3.3, p=0.001).

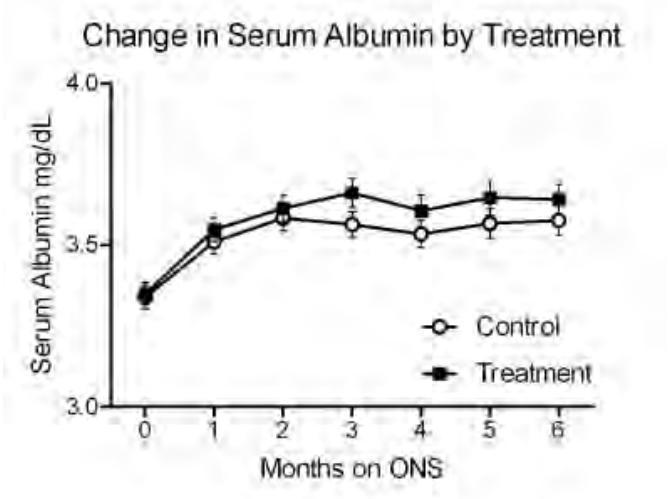
**Conclusion:** Whereas generic QOL declined in HD patients over time, it remained stable in HDF. After 24 months of follow-up, these changes did however not reach a statistical significant difference between HD and HDF. The remarkable decline in patient satisfaction over time needs further evaluation.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC047**

**Oral Nutritional Supplement (ONS) Provided during Dialysis Is Not Superior to Dietary Counseling Provided by Registered Dietitians (RDs) in Improving Serum Albumin** Deborah A. Benner, Mary B. Burgess, Marcia Davis, Steven M. Wilson, Tracy Jack Mayne, Allen R. Nissenson. *DaVita Inc., Denver, CO.*

**Background:** In hemodialysis (HD) patients, albumin is decreased by nutritional factors (protein, calorie, vitamin, and fluid intake) as well as non-nutritional factors (infection, inflammation, catabolism, and surgery). The extent of nutritional vs. non-nutritional factors affect albumin levels in HD patients is not well understood. **Objective:** Determine the effect of a 3 times-a-week ONS provided during dialysis vs. nutritional counseling alone on serum albumin levels in malnourished (serum albumin <3.5 g/dl) prevalent maintenance HD patients. **Methods:** Phase 4 trial with HD patients randomized to receive 1 serving of ONS during each dialysis treatment along with nutritional counseling (n=63) vs. nutritional counseling alone (n=72) for 6 months. Nutritional counseling was standardized for both groups and provided by RDs. Additional ONS use was prohibited. The primary endpoint was change in serum albumin from baseline to months 3 and 6. Primary analysis was conducted using mixed linear models. **Results:** There was a main effect of time between months 0 and months 3 & 6, but no significant effect of treatment group or treatment by time iteration on serum albumin. Pre-albumin levels did not differ by treatment at baseline (treatment 22.9 ± 1.1 mg/dL vs. control 23.6 ± 1.1 mg/dL) or month 6 (treatment 26.0 ± 1.4 mg/dL vs. control 23.1 ± 1.4 mg/dL).



**Conclusion:** Both groups showed improved serum albumin. The addition of an ONS (425 kcal /19 g protein), provided 3x/wk during dialysis, however, was not superior to nutritional counseling alone, when provided by RDs. It is not known whether more frequent ONS would have a greater effect on albumin. These results reinforce the importance of the dietitian's role in modifying patient behavior to improve biomarkers.

**TH-FC048**

**Chronic Inflammation and Interleukin 1 beta (IL-1b) Inhibition in Chronic Hemodialysis (CHD) Patients** Adriana Hung,[1,2] Charles D. Ellis,[1] Ayumi Shintani,[1] Cindy Booker,[1] T. Alp Ikizler.[1,2] *[1]Vanderbilt University, TN; [2]Nashville VA, Nashville, TN.*

Chronic inflammation is highly prevalent in CHD patients and has been consistently associated with poor outcomes. IL-1b is a major pro-inflammatory cytokine which is elevated in CHD patients. IL-1 family gene polymorphism has also been associated with development of ESRD. A balance between IL-1b and its naturally occurring receptor antagonist IL-1ra may play a pivotal role in controlling the inflammatory response and its consequences in this population.

We conducted a pilot and feasibility double blinded RCT to evaluate the safety and the efficacy of the administration of recombinant human IL-1ra (Anakinra) on biomarkers of inflammation and nutrition. Inclusion criteria included hsCRP > 5 mg/dL for 3 consecutive months. Exclusion criteria included active infection and use of HD catheters.

Seventeen CHD patients (mean age 49±13 yrs, 71% African American, 71% males, 21% diabetics, mean BMI 31.8 ± 8, mean KTV 1.60±0.33, median vintage 35 months) were randomly assigned to placebo or Anakinra (100 mg at each HD session for 4 weeks) in a 1:1 ratio. The median CRP and IL-6 at baseline were 10.8 mg/dL (IQR 7.85, 17.4) and 4.76 pg/mL (IQR 2.89, 10.6), respectively. Patients in the intervention arm had a mean % drop in serum CRP of 53% vs. 1% in the placebo arm (p=0.008) and a mean % drop in IL-6 of 40% vs. a mean increase of 20% in the placebo arm (p=0.03). Serum pre-albumin increased 23% in the intervention arm and 6% in the placebo arm (p=0.1). Serum albumin increased by 3% in the intervention arm and there was no change in the placebo arm. There were no serious adverse events but there were two injection site reactions and a mild soft tissue infection at the access site in the intervention arm--these 3 subjects were withdrawn from the study, but 1 had outcomes recorded. A subject had asthma requiring steroid in the placebo arm was also withdrawn.

Administration of IL-1ra is safe and effective in lowering biomarkers of inflammation in CHD patients. These data provide strong rationale for future studies evaluating the impact of this anti-cytokine treatment on other intermediate and long-term (hospitalization and death) outcomes.

**TH-FC049**

**Rosuvastatin and LDL-Cholesterol in Diabetic Patients Receiving Hemodialysis – A Post Hoc Analysis of the AURORA Trial** Hallvard Holdaas,[1] Bengt C. Fellstrom,[2] Ingar Holme,[3] Roland E. Schmieder,[4] Faiez Zannad,[5] Alan G. Jardine.[6] *[1]Oslo University Hospital, Rikshospitalet, Oslo, Norway; [2]Uppsala University, Uppsala, Sweden; [3]Ulleval Hospital, Oslo, Norway; [4]University Hospital Erlangen, Erlangen, Germany; [5]CHU & University Henri Poincare, Nancy, France; [6]University of Glasgow, Glasgow, United Kingdom.*

**Background:** Patients with chronic kidney disease and renal transplanted recipients are at high risk for cardiovascular events. Use of statins reduces cardiovascular risk in these populations. Two randomized controlled trials in hemodialysis populations (4D, AURORA) showed no benefit of statin treatment.

**Methods:** We performed a post hoc-analysis of the pre-specified subgroup of diabetes patients in the AURORA trial. Of the 2776 patients recruited to the AURORA trial, 731 patients had a diagnosis of diabetes mellitus at inclusion. We examined whether the effect of rosuvastatin treatment on clinical outcome was dependent on LDL cholesterol at baseline.

**Results:** Patients randomized to rosuvastatin in the highest quartile of LDL cholesterol (greater than 3.04 mmol/L) had a 37% reduced risk of the primary combined endpoint; death from cardiovascular causes, or nonfatal myocardial infarction, or nonfatal stroke (hazard ratio [HR] 0.63, confidence interval [CI] 0.40 – 0.99, p = 0.045).There was also a 46% risk reduction in the secondary cardiac event; cardiac death or nonfatal myocardial infarction (HR 0.54, CI 0.31 – 0.93, p = 0.026). No such decreases were observed in any of the other quartiles of LDL cholesterol at baseline.

The clinical events for total mortality and stroke did not differ significantly in any quartile of LDL cholesterol.

**Conclusion**: Use of rosuvastatin reduced the risk of death from cardiovascular causes, nonfatal myocardial infarction and nonfatal stroke in diabetic hemodialysis patients with LDL cholesterol > 3,04 mmol/L. Rosuvastatin also reduced the risk of the secondary cardiac endpoint. Diabetic patients undergoing hemodialysis with elevated LDL cholesterol may be considered for lipid lowering therapy.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC050**

**Long QTc, Alteration of Calcium Phosphate Product, Prevalence of Ventricular Arrhytmias and Sudden Death in Peritoneal Dialysis Patients: An Holter Study** Pierluigi Di Loreto,[1] Francesca K. Martino,[1] Claudio Ronco,[1] Giorgio Vescovo.[2] *[1]Nephrology, S Bortolo Hospital; [2]Internal Medicine, S Bortolo Hospital.*

Patients in peritoneal dialysis very often show elongation of the QTc interval. This can carry an arrhythmogenic risk that can be worsened by ischaemia or by electrolitic abnormalities.

We have measured the duration of the QTc interval and recorded a 24 h ECG Holter in 79 patients in peritoneal dialysis and we correlated the duration of QTc and the arrthymias with plasma levels of Ca++, PO4--, PTH, K+, Na+ and Mg++. Qtc was calculated on 12 leads surface ECG with the Bazzetts formula. Statistical analysis performed in SPSS version 10 (SPSS Inc., Chicago, IL, USA).

Mean QTc duration in dialyzed patients was 0.445±0.04 sec. 55 patients showed a long QTc (>0.45 sec).PTH was 344±25 pg/ml, Ca++ 9.27±0.11 mg/dl, PO4-- 5.5±1,5 mg/dl, Na+ 139,6± 3,4 mMol, K+ 4.04±0.64 mMol/L,. Mg 2.52±043 mg/dl. We found at 24 h ECG Holter supraventricular arrhytmias in 38 patients, complex premature ventricular contractions in 44 patients, monomorphic premature ventricular contractions in 16 patients, non sustained ventricular tachycardia (NSVT) in 10 patients. We also found the following statistically significant positive correlations: QTc / P r= 0.045 p<0.05,QTc / PTH r= 0.077 p<0.02, QTc / Ca r= 0.076 p<0.02. Five patients had sudden death and their QTc was 465± 0,03 msec, 11 patients belonged to Lown class 4a or 4b and their QTc was 465±0,02 msec, 10 patients showed NSVT and their QTc was 464±0,03 msec. The 5 sudden death patients showed a NSTV and belonged to Lown class 4.

QTc is prolonged in the majority of patients with peritoneal dialysis. The QTc value is correlated with the plasma levels of PTH, PO4—and Ca++. To our knowledge this is the first study to examine the relationship between phosphorus and arrthymias in peritoneal dialysis patients. Long Qtc seems to be correlated to increased prevalence of ventricular arrhytmias that may be in turn the cause of sudden cardiac death. The role of hyperparathyroidism and elevated levels of calcium and phosphates in the prolongation of QTc and in the alterations of ventricular repolarization has to be established with perspective studies.

**TH-FC051**

**Coagulation Activation Induces Increased NADPH-Dependent Reactive Oxygen Species (ROS) Generation in Haemodialysis (HD)** S. Simone, M. Cariello, S. Pietanza, Francesco Paolo Schena, G. Grandaliano, G. Pertosa. *Nephrology, Dialysis and Transplantation Unit, Univ. of Bari, Italy.*

Increased oxidative stress (OS) is a non-traditional cardiovascular risk factor in HD patients (pts). We demonstrated that EVAL, a low coagulation-activating membrane, reduces inflammation in HD. The aims of the study were to investigate: i) the role of NADPH oxidase in ROS generation in HD pts ii) the link between coagulation system activation and ROS production in these pts. Intracellular ROS generation (2',7'-dichlorodihydrofluorescein) and NADPH-dependent superoxide generation (chemiluminescence) were evaluated in peripheral blood mononuclear cell (PBMC) isolated from HD pts dialyzed for at least 6 months with synthetic membranes (S group) (polysulphon/polyamide, n=15) or EVAL (E group, n=15) and in healthy subjects (C, n=15). Protein expression of NADPH oxidase subunits, NOX2, p22phoX was analyzed by western-blot analysis. The activation of coagulation factor X (FX) was evaluated measuring plasma levels of prothrombin fragment F1+2 by ELISA. Coagulation FX activation, intracellular ROS and superoxide generation, NOX2 and p22 protein expression were markedly induced in the S group and significantly reduced by EVAL treatment (table, mean±SEM).

| | C | S group | E group | p value |
|---|---|---|---|---|
| F1+2 plasma levels (pmol/ml) | 184.9±7.3 | 388.5±64.3 | 225.1±60.2 | .03 S vs E .01 C vs S |
| ROS generation (AU) | .10±.05 | .33±.28 | .19±.15 | .03 S vs C |
| NADPH-dependent superoxide generation (RLU/mg) | 15.4±.8 | 36.7±5.9 | 20.1±2.6 | .01 S vs C .05 S vs E |
| NOX2 protein expression (AU) | 1.0±1.0 | 3.4±1.4 | 2.8±1.9 | .0005 S vs C .02 S vs E |
| P22phox protein expression (AU) | .8±.4 | 3.3±1.9 | 2.8±.7 | .0008 S vs C <.0001 S vs E |

An increase of NADPH-dependent superoxide generation was observed only in S Group after HD treatment (2.5±.13; p=.01). Incubation of PBMC with activated FX induced a significant increase of superoxide generation (p=.04) and NOX2 protein expression (p=.03). In conclusion, the use of EVAL, by reducing coagulation FX activation, inhibits NADPH-related ROS production in HD pts, contributing to improve their cardiovascular risk profile.

**Effects of Liposome Encapsulated Clodronate on Chlorhexidine Gluconate-Induced Peritoneal Fibrosis in Rats** Taketoshi Kushiyama,[1] Takashi Oda,[1] Keishi Higashi,[1] Kojiro Yamamoto,[1] Takahiro Uchida,[1] Naoki Oshima,[1] Yutaka Sakurai,[2] Soichiro Miura,[1] Hiroo Kumagai.[1] *[1]Nephrology, National Defense Medical College, Tokorozawa, Saitama, Japan; [2]Preventive Medicine and Public Health, National Defense Medical College, Tokorozawa, Saitama, Japan.*

**Backgound.** Long-term peritoneal dialysis (PD) causes morphologic and functional changes in the peritoneum, which hampers the continuation of PD therapy. Macrophage plays important roles in the development of the peritoneal fibrosis. We examined the effect of liposome encapsulated clodronate (LC), which induce apoptosis of macrophage, on chlorhexidine gluconate (CG)-induced peritoneal fibrosis in rats. **Methods.** Fifty Sprague-Dawley rats were intraperitoneally injected either with saline (n=10) or with CG (1.5ml/100g, n=40) three times a week. Forty CG injected rats were randomly assigned into 4 groups (n=10, each): without intravenous injection (CG group), 3 groups with intravenous injection twice a week (10mg of LC, 20mg of LC, and 10mg of non-encapsulated clodronate). After 21 days, the rats were sacrificed and the parietal peritoneum was harvested. **Results.** CG induced massive infiltration of ED-1 positive macrophage with prominent peritoneal thickening. LC administration significantly reduced the number of peritoneal macrophages (27.2±2.8 cells/field in LC20 vs 92.0±4.6 cells/field in CG). This decrease in macrophage number paralleled well with decreases in mRNA expression for TGF-β1, collagen type I and III, and in peritoneal thickening (59.6±5.4 μm in LC20, 147±9.7 μm in CG). Double staining for cytokeratin and α-smooth muscle actin (α-SMA) revealed that α-SMA-positive-mesothelial-cells were prominently increased by CG injection and significantly decreased by LC treatment. **Conclusions.** These data suggest the critical role of macrophages in the development of peritoneal fibrosis. LC may be a new therapeutic strategy for the treatment of peritoneal fibrosis in PD patients.

**Association of Ankle Brachial Pressure Index and C-Reactive Protein with Cardiovascular and All-Cause Mortality in Hemodialysis Patients** Tetsuya Yamada,[#1] Takanobu Toriyama,[#2] Seiichi Matsuo,[#3] Hirohisa Kawahara.[#2] *[1]Seto Kyoritsu Clinic, Seto, Aichi, Japan; [2]Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Aichi, Japan; [3]Nephrology, Nagoya University Hospital, Nagoya, Aichi, Japan.*

**Background:** Ankle Brachial Pressure Index (ABPI) has been established as an indicator of not only peripheral artery disease but also systemic atherosclerosis. C-reactive protein (CRP) also has been reported to reflect vascular wall inflammation and can predict future cardiovascular (CV) events. We investigated the association of ABPI, CRP and their joint role with prediction of CV and all-cause mortality in patients on hemodialysis (HD).

**Methods:** ABPI and serum CRP levels were measured consecutively in 442 HD patients. The patients were divided into tertiles according to ABPI levels; tertile 1 (T1): <1.02, T2: 1.02-1.20 and T3: > 1.20, and also to serum CRP levels; T1: <0.9 mg/l, T2: 0.9-3.7mg/l and T3: >3.7mg/l, respectively. All patients were prospectively followed up to 8 years.

**Results:** Serum CRP levels was 7.7±12.9mg/l, 4.5±0.74mg/l and 3.6±5.5mg/l in T1, T2 and T3 of ABPI, respectively (p=0.0006), and was independently associated with T1 of ABPI (odds ratio 1.40, 95%CI 1.07-1.83, p=0.013). Mean follow-up period was 71±27months. Adjusted hazard ratio (HR) of lower ABPI was 3.69 (95%CI 1.85-7.35, p=0.0006 for T1 vs. T3) for CV mortality and 2.23 (95%CI 1.38-3.61, p=0.0016 for T1 vs. T3) for all-cause mortality, respectively. Similarly, adjusted HR of elevated CRP levels was 2.58 (95%CI 1.33-5.01, p=0.019 for T3 vs. T1) for CV mortality and 2.52 (95%CI 1.56-4.09, p=0.0002 for T3 vs. T1) for all-cause mortality, respectively. In the joint setting of ABPI and CRP, the risk of CV and all-cause mortality was 15.1-fold (p=0.0024) and 11.2-fold (p=0.0009) in the T1 of ABPI with T3 of CRP compared to the T3 of ABPI with T1 of CRP even after adjustment, respectively.

**Conclusions:** Lower ABPI and elevated CRP levels might be closely associated, and the combination of these variables is more markedly related to increased mortality than either variable alone in HD patients. The measurement of ABPI and serum CRP is useful for the stratification of CV and all-cause mortality risk in this population.

**Effects of Neutral pH and Low Glucose Degradation Product Peritoneal Dialysis Fluid on Systemic Markers of Inflammation and Endothelial Dysfunction: A Randomized Controlled 1-Year Follow-Up Study** Sun-Hee Park,[1] Jun-Young Do,[2] Yeong Hoon Kim,[3] Ho Yung Lee,[4] Beom Seok Kim,[4] Sug Kyun Shin,[5] Hyun Chul Kim,[6] Yoon-Kyung Chang,[7] Jong-Oh Yang,[8] Hyun Chul Chung,[9] Se-Hee Yoon,[1] Chan-Duck Kim,[1] Yong-Lim Kim.[1] *[1]Kyungpook National University Hospital; [2]Yeungnam University Hospital; [3]Inje University Busan Paik Hospital; [4]Yonsei University Severance Hospital; [5]NHIC Ilsan Hospital; [6]Keimyung University Dongsan Hospital; [7]Daejeon St. Mary's Hospital; [8]Soonchunhyang University Cheonan Hospital; [9]Ulsan University Hospital, Korea.*

**Purpose**: To examine the effects of neutral pH and low glucose degradation product (GDP) peritoneal dialysis fluid (PDF) on systemic inflammation and endothelial dysfunction in PD patients. **Methods**: A multicenter, open labeled, randomized controlled trial of new PD patients. Patients were randomly allocated into standard PDF (Stay safe®, Fresenius Medical Care, Germany) and low GDP PDF (Balance®) group and were followed up to 1 year. Primary efficacy variable was inflammation-endothelial-dysfunction index (IEDI), composite score from serum hs-CRP, soluble ICAM (sICAM)-1 and sVCAM-1. The individual markers of the IEDI, peritoneal clearance, ultrafiltration, residual renal function (RRF), nutritional indices, peritonitis rate and technique survival were secondary efficacy variables. Statistical comparisons between the groups were performed using analysis of covariance (ANCOVA) with baseline values as covariates. **Results:** Of 152 patients, 146 (low GDP: standard 79:67) patients entered this trial (Male 46%, Diabetes 53%). IEDI, sICAM-1 and sVCAM-1 were significantly lowered in low GDP compared to standard group at 12 month, whereas hs-CRP was not different. The change of peritoneal transport, RRF and nutritional indices were not different between the two groups. Moreover, the incidence of peritonitis and technique survival were not different. **Conclusions:** Neutral pH and low GDP PDF is likely to be beneficial on inflammation and endothelial dysfunction compared to standard PDF in incident PD patients. The effects of neutral pH and low GDP PDF on long-term clinical outcomes need to be answered.

### TH-FC055

**Is Neutrophil-to-Lymphocyte Ratio a Marker of Inflammation in Chronic Hemodialysis Patients?** Georges Ouellet,[1,2] Laura Rosales,[1] Stephan Thijssen,[1,2] Nathan W. Levin,[1,2] Peter Kotanko.[1,2] *[1]Renal Research Institute; [2]Beth Israel Medical Center, New York, NY.*

**Background**

Neutrophil-to-lymphocyte ratio (NLR), defined as neutrophil count divided by lymphocyte count, is a marker of inflammation and is sometimes used as a proxy for C-reactive protein (CRP). However, its correlation with inflammatory markers has not been investigated in chronic hemodialysis (CHD) patients. We aimed to study the relationship between NLR and commonly used markers of inflammation (CRP, interleukin-6 (IL-6), and epoetin resistance index (ERI)) in CHD patients.

**Methods**

Stable CHD patients were recruited. Complete blood count and high sensitivity CRP were measured pre-dialysis by routine laboratory techniques. IL-6 was determined by quantitative sandwich enzyme immunoassay (Quantikine, R&D, Minneapolis, MN). Epoetin resistance index was computed as units of EPO per week per g/dL hemoglobin per kg body weight. Correlations were assessed by Spearman test.

**Results**

We studied 164 patients (age 61±14 years; median dialysis vintage 2.4 years; 52% male; 45% Hispanics, 45% Blacks; 8.5% HIV+; 21% HCV+; 12% catheters). The distributions of NLR, CRP and IL-6 were skewed. The median NLR was 2.88 [interquartile range: 2.15-4.00]; median CRP was 7.1 mg/L [interquartile range: 3.3-13.8], median ERI was 10.7 U EPO/ g/dl Hb /kg body weight [interquartile range: 5.2-22.8] and median IL-6 was 2.08 pg/mL [range: 2.08-78.2]. NLR was positively correlated with CRP, IL-6 and ERI (table 1), irrespective of HIV status.

Table 1. Spearman correlations of NLR with inflammatory markers

| | CRP | IL-6 | ERI |
|---|---|---|---|
| NLR | rho=0.238, P=0.002 | rho=0.288, P<0.001 | rho=0.159, P=0.043 |

**Conclusions**

In a group of stable CHD patients, NLR was positively correlated with CRP, IL-6 and ERI. NLR could therefore be used as a surrogate marker of inflammation when CRP and IL-6 are not available.

### TH-FC056

**Proteinkinase C-alpha Mediates the Peritoneal Dialysis Related Peritoneal Membrane Changes** Hermann G. Haller, Joon-Keun Park, Vega Goedecke, Marcus Hiss, Nelli Shushakova, Jan Menne. *Clinic of Hypertension and Nephrology, Hannover Medical School, Hannover, Germany.*

Introduction: Peritoneal dialysis (PD) is a well established renal replacement therapy. One of its major limitations are the negative long-term effects of dialysis on the peritoneal membrane associated with mesothelial apoptosis, fibrosis and vascular changes. We have recently shown that effects of high glucose and glucose degradation products in diabetic kidneys are mediated by proteinkinase C isoform alpha (PKC-α). Using gen-deficient mice for PKC-α (PKCα$^{-/-}$) we tested the hypothesis that the deleterious effects of the high-glucose solution in PD are also mediated by PKC-α and that inhibition of PKC-α prevents glucose-induced peritoneal damage.

Material and Methods: We used (PKCα$^{-/-}$) (n=12) and SV 129 mice (n=12) and performed peritoneal dialysis for 4 weeks using twice daily intraperitoneal injections of a sterile pre-warmed dialysis solutions (Physioneal, 3,86%, Baxter). We used 75 ml/kg body weight, on average 1,5 ml, of dialysis fluid for each injection. After four weeks we analyzed peritoneal membrane thickness, expression of collagen IV, fibronectin, VEGF, VEGF receptors, and perlecan.

Results: Peritoneal membrane thickness was significantly reduced in (PKCα$^{-/-}$) as compared to controls. In the control group markers of peritoneal cell differentiation (perlecan) were lost and apoptosis was pronounced while in (PKCα$^{-/-}$) mice perlecan expression persisted and apoptosis was rare. Expression of VEGF and ist receptors in the peritoneum was also induced by dialysis in control animals while (PKCα$^{-/-}$) mice showed only minor changes.

Conclusion: Our results demonstrate that PKC-α is a major mediator of the glucose-induced changes in the peritoneal cavity and suggest a potential therapeutic use of PKC-alpha inhibition for the prevention of dialysis related changes of the peritoneal membrane

**Impact of Continuous Veno-Venous Hemofiltration at Different Ultrafiltration Rate on Inflammatory Status and Immune Response of Porcine Endotoxemic Shock** Yimei Wang, Xiaoqiang Ding, Jianzhou Zou, Jie Teng, Yihong Zhong, Yi Fang. *Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

*Objective:* To study the impact of continuous veno-venous hemofiltration (CVVH) at different ultrafiltration rate on inflammation, immunology, hemodynamics, organ injury in porcine endotoxemic shock model, and to investigate the related mechanisms.

*methods:* Eighteen porcines received endotoxin infusion, then randomized into three groups. Control group received no further intervention, CVVH group and HVHF group received pre-dilution hemofiltration for 24 hours with a corresponding post-ultrafiltration rate of 45 ml/ kg· h and 70 ml/ kg· h respectively.

*Results:* Left ventricular stroke work index (LVSWI) and oxygen index (OI) were improved significantly in HVHF and CVVH group at T24($P < 0.05$). The survival time in CVVH group (21.4 ± 4.1) h, HVHF group (22 ± 6.7) h was significantly longer than that in control group (15.4 ± 5.2 h, $P < 0.05$). A significant decrease of plasma IL-10 levels was observed at T6, T12 and T24 in CVVH group compared with control group ($P < 0.05$). HVHF group accomplished a greater decrease in plasma TNF-α (T6) and IL-10 (T6,T12,T24) compared with control group and CVVH group. There was a significant negative correlation between IL-6 and survival time. HVHF increased PMN apoptosis and decreased the number of peripheral PMN ($P < 0.05$). The expression of ICAM-1 and p65, the degree of NF-κB/ DNA binding activity in lung and kidney were reduced in CVVH group and HVHF group ($P < 0.05$).

*Conclusion:* HVHF and CVVH can improve survival time, blood pumping and arterial oxygenation of porcine endotoxemic shock. IL-6 was a powerful independent predictive factor for survival time. HVHF can alleviate the decrease of PMN apoptosis, CVVH and HVHF can offer both renal and lung protection, which may be related to suppression of inflammation and NF-κB.

### TH-FC058

**Cell Stretch during Peritoneal Dialysis Increases Mesothelial TGFβ and VEGF Production** Michael F. Flessner,[1] Zhi He,[2] Rebecca Potter,[2] Xiaorong Li.[1] *[1]Medicine, University of Mississippi Medical Center, Jackson, MS; [2]Pathology, University of Mississippi Medical Center, Jackson, MS.*

Peritoneal dialysis (PD) requires indwelling of large volumes of solution that increase the abdominal girth and stretch the mesothelial cells of the abdominal wall. To address the hypothesis that stretch stimulates these cells to increase synthesis and production of inflammatory cytokines, we grew MeT-5A human peritoneal mesothelial cells to confluence and then placed the cells in growth arrest (0.1% fetal bovine albumin) on Flexercell BioFlex membranes coated with Collagen in multiple duplicate wells. After 48 hours, cells were either left stationary (STA) or cycled with a sinusoidal stretch (STR) frequency of 10/ min and maximal amplitude of 30% with a Flexercell 3000T system. The supernatant and cells of individual wells were removed at 0, 4, 12, 24, 48, 72, and 96 hours. Supernatant was assayed with ELISA for TGFβ, IL-6 and VEGF. After trypsinization, the total number of viable cells in each well was estimated from their volume, cell count in a standard

hemacytometer, and lack of staining with methylene blue to determine the % viable cells. Total RNA from cells were extracted and Reverse Transcription - real time PCR (RT-PCR) was carried out to determine mRNA for IL-6, TGFβ, VEGF, TGFβ-R2, TGFβ-R3, KDR and FLT1. Results for STR were compared with STA for each time interval. Analysis was restricted to ≤ 72 hours due to decline of cell number and viability. mRNA for TGFβ, VEGF, TGFβ-R3 and KDR were significantly higher in the STR group throughout the 72 hours, while STR IL-6 mRNA declined in a non-significant way. Supernatant IL-6, TGFβ, and VEGF, normalized to the number of viable cells were not significantly different in the two groups. We conclude that mechanical stress due to mesothelial stretch does not enhance mesothelial cell secretion of IL-6, TGFβ or VEGF, but increases the expression of TGFβ, VEGF and their correspond receptors TGFβ-R3 and KDR. Upregulation of cytokine receptor may result in decreased cell secretion.

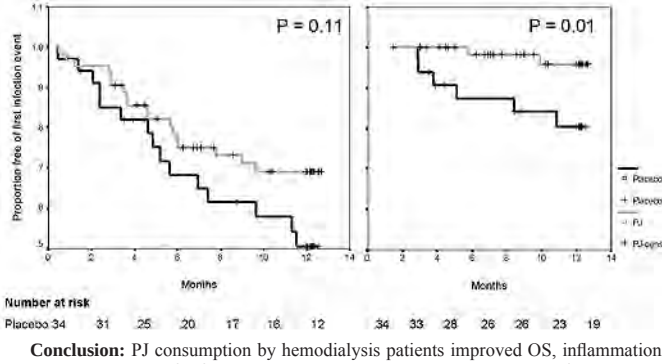
## TH-FC059

**One Year of Pomegranate Juice Consumption Decrease Oxidative Stress, Inflammation and Incidence of Infections in Hemodialysis Patients** Batya Kristal,[1] Lilach Shema,[1] Liora Ore,[2] Galina Shapiro,[3] Ronit Geron,[1] Shifra Sela.[3] *[1]Nephrology, Western Galilee Hospital, Nahariya; [2]School of Public Health, University of Haifa, Haifa; [3]Eliachar Research Lab, Western Galilee Hospital, Nahariya.*

**The aim** of the present study was to investigate the effect of Pomegranate juice (PJ) consumption, on oxidative stress, inflammation and incidence of infections after one year of intervention.

**Methods:** 101 HD patients were randomized to receive 100 cc of PJ or matching placebo, in the beginning of each dialysis session, three times a week for one year. The primary endpoints were levels of neutrophil priming expressed by CD11b, protein oxidation expressed by oxidized fibrinogen, IL-6 and albumin as inflammation markers. Secondary endpoints were hospitalization due to infections.

**Results:** PJ consumption, but not placebo intake, yields a significant time response improvment in CD11b (P=0.003), oxidized fibrinogen (P=0.001), IL-6 (P<0.001) and albumin (P=0.005). Incidence rate of first and second infection event were lower among PJ group compared to placebo (for first event: 32.5/1000pm vs. 54.9/1000pm, for second event: 3.1/1000pm vs. 17.9/1000pm). Survival analysis demonstrated a significant higher proportion free of second infection event among PJ group.



**Conclusion:** PJ consumption by hemodialysis patients improved OS, inflammation and reduce incidence of infections. Those results highlight the important of the relation between *OS & Inflammation & Innate immune dysfunction* originating from primed PMNLs. It apparent, that PJ consumption may have a beneficial effect on the above relation, and as such favor a reduction in the morbidity and mortality of HD patients

**Inflammation Affects Endothelial Progenitor Cells in Patients on Different Extracorporeal Dialysis Therapies** Detlef H. Krieter, Christoph Wanner. *Nephrology, University Hospital Würzburg, Würzburg, Germany.*

*Introduction:* Enhancing middle molecule removal of dialysis treatment is considered to exert beneficial effects on endothelial progenitor cells (EPCs) in maintenance dialysis patients.

*Methods:* In a prospective, randomized, cross-over trial, 18 maintenance dialysis patients were subjected to 4 weeks of each low-flux HD (LF-HD), high-flux HD (HF-HD), and online predilution hemodiafiltration (HDF). EPCs were determined at baseline and at the end of each 4 week period. 16 healthy volunteers served as control. EPCs derived from isolated PBMNCs were determined in colony assays after culture on fibronectin (CFU-Hill) and collagen-1 (ECFC), respectively, and were further analyzed for the coexpression of CD34, CD45, and VEGFR2-KDR.

*Results:* There was no difference in the effects of LF-HD, HF-HD, and HDF on EPCs. Differences were found between dialysis patients and healthy controls consisting of a lower total number of ECFCs (median from 5.4 x $10^3$ to 12.7 x $10^3$ (range 0.2 x $10^3$ to 101 x $10^3$) vs. controls 75.9 x $10^3$ (32.0 x $10^3$ to 318 x $10^3$) per $10^7$ MNC; $p<0.001$) and reduced fraction of vital ECFCs (mean between 54 ± 25% and 68 ± 20% vs. controls 86 ± 9%; $p<0.05$), whereas the formation of endothelial cell colonies (ECC) was increased in the dialysis patients (median between 0.0 and 0.8 (range 0.0 to 17.5) vs. controls 0.0 (0.0 to 0.3) per $10^7$ MNC; $p<0.05$). The number of prototypical EPCs (ECFC with the immunophenotype $CD34^+/VEGFR2\text{-}KDR^+/CD45^-$) was similar between patients and controls. Correlations of the CRP plasma level with the ECC count ($r=0.556$; $p<0.001$), the CFU-Hill colony count ($r=0.223$; $p=0.016$) and the $CD34^+/VEGFR2\text{-}KDR^+/CD45^-$ subpopulation of both ECFC ($r=0.364$; $p<0.001$) and CFU-Hill cells ($r=0.372$; $p<0.001$) were observed.

*Conclusions:* Enhanced middle molecule removal by dialysis therapy has no favorable effect on EPCs. A reduced vitality of EPCs and enhanced ECC formation in dialysis patients suggest growth induction of impaired EPCs in chronic renal failure. In this respect, inflammation seems to play an important role.

## TH-FC061

**MiR-29 Regulate Collagen Expression by Target Sp1 in Tubular Epithelial Cells** Lei Jiang, Ruoyun Tan, Junwei Yang. *Center of Kidney Disease, the 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu, China.*

**Objective**: Deposition of collagen in proximal tubular cells plays an important role during obstructive nephropathy, but the mechanism underlying excessive production of collagen remains poorly understood. MicroRNAs (miRNAs) have emerged rapidly as a major new direction in many fields of research including kidney disease. The aim of this study is to investigate the role of miR-29 family on collagen expression.

**Methods:** We analyzed the expression of miR-29 family in murine interstitial fibrotic kidneys induced by unilateral ureteral obstruction (UUO) using miRNAs array, and miR-29a, miR-29b, miR-29c expression in NRK-52E cells after TGF-β1 stimulation by Real-time Quantitative PCR. Then we transfected miR-29 mimics or miR-29 inhibitors to NRK-52E cells, and detected collagen I and collagen III expression though Real-time Quantitative PCR and western blot analysis.

**Results**: In obstructed kidneys induced by UUO, miR-29 family expression declined in miRNAs array. TGF-β1 significantly induced down-regulation of miR-29 expression. miR-29 mimics could reduce collagen I and collagen III mRNA and protein expression induced by TGF-β1, and miR-29 inhibitors alone could upregulate collagen I and collagen III mRNA and protein expression. MiR-29 mimics also could reduce smad2/3 phosphorylation and transcription factors Sp1 expression. Furthermore, transfection of Sp1 siRNA could decrease collagen I and collagen III expression and smad2/3 phosphorylation stimulated by TGF-β1, while downregulation of Sp1 also could ameliorate collagen I and collagen III induced by miR-29 inhibits.**Conclusions:** MiR-29 could negatively regulate collagen expression induced by TGF-b1 though target transcription factor Sp1 in tubular epithelial cell.

## TH-FC062

**miR-29 Inhibits TGF-beta/Smad3-Mediated Renal Fibrosis In Vitro and In Vivo** Wei Qin,[1,2] Arthur Chi-Kong Chung,[1] Xiao Ru Huang,[1] Xiaoming Meng,[1] Hui Y. Lan.[1] *[1]Department of Medicine and Therapeutics, and Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Hong Kong, Hong Kong SAR, China; [2]Department of Medicine-Nephrology, West China Hospital, Sichuan University, Chengdu, Sichuan, China.*

TGF-beta acts by stimulating Smad3 to play opposite roles in fibrosis and immunity. Thus, strategies aimed to treat renal fibrosis need to precisely target the Smad3-specific regulatory gene(s) related to fibrosis. In the present study, we tested the hypothesis that **miR-29 may be a downstream inhibitor and therapeutic molecule specifically for Smad3-mediated renal fibrosis.** This hypothesis was tested in Smad3 KO kidney tubular cells (TEC)/fibroblasts and in a mouse model of unilateral ureteral obstructive kidney disease (UUO) induced in Smad3 KO mice or by overexpressing a doxycycline-inducible miR-29b mimic using the ultrasound-microbubble-mediated technique.

Using microRNA array and real-time PCR, we found that miR-29 was a downstream inhibitor of TGF-beta/Smad3-mediated fibrosis because TGF-beta1-mediated renal fibrosis in vitro and in the UUO kidney was associated with a loss of miR-29abc, which was prevented in Smad3 KO cells and Smad3 KO UUO kidney. In vitro, Smad3 bound miR-29 promoter physically as determined by the ChiP assay and regulated a loss of miR-29 in response to TGF-beta1. The protective role of miR-29 in TGF-beta/Smad3-mediated fibrosis was revealed by the findings that overexpression of miR-29b mimic blocked, but knockdown of miR-29 enhanced, TGF-beta1-induced collagen I and III expression. Importantly, in vivo overexpression of miR-29b mimic in the normal kidney was able to prevent UUO-induced renal fibrosis. Furthermore, in the established UUO kidney, restored miR-29b in the fibrotic kidney by ultrasound-microbubble technique on day 4 after UUO was able to block the progression of renal fibrosis at day 10, demonstrating the therapeutic effecacy of miR-29b mimic on renal fibrosis. In conclusion, miR-29 is a downstream inhibitor of TGF-beta/Smad3-mediated renal fibrosis. Targeting the Smad3-miR-29 axis may represent a novel and specific therapy for renal fibrosis.

Disclosure of Financial Relationships: nothing to disclose

## TH-FC063

**Role of Specific Phosphorylations outside the Carboxyl-Terminus of Smad3 in the Collagen Response to TGF-β** James A. Browne, Tomoko Hayashida, H. William Schnaper. *Division of Kidney Diseases, Department of Pediatrics, Feinberg School of Medicine, Northwestern University, Chicago, IL.*

Regulation of TGF-β/Smad3-mediated fibrogenesis is a complex process. We previously described several non-canonical signaling pathways that contribute to renal cell collagen expression. Here, we report the importance of several potential phosphoacceptor sites outside the carboxyl-terminal serines targeted by the activated TGF-β receptor. Four of

these (Thr 179, Ser 204, Ser 208, and Ser 213) are within the Smad3 linker region (LR). Some groups propose that LR phosphorylation inhibits Smad3 signaling. However, we have previously described phosphorylation of the LR by ERK MAP kinase, and that inhibiting ERK blocked both LR phosphorylation and the collagen response to TGF-β. Therefore, we and others believe that the effect of LR phosphorylation is cell-context dependent. We propose that specific phosphorylations could enhance, inhibit or have no effect on TGF-β-induced type-I collagen expression; and different sites could have different and even opposing effects.

To dissect these possibilities, we evaluated COL1A2-luciferase activity induced by TGF-β1 in Smad3-null murine embryonic fibroblasts (MEFs) transfected with Smad3 constructs, mutated at Thr8 or at various LR sites (Thr179, Ser204, Ser208, and Ser213). A collagen response to TGF-β1 in wild type MEFs, but not in Smad3-null MEFs, was confirmed. Transfection of wild type Smad3 into Smad3-null MEFs reconstituted the collagen response. Smad3-null MEFS transfected with Smad3-EPSM (all four LR phosphoacceptor sites mutated) responded to TGF-β. Reconstitution with Smad3 mutated at Thr178, Ser204 and/or Ser212 maintained COL1A2 activity. However, Smad3-null MEFs reconstituted with Smad3 mutated only at Ser208 of the LR showed a significantly reduced collagen response. Therefore, although Ser208 in the LR of Smad3 may enhance the collagen response, the remaining sites (Thr178, Ser204 and Ser212) may have different and even opposing effects. Further investigation of the role of the Smad3 linker region in renal cell function may offer new approaches to selectively modifying TGF-β1-stimulated responses in progressive kidney disease.

**Type I Collagen Induced by TGF-β1 Is Negatively Regulated through the Autophagic Pathway** Hee-Jun Na, Sung I. L. Kim, Yan Ding, Mary E. Choi. *Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Type I collagen (Col-I) is a major component of the extracellular matrix (ECM) whose regulated expression is important maintaining tissue homeostasis, and its relentless production and progressive accumulation is a hallmark of renal fibrosis in progressive kidney disease. Autophagy is a highly conserved cellular process regulating turnover of cytoplasmic proteins and organelles via a lysosome-dependent pathway. Here we show a novel role of autophagic process as a mechanism to negatively regulate and prevent excess collagen/ECM accumulation in the kidney. Kidneys from mice deficient in autophagic protein beclin 1 (*beclin 1*$^{+/-}$) exhibited pro-fibrotic phenotype, with increased ECM deposition as assessed by Masson's trichrome staining, compared to wild-type (*beclin 1*$^{+/+}$) littermates. Increased renal expression of Col-I protein was confirmed by western blot analysis of kidneys from *beclin 1*$^{+/-}$ mice and in mice with null mutation of microtubule-associated protein 1 light chain 3 (*LC3*$^{-/-}$), compared to their wild-type littermates. Moreover, mouse mesangial cells (MMC) deficient in autophagic proteins, either by targeted knockdown of beclin 1 with specific siRNA, or in MMC from *beclin 1*$^{+/-}$ and *LC3*$^{-/-}$ mice also expressed increased levels of Col-I protein. Interestingly, treatment with TGF-β1, a potent inducer of Col-I, induced both beclin 1 and LC3 expression in MMC, indicating dual nature of this multifunctional cytokine TGF-β1. Furthermore, inhibition of autophagy using bafilomycin A1, a potent inhibitor of lysosomal degradation pathway, did not alter the Col-I mRNA expression but led to increased Col-I protein levels, which was further enhanced by co-treatment with TGF-β1 and bafilomycin A1, suggesting an important role of autophagy in Col-I degradation. Blockade of MKK3-p38, a major TGF-β1 signaling pathway, either by using MMC from MKK3$^{-/-}$ null mice or p38 inhibitor SB203580 abrogated LC3 expression and beclin 1 induced by TGF-β1. Our findings are the first demonstration that, at least in part, renal Col-I protein levels are regulated by autophagy and that collagen degradation is dependent on the autophagy-lysosomal pathway.

**Inhibition of β-Catenin Signaling Attenuates Renal Interstitial Fibrosis** Sha Hao,[1] Weichun He,[1] Hong Ding,[1] Michael Kahn,[2] Youhua Liu.[1] *[1]Department of Pathology, University of Pittsburgh, Pittsburgh, PA; [2]Center for Regenerative Medicine and Stem Cell Research, University of Southern California, Los Angeles, CA.*

Renal interstitial fibrosis is the common final outcome of a wide variety of progressive chronic kidney diseases, and current clinical therapy to halt and reverse renal fibrosis is ineffective. Recent studies demonstrate that Wnt/β-catenin signaling plays an important role in the pathogenesis of renal fibrosis, suggesting that this pathway could be exploited as a potential target for antifibrotic therapy. In this study, we examined the therapeutic efficacy of a highly specific small molecule β-catenin inhibitor (ICG-001) on renal interstitial fibrosis in obstructive nephropathy. In vitro, ICG-001 dose-dependently suppressed the β-catenin-driven gene transcription in a Topflash luciferase reporter assay. ICG-001 also abolished the expression of plasminogen activator inhibitor-1 (PAI-1), a direct target gene of the canonical Wnt/β-catenin signaling. In human proximal tubular epithelial cells (HKC-8), β-catenin was activated by TGF-β1, and ICG-001 abolished TGF-β1-induced α-smooth muscle actin (α-SMA), fibronection, type I collagen expression. This anti-fibrotic effect of ICG-001 was clearly independent of a disruption of Smad signaling, as it did not affect TGF-β1-triggered Smad2 and Smad3 phosphorylation in HKC-8 cells. In vivo, administration of ICG-001 (5 mg/kg body wt) through daily intraperitoneal injections significantly inhibited β-catenin signaling and attenuated renal fibrosis in the obstructed kidneys at 7 days after unilateral ureteral obstruction (UUO). Real-time RT-PCR, Western blotting and immunostaining revealed that ICG-001 significantly suppressed renal expression of α-SMA, fibronectin and type I collagen, as well as fibroblast-specific protein-1 (Fsp1). ICG-001 also repressed renal expression of Snail1, Snail2/Slug and Twist1, key transcriptional factors that regulate epithelial-mesenchymal transition (EMT). These results suggest that targeting β-catenin signaling by small molecule inhibitor could be a novel and effective approach for the treatment of fibrotic kidney diseases.

### TH-FC066

**Vitronectin Accumulates in the Interstitium without Impacting Fibrosis Severity in Experimental Chronic Kidney Disease** Allison A. Eddy, Allen Rassa, Sarah J. Collins, Jesus M. Lopez-Guisa. *Pediatrics, Seattle Children's Research Institute & University of Washington, Seattle, WA.*

Vitronectin (VN) is a glycoprotein normally found in serum (also known as complement S-protein) and in the extracellular matrix during certain disease states. Given its known interactions with plasminogen activator inhibitor-1 (PAI-1) and VN cellular receptors – the αvβ3 integrin and the urokinase receptor (uPAR) – this study was designed to investigate its potential role in renal fibrogenesis using the mouse model of unilateral ureteral obstruction (UUO). We have previously reported increased uPAR expression and its anti-fibrotic function in this model (JASN 14:1254, 2003). By Western blotting, VN protein was increased 1.9-3.0x on days 7, 14 and 21 after UUO compared to sham kidneys levels. αvβ3 protein levels increased 6-8x after UUO (days 7 and 14; declining to near sham levels on day 21). By immunofluorescence confocal microscopy the VN protein was localized within glomeruli and the interstitium. Phenotypically normal VN knockout (-/-) mice on a C57BL/6 background were re-derived from cryopreserved embryos and the genotype confirmed by PCR and by the absence of a protein band by immunoblotting. Groups of age-matched C57BL/6 wild-type (VN+/+) and VN-/- mice (n = 10-11/group) were sacrificed 7, 14 or 21 days after UUO. Absence of VN resulted in significantly fewer αSMA+ interstitial myofibroblasts by immunostaining (0.53x) and significantly lower PAI-1 protein (0.23x) and αvβ3 protein (0.32x), but only on day 14. The number of CD68+ macrophages did not differ between the genotypes. Despite these differences, the absence of VN had only a modest effect on fibrosis severity based on both picrosirius red+ interstitial area and total kidney collagen measured by the hydroxyproline assay: only the day 21 total collagen levels were significantly lower in the VN-/- mice (9.8 ± 1.6 vs 11.9 ± 2.9 mm/mg wet kidney wt). These findings suggest that despite significant interstitial VN deposition in the UUO model of chronic kidney disease, its fibrogenic role is either non-essential or redundant. These data are remarkable given its strong affinity for the potent fibrogenic molecule PAI-1.

**Progenitor Cell Secretory Products Are Renoprotective *In Vitro* and *In Vivo*: Efficacy of Cell Free Conditioned Medium in the Remnant Kidney Model** Darren A. Yuen, Andrew Advani, Yanling Zhang, Kim Connelly, Richard E. Gilbert. *St. Michael's Hospital, Toronto, Canada.*

**Background:** The mechanisms underlying the beneficial effects of progenitor cells are poorly understood with most contemporary studies suggesting a paracrine mode of action. Recently, however, an endocrine effect has also been postulated in kidney disease models, wherein progenitor cells mediate their beneficial effects by secreting renoprotective factor(s) from a reticulo-endothelial system niche. To test this 'endocrine' hypothesis we examined the secretory products of early outgrowth endothelial progenitor cells (EPCs), focusing on their angiogenic and anti-fibrotic activities in both the *in vitro* and *in vivo* settings. **Methods:** EPCs were grown from donor F344 rat bone marrow. Cell free conditioned medium (CF-CM) was generated by incubating EPCs with serum-free EBM-2 medium to collect their secreted factor(s). *In vitro* antifibrotic and angiogenic activities of CF-CM were assessed using $^{3}$H-proline incorporation and capillary tube formation assays. For the *in vivo* studies, subtotally nephrectomised (SNX) F344 rats, 4 wks post-SNX, received thrice weekly tail vein injections of either 10 x concentrated CF-CM or EBM-2 medium for 2 wks. FITC-inulin GFR, urinary protein, and renal collagen IV deposition were measured 4 wks later (8 wks post-SNX). **Results:** CF-CM demonstrated robust antifibrotic activity *in vitro*, potently reducing TGF-β and angiotensin II-induced fibroblast collagen synthesis ($IC_{50}$ >1:1000 dilution). CF-CM also displayed potent angiogenic activity in an endothelial tube-formation assay. Compared with EBM-2, infusion of CF-CM into SNX rats attenuated disease progression, as evidenced by improved GFR (CF-CM vs EBM-2: 1.8 ± 0.1 vs 1.1 ± 0.2 μL/min/g body wt), reduced urinary protein (CF-CM vs EBM-2: 1.4 ±0.3 vs 2.6 ±0.4 g/mmol creatinine), and reduced mesangial collagen IV (CF-CM vs EBM-2: 0.14 ± 0.01 vs 0.26 ± 0.06 AU, $p < 0.05$ for all). **Conclusions:** The systemic administration of EPC-derived secreted factor(s) mimics the therapeutic effects of cell infusion. Identification of the responsible factor(s) and their subsequent synthesis may provide a new therapeutic strategy for CKD.

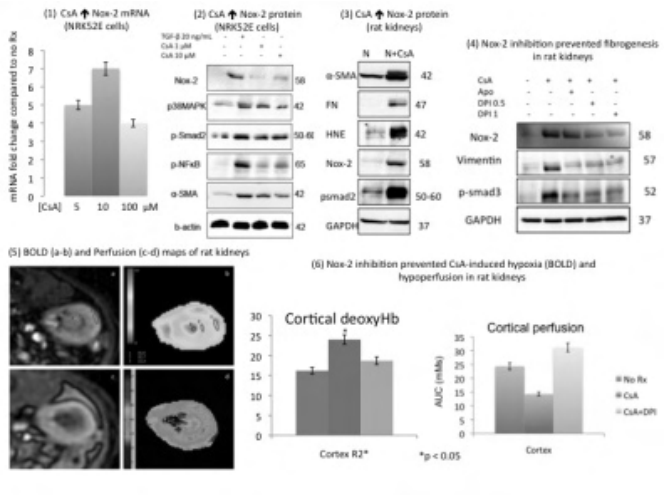
### TH-FC068

**Nox-2 May Regulate CsA-Induced Kidney Injury** Lingjin Huang, Aparna Vidyasagar, Shannon Reese, Arjang Djamali. *Medicine and Surgery, UW Madison School of Medicine and Public Health, Madison, WI.*

We hypothesized that the classical phagocytic Nox-2 enzyme plays an important role in renal hypoxia and fibrosis mediated by CNIs. We tested this hypothesis in vitro, studying CsA-mediated injury of renal tubular epithelial cells (NRK52E) and in vivo, using the CsA-induced model of chronic nephrotoxicity. We first demonstrated that CsA (5, 10 and 100 M) increased tubular Nox-2 mRNA 3-7 fold (Figure 1).



Next we confirmed these studies by immunoblot analyses demonstrating that CsA increased Nox-2 protein levels and fibrogenesis (phospho-MAPK, smad2, NFκB and α-SMA) in NRK52E cells (Figure 2). We further examined the effects of CsA on Nox-2 and fibrogenesis in vivo. Fisher344 rats received CsA 15mg/kg/24h, vehicle or CsA + Diphenyleneiodonium (DPI) a flavoprotein inhibitor that inhibits Nox activity (n=6-8 in each group). All animals were treated for 1 month. Immunoblot analyses of whole kidney tissue lysates demonstrated that CsA therapy increased Nox-2, oxidative stress (HNE) and fibrogenesis (α-SMA, fibronectin and phospho-smad2) (Figure 3). DPI downregulated Nox-2 and fibrogenesis (vimentin and phospho-smad3) suggesting that Nox-2 is a mediator of CsA-induced renal fibrosis (Figure 4). To characterize the effects of CsA on intrarenal oxygenation and perfusion, rats underwent blood oxygen level dependent MRI (BOLD-MRI) and perfusion studies (Figures 5 and 6). BOLD-MRI is a non-invasive imaging method that uses hemoglobin as an endogenous contrast agent. These studies demonstrated that CsA therapy significantly decreased cortical oxygenation (increased R2* levels) while decreasing cortical perfusion. Nox inhibition by DPI prevented these changes. In conclusion, these studies indicate that Nox-2 is involved in the pathogenesis of CsA-induced fibrogenesis and hypoxia. Specific Nox-2 inhibition may prevent CNI nephrotoxicity.

## TH-FC069

**Gadodiamide (Gd-OMN) Binds Circulating ASARM-Peptides: A Model for Nephrogenic Systemic Fibrosis (NSF)** Peter S. N. Rowe,[1] Anne-Marie Hedge,[1] Jennifer S. Laurence,[2] Sang-Pil Lee,[1] William M. Brooks,[1] Ellen T. McCarthy.[1] *[1]University of Kansas Medical Center, KS; [2]The University of Kansas, KS.*

Nephrogenic systemic fibrosis (NSF) is a devastating condition associated with gadolinium (Gd) containing contrast-agents and chronic kidney disease (CKD). The primary cause of NSF remains unknown. Bone matrix ASARM-peptides are linked with renal-handling defects and bone-mineralization abnormalities. We hypothesize that increased levels of these acidic, highly reactive and phosphorylated ASARM-peptides: 1. Bind to gadodiamide (Gd-OMN) and 2. Destabilize the Gd-OMN complex resulting in release of toxic Gd and thus NSF.

To test our hypothesis, injections of Gd-containing Omniscan (Gd-OMN) were given to, 1. Normal mice (WT): 2. PHEX defective, X-linked hypophosphatemic rickets mice (HYP) that have high circulating levels of ASARM-peptides: 3. HYP-mice treated with a 4.2 kDa synthetic PHEX-related peptide (SPR4). SPR4 binds with affinity to ASARM-peptides, neutralizing biological activity. Finally, we used magnetic resonance imaging (MRI), HPLC and $^{1}H/^{15}N$ nuclear-magnetic-resonance (NMR) to study Gd-OMN-ASARM binding and competitive-inhibition of this binding with SPR4.

Renal *ex vivo* MRI scans of WT-mice treated with Gd-OMN showed a strong signal indicative of a sequestered gadodiamide complex. In contrast, the signal was almost absent in Gd-OMN treated HYP mice but restored in SPR4 treated HYP mice. Using HPLC and solution NMR we showed ASARM-peptide binds to Gd-OMN *in vitro*. Also, $^{15}N$ labeled SPR4 and $^{1}H/^{15}N$ NMR confirmed Gd-OMN binds to SPR4. Finally, HPLC data indicated SPR4 disrupts Gd-OMN binding to ASARM-peptide.

In summary: 1. High levels of ASARM-peptide in HYP mice results in altered metabolism of a Gd-contrast agent, Gd-OMN; 2. ASARM-peptide binds to Gd-OMN *in vitro*; 3. The ASARM-Gd-OMN complex likely launches reactive de-sequestration and toxic release of Gd. 4. SPR4-peptide binds competitively to ASARM-peptide and thus indirectly stabilizes the Gd-OMN complex. In conclusion, SPR4-peptide might be an ideal adjuvant to prevent NSF. Specifically, such a protective agent could allow safe use of MRI in the care of patients with CKD.

**Targeted Expression of Pan-Caspase Inhibitor Protein p35 in Tubular Epithelium Protects Mice Against Renal Fibrogenesis Following Nephrotoxic Serum Nephritis (NTN)** Tsutomu Inoue, Hiromichi Suzuki, Hirokazu Okada. *Department of Nephrology, Saitama Medical University, Irumagun, Saitama, Japan.*

Background: The caspase family of enzymes participates in cell apoptotic and proinflammatory reactions. Although caspase activation was known to be involved in renal fibrogenesis in NTN, in such a nephritic kidney how caspase activation plays a role remains to be determined.

Methods: Two lines of transgenic (tg) mice were used. p35 tg mice that bear the baculovirus pan-caspase inhibitor protein *p35* gene separated from a universal CAG promoter by a floxed STOP sequence were crossed with γGT.Cre tg mice that express Cre recombinase in tubular epithelium. Double-tg mice (γGT.Cre;p35) and wild-type mice were then challenged with NTN. Cell apoptosis was defined by in situ end labeling and the point-counting method. Fibrosis-related parameters in the kidneys were determined by real-time RT-PCR and immunohistochemistry.

Results: Either urinary protein excretion or glomerular damage such as crescent formation was significantly increased at the similar degree in the γGT.Cre;p35 and wild-type mice with Day14 NTN. In contrast, F4/80$^{+}$ monocyte infiltration and matrix deposition by Masson's trichrome staining in the peritubular interstitium were significantly decreased in the NTN kidneys of the γGT.Cre;p35 mice, compared to those of the wild-type mice, possibly due to cell-type specific caspase inhibition by p35 gene product (10.2±4.2 vs. 15.6±6.7 [monocytes/hpf], and 8.4±2.1 vs. 17.2±3.4 [% blue area], respectively). mRNA levels of IL-1β, MCP-1 and fibronectin-EIIIA were also significantly decreased in the NTN kidneys of the γGT.Cre;p35 mice, compared to those of the wild-type mice. Surprisingly, the number of apoptotic tubular cells in the NTN kidneys was small and not significantly different between the γGT.Cre;p35 and wild-type mice (0.5±0.7 vs. 0.3±0.5 [apoptotic tubular cells/hpf]).

Conclusion: Targeted expression of p35 in the tubular epithelium provides evidence of the critical role of caspase activation in the tubular epithelium in proinflammatory cell recruitment, but not apoptosis induction, and subsequent fibrogenesis in the NTN kidneys.

## TH-FC071

**Downregulation of Hedgehog Signaling Prevents Renal Cystogenesis in Mouse Models of Ciliopathies** Pamela Vivian Tran, David Beier. *Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Cystic kidney disease (CKD), a leading cause of renal failure, is proposed to originate from an underlying ciliary defect. There are no proven therapies for CKD and molecular mechanisms remain unclear. In our characterization of the ENU mutant mouse *alien (aln)*, we identified a novel ciliary protein, THM1 (Tetratricopeptide Repeat Containing Hedgehog Modulator 1, also IFT139), which negatively regulates Hedgehog (Hh) signaling. Mutations in IFT139 have been identified in patients with several ciliopathies that feature renal cysts as a major clinical component, including nephronophthisis, Bardet-Biedl Syndrome and Meckel-Gruber Syndrome. By E16.5, the *aln* mutant also develops renal cysts. Importantly, *aln* cysts were prevented by genetic deletion of *Gli2*, the main transcriptional activator of Hh signaling, implicating a role for increased Hh signaling in the etiology of *aln* renal cystogenesis. To explore whether the Hh pathway might present a novel target for CKD, we examined the effects of small molecule Hh inhibitors in a cAMP-induced cystogenic kidney explant assay. In the presence of cAMP, cultured *aln* kidneys exhibited a three-fold greater cystogenic potential than wild-type. This was prevented by small molecule Hh inhibitors, Gant61 or Sant2, supporting a role for increased Hh signaling in *aln* renal cystogenesis. Surprisingly, the small molecules also abrogated cAMP-induced cysts in wild-type kidneys, indicating a beneficial role for Hh inhibitors in cAMP-mediated renal cystogenesis, which is proposed as a general mechanism in CKD. We thus questioned whether the preventive effects of Gant61 and Sant2 might extend to other models of CKD, such as the *jck* mutant, a mouse model for NPHP9. This mutant develops severe CKD by P21 and also showed a three-fold higher cystogenic potential than wild-type using the cAMP cystogenic assay. This increased cystogenesis was dramatically reduced by both Gant61 and Sant2. Our results indicate a protective role for small molecule Hh antagonists in CKD and demonstrate the potential of developing Hh inhibitors as targeted therapies.

**Exome Capture and Massively Parallel Sequencing Reveals Mutations in *SDCCAG8* as a New Cause of Nephronophthisis-Related Ciliopathy**
Friedhelm Hildebrandt,[1] Toby W. Hurd,[1] Rannar Airik,[1] Moumita Chaki,[1] Weibin Zhou,[1] Amiya K. Ghosh,[1] Rachel H. Giles,[2] Peter Nuernberg,[3] Eric Pierce,[4] Corinne Antignac,[5] Sophie Saunier,[5] Ronald Roepman,[6] Edgar Otto.[1] *[1]Dept of Pediatrics & HHMI, Univ of Michigan, Ann Arbor, MI; [2]Dept of Medical Oncology, Univ Med Center, Utrecht, Netherlands; [3]Cologne Center for Genomics, Univ of Cologne, Cologne, Germany; [4]F.M. Kirby Center for Molecular Ophthalmology, UPenn School of Medicine, Philadelphia, PA; [5]INSERM U-983, Hospital Necker-Enfants Malades, Paris, France; [6]Dept of Human Genetics, Radboud Univ, Nijmegen, Netherlands.*

Nephronophthisis-related ciliopathies (NPHP-RC) are recessive disorders featuring dysplasia or degeneration in kidney, retina and cerebellum. We combined homozygosity mapping with "ciliopathy candidate exome capture" of 828 candidate genes followed by massively parallel sequencing. Candidates were derived from ciliopathy animal models, the centrosomal and photoreceptor cilia proteomes. We detected 6 homozygous null mutations in the gene *SDCCAG8* in 5 NPHP-RC families. Subcellular localization studies revealed that SDCCAG8 occurs at centrosomes throughout the cell cycle and is located e.g. in mouse photoreceptor basal bodies and connecting cilia transition zone together with other NPHP-RC proteins including NPHP5. We identified OFD1, another cystic kidney disease associated NPHP-RC protein, as a direct interaction partner of SDCCAG8 by yeast-2-hybrid screening. Depletion of *sdccag8* in zebrafish resulted in kidney cysts and body axis defects. Furthermore, siRNA knockdown of *Sdccag8* disturbed lumen formation of renal epithelial cells in 3D spheroid cultures, indicative for a cell polarity defect. We observed SDCCAG8 at cell-cell junctions. Interestingly, SDCCAG8 abandons cell-cell junctions in response to increased intracellular cAMP levels, which have been described as a therapeutic target in cystic kidney disease. In summary, this work identifies *SDCCAG8* loss of function as a novel cause of NPHP-RC, thus contributing to the understanding of disease mechanisms of retinal-renal ciliopathies.

Disclosure of Financial Relationships: nothing to disclose

**How To Build a Primary Cilium with the Exocyst**
Ben Fogelgren,[1] Shin-Yi Lin,[2] Xiaofeng Zuo,[1] Heather H. Ward,[3] Ryan J. Reichert,[4] Kwon Moo Park,[5] P. Darwin Bell,[4] Angela Wandinger-Ness,[3] Rebecca D. Burdine,[2] Joshua H. Lipschutz.[1,6] *[1]Department of Medicine, University of Pennsylvania; [2]Department of Molecular Biology, Princeton University; [3]Department of Pathology, New Mexico Health Sciences Center; [4]Department of Medicine, Medical University of South Carolina; [5]Department of Anatomy, Kyungpook National University, Daegu, Korea; [6]Nephrology, Philadelphia VAMC.*

The pathogenesis of cystic kidney disease is dependent on disruptions in primary cilia function in renal epithelial cells. This includes ADPKD, which is caused by mutations in genes that encode polycystins-1 and-2. Despite intense study of cilia and associated ciliopathies, it is not understood how ciliary proteins are targeted and delivered to cilia. We previously showed that the exocyst, a highly conserved eight-protein trafficking complex, is required for ciliogenesis. Based on our findings, we developed a "construction" model for primary cilia: the GTPase Cdc42 localizes the exocyst to primary cilia, the exocyst is stabilized by binding to the Par complex, and the exocyst then docks Rab8-positive vesicles carrying ciliary proteins. In support of this model, we show that Cdc42 co-localized with the exocyst at primary cilia; Cdc42 biochemically interacted with exocyst Sec10; and expression of dominant negative Cdc42 prevented ciliogenesis in MDCK cells. The exocyst co-localized and co-immunoprecipitated (co-IP) with Par3, and the exocyst also co-IP'd with Rab8, a GTPase found on vesicles necessary for ciliogenesis. We also show that exocyst Sec10 interacted with ciliary proteins polycystin-2, IFT20, and IFT88. To further support this model, knockdown of Sec10 in MDCK cells led to a cellular phenotype similar to ADPKD cells: loss off flow-generated calcium release; hyperproliferation; and activation of the MAPK pathway. In vivo Sec10 knockdown in zebrafish phenocopied many aspects of polycystin-2 knockdown, including: curly tail up; glomerular expansion; left-right patterning defects; and MAPK activation. Importantly, co-injection of small amounts of sec10 and pkd2 morpholinos, which individually had no effect, together resulted in a severe phenotype.

**Pkhd1 Deficiency Identifies a Novel Functional Relationship between Fibrocystin/Polyductin, SMURF-Mediated Endocytosis, and TGF-beta Signaling**
Jun-Ya Kaimori,[1] Aki Kaimori,[2] Luis F. Menezes,[2] Miguel A. Garcia-Gonzalez,[2] Erum A. Hartung,[2] Shiro Takahara,[1] Guanqing Wu,[3] Yoshitaka Isaka,[1] Hiromi Rakugi,[1] Luiz Fernando Onuchic,[4] Lisa M. Guay-Woodford,[5] Gregory G. Germino.[6] *[1]Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]JHU, Baltimore, MD; [3]Vanderbilt University School of Medicine, Nashville, TN; [4]University of Sao Paulo, Sao Paulo, Brazil; [5]UAB, Birmingham, AL; [6]NIDDK, NIH, Bethesda, MD.*

Individuals with human autosomal recessive polycystic kidney disease (ARPKD) typically develop collecting duct cysts lined by flattened epithelial cells, and congenital hepatic fibrosis. These features have been attributed to altered cellular morphology and spatial orientation, and increased TGF-b signaling in the biliary tract, respectively. The pathogenic mechanisms underlying these abnormalities have not been determined. In characterizing a renal epithelial cell line with inducible expression of PKHD1, the gene mutated in ARPKD, we observed cytomorphic changes opposite those of cystic epithelial cells and corresponding changes in Rho protein expression. In characterizing these findings, we discovered by co-IP and by IF that PD1 and Smurf1 form a complex. PD1 also associates with Smurf2, and levels of the Smurf2 target, Rap1B, changed in parallel with those of RhoA. Smurf1, 2 and their respective targets RhoA and Rap1B were localized differently in Pkhd1-deficient cells (PDCs) compared to controls, and these changes were associated with differences in the F-actin cytoskeleton and trafficking of E-cadherin. We also found enhanced clathrin-mediated endocytosis (CME) and reduced raft-mediated endocytosis (RME) in PDCs, with large vacuole-like lysosomes and intracellular cholesterol accumulation. Consistent with the roles of Smurfs and RME in down-regulating TGF-b activity and the converse role of CME in sending TGF-b signals to the nucleus, we found increased TGF-b activation in Pkhd1-defecient cholangiocyte cells. Our results provide a mechanistic explanation for both the cellular effects of PKHD1and in vivo phenotypic abnormalities that result from its mutation.

**The gamma-Secretase Cleavage Product of Polycystin-1 Regulates Tcf and CHOP-Mediated Transcriptional Activation through a p300-Dependent Mechanism**
David Merrick,[1] Hannah Chapin,[1] Zhiheng Yu,[2] Stefan Somlo,[2] John B. Hogenesch,[3] Michael J. Caplan.[1] *[1]Cellular and Molecular Physiology, Yale University, New Haven, CT; [2]Department of Medicine, Section of Nephrology, Yale University, New Haven, CT; [3]Pharmacology, University of Pennsylvania, Philadelphia, PA.*

Mutations in the gene encoding Polycystin-1 cause Autosomal Dominant Polycystic Kidney Disease. We show that the carboxy-terminal tail of Polycystin-1 is released by a gamma-secretase-mediated cleavage, and translocates to the nucleus where it is involved in the regulation of the Wnt and CHOP signaling pathways. Loss of Polycytin-1 expression results in increased proliferation and apoptosis, while re-introduction of its C-terminal tail fragment into polycystin-1 null cells reestablishes normal growth rate and apoptosis, and prevents cyst formation in three dimensional culture. Inhibition of gamma-secretase impairs the growth and apoptosis suppressive effects produced by full length polycystin-1 expression. The released polycystin-1 C-terminal tail fragment interacts with the transcription factors Tcf and CHOP, which regulate proliferation and apoptosis, respectively. Thus, the shedding of the extracellular domain of PC1, together with the cleavage and nuclear translocation of its cytoplasmic domain, mark PC1 as a member of a growing collection of plasma membrane proteins that are cleaved by gamma-secretase and participate in direct signaling to the nucleus. We find that the polycystin-1 tail employs a convergent mechanistic pathway for the regulation of Tcf and CHOP by disrupting these protein's interactions with their common transcriptional co-activator, p300. Regulation of Tcf and CHOP by the cleaved polycystin-1 C-terminal tail fragment explains how mutation of the gene encoding polycystin-1 can lead to the increased proliferation and apoptosis seen in Autosomal Dominant Polycystic Kidney Disease.

**Regulation of Wnt Pathway Genes by the Transcription Factor HNF-1β**
Sachin S. Hajarnis, Zhendong Ma, Peter Igarashi. *Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX.*

Mutations in hepatocyte nuclear factor-1β (HNF-1β), an epithelial- specific transcription factor, produce kidney cysts in humans. Recent studies in three rodent models of cystic kidney disease, including kidney-specific inactivation of HNF-1β, have shown that cyst formation is preceded by randomization of the orientation of cell division, a hallmark of altered planar cell polarity (PCP) and non-canonical Wnt signaling. Canonical (β-catenin-dependent) Wnt signaling is upregulated in some forms of PKD. We used SuperTopFlash luciferase reporter assays to measure canonical Wnt signaling in renal epithelial cells that express dominant-negative mutant HNF-1β (DN-HNF-1β). Treatment with LiCl or Wnt3a, known activators of canonical Wnt signaling, produced higher luciferase activity in cells expressing DN-HNF-1β compared with control cells. Western blot analysis showed that the levels of activated β-catenin were higher in cells expressing DN-HNF-1β. ChIP-chip analysis of renal epithelial cells identified several components of the canonical and non-canonical Wnt signaling pathways as novel transcriptional targets of HNF-1β. Consensus HNF-1β binding sites were identified within the gene promoters and chromatin-immunoprecipitation (ChIP) confirmed that HNF-1β binds to the promoters in vivo. Quantitative RT-PCR (Q-RT-PCR) confirmed that the expression of the Wnt pathway genes was altered in kidney cells expressing DN-HNF-1β. An unbiased microarray-based approach identified additional Wnt pathway genes whose expression is altered in cells expressing DN-HNF-1β. These results indicate that HNF-1β directly and indirectly regulates the expression of genes that are involved in the canonical and non-canonical Wnt pathways. Further elucidation of the molecular mechanism may provide new avenues for therapy of PKD directed at correcting the abnormalities in Wnt signaling.

**TH-FC077**

**PC2 Regulates Canonical Wnt Signaling Requiring PC1 Expression** Ao Li, Bo Hu, Dan Liang, Guanqing Wu. *Medicine and Cell & Developmental Biology, Vanderbilt University, Nashville, TN.*

Autosomal dominant polycystic kidney disease (ADPKD), one of the most common monogenic disorders, exhibits numerous fluid-filled cysts in both kidneys. ADPKD is caused by at least two genes, *PKD1* and *PKD2*, and is therefore considered a genetically heterogeneous disease. Although recent studies have suggested that the gene products of both polycystin-1 and -2 (PC1 and PC2) are linked to β-catenin-dependent signaling, the precise molecular basis by which PC1 and PC2 affect this signaling pathway remain largely unknown. We established immortalized renal collecting duct cell lines from the kidneys of Im::*Pkd1*$^{-/-}$ mice and their wildtype littermates. Using these cell lines we demonstrate that PC2 participates in the regulation of canonical Wnt signaling and PC2 interacts with the β-catenin/E-cadherin complex required PC1 expression. Thus, it appears that PC1 may mediate PC2-associated canonical Wnt signaling. Utilizing a previously established null-*Pkd2* cell lines, we also found that loss of PC2 significantly downregulates PC1 expression *in vitro* and *in vivo* and the PC2-dependent PC1 reduction may result from increased E3 ubiquitin ligase Siah-1, which has been demonstrated to physically interact with PC1 and regulate PC1 proteasomal degradation. Our findings indicate that polycystins are important participants in canonical Wnt signaling in ADPKD, and provide new insight into the precise molecular hierarchy between polycystins onto the β-catenin/E-cadherin complex.

**Identification of a Polycystin-1 Cleavage Product, P100, That Regulates Store Operated Ca2+ Entry through Interactions with STIM1** Owen M. Woodward,[1] Shengqiang Yu,[2] Alessandra Boletta,[3] William B. Guggino,[1] Feng Qian.[2] *[1]Dept. of Physiology, Johns Hopkins School of Medicine, Baltimore, MD; [2]Dept. of Medicine, Div. of Nephrology, Johns Hopkins School of Medicine, Baltimore, MD; [3]Dulbecco Telethon Institute, Div. Genetics & Cell Biology, San Raffaele Scientific Institute, Milan, Italy.*

Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a genetic disorder resulting in large kidney cysts and eventual kidney failure. Mutations in either the PKD1 or PKD2 / TRPP2 genes and their respective protein products, polycystin-1 (PC1) and polycystin-2 (PC2) result in ADPKD. PC2 is known to function as a non-selective cation channel, but PC1's function, and the function of PC1 cleavage products are not well understood. Here we identify an endogenous PC1 cleavage product, P100, a 100kDa fragment found in both wild type and epitope tagged PKD1 knock-in mice. Expression of full length human PC1 (FL PC1) and the resulting P100 and c-Terminal Fragment (CTF) cleavage products in both MDCK and CHO cells significantly reduces the store operated Ca2+ entry (SOCE) resulting from thapsigargin induced store depletion. Exploration into the roles of P100 and CTF in SOCE inhibition reveal that P100, when expressed in *Xenopus laevis* oocytes, directly inhibits the SOCE currents but CTF does not, nor does P100 when containing the disease causing R4227X mutation. Interestingly, we also found that in PC1 expressing MDCK cells, translocation of the ER Ca2+ sensor protein STIM1 to the cell periphery was significantly altered. In addition, P100 Co-immunoprecipitates with STIM1 but CTF does not. The expression of P100 in CHO cells recapitulates the STIM1 translocation inhibition seen with FL PC1. These data describe a novel polycystin-1 cleavage product, P100, which functions to reduce SOCE via direct inhibition of STIM1 translocation; a function with consequences for ADPKD. **Multi-Target Based Therapy by Curcumin Delays Cystogenesis in a *Pkd1*-Deletion Mouse Model for ADPKD** Wouter N. Leonhard,[1] Anne Marike Van der Wal,[2] Zlata Novalic,[1] Martijn H. Breuning,[1] Emile De Heer,[2] Dorien J. M. Peters.[1] *[1]Human Genetics, Leiden University Medical Center, Leiden, Netherlands; [2]Pathology, Leiden University Medical Center, Leiden, Netherlands.*

Autosomal Dominant Polycystic Kidney Disease (ADPKD) caused by mutations in either the *PKD1* or *PKD2* gene, is a major cause for end-stage renal failure resulting from progressive cyst formation and fibrosis. Few compounds targeting specific cellular signaling pathways were able to inhibit cystogenesis in rodent models and are currently being tested in clinical trials. However, given the complex signaling in ADPKD, an ideal therapy would likely have to comprise several pathways at once. Therefore, multi-target compounds may provide promising therapeutic interventions for treatment of ADPKD.

To test this hypothesis we treated tamoxifen-inducible kidney epithelium-specific *Pkd1*-deletion mice with Curcumin (diferuloylmethane), a compound with limited side effects which is known to modulate several pathways. Curcumin-mediated inhibition has been reported for AP-1, STAT3, NF-κβ, Wnt/β-catenin signaling, TNFα, MAPKs, EGR-1, HIF-1α, Notch-1, and mTOR-regulated signaling. Many of these signaling pathways are altered in kidneys from patients with ADPKD.

Cystic kidneys of inducible *Pkd1*-deletion mice indeed demonstrated increased expression of phosphorylated rpS6 acting downstream of mTOR/S6K ($p<0.05$). In addition, we observed activation of STAT3, which strongly correlated with cyst progression ($p<0.05$ and $R^2=0.86$). Curcumin treatment reduced both mTOR and STAT3 activation *in vitro* and *in vivo* ($p<0.05$ and $p<0.01$). Importantly, Curcumin reduced KW/BW ratio at an intermediate stage of PKD (from 2.59 to 1.95%; $p<0.01$; n=5 for both groups) and postponed renal failure (from 105 to 119 days after *Pkd1* disruption; $p<0.001$; untreated n=11, Curcumin treated n=12).

In conclusion, this study provides evidence that multi-target compounds like Curcumin are able to delay cyst progression without apparent side effects. Current developments in the field of Curcumin analogues and other compounds acting in a similar fashion are highly promising and should be further evaluated as possible therapeutics for ADPKD.

**Modulation of Glycosphingolipid Metabolism as a New and Effective Approach for the Treatment of PKD** Thomas A. Natoli,[1] Herve Husson,[1] Kelly A. Rogers,[1] Laurie A. Smith,[1] Bing H. Wang,[2] Svetlana Komarnitsky,[2] Yeva Budman,[2] Alexei Belenky,[2] Nikolay Bukanov,[1] William R. Dackowski,[1] Ryan J. Russo,[1] James A. Shayman,[3] Steven R. Ledbetter,[1] John P. Leonard,[4] Oxana Beskrovnaya.[1] *[1]Cell Biology, Genzyme Corp., Framingham, MA; [2]Analytical Research & Development, Genzyme Corp., Waltham, MA; [3]Internal Medicine, University of Michigan, Ann Arbor, MI; [4]Pharmacology, Genzyme Corp., Waltham, MA.*

Polycystic kidney diseases (PKD) are characterized by growth of fluid-filled cysts in kidneys and other organs ultimately leading to ESRD. Sphingolipids (SL) and glycosphingolipids (GSL) have recently been recognized as playing important roles in the regulation of numerous cellular processes, including proliferation, apoptosis, and modulation of mitogenic signaling pathways. Many of these processes are affected in multiple forms of PKD regardless of the causative mutation. We sought to evaluate the therapeutic potential for GSL modulation as a new approach to treat PKD. We demonstrate that glucosylceramide (GlcCer) and ganglioside GM3 levels are elevated in human PKD kidneys and in cystic kidneys of mouse models orthologous to ADPKD and nephronophthisis as compared to normal counterparts. To reduce the levels of GlcCer and its derivatives in cystic kidneys we used a highly specific inhibitor of GlcCer synthase that blocks the conversion of ceramide to GlcCer. Treatment with GlcCer synthase inhibitor reduced kidney GlcCer and GM3 levels and effectively attenuated PKD progression in mouse model with conditionally inactivated *Pkd1* gene as well as in two models of nephronophthisis: *pcy* and *jck*. Mechanistic studies showed that inhibition of GSL synthesis leads to effective cell cycle blockade and inhibition of Akt-mTOR signaling in cystic kidneys. Together, these data demonstrate for the first time that modulation of GSL metabolism is a new and effective approach to treat PKD.

**CKD-EPI and MDRD Study Equations for GFR Estimation and Mortality: The Third National Health and Nutrition Examination Survey (NHANES III)** Tariq Shafi,[1] Kunihiro Matsushita,[1] Brad C. Astor,[1] Elizabeth Selvin,[1] Lesley A. Stevens,[2] Josef Coresh.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Tufts Medical Center, Boston, MA.*

The Chronic Kidney Disease Epidemiology (CKD-EPI) equation improves glomerular filtration rate estimation (eGFR) compared with Modification of Diet in Renal Disease (MDRD) Study equation but its association with mortality in the general population has not been studied. We compared the associations between eGFR, estimated from serum creatinine by the CKD-EPI ($eGFR_{CKDEPI}$) and MDRD equations ($eGFR_{MDRD}$), and mortality in 15,818 NHANES III participants aged ≥17 yrs with 18yrs of mortality follow-up (till 12/31/2006). To evaluate the effect of reclassification by $eGFR_{CKDEPI}$, we calculated the net reclassification improvement (NRI). NRI=clinically correct classification-clinically incorrect classification. NRI ranges from 0 (no improvement) to 1 (perfect). $eGFR_{CKDEPI}$ reclassified 1,472 (20%), 1,819 (43%), 114 (24%) and 8 (4%) of the participants with $eGFR_{MDRD}$ categories 90-119, 60-89, 45-59 and 30-44 ml/min/1.73m$^2$, respectively, to a higher eGFR category. <5% participants were reclassified to a lower eGFR category. Participants with $eGFR_{MDRD}$ 45-59 ml/min/1.73m$^2$ who were reclassified upward had a 44% lower risk of all-cause mortality (adjusted incidence rate ratio [IRR], 0.56; 95% CI, 0.35-0.88) and a trend towards lower risk of cardiovascular disease (CVD) mortality (adjusted IRR, 0.55; 95% CI, 0.28-1.06) than those not reclassified. Those reclassified upwards were more likely to be younger, female, white, had less CVD and lower blood pressure. NRI was significantly improved across all sub-groups. In the general US population, the CKD-EPI equation improved risk stratification of persons at risk for mortality. These data support the adoption of CKD-EPI equation for GFR estimation.

NRI* by CKD-EPI eGFR

| | Mortality | |
|---|---|---|
| Group | All-Cause | CVD |
| All | 0.28 | 0.29 |
| Age ≥65 yrs | 0.15 | 0.10 |

**Risk Implications of the CKD-EPI Creatinine GFR Equation Compared to the MDRD Study Equation** Kunihiro Matsushita,[1] Marcello Tonelli,[2] Anita Lloyd,[2] Andrew S. Levey,[4] Josef Coresh,[1] Brenda Hemmelgarn.[3] *[1]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Departments of Medicine, University of Alberta, Edmonton, AB, Canada; [3]Departments of Medicine, University of Calgary, Calgary, AB, Canada; [4]Division of Nephrology, Tufts Medical Center, Boston, MA.*

**Purpose:** To evaluate whether the CKD-EPI creatinine equation for estimated GFR (eGFR) predicts clinical outcomes better than MDRD Study equation in a large cohort derived from the Alberta Kidney Disease Network with mean follow-up time of 2.3 years.

**Methods:** We categorized 690,202 participants into five groups of eGFR (≥90, 60-89, 45-59, 30-44, 15-29 ml/min/1.73m$^2$) by both equations and assessed reclassification by CKD-EPI equation and its association with clinical outcomes.

**Results:** The CKD-EPI equation reclassified 33.5% of participants with $eGFR_{MDRD}$ 60-89, 39.1% with $eGFR_{MDRD}$ 45-59, and 15.5% with $eGFR_{MDRD}$ 30-44.

| eGFR (MDRD) | eGFR (CKD-EPI) ≥90 | 60-89 | 45-59 | 30-44 | 15-29 | Reclassification |
|---|---|---|---|---|---|---|
| ≥90, n | 182,502 | 3,106 | 0 | 0 | 0 | 1.7% |
| ESRD | 0.05 (0.0-0.1) | 0.14 (0.0-1.0) | - | - | - | |
| Death | 4.5 (4.3-4.7) | 67.5 (62-74) | - | - | - | |
| AMI | 0.7 (0.6-0.8) | 5.8 (4.3-7.9) | - | - | - | |
| 60-89, n | 143,284 | 286,305 | 1,019 | 0 | 0 | 33.5% |
| ESRD | 0.03 (0.0-0.1) | 0.05 (0.0-0.1) | 0.45 (0.1-3.2) | - | - | |
| Death | 2.0 (1.9-2.2) | 8.2 (8.0-8.4) | 94.0 (82-107) | - | - | |
| AMI | 0.7 (0.6-0.8) | 2.2 (2.1-2.3) | 12.2 (8.4-18) | - | - | |
| 45-59, n | 0 | 22,316 | 36,189 | 938 | 0 | 39.1% |
| ESRD | - | 0.02 (0.0-0.1) | 0.40 (0.3-0.6) | no event | | |
| Death | - | 5.0 (4.5-5.6) | 29.1 (28-30) | 127 (112-144) | | |
| AMI | - | 1.8 (1.4-2.1) | 5.9 (5.5-6.3) | 11.9 (8.0-18) | - | |
| 30-44, n | 0 | 0 | 1,475 | 9,993 | 359 | 15.5% |
| ESRD | - | - | 1.6 (0.7-3.6) | 3.4 (2.7-4.2) | 4.1 (1.3-13) | |
| Death | - | - | 16.0 (12-21) | 72.7 (69-76) | 182 (154-216) | |
| AMI | - | - | 3.8 (2.2-6.3) | 10.4 (9.2-12) | 15.3 (8.5-28) | |
| 15-29, n | 0 | 0 | 0 | 99 | 2,617 | 3.8% |
| ESRD | - | - | - | 12.9 (4.2-40) | 32.8 (26-38) | |
| Death | - | - | - | 21.0 (6.7-50) | 139 (130-150) | |
| AMI | - | - | - | 4.2 (0.6-30) | 15.2 (12-19) | |

The reclassification was mostly upward to a higher eGFR category, lowering the prevalence of CKD stage 3-4 from 10.7% to 7.6%. Participants who were reclassified upward had lower incidence rates per 1,000 person-years compared to those who were not reclassified (ESRD: 0.02 vs. 0.4, deaths: 5.0 vs. 29.1 and acute myocardial infarction [AMI]: 1.8 vs. 5.9 in $eGFR_{MDRD}$ 45-59, all P-values <0.001) (figure). Similar results were observed after the adjustment for age and sex. Significant net reclassification improvement by CKD-EPI equation was observed for all outcomes (ESRD: 0.191, deaths: 0.246, AMI: 0.162, all P-values <0.001). Similar results were observed across dipstick (negative, trace/1+, ≥2+) and age (<45, 45-54, 55-64, ≥65 y) categories.

**Conclusion:** The CKD-EPI equation more accurately categorized individuals as compared to MDRD Study equation regarding clinical risk, suggesting its clinical usefulness.

**Applicability of the MDRD and CKD-EPI Equations for Estimation of GFR in Older People** Hannah Kilbride,[1] Gillian Lorraine Eaglestone,[1] Sarah J. Knight,[1] Paul E. Stevens,[1] Michael Delaney,[1] Christopher K. T. Farmer,[1] Shelagh E. O'Riordan,[1] R. Neil Dalton,[2] Edmund J. Lamb.[3] *[1]Kent Kidney Care Centre, East Kent Hospitals, Canterbury, Kent, United Kingdom; [2]Well Child Laboratory, St Thomas' Hospital, London, United Kingdom; [3]Department of Clinical Biochemistry, East Kent Hospitals, Canterbury, Kent, United Kingdom.*

Introduction

Measurement of glomerular filtration rate (GFR) is an essential tool in the detection, management and evaluation of CKD. GFR is commonly estimated using the Modification of Diet in Renal Disease (MDRD) Study equation. Recently the CKD epidemiology collaboration (CKD-EPI) equation has been proposed, claiming reduced bias. Neither equation has been extensively validated in older people and it is frequently claimed that these equations under estimate true GFR in this population.

Aim

To examine the relationship between true GFR and estimated GFR in older people.

Methods

Using difference plot analysis on log transformed data we examined the relationship between GFR measured by a reference iohexol method and estimated GFR from the MDRD and CKD-EPI equations in people aged over 74 y. Subjects were asked to avoid meat consumption prior to the test and following a 5 mL IV bolus of Omnipaque 240 venous samples were taken at 5, 120, 180 and 240 mins post-injection. Iohexol was measured by isotope dilution mass spectrometry (IDMS) and iohexol clearance was calculated. Serum creatinine was measured by IDMS and the IDMS-related MDRD and CKD-EPI GFRs were calculated.

Results

To date 127 subjects with a median age of 80 y (range 74-97), 67 female and 61 male, have been studied.

Performance characteristics of the MDRD and CKD-EPI equations versus true GFR

| | Median GFR (mL/min/1.73m$^2$) | Bias, % (± 95% CI) | Percent within 30% | 95% limits of agreement |
|---|---|---|---|---|
| Iohexol | 43, IQR 30 to 62 | | | |
| MDRD | 48, IQR 30 to 71 | 7.0 (2.1 to 12.0) | 75 | 36 to 79 |
| CKD-EPI | 46, IQR 29 to 71 | 2.3 (-2.3 to 7.2) | 78 | 39 to 71 |

Conclusion

This study shows no evidence to support the contention that the MDRD equation over diagnoses CKD in older people. Our data suggests that the CKD-EPI equation may be slightly more accurate than the MDRD equation in this population.

**TH-FC084**

**Relative Performance of the MDRD and CKD-EPI Equations for Estimating Glomerular Filtration Rate in Different Patient Populations** Kazunori Murata,[1] Timothy S. Larson,[1,2] Amy K. Saenger,[1] Andrew D. Rule,[2] Nikola A. Baumann,[1] John C. Lieske.[1,2] *[1]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; [2]Department of Internal Medicine, Mayo Clinic, Rochester, MN.*

The objective of our study was to examine the ability of both the MDRD and CKD-EPI equations to estimate glomerular filtration rate (GFR) in a variety of patient populations, including the elderly, healthy patients, nephrectomized patients, and kidney transplant recipients.

A cross sectional study was conducted of patients who underwent renal function assessment for clinical purposes by simultaneous measurements of serum creatinine (IDMS-traceable method), estimation of GFR using the MDRD and CKD-EPI equations, and renal iothalamate clearance (n=5238). The study population consisted of CKD patients (n=2324), nephrectomized kidney donors (n=97), potential kidney donors (n=583), kidney transplant recipients (n=1375), and non-kidney transplant recipients (n=859); 16.6% (n=870) were > age 70.

The MDRD and CKD-EPI equations performed similarly in elderly and non-elderly patients regarding ability to correctly stage CKD patients. Overall, % bias (estimated GFR minus measured GFR) with either equation did not differ by age. Within the nephrectomized and healthy populations the CKD-EPI equation demonstrated less bias than the MDRD equation, and classified patients better into CKD stage. The CKD-EPI equation gave estimates that were biased by 6, 8, -8, and -7% in CKD patients, kidney transplant recipients, potential donors, and nephrectomized donors, respectively, while the MDRD equation gave estimates that were biased by 3, 1, -18, and -15%. Notably, among potential kidney donors the CKD-EPI equation had greater specificity for detecting measured GFR <60 ml/min/1.73m$^2$ than the MDRD equation (98 vs 94%) but lower sensitivity (50 vs 70%).

Therefore, the MDRD and CKD-EPI equations perform similarly in elderly and nonelderly patients with CKD and/or status post organ transplantation. Among people who present in good health, the CKD-EPI equation is more specific for measured GFR < 60 ml/min/1.73m$^2$, but also less sensitive.

**CKD, Metabolic Abnormalities and Outcomes in US Adults < 65: CKD-EPI or MDRD Formulas?** Yi Peng,[1] Robert N. Foley,[1,2] David T. Gilbertson,[1] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

**Background:**

It has recently been suggested that the CKD-EPI creatinine equation (Ann Intern Med. 2009;150:604-612.) is more accurate than the MDRD equation for GFR estimation and should replace it for routine clinical use. However, outcome comparisons in the setting of large administrative databases are lacking.

**Methods:**

This analysis considered 724,205 subjects aged 20-64, enrolled in fee-for-service plans, and had at least one serum creatinine measured in the U.S. throughout 2008 (Ingenix i3 database). eGFR < 60 was defined with the MDRD and CKD-EPI equations. ICD-9-CM claims were used to define comorbidity and hospitalization and metabolic abnormalities were identified from laboratory measurement files.

**Results:**

4.2 % had GFR < 60 with the CKD-EPI formula and 8.0% with the MDRD formula. For eGFR < 60, use of the CKD-EPI formula (vs. the MDRD formula) was associated (P < 0.05) with a higher prevalence (%) of WHO anemia (21.4/15.6), hypertension (63.2/52.9), cardiovascular disease (23.4/18.8), high PTH (33.8/29.8), low HDL (41.2/37.3), high triglycerides (33.8/29.8), high uric acid (35.3/28.1), low calcium (6.5/5.5) and high glucose (43.1/37.2). The corresponding values for hospitalization for 1 to 7 days, hospitalization for > 7 days, 1 admission and 2+ admissions were 9.0/7.6, 5.0/3.6, 9.4/7.8 and 4.7/3.4, respectively.

**Conclusions:**

Regarding metabolic abnormalities and hospitalization outcomes, low GFR defined with the CKD-EPI formula has substantially more sensitivity than with the MDRD formula.

## TH-FC086

**Evaluation of Creatinine Based GFR Estimating Equation in an HIV Positive Population** Lesley A. Stevens,[1] Christina M. Wyatt,[2] Rebecca Creamer,[3] James Hellinger,[1] Mathew Hotta,[2] Maia Leppo,[1] Andrew S. Levey,[1] Aghogho A. Okparavero,[1] Sunila Reddy,[4] Martin Rhee,[1] Karen Savage,[3] Fran Wallach,[2] Zipporah Krishnasami.[3] *[1]Tufts Medical Center; [2]Mt. Sinai School of Medicine; [3]University of Alabama; [4]Gilead Sciences, Inc.*

**Background** Changes in muscle mass and fat distribution may occur with advanced HIV disease and with the use of some anti-retroviral agents. These changes may affect the accuracy of creatinine based GFR estimating equations.

**Methods** We will measure GFR using plasma clearance of iohexol in 200 HIV positive patients on stable antiretroviral therapy. Here we report preliminary results from the first 125 participants. Creatinine was assayed using standardized methods. GFR was estimated by the MDRD Study and CKD-EPI equations, and performance is described for the whole cohort and for subgroups defined by eGFR, age, sex, race, and body mass index (BMI).

**Results** Mean (SD) measured GFR was 86 (25) ml/min/1.73 m$^2$. The table shows median difference and interquartile range (IQR) overall and by subgroup.

**Conclusions** The CKD-EPI equation is more accurate than the MDRD Study equation in all subgroups except BMI less than 20 kg/m$^2$, although sample size was small. The relative improvement of tbe CKD-EPI equation compared to the MDRD study equation is similar to those reported in non-HIV populations. Creatinine based GFR estimating equations can be used in HIV positive patients.

Table: Performance by Subgroup

| | | MDRD | | | CKD-EPI | | |

**Discordant Glomerular Filtration Rate Determinations between Iothalamate and Iohexol Renal Clearances** Jesse C. Seegmiller,[2] Bradley E. Burns,[2] John C. Lieske,[1,2] Timothy S. Larson.[1,2] *[1]Division of Nephrology and Department of Internal Medicine, Mayo Clinic; [2]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.*

***Purpose:*** Few studies have compared renal clearances of iothalamate with iohexol, and controversy exists as to their comparability. The purpose of this study was to directly compare the renal clearances of these analytes across a wide range of glomerular filtration rate (GFR).

***Methods:*** 150 study subjects received concurrent subcutaneous injections of iothalamate (iothalamate meglumine 600 mg/mL) and iohexol (iohexol 647.1 mg/mL) followed by timed urine and plasma collections. Iothalamate and iohexol were measured in urine and plasma specimens by a novel liquid chromatography tandem mass spectrometry method (LC-MS/MS; ABSCIEX 5500), and GFR calculated from the clearance of each analyte by standard formulae. Both iothalamate and iohexol were analyzed using multiple reaction monitoring (MRM) transitions. Simultaneous creatinine clearance was also measured. To evaluate for possible protein complexation by either analyte, plasma samples from 3 study subjects were dialyzed using a 2000 molecular weight cutoff membrane against a phosphate buffered saline dialysate (Slide-a-lyzer; ThermoFisher).

***Results:*** Among the 150 study subjects the range of iothalamate and iohexol renal clearances was 1-132 mL/min/1.73m$^2$. The renal clearance of iohexol was consistently lower than iothalamate clearance (%mean difference =-14.7% (95% CI -16.3% to -13.0%; p= <0.0001). The % difference was constant throughout the range of measured GFRs. As expected, creatinine clearances were significantly greater than both iothalamate and iohexol clearances by 24% (95% CI 19.57% to 28.29%) and 38% (95% CI 33.72% to 42.35%) respectively. Plasma dialysis experiments revealed significantly greater post dialysis concentration ratios for iohexol compared to iothalamate suggesting greater protein binding of iohexol.

***Conclusion:*** These results demonstrate that renal clearance of iohexol is significantly lower than renal clearance of iothalamate across a wide range of GFRs. This difference may be due to greater plasma protein binding of iohexol as compared to iothalalmate.

**Drift in Dade Behring Cystatin C Assay 2003 to 2009** Lesley A. Stevens,[1] Jane Manzi,[2] Andrew S. Levey,[1] John H. Eckfeldt,[3] Frederick Van Lente,[0] Josef Coresh.[2] *[1]Nephrology, Tufts Medical Center, Boston, MA; [2]Johns Hopkins University; [3]University of Minnesota.*

**Background:** Variation in GFR estimating equation performance is in part due to measurement biases of filtration markers among laboratories. The CKD-EPI cystatin C (CysC) 2008 equation was developed in 2003 using samples assayed at the Cleveland Clinic (CC) (Stevens et al. AJKD 2008). We and others observed a drift in CysC concentrations. Magnitude of the drift was determined by comparing a calibration panel assayed in 2003 and 2009. An equation re-expressing 2009 values as 2003 values was developed.

**Methods:** Serum calibration panels were created in 2003 at CC and stored at -70$^o$. The panel includes 40 pooled donor sera covering serum reatinine concentrations from 0.5 to 5.0 mg/dL. The panel was assayed at CC in 2003 using Dade Behring (DB) PENIA reagents and a BNII nephelometer, and at the University of Minnesota (UMN) in 2009 using the same PENIA reagent on a DB ProSpec nephelometer. Conversion factors were determined using Deming linear regression. eGFR from CysC was calculated using '03 and '09 CysC values.

**Results:** Mean (SD) level of CysC was 2.01 (0.74) mg/L in CC'03 and 1.67 (0.58) mg/L in UMN '09. The mean (SD) difference was -0.34 (0.16) mg/L (p-value <0.01). Deming regression shows $\mathbf{CysC_{CC'03} = 1.267 * CysC_{UMN'09} - 0.105}$ ($R^2$=0.9951). The table shows the impact on eGFR.

**Conclusion:** CysC concentrations measured by DB methods have changed substantially. Without correction, the downward drift in CysC values from 2003 to 2009 would lead to substantially higher eGFR and underestimate CKD prevalence. CysC methods should be made traceable to international reference materials. In the interim, the equation above allows for conversion of DB 2009 CysC values to DB 2003 values.

| CysC (mg/L) | | | eGFR-cys 2003 Equation (ml/min/1.73 m$^2$) | | |
|---|---|---|---|---|---|
| 2009 | 2003 | Difference (2009-2003) | 2009 | 2003 | Difference (2009-2003) |
| 0.87 | 1.00 | -0.13 | 91 | 77 | 14 |
| 1.00 | 1.16 | -0.16 | 77 | 64 | 13 |
| 1.10 | 1.29 | -0.19 | 68 | 57 | 12 |
| 1.20 | 1.42 | -0.22 | 62 | 51 | 11 |

## TH-FC089

**Estimating Progression Risk in a CKD Population in Hawaii** Brian J. Lee. *Nephrology Division, Hawaii Permanente Medical Group, Honolulu, HI.*

Current guidelines subdivide CKD based on degree of impaired renal function, rather than by risk of progression. Within a health maintenance organization in Hawaii with 220,000 patients, we noticed that proteinuria seemed to improve prediction of risk. We developed a model of GFR-proteinuria stratification and compared with GFR stratification.

Methods: a cohort of 8831 with baseline estimated GFR (MDRD 4 variable) between 20 and 59 mL/min/1.73m2 was followed for 2 years. Fewer than 5% were lost to follow-up. The GFR was divided into 20s, 30s, 40s and 50s; Proteinuria as urine protein/creatinine ratio was divided into 1, 1-2, 2-4 and over 4 mg/mg. The sixteen categories were ranked by rate of ESRD for purposes of ROC analysis.

Results:

2 year ESRD risk, by baseline GFR and urine protein/creatinine ratio

| | < 1 | 1-1.999 | 2-3.999 | 4+ | unknown | Total |
|---|---|---|---|---|---|---|
| 20-29 | 2.65% | 7.41% | 17.39% | 38.24% | 5.15% | 9.04% |
| 30-39 | 0.62% | 5.00% | 7.84% | 36.67% | 1.08% | 2.50% |
| 40-49 | 0.15% | 2.78% | 6.38% | 10.00% | 0.00% | 0.38% |
| 50-59 | 0.00% | 0.00% | 4.00% | 5.26% | 0.08% | 0.12% |
| Total | 0.26% | 2.51% | 8.76% | 24.78% | 0.28% | 0.84% |

ROC curve areas were 0.859 (continuous GFR) and 0.945 (GFR-proteinuria categories)

Conclusions: Progression risk was highly dependent on proteinuria, and estimating risk using both GFR and proteinuria was superior to using GFR alone. A two dimensional stratification system should guide selection of patients for referral and other intensive management. Our data supports efforts to create a new CKD staging system.

## TH-FC090

**Racial Differences in Kidney Function Decline among Persons without Chronic Kidney Disease – The Multi-Ethnic Study of Atherosclerosis** Carmen A. Peralta,[1] Ronit Katz,[2] Ian H. de Boer,[2] Joachim H. Ix,[5] Holly J. Kramer,[3] Mark J. Sarnak,[4] Bryan R. Kestenbaum,[2] Moyses Szklo,[6] Steven Shea,[7] David Siscovick,[2] Michael Shlipak.[1] *[1]University of California San Francisco and SF VA Medical Center; [2]University of Washington; [3]Loyola Medical Center; [4]Tufts Medical Center; [5]University of California San Diego; [6]Johns Hopkins University; [7]Columbia University.*

It is currently unknown whether or not race/ethnic groups differ in their rate of kidney function decline prior to the onset of CKD (eGFR <60ml/min/1.73m$^2$).

We studied race/ethnic differences in kidney function decline among White, Black, Hispanic and Chinese participants in MESA using linear mixed models over a five year

follow up with with 2 to 3 repeated measures of kidney function. GFR was estimated by cystatin C (eGFRcys) and creatinine- CKD Epi (eGFRcreat). We evaluated potential mediators in staged models.

Among 5179 adults aged 60±10 years with eGFRcreat >60 ml/min/1.73m$^2$ at baseline, mean (SD) changes in eGFRcys and eGFRcreat were -1.1 (4.4) and -1.5 (2.8) ml/min/1.73m$^{2/}$ year, respectively. Blacks had higher rates of eGFRcys decline compared with whites: -1.4 (4.8) vs. -0.88 (4.3) ml/min/1.73m$^2$/year. This difference was not attenuated by adjustment for age, sex, income, education, HDL, LDL, BMI, C-reactive protein, smoking, diabetes, hypertension, or systolic blood pressure : β: 0.31 ml/min/1.73m$^2$/year faster decline for Blacks, p=0.001. Hispanics also had faster rates of decline, but these varied by country of origin. Dominicans declined the fastest compared with whites (β 0.55, p < 0.011), followed by Puerto Ricans (β 0.47, p 0.03) after full adjustment, whereas Mexicans, South American and Other Hispanics did not differ significantly from Whites. Chinese had similar rates of eGFRcys decline compared with Whites (β 0.16, p 0.18). Findings were similar when we used eGFRcreat as the outcome.

Race/Ethnic differences in kidney function decline occur early, prior to the onset of clinical CKD, and are not explained by differences in traditional mediators. Future studies should focus on identifying persons at highest risk in order to develop targeted prevention strategies.

**Modulation of Inflammatory Kidney Injury with Leukadherins** Vineet Gupta, Jochen Reiser, Dony Maiguel, Hafeez Faridi, Changli Wei. *Division of Nephrology & Hypertension, Dept of Medicine, Miller School of Medicine, University of Miami, Miami, FL.*

Inflammatory renal diseases classically affect the glomerulus or the interstitium. Leukocyte tissue accumulation is a hallmark of renal ischemia-reperfusion (I/R) injury and also key to the pathogenesis of anti-GBM nephritis. The integrin CD11b/CD18 (a.k.a αMβ2, Mac-1) is the predominant integrin receptor expressed on the surface of leukocytes and plays a central role in mediating pro-inflammatory functions of these cells. Current treatments include non-steroidal and steroidal medications to reduce inflammatory damage. Unfortunately, these treatments are not always effective and harbor potential serious side effects. While blocking integrin-mediated leukocyte adhesion provided some additional benefit in many experimental models of inflammatory diseases, the blocking agents have had little success in treating inflammatory/autoimmune diseases in humans and β2 integrin blockers have also shown unexpected side effects.

We have pursued an alternative approach that involves pharmacologic activation, rather than inhibition, of leukocytic integrin CD11b/CD18 as a mechanism for reducing inflammatory injury. By screening a chemical library of >100,000 compounds, we recently discovered three novel small molecules that we have termed leukadherins. Leukadherins bind to CD11b/CD18, whereby they increase CD11b/CD18-dependent cell-adhesion and decrease cell migration in vitro. Using murine models of I/R injury and anti-GBM nephritis, we show that leukadherin administration reduces leukocyte recruitment and tissue accumulation in vivo and preserves renal function upon kidney injury. Mechanistically, we find that leukadherin treatment decreases both, leukocyte migration as well as the secretion of soluble factors. Our results suggest that leukadherins constitute a novel class of anti-inflammatory compounds that offer a unique approach for modulating inflammatory diseases of the kidney and other organs, via pharmacological activation of CD11b/CD18 and modulating leukocyte infiltration and function.

**TH-FC092**

**Ischemia-Reperfusion Induces Interferon-Regulatory-Factor-4 in Renal Dendritic Cells Which Suppresses Postischemic Inflammation and Prevents Acute Renal Failure** Maciej Lech, Saraswati Linda Lassen, Hans J. Anders. *Medizinische Poliklinik, University of Munich, Munich, Germany.*

Ischemia-reperfusion (IR) activates Toll-like receptors which fosters sterile inflammation, for example in postischemic acute renal failure. Unexpectedly, TLR signaling predominates in intrinsic renal cells and not in intrarenal antigen-presenting cells in the postischemic kidney. We hypothesized that certain factors suppress antigen-presenting cell activation and thereby limit sterile renal inflammation, e.g. interferon-regulatory-factor (IRF)-4, an inducible inhibitor of LPS signaling.

Oxidative stress was induced in vitro and found to be a trigger for IRF4 induction in myeloid cells in-vitro as well as in CD45+/CD11c+ cells in the postischemic kidney. Oxidative stress did not induce IRF4 in tubular epithelial cells. Lack of IRF4 aggravated acute renal failure 24 hours after renal artery clamping together with increased intrarenal expression of TNF-α, IL-6, CXCL2, and CCL2 as well as excessive tubular necrosis and peritubular neutrophil influx as compared to wildtype IR kidneys. This effect almost entirely depended on the role of IRF4 to suppress TNF-α release by intrarenal antigen-presenting cells because either clodronate liposome depletion of these cells or TNF-α blockade with etanercept entirely abrogated the aggravation of cytokine expression and acute renal failure in *Irf4*-deficient mice.

Thus, loss-of-function mutations in the IRF4 gene predispose to IR injury because the postischemic induction of IRF4 in resident antigen-presenting cells like CD11c+ dendritic cells, suppresses them to secrete TNF-α, and thereby limits inappropriate immunopathology.

**Slit2 Impairs Neutrophil Adhesion and Improves Renal Function in Ischemia Reperfusion Injury** Swasti Chaturvedi,[1] Soumitra Tole,[2] Liping Huang,[3] Ilya Mukovozov,[2] Guang Ying Liu,[2] Yi-Wei Huang,[2] Mark D. Okusa,[3] Lisa Robinson.[1] *[1]Nephrology, The Hospital for Sick Children, Toronto, Canada; [2]Research Institute, The Hospital for Sick Children, Toronto, Canada; [3]Medicine, University of Virginia Health System, Charlottesville, VA.*

Acute Kidney Injury (AKI) occurs in approximately 5% of hospitalized patients and leads to significant morbidity and mortality. Inflammation marked by recruitment of circulating leukocytes, particularly neutrophils, in the injured kidney is a key component of AKI caused by ischemia-reperfusion injury (IRI). Recruited leukocytes exacerbate injury by releasing inflammatory mediators. Therapies targeting different leukocyte subsets help in ameliorating injury. However no single therapy is entirely effective because of diversity of recruiting signals and the cells recruited. The neuronal guidance cue, Slit2 and its transmembrane receptor roundabout (Robo) prevents axonal migration during the central nervous system development. Recently it has also been shown that Slit2 inhibits chemotaxis of neutrophils and lymphocytes towards diverse chemoattractants by preventing activation of the small GTPases, Rac and Cdc42.

To determine whether Slit2 could be used to prevent AKI, we examined whether Slit2 prevents adhesion of human neutrophils to human vascular endothelial cells subjected to IRI. Slit2 significantly reduced neutrophil adhesion to endothelial cells subjected to hypoxia and periods of reperfusion ranging from 30-180 minutes ($p<0.05$). In an *in vivo* mouse model of renal IRI, where mouse kidneys were subjected to 28 min ischemia followed by 24 h reperfusion, Slit2 administered intraperitoneally 1 hr prior to reperfusion significantly prevented the rise in serum creatinine in a dose dependent manner (0.5-2.0 μg). Because activation of Rac and Cdc42 plays a role in protective immune functions of neutrophils, we determined the effects of Slit2 on these functions. Slit2 did not impair the ability of neutrophils to phagocytose opsonised particles, nor to produce superoxide production following inflammatory stimulation. These findings suggest that Slit2 could be used to prevent and treat the inflammatory cell recruitment in AKI.

**TH-FC094**

**TNFR2 Interposes the Proliferative and NF-κB-Mediated Inflammatory Response by Podocytes to TNF-α** Leslie A. Bruggeman,[1] Paul E. Drawz,[1] Nicole Kahoud,[3] Ke Lin,[2] Laura M. C. Barisoni,[2] Peter J. Nelson.[3] *[1]Divison of Nephrology, MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH; [2]Department of Pathology, New York University, New York, NY; [3]Division of Nephrology, University of Washington, Seattle, WA.*

The development of proliferative podocytopathies has been linked to ligation of TNFR2 expressed on the renal parenchyma; however, the TNFR2 positive cells within the kidney responsible for podocyte injury are unknown. We detected de novo expression of TNFR2 on podocytes prior to hyperplastic injury in crescentic glomerulonephritis of mice with nephrotoxic nephritis, and in collapsing glomerulopathy of Tg26 mice (a model of HIVAN) and B6 *kd/kd* mice, as well as human biopsies with collapsing glomerulopathy, but not primary FSGS or normal transplant tissue. We further found that serum levels of soluble TNF-α and TNFR2 correlated significantly with renal injury in Tg26 mice. Thus, we asked whether ligand binding of TNFR2 on podocytes ex vivo precipitates the characteristic proliferative and pro-inflammatory diseased podocyte phenotypes. Soluble TNF-α activated NF-κB and dose-dependently induced podocyte proliferation, marked by expression of the podocyte G1 cyclin and the NF-κB target gene cyclin D1. Microarray gene and chemokine protein expression profiling showed a marked pro-inflammatory NF-κB signature, and activated podocytes secreted CCL2 and CCL5 and induced macrophage migration in transwell assays. Neutralization of TNFR2 on podocytes with blocking antibodies abrogated NF-κB activation and the induction of cyclin D1 by TNF-α. In similar studies, IκBα degradation, the initiating event in NF-κB activation, was dependent on TNFR2 signaling. These results suggest that TNFR2 expressed on podocytes and its canonical NF-κB signaling may directly interpose the compound pathogenic responses by podocytes to TNF-α.

**TH-FC095**

**PKC-Theta Mediates Inflammatory Responses Via Activation of Resident Macrophages and Neutrophil Adhesion Strengthening** Anna Bertram,[1] Sibylle Von Vietinghoff,[2] Hermann G. Haller,[1] Klaus Ley,[2] Nelli Shushakova.[1] *[1]Nephrology and Hypertensiology, Hannover Medical School, Hannover, Germany; [2]Inflammation Biology, La Jolla Institute for Allergy and Immunology, La Jolla, CA.*

Activation of resident macrophages leading to proinflammatory mediator release and subsequent leukocyte trafficking into the site of inflammation are critical components of the host defence response. Here, we investigated the role of PKC-Θ in the development of inflammatory response in a murine model of acute peritonitis and LPS-induced lung injury. Thioglycollate-induced peritonitis in wild type SV129 mice resulted in increased production of TNF-a as well as CXCL-1 and -2 in peritoneal lavage fluid accompanied by strong neutrophil accumulation into the peritoneal cavity. PKC-Θ deficient mice showed a marked reduction in PMN infiltration, TNF-a, CXCL-1 and -2 levels. These results were confirmed *in vitro* using resident peritoneal WT or PKC-Θ deficient macrophages stimulated with LPS, demonstrating a significant contribution of PKC-Θ to activation of resident

macrophages and inflammatory mediator release. In mixed chimeric mice reconstituted with bone marrow cells from GFP$^+$ wildtype (WT) and GFP$^-$ PKC-Θ deficient (KO) mice, migration of KO neutrophils was strongly reduced in acute peritonitis and LPS-induced acute lung injury. In inflamed mouse cremaster postcapillary venules *in vivo*, CXCL-1 increased the number of firmly adherent cells to a similar extent for both WT and KO cells. However, while most adherent WT neutrophils remained adherent for at least 180 sec after CXCL1 injection, 50% of KO neutrophils were detached after 105 sec, and in the remaining cells adhesion and spreading were diminished. These data suggest that PKC-Θ may mediate divergent downstream effector pathways in inflammatory responses. In resident macrophages, PKC-Θ is required for their activation and proinflammatory mediator release. In neutrophils, PKC-Θ is required for sufficient migration to the site of inflammation by sustaining firm adhesion on the endothelium.

**TH-FC096**

**Heme Oxygenase-1 (HO-1) Expression Regulates Immune Cell Infiltration in Renal Inflammation** Anjana Perianayagam,[1] Abolfazl Zarjou,[1] Reny Joseph,[1] James George,[2] Anupam Agarwal.[1] *[1]Medicine, Division of Nephrology, University of Alabama at Birmingham, Birmingham, AL; [2]Surgery, University of Alabama at Birmingham.*

HO-1 modulates innate and adaptive immune responses. Previous studies showed increased renal macrophage infiltration following unilateral ureteral obstruction (UUO) in HO-1$^{-/-}$ mice compared to wild-type (WT) mice. In WT mice, M1 (classically activated) macrophages predominate early, whereas M2 (alternatively activated) macrophages predominate at 72h after kidney injury. The purpose of this study was to determine the effect of HO-1 on the distribution of renal macrophage subtypes following UUO. Kidneys were harvested 48h following UUO and sham surgery in HO-1$^{-/-}$ and WT mice. Cell suspensions isolated from kidneys were stained using CD45, CD11b, CD11c, MHC II, Ly6C and Gr-1 antibodies and analyzed by flow cytometry. Compared to WT mice, UUO kidneys of HO-1$^{-/-}$ mice showed a significantly increased infiltration of macrophages (CD45$^+$, F4/80$^+$ and CD11b$^+$)(31.5±8% vs 56.9±16%, p= 0.02). A two-fold increase in inflammatory M1 macrophages (CD45$^+$, MHC II$^+$, Ly6C$^+$ and Gr-1$^+$) were observed in UUO kidneys of HO-1$^{-/-}$ mice (30±5.8%) compared to WT mice (17.2±5.3%, p= 0.008). The increase in M1 macrophages was also significant using another set of markers which included CD45$^+$, MHC II$^+$, CD11b$^+$ and Gr-1$^+$ (HO-1$^{-/-}$ vs WT, 33.5±5.1%, 22.3±6.6%, respectively, p= 0.02). Real time PCR analysis for M1 (TNFα) and M2 (mannose receptor and arginase-1) markers was also performed. There was a 1.54 fold increase in TNFα mRNA in HO-1$^{-/-}$ mice kidneys compared to WT mice. For M2 markers, a 2.3 fold increase in mannose receptor and 15.6 fold increase in arginase-1 mRNA were observed in HO-1$^{-/-}$ mice kidneys compared to WT mice with UUO. No difference in the proportion of dendritic cells (CD45$^+$, MHC II$^+$, CD11c$^+$ and Gr-1$^-$) were found between UUO kidneys of HO-1$^{-/-}$ (22.1±4.6%) and WT mice (26.43±4.2%, p=n.s). These data suggest that HO-1 expression modulates pro-inflammatory macrophage infiltration following UUO and that increased M1 macrophage infiltration maybe responsible for the increased renal fibrosis and inflammation observed in HO-1 deficient mice.

**TH-FC097**

**The Influence of Sirolimus on Lipid Accumulation in Inflamed Apolipoprotein E Knockout Mice** Kun Ling Ma,[1] Xiong Zhong Ruan.[2] *[1]Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China; [2]Centre for Nephrology, Royal Free and University College Medical School, Royal Free Campus, University College London, United Kingdom.*

**Objective:** Inflammatory stress, combined with dyslipidemia, exacerbates the progression of atherosclerosis. Our *in vitro* studies have demonstrated that Sirolimus inhibits foam cell formation through the influence of intracellular cholesterol homeostasis. This study was to investigate the effect of Sirolimus on lipid accumulation in inflamed apolipoprotein E knockout mice and its underlying mechanisms.

**Methods:** Apolipoprotein E knockout (apoE KO) mice were randomly divided into four groups: phosphate saline injected mice (Control), Sirolimus injected mice (Sir), casein injected mice, Sir plus casein injected mice (Sir+casein). Serum levels of inflammatory cytokines and lipid profile were respectively measured by enzyme-linked immunosorbent assay and clinical biochemistry assay. The effects of Sirolimus on lipid accumulation in aorta, liver and kidney were evaluated by Oil Red O staining and intracellular cholesterol quantitative assay. The protein expression of low density lipoprotein receptor (LDLr), sterol regulatory element binding protein-2 (SREBP-2) and SREBP-cleavage-activating protein (SCAP) in tissues was checked by immunohistochemical staining or Western Blot.

**Results:** There is a significantly elevated serum levels of TNF-α and serum amyloid A in casein injected mice, suggesting the successful induction of inflamed model. Serum levels of lipid profile (total cholesterol and triglyceride, LDL and high density lipoprotein) in flamed mice were markedly decreased compared to controls. Inflammatory stress increased lipid accumulation in aorta, liver, and kidney, interestingly, which was significantly inhibited by Sirolimus. Further analysis showed that Sirolimus overrode inflammatory stress induced protein expression increase of LDLr, SREBP-2, and SCAP in aorta, liver and kidney of inflamed mice.

**Conclusion:** Sirolimus provided protective effects on the multiple-organ lipid accumulation induced by inflammatory stress, which was through reestablishing LDLr feedback regulation.

**TH-FC098**

**Circulating and Intra-Renal CSF-1 Expression Distinctively Contribute to Macrophage-Rich Lupus Nephritis** Julia Menke,[1] Yasunori Iwata,[2] Vicki R. Kelley.[2] *[1]I. Dept Med, Johannes Gutenberg-Univ, Mainz, Rheinland-Pfalz, Germany; [2]Renal Division, Brigham&Women's Hosp, Boston, MA.*

CSF-1, the major macrophage (Mø) growth factor, is a potential therapeutic target for lupus since: 1) over-expressing CSF-1 hastens the onset of Mø-rich lupus nephritis in MRL-Faslpr mice, 2) deleting CSF-1 eliminates Mø-rich lupus nephritis in MRL-Faslpr mice and 3) CSF-1 is elevated in serum/urine and kidney in patients with active lupus nephritis. As CSF-1 is rises in the circulation and kidney in lupus MRL-Faslpr mice and patients, we hypothesized that CSF-1 in the circulation and kidney distinctively contribute to Mø-rich lupus nephritis. To test this hypothesis, we injected CSF-1 into the circulation of CSF-1-deficient MRL-Faslpr mice (sole source of CSF-1 is circulation). We detected an increase in circulating monocytes (Mo), seeded from the bone marrow, and a shift to circulating Mo phenotypes (Ly6Chi,CD69+) more readily recruited to the kidney that, in turn, initiate renal injury (TEC apoptosis). Conversely, using mutant TgCS/+;MRL-Faslpr mice that express only the cell surface(cs) CSF-1 isoform (CSF-1 in kidney, not circulation) we detected: 1) intra-renal recruitment of the Mo (GFP+) comparable to WT mice, 2) skewing of circulating Mo towards an "inflammatory" (Ly6Chi), activated Mo (CD69+) phenotype and 3) intra-renal proliferation of Ly6ChiMø. This suggests that intra-renal rogue Mø activated by csCSF-1 may initiate inflammation, thereby releasing chemokines from the kidney responsible for recruiting additional Mo and amplifying renal inflammation. In conclusion, circulating and intra-renal csCSF-1 distinctively contribute to Mø-rich lupus nephritis. This suggests that blocking CSF-1 in the circulation and kidney is required to halt lupus nephritis.

**TH-FC099**

**IgA Mediated Proximal Tubular Cell Activation and Tubulointerstitial Scarring in IgA Nephropathy** Karen Molyneux,[1,2] Ravinder S. Chana,[1] Joanna Boyd,[2] Alice C. Smith,[1,2] Richard J. Baines,[1,2] Nigel J. Brunskill,[1,2] Jonathan Barratt.[1,2] *[1]Infection, Immunity & Inflammation, University of Leicester, Leicester, United Kingdom; [2]John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom.*

One of the most powerful determinants of progressive kidney disease in IgAN is the development of tubulointerstitial inflammation, atrophy and scarring. The extent of tubulointerstitial damage does not however correlate with intensity of mesangial IgA deposition and is associated with the development of chronic kidney disease and ESRD independently of changes in glomerular morphology. Normally the glomerular barrier is impermeable to immunoglobulins but glomerular barrier pore size can significantly increase in glomerular disease and an increase in urinary IgA concentration has been reported in IgAN. We studied the interaction of IgA with cultured proximal tubule epithelial cells (PTEC) to establish whether IgA filtered into the proteinuric proximal tubule could independantly generate a proinflammatory environment in the renal tubulointerstitium that favours the development of fibrosis.

Growth arrested HK2 cells were exposed to IgA1 (100μg/ml) from healthy subjects or patients with IgAN (100μg/ml), IgM (100μg/ml) or medium alone for 0, 5, 10, 30 or 60 minutes. IgA1 (IgAN) activated extracellular signal-regulated protein kinase in PTEC to a much greater extent than IgM or IgA1 from healthy subjects. Similarly, IgA1 (IgAN) induced PTEC synthesis of fibronectin, TGF-beta and IL-6. Exposure to IgA1 also stimulated PTEC production of complement component C3 and activation of the complement cascade with generation of the chemotactic component C5a. We have also shown that IgA1 phosphorylates a megalin cytoplasmic tail-GST fusion protein in HK-2 cells suggesting that IgA1 binding to PTEC may trigger the same intracellular signalling pathways as those activated following exposure to albumin.

We provide clear evidence that exposure to IgA1 results in a profibrotic and proinflammatory phenotypic transformation of PTEC and that interaction between filtered IgA1 and PTEC in IgAN may be one of the principle factors in initiating and driving tubulointerstitial damage in IgAN.

**TH-FC100**

**Pentraxin-2/Serum Amyloid P Inhibits Fibrosis through FcgR Dependent Monocyte/Macrophage Release of IL10 In Vivo** Jeremy S. Duffield. *Medicine, Brigham and Women's Hospital, Boston, MA.*

In models of kidney fibrosis, systemic administration of Serum amyloid P or Pentraxin-2 (PTX-2) significantly inhibits fibrosis through a monocyte/macrophage-dependent mechanism, and as such represents a potential novel therapy for the treatment of chronic inflammation with fibrosis. In transgenic Coll-GFP reporter mice, PTX-2 inhibited myofibroblast synthesis of collagen, but myofibroblast numbers were unaffected. PTX-2 is deposited on injured tissue and debris in the kidney, and is detected in endosomes/phagosomes of macrophages (Mφs). It does not bind to, or inhibit collagen production by, fibroblasts in vitro, but it binds with high affinity to activating Fcγ receptors on monocytes/Mφs. Purified Mφs from fibrotic kidney are less activated and produce 20 fold more IL10 in mice treated with PTX-2. To test the direct role of IL10 in the inhibition of fibrosis mediated by PTX-2, we systemically administered IL10 producing adenovirus (Ad-IL10 and control virus (Ad-mock) in models of kidney fibrosis. Ad-IL10 resulted in high levels of systemic IL10 and markedly attenuated fibrosis accumulation in the kidney. Systemic IL10 inhibited both monocyte/ Mφ activation and myofibroblast proliferation and activation in

vivo. We propose that the major mechanism of action of PTX-2 is to switch M2 or wound healing Mφs into regulatory Mφs. Local generation of IL10 blocks Mφs driven fibrosis and directly inhibits myofibroblasts.

Disclosure of Financial Relationships: nothing to disclose

### TH-FC101

**Intrarenal Dopamine Deficiency Is Associated with Hypertension and Decreased Longevity** Mingzhi Zhang, Shilin Yang, Raymond C. Harris. *Department of Medicine, Vanderbilt University School of Medicine, Nashville, TN.*

The kidney possesses an intrarenal dopaminergic system, and intrarenal dopamine levels can reach high nanomolar concentrations. Intrarenal dopamine is primarily biosynthesized through the actions of aromatic amino acid decarboxylase (AADC) in the proximal tubule. We have generated mice with kidney dopamine deficiency through selective deletion of AADC in proximal tubule by crossing AADCflox/flox mice with γ-GT Cre mice onto a 129/sv background (AADC KO). Here, we report our unexpected finding that AADC KO mice exhibit a significantly shorter life span compared to wild type mice. At 19 months of age, only 8 of 19 AADC KO mice still survived while 19 out of 20 wild type mice survived. Intrarenal dopamine may modulate components of the renal renin-angiotensin system (RAS) and antagonize Ang II actions in the kidney. Q-PCR and immunoblotting demonstrated that aged AADC KO mice exhibited increased renin and AT1b receptor expression and decreased AT2 and Mas (Ang1-7) receptor expression in the kidneys but not in aorta and heart. It has been reported that deletion of AT1a receptors promotes longevity in mice along with upregulation of the prosurvival genes nicotinamide phosphoribosyltransferase (Nampt) and sirtuin 3 (Sirt3) in the kidney. Aged AADC KO mice were found to have markedly decreased renal expression of Nampt and Sirt3. In addition there was increased expression of nitrotyrosylated protein, a marker of oxidative stress, and CTGF as well as increased renal expression of Kim-1 and α-smooth muscle cell actin, markers of kidney injury. Aged AADC KO mice also had increased lymphocyte and macrophage infiltration. Aged AADC KO mice were hypertensive (135 ± 3 vs. 105 ± 2 mmHg of wild type). These results indicate that the intrarenal dopamine system normally mediates increased renal expression of vasodilatory and cytoprotective components of the RAS, and inhibition of intrarenal dopamine production leads to increased oxidative stress, hypertension, renal injury and decreased longevity, which may be at least in part a result of the unopposed upregulation of vasoconstrictive, proinflammatory AT1 activity.

**Human GRK4γ Wild-Type Gene Prevents Salt Sensitivity by Inhibition of Renal Proximal Tubular Sodium Transport in Transgenic Mice** Zheng Wang,[1] Laureano D. Asico,[1] Crisanto Escano,[1] Magali Araujo,[2] William J. Welch,[2] Pedro A. Jose.[1] *[1]Center for Molecular Physiology Research, Children's National Medical Center, Washington, DC; [2]Georgetown University, Washington, DC.*

High NaCl intake is associated with increased cardiovascular risk. Mortality and morbidity are higher in hypertensive and NaCl-sensitive normotensive subjects than in NaCl-resistant normotensive subjects. However, the genetic cause of salt sensitivity is not known. GRK4 variants (R65L, A142V, and A486V) are associated with human essential hypertension. Human(h) GRK4γ142V transgenic mice are hypertensive on normal NaCl intake while hGRK4γ486V transgenic mice develop hypertension on high NaCl intake. The role of hGRK4γ wild-type gene on sodium metabolism and blood pressure (BP) was studied in salt-sensitive C57BL/6J mice. On normal NaCl diet, BPs of hGRK4γ wild-type transgenic mice (WT-Tg) and non-transgenic littermates (NT-Tg) were similar. However, 3 wks of 6% NaCl diet increased the BP (aorta under anesthesia) in NT-Tg (102±2 to 122±1mmHg, n=8-11/group, P<0.001), but not in WT-Tg (101±2 to 103±2 mmHg, n=7/group). The 24 hr BP (telemetry) of conscious mice confirmed that 6% NaCl diet increased the BP in NT-Tg (+14±1%, n=4), but not in WT-Tg (+0.8±1%, n=4) mice. Therefore, GRK4γ wild-type prevents the salt sensitivity of C57BL/6J mice. We next studied the relationship between BP and $Na^+$ excretion. 6% NaCl diet increased urinary $Na^+$ excretion to a greater extent in WT-Tg than NT-Tg (5.2±0.7 vs. 2.8±0.4 mmol/mg creatinine, n=10, P<0.01). The pressure-natriuresis plot in WT-Tg was shifted to the left of the plot of salt-sensitive NT-Tg, indicating facilitation of $Na^+$ excretion. This involved the proximal nephron because the pressure-lithium excretion plot of WT-Tg mice was also shifted to the left of the plot of NT-Tg (n=5/group) on 6% NaCl diet. Furthermore, renal micropuncture studies (S2 segment, proximal tubule) showed that the tubular fluid to plasma inulin ratio was lower in NaCl-loaded WT-Tg than in NT-Tg (1.6±0.1 vs. 2.2±0.3, n=7, P<0.05) mice. We conclude that GRK4γ wild-type prevents salt sensitivity, in part, by decreasing renal proximal tubule $Na^+$ transport.

**Catalase Overexpression Prevents Programming of Hypertension and Kidney Injury in Offspring of Diabetic Dams** Shao-Ling Zhang, Yun-Wen Chen, Isabelle Chenier, Shiao-Ying Chang. *Research Center, CRCHUM-Hotel-Dieu Hospital, Montreal, QC, Canada.*

We investigated whether overexpression of catalase (CAT) in renal proximal tubular cells (RPTCs) could prevent maternal diabetes-induced perinatal programming of hypertension and kidney injury in offspring and examined potential underlying mechanisms.

Offspring of non-diabetic and diabetic dams of Hoxb7-green fluorescence protein (GFP)-transgenic (Tg) and Hoxb7-GFP/Catalase (CAT)-Tg mice were studied. Systolic blood pressure, microalbuminuria, nephron number, glomerular filtration rate, glomerular tuft volume, renal morphology and reactive oxygen species (ROS) generation, as well as gene expression of transforming growth factor-beta 1 (TGF-β1), plasminogen activator inhibitor-1 (PAI-1), angiotensingen (Agt), angiotensin II type I receptor (AT1R), angiotensin converting enzyme (ACE) and angiotensin converting enzyme 2 (ACE2), were assessed.

Offspring of Hoxb7-GFP-Tg dams with maternal diabetes developed hypertension, renal hyperfiltration, microalbuminuria and kidney injury. Renal ROS generation and gene expression of TGF-β1, PAI-1, Agt, AT1R and ACE were markedly upregulated, but ACE2 gene expression was lower in kidneys of hypertensive Hoxb7-GFP-Tg offspring of diabetic dams. These changes were normalized in offspring of diabetic CAT-Tg dams.In conclusion, our data demonstrate that overexpression of CAT in RPTCs prevents perinatal programming of hypertension and renal injury in offspring of dams with maternal diabetes. Enhanced intrarenal oxidative stress and RAS activation with down-expression of ACE2 are intimately associated with this process.

### TH-FC104

**Dec1 Regulates Circadian Variation of Blood Pressure** Ayumu Nakashima,[1,2] Takeshi Kawamoto,[3] Mitsuhide Noshiro,[3] Kiyomasa Honda,[3] Noritsugu Ozaki,[3] Toshinori Ueno,[2] Yoshihiko Taniguchi,[4] Junko Tanaka,[1] Noriaki Yorioka,[2] Yukio Kato.[3] *[1]Department of Epidemiology, Infectious Disease Control and Prevention, Graduate School of Biomedical Sciences, Hiroshima University; [2]Department of Advanced Nephrology, Graduate School of Biomedical Sciences, Hiroshima University; [3]Department of Dental and Medical Biochemistry, Graduate School of Biomedical Sciences, Hiroshima University; [4]Division of Clinical Pharmacotherapeutics, Hiroshima International University, Japan.*

All living things on the earth need to follow earth's rotation period of 24 hours. The molecular clock, which consists of many regulatory factors including DEC1, is a system to generate and maintain circadian rhythms of various physiological processes. DEC1 is a transcription factor that binds to E-boxes and suppresses the expression of clock-controlled genes.

To identifiy target genes of DEC1, we utilized genome-wide chromatin immunoprecipitation (ChIP)-on-chip assay and found that DEC1 bound to the regulatory region of one of Na/K-ATPase genes in human embryonic kidney 293 cells. ChIP and luciferase reporter assays revealed that an E-box on the Na/K-ATPase gene promoter is a functional element governed by clock components such as CLOCK, BMAL1, and DEC1. In addition, DEC1 deficiency resulted in the increased expression of Na/K-ATPase, whereas overexpression of DEC1 decreased the expression level of Na/K-ATPase.

Since Na/K-ATPases are known to be involved in the blood pressure regulation, we focused on the functional significance of DEC1 in homeostasis and circadian regulation of blood pressure. In both kidney and aorta, robust circadian rhythms of the Na/K-ATPase expression were detected at mRNA and protein levels. $DEC1^{-/-}$ mice showed higher expression of Na/K-ATPase than wild type mice, although the circadian rhythmicities still existed. In addition, $DEC1^{-/-}$ mice showed lower blood pressure and larger amplitude of circadian variation of blood pressure than wild-type mice. In contrast, in CLOCK mutant mice, the expression level of Na/K-ATPase was lower than wild-type mice, and lost circadian rhythmicities.

We conclude that DEC1 regulates circadian variation of blood pressure via Na/K-ATPase.

### TH-FC105

**Impaired Na Pump Signaling Characterizes Hypertension in Dahl Salt Sensitive Rats** Yanling Yan,[1] Lijun Liu,[2] Zi-Jian Xie,[2,1] Deepak K. Malhotra,[1] Bina Joe,[2] Joseph I. Shapiro,[1,2] Jiang Liu.[1] *[1]Medicine, University of Toledo College of Medicine, Toledo, OH; [2]Physiology and Pharmacology, University of Toledo College of Medicine, Toledo, OH.*

Cardiotonic steroids (CTS) such as ouabain signal through the plasmalemmal Na/K-ATPase (NKA) and inhibit transcellular 22Na+ transport by inducing endocytosis of NKA and NHE3 in proximal tubule (PT) cells. This phenomenon was also observed in vivo using Sprague Dawley rats treated with high salt diet or ouabain-infusion for 7 days. When we examined age-matched male Dahl salt resistant (R) and sensitive (S) strains, we found that a high (HS 2% NaCl) compared to a low salt diet, (LS 0.3% NaCl, 7 days,n=12/strain/treatment) caused disparate effects on BP, renal sodium excretion, Src kinase activation, as well as surface expression and activity of the PT NKA and NHE3. Plasma Na+ and K+ remained the same in all groups. HS caused a significant increase in systolic BP in the S (ΔBP=23.6±4.5, n=12 rats/treatment/strain. P<0.01) but not the R rats (ΔBP=2.6±1.8, n=12, p=NS). HS had same effect on creatinine clearance on both R and S rats. In the R rats, HS significantly reduced the NKA enzymatic activity in PT plasma membrane fraction and NHE3 activity in PT brush-border membrane fraction (n=6, p<0.01), increased total and fractional urinary Na+ excretion (n=8, p<0.01), stimulated c-Src phosphorylation (n=4, p<0.01), and induced endocytosis of PT NKA and NHE3 (n=12, p<0.01). These HS-induced changes in the R rats were either markedly reduced or absent in the S rats. This differential regulation of endocytosis and NKA signaling was confirmed in PT primary cultures derived from R and S rats. In these PT primary cultures, ouabain (25μM, 1h) stimulated c-Src phosphorylation (n=4, p<0.01) and redistribution of NKA and NHE3 (from cell surface to intracellular compartments) in R but not in S rats (n=6, p<0.01). We conclude that CTS-induced "trafficking" regulation of the PT NKA

and NHE3 that observed in R rats is "impaired" in S rats. This "impaired" CTS-induced signaling and "trafficking" may characterize salt-sensitive hypertension in experimental animals and possibly clinical subjects.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC106**

**The Activity of the Thiazide Sensitive Na-Cl Cotransporter NCC Is Regulated by a Protein Phosphatase, PP4** Mark Glover, Kevin O'Shaughnessy. *Clinical Pharmacology Unit, University of Cambridge, Cambridge, England, United Kingdom.*

Regulation of NCC, the target of thiazide diuretics, is crucial for salt homeostasis and blood pressure regulation. It is clear that NCC transporter trafficking and membrane expression is orchestrated by a scaffold of interacting proteins including WNK1 and WNK4 that are mutated in Pseudohypoaldosteronism type II. There are two phosphorylation controlled regulatory pathways for NCC: *Type 1*, mediated by WNK4 affecting trafficking to the surface membrane; and *Type 2*, affecting intrinsic transporter kinetics by phosphorylation of conserved N-terminal S/T amino acids especially threonine 58. Dynamic regulation of NCC function by kinases must involve dephosphorylation by phosphatases as illustrated by the role of PP1 and PP2B in the regulation of KCC members of the SLC12 family, yet no such phosphatase has been described for NCC.

Site mutation was used to produce plasmids expressing ECFP-NCCT T58D or T58A and a kinase-dead phosphatase, PP4R235L. *Xenopus* oocytes were injected with cRNA for these plasmids or wild-type cRNAs. NCCT function was assessed by $^{22}Na^{+}$ flux and confocal microscopy of the blue fluorescent ECFP-NCCT protein. Immunohistochemistry was performed on murine kidney sections.

PP4 reduced the activity of NCC by 78% without affecting surface membrane expression. The inhibitory effect of PP4 on NCC activity was abolished by either phosphatase dead site mutation of PP4, incubation with the PP4 inhibitor Fostreicin or mutation of NCC T58. WNK4 reduced the surface membrane expression of NCC as previously reported and this was unaffected by PP4. Immunohistochemistry of murine kidney showed that PP4 was expressed in the distal convoluted tubule and collecting duct.

Thus PP4 inhibits NCC activity but not trafficking to the surface membrane by a mechanism that requires phosphatase activity and a conserved N-terminal amino acid of NCC, threonine 58. This action is distinct from WNK4 regulation of membrane trafficking. In the mouse kidney, PP4 is selectively expressed in the distal nephron including cells of the distal convoluted tubule cells suggesting that PP4 may have a physiological role in regulating NCC and hence NaCl reabsorption *in vivo*.

**TH-FC107**

**Cryo-Denervation of the Clipped Kidney in Two-Kidney One-Clip (2K1C) Hypertensive Rats Decreases Systemic Blood Pressure (BP), Contralateral Renal Sympathetic Nerve Activity (RSNA) and Plasma Angiotensin II (Ang II)** Russell Pajewski,[1] Haiping Chen,[1] Peter John Littrup,[2] Jesse J. Veenstra,[1] Noreen F. Rossi.[1] *[1]Internal Medicine and Physiology, Wayne State University School of Medicine, Detroit, MI; [2]Intervential Oncology - Karmanos Cancer Center, Wayne State University School of Medicine, Detroit, MI.*

Besides an activated renin-angiotenin system, increased RSNA contributes to elevated BP in 2K1C hypertension. Previous studies indicate that renal denervation with transection of the renal nerve plus application of phenol decreases BP in this model. Ablation of the renal nerves with radiofrequency catheters was recently shown to be effective in refractory human hypertension but may result in thermal damage to the vasculature. We hypothesized that cryoablation of the renal nerve on the clipped side of 2K1C rats would decrease BP and serum ang II. Male Sprague Dawley rats (5 wk-old) underwent sham (SC) or renal artery clipping (2K1C) and placement of telemetry transmitters for continuous BP monitoring. After 6 wks, rats were randomly assigned to cryo (crDN) at -155°C x 30 sec x 3 freeze-thaw cycles or sham (shDN) denervation and pair fed a 0.4% Na diet. Mean BP was 141±4 mmHg in the 2K1C group and decreased by 14±3 mmHg 1 week after crDN ($P<0.025$). SC rats had a mean BP of 115±4 mmHg that decreased by 10±4 mmHg after crDN. BP did not change in either 2K1C or SC with shDN. Mean BP continued to remain significantly lower for up to 5 wks post crDN. Plasma ang II decreased by 66% in the 2K1C crDN groups to values not different from the SC rats. A limited number of rats had telemetric nerve electrodes placed on the contralateral renal nerve. Post crDN, contralateral RSNA decreased significantly. Urine output and electrolyte excretion was higher in the crDN groups. The present findings are comparable to our results with surgical denervation. We conclude that cryoablation of the renal nerve on the clipped side of the 2K1C model of renovascular hypertension is effective in decreasing BP. These results provide proof of principle that cryodenervation may be a viable modality for translation to treat refractory human renovascular hypertension.

Disclosure of Financial Relationships: nothing to disclose

**Podocyte Injury during Nephrotic Syndrome in Children Results in Secretion of Vesicles from Microvillus Tips** Masanori Hara, Toshio Yanagihara. *Department of Pediatrics, Yoshida Hospital, Tsubame, Niigata, Japan.*

Podocyte(s) (Pod) injury is involved in both the onset and progression of glomerular diseases. Our previous studies revealed that apical cell membranes of Pod are shed into the urine and that urinary podocalyxin (u-PCX) is a useful biomarker of Pod injury. In this study we examined the pathological process of urinary shedding of podocyte cell membranes in nephrotic syndrome. Urine samples and kidney specimens from normal children (N=120) and children with glomerular diseases (N=59) were analyzed by immunohistological methods. The renal diseases included: Idiopathic nephrotic syndrome (N=44) and nephrotic syndrome secondary to glomerular diseases such as lupus nephritis, IgA nephropathy and Schoenlein-Henoch purpura nephritis (N=15). To quantify u-PCX, an ELISA was developed using monoclonal antibodies to PCX, as reported previously.

Larger amounts of u-PCX were shed into the urine in idiopathic nephrotic syndrome (281.5±56.7 ng/mg creatinine) and secondary nephrotic syndrome (239.7±24.1 ng/mg creatinine), compared to normal controls (17.6±2.5 ng/mg creatinine). In idiopathic nephrotic syndrome, the level of u-PCX in steroid-resistant cases (444.2±126.0 ng/mg creatinine) was significantly higher than that in steroid-sensitive cases (77.8±13.2 ng/mg creatinine). Immuno-EM revealed that the urinary PCX from nephrotic patients was present in vesicles. IF studies indicated that the urine vesicles did not contain cytoskeletal components such as actin filaments. EM revealed vesiculation of apical Pod membranes at microvillar tips (tip vesiculation) and shedding of vesicles into Bowman's space. Membranes generating vesicles were devoid of electron-dense material, while microvilli at the trunk regions contained electron-dense material, including cytoskeletal components such as actin bundles. The size of the urinary vesicles were similar to that of Pod microvilli.

We conclude that significantly greater amounts of PCX were excreted into the urine of nephrotic vs. control children, and that they were excreted as small membrane vesicles originating from microvilli of Pod membrane surface by tip vesiculation which did not include apparent cytoskeletal components.

**TH-FC109**

**Collapsing Glomerulopathy (CG) in 19 Patients with Systemic Lupus Erythematosus (SLE): Cause or Coincidence?** Steven P. Salvatore,[1] Laura M. C. Barisoni,[2] Andrew M. Herzenberg,[3] Praveen N. Chander,[4] Volker Nickeleit,[5] Surya V. Seshan.[1] *[1]Weill Cornell Med Coll, NY; [2]NYU Medical Center, NY; [3]University of Toronto; [4]NY Med Coll; [5]UNC School of Med.*

Purpose: CG is a podocytopathy characterized by segmental or global collapse of capillary walls with wrinkling of the GBM and overlying podocyte proliferation. Idiopathic CG is a distinct clinicopathologic entity with poor response to immunosuppressive therapy and rapid progression to renal failure. CG is associated with viral infections, autoimmune disease, and drugs. We present the largest group of CG in patients with SLE.

Methods: Clinicopathological features in renal biopsies were retrospectively studied from 19 patients with SLE (16) or SLE-like (3) disease diagnosed with CG.

Results: The patients ranged from 16-65 years, M:F-4:15, 89% of African descent. Initially, 95% of patients had nephrotic syndrome with mean proteinuria (7g/24hr +/- 3.5), creatinine (Cr) 4 +/- 2.7 and BUN 37 +/- 27, except in one patient (Cr/BUN was 26.5/155). Serologies: C3 92 (M), C4 22 (M), ANA+ 93%, anti-dsDNA 73%, and anti-Smith 33%. HIV (19), HCV (11) and Parvovirus (7) serologies were negative in patients tested. On morphology, globally collapsed glomeruli ranged from 1-65% (mean 19%), segmentally collapsed (0-40%), and globally sclerosed (0-50%). Varied tubular atrophy and interstitial fibrosis was seen in 35% with focal microcystic changes. Minimal glomerular mesangial deposits were noted by IF and/or EM in 70%, and extensive foot process effacement in 83%. Initial treatment was pulse/oral steroids and dialysis (12). Follow-up from 13 patients: 7 with end-stage renal disease, 0-21 months after biopsy;2 patients returned to normal cr and 4 had cr 1.2-3.6mg/dl.

Conclusions: Immunologic (antibody or cytokine) mediated injury may lead to mild to severe glomerular podocytopathy in SLE (minimal change disease, FSGS, and CG). However, other known causes of CG should be considered in this setting. The high predominance of patients of African descent in our study suggests that collapsing features could result from immunologic and/or environmental factors on a genetic predisposition to epithelial injury.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC110**

**Childhood Onset Lupus Nephritis Presents More Severe When Compared with Late Onset Disease** Victor Sato, Igor Marques, Patricia T. Goldenstein, Lilian P. F. Carmo, Lectícia Jorge, Rui Toledo Barros, Viktoria Woronik. *Nephrology, University of Sao Paulo, Sao Paulo, Brazil.*

The aim of this study was to evaluate the clinicopathologic features and response to treatment of patients with lupus nephritis (LN) in different ages of disease onset. We retrospectively analyzed clinical presentation, treatment and one year follow-up of patients with diagnosis of LN with age ≤ 18 (n=23) and ≥ 50 (n=13) years submitted to renal biopsy (Bx) between 1999 and 2008 in a single center. The clinical and laboratory features at the time of Bx in childhood onset LN and late onset LN were, respectively: female gender 87 *vs* 92% (ns), hypertension 82 *vs* 31% (p=.01), SLEDAI 29±9 *vs* 18±7 (p=.01), estimated glomerular filtration rate (eGFR) 75±48 *vs* 70±18 mL/min/1.73m² (ns), proteinuria 3.3±2.7 *vs* 2.0±1.7 g/24h (ns) and hematuria 81 *vs* 54 % (p=.007). LN was diagnosed simultaneously with SLE in 90% of the patients with childhood onset LN, compared to only 17% in late onset LN group (p<.001). Analyzing Bx data, adolescents, in relation to elderly, showed the following distribution of WHO classes: III + IV 81 *vs* 61% and V 19 *vs* 39% (ns). Crescents were more frequent in childhood onset LN patients (74 *vs* 39 %, p=.001), who also showed a higher activity index (4.8±2.6 *vs* 3.3±1.9, p=.007). Diffuse interstitial fibrosis (>50%) was present in 9% of the adolescents and in none in elderly. Treatment employed for one year consisted mainly of methylprednisolone, prednisone and cyclophosphamide in both groups, with similar average cumulative doses. The final eGFR and proteinuria were 103±41*vs* 78±21 mL/min/1,73m² (p=.02) and 0.6±0.6 *vs* 0.6±0.7 g/24h (ns), in adolescents and elderly,

respectively. In childhood onset LN group, 3 patients presented in hemodialysis and did not recover renal function. Fifteen percent of the remaining reached the composite end point of duplication of serum creatinine or dialysis. No patient in late onset LN group reached this end point, however they had a smaller increase in eGFR (8±13 *vs* 26±36 mL/min/1,73m², p=.06). In conclusion, childhood onset LN presents more severe when compared with late onset disease, however with good responses to intensive treatment regimens.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC111**

**Results of Aspreva Lupus Management Study (ALMS) Maintenance Phase** David R. W. Jayne,[1] Gerald B. Appel,[2] Mary Anne Dooley,[3] Ellen Ginzler,[4] David Isenberg,[5] David Wofsy,[6] Neil Solomons,[7] Laura J. Lisk.[8] *[1]Addenbrooke's Hospital, Cambridge, United Kingdom; [2]Columbia University, New York; [3]University of North Carolina, Chapel Hill; [4]State University of New York, New York; [5]University College London, London, United Kingdom; [6]University of California, San Francisco; [7]Vifor Pharma (formerly Aspreva Pharmaceuticals), Vancouver, Canada; [8]Vifor Pharma, Surrey, United Kingdom.*

Aim: The 36-month, maintenance phase of the ALMS study compared the efficacy and safety of mycophenolate mofetil (MMF) with azathioprine (AZA) in patients with lupus nephritis (LN) classes III, IV and V achieving partial or complete response during the 6-month induction phase with corticosteroids (CS) and either MMF or cyclophosphamide (IVC).

Methods: Patients were re-randomized 1:1 to a double-blind comparison of either oral MMF (2 g/d) or oral AZA (2 mg/kg/d) both with CS (predniso[lo]ne ≤10mg/day). The primary efficacy measure was time to treatment failure (death; end-stage renal disease [ESRD]; doubling of serum creatinine (x2 Cr); and/or renal flare [proteinuric/nephritic]). Secondary efficacy assessments included time to event for each component of treatment failure; complete renal remission; and adverse events (AEs).

Results: 227 patients were randomized (ITT population); 127 completed the study (MMF, 73/116 [62.9%]; AZA, 54/111 [48.6%]). MMF was superior (log-rank test) to AZA in time to treatment failure (P=0.003) and renal flare (P=0.027). Other elements of the primary efficacy parameter showed numerical benefit in favor of MMF: time to ESRD (P=0.069) and x2 Cr (P=0.073). The incidence of AEs was similar between MMF and AZA; the most common AEs in both groups were infections and GI disorders. Numerically fewer patients treated with MMF than AZA reported at least one serious AE (27/115 [23.5%] vs 37/111 [33.3%]. One death (AZA group, unrelated to treatment) occurred during the study.

Conclusions: MMF was superior to AZA in maintaining renal response and preventing relapse in subjects with active LN who had responded to induction therapy with CS and either MMF or IVC.

**B Lymphocyte Related Signatures Are Associated with Active Lupus Nephritis** Worapot Treamtrakanpon,[1] Yingyos Avihingsanon,[1,2] Somchai Eiam-Ong.[1] *[1]Medicine, Chulalongkorn University, Pthumwan, Bangkok, Thailand; [2]Lupus Research Unit, Chulalongkorn University, Pthumwan, Bangkok, Thailand.*

BLyS and APRIL are tumor necrosis factor-family cytokines that play an important role in generating and maintaining the mature B-cell pool. BLyS and APRIL mRNA levels were associated with active disease both in serum of SLE patients and renal tissue of nephritis patients. BLyS blockade is a potential therapy for active SLE. We assessed correlation between blood levels of BLyS and APRIL with clinical and renal histology of lupus nephritis patients.

**Methods**: Fifty-two lupus nephritis patients that underwent kidney biopsy were evaluated prospectively for at least 6 months. Renal SLEDAI score, anti-dsDNA, complements, blood BLyS and APRIL on biopsy day and renal histology were assessed. All patients were treated with the standard therapy (mycophenolate or cyclophosphamide plus steroid). Response to treatment was determined at 6 months of treatment.

**Results:** All patients had biopsy-proven lupus nephritis (class 3 or 4 ISN/RPS classification). Mean(SD) age of patients was 33(9) and duration of disease was 6(4) years. Twelve of fifty-two patients had extra-renal symptoms at the time of study. Dosage of prednisolone was 22.5(10) mg/day. Serum creatinine was 1.06(0.55) mg/dL, proteinuria was 3.59(2.18) gm/day, and erythrocyturia was 50.85(85.5) cells per high power field. APRIL levels were correlated with renal histology score ($r = 0.35$; $p < 0.05$) and proteinuria ($r = 0.44$; $p < 0.01$) whereas BlyS levels were correlated with all serum complement levels ($r = 0.60$; $p < 0.01$), anti-dsDNA ($r = -0.36$; $p < 0.01$), and dose of steroid usage ($r = -0.54$; $p < 0.01$). Blood APRIL levels above 3.6 ng/mL could precisely predict failure of standard treatment treatment. (PPV 95.8 %; NPV 38.1%)

**Conclusion:** Blood APRIL and BLyS levels were correlated with activity of lupus nephritis. APRIL is a potential biomarker for predicting treatment failure.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC113**

**Dense Deposit Disease Associated with Monoclonal Gammopathy of Undetermined Significance** Sanjeev Sethi,[1] William R. Sukov,[1] Yuzhou Zhang,[2] Lynn D. Cornell,[1] Richard J. Smith.[2] *[1]Mayo Clinic; [2]University of Iowa.*

Dense Deposit Disease (DDD) is a rare glomerular disease that typically affects children and young adults and much less commonly older patients. The pathophysiology underlying DDD is uncontrolled activation of the alternative pathway (AP) of complement most frequently secondary to an autoantibody to C3 convertase called C3 nephritic factor, although mutations or autoantibodies to Factor H can impair its function and also cause DDD. Since 1995, we have diagnosed DDD in 14 patients 49 years of age or older; ten of these patients (71.4%) carry a concomitant diagnosis of monoclonal gammopathy of undetermined significance (MGUS). In all patients, a monoclonal IgG protein was identified by serum protein electrophoresis and one patient also had a monoclonal IgA (biclonal). None of the patients had progressed beyond MGUS at the time of kidney biopsy and therefore none of the patients were receiving chemotherapy for plasma cell dyscrasia. Six patients had progressed to ESRD; one patient received an allograft but developed recurrent disease within one month of transplant. In one of ten, the index case that prompted this study, we evaluated the AP and demonstrated low serum AP protein levels consistent with AP activity, heterozygosity for H402 allele of Factor H, and low levels of Factor H autoantibodies, which can affect the ability of Factor H to regulate AP activity.

Work up of AP in DDD with MGUS

| Assay | Result |
|---|---|
| C3 nephritic factor | Negative |
| AP functional assay | Low at 25.8% (normal 65-130). |
| Hemolytic assay | Negative |
| Factor H autoantibody | Positive (1:100) |
| Mutational analysis for Factor H | 1 copy of H402 allele and Y402 allele |
| Mutational analysis for Factor I | Normal alleles |
| Mutational analysis for CD46 | Normal alleles |

In aggregate, these findings suggest that DDD may develop in some adults with MGUS as a result of autoantibodies to Factor H (or other complement proteins) that on a permissive genetic background (H402 allele of Factor H) lead to dysregulation of the AP with subsequent glomerular injury. Thus DDD in some older patients may be a distinct clinicopathologic entity that represents an uncommon complication of MGUS.

**Laser Dissection and Mass Spectrometry Based Proteomics for Diagnosis and Typing of Renal Amyloid** Sanjeev Sethi, Samih H. Nasr, Julie A. Vrana, Jason David Theis, Lynn D. Cornell, Mary E. Fidler, Nelson Leung, Ahmet Dogan. *Pathology, Mayo Clinic, Rochester, MN.*

Amyloidosis is a group of disorders characterized by extracellular deposition of proteins as insoluble aggregates. The clinical management of amyloidosis is based on accurate typing of the amyloid. Typing of renal amyloidosis can be difficult when heavy chain amyloid (AH) or other rare forms of amyloid including hereditary and familial forms are present. In this study, we describe the use of laser microdissection (LMD) and mass spectrometry (MS) based proteomic analysis for typing of renal amyloid. Between 2-4 microdissections of Congo red positive areas in each case was performed. We compare the LMD/MS proteomic prolife (PP) of 16 cases of amyloidosis including 4 cases of immunoglobulin (Ig) AH, 4 cases of light chain (AL), 2 cases of SAA, 2 cases of fibrinogen A-α chain (Afib), 2 cases of leukocyte cell-derived chemotaxin-2 (LECT2) and 2 cases of TTR (non renal) amyloid. The PP of 3 AL amyloid cases showed Ig lambda chain constant regions, while case 4 showed kappa chain constant and variable III regions, all with >95% probability, with 8, 11, 12, and 14 spectra. The PP of 2 cases of Afib amyloid showed fibrinogen A α-chain, all with >95% probability, and 96 and 23 spectra. The PP of 2 cases of SAA amyloid showed serum amyloid protein A, all with >95% probability, and 24 and 57 spectra. The PP of 2 cases with TTR amyloid showed transthyretin, all with 100% probability, and 17 and 35 spectra. The PP of 2 cases of LECT2 amyloid showed LECT2, all with >95% probability, and 9 and 11 spectra. The PP of SAA, Afib, LECT-2 and TTR amyloid did not show Ig heavy or light chains. The PP of 4 cases of Ig AH renal amyloid showed Ig heavy chains (AH) with (2 cases) or without (2 cases) light chains. In addition, amyloid P component (SAP), Apolipoprotein E and A-IV were also present in all cases. The results by LMD/MS correlated with clinical findings of plasma cell disorders, genetic testing for LECT2 and TTR variants, and immunohistochemistry for TTR, SAA, Ig light chains and SAP. We conclude that LMD/MS is a sensitive and specific tool for diagnosis and accurate typing of renal amyloid.

**PR3-ANCA Positivity in Patients without Primary Systemic Vasculitis** Stephen Paul McAdoo, Angela E. Hall, Jeremy B. Levy, Charles D. Pusey, Alan D. Salama. *Imperial College, London.*

Background: We recently indentified 3 patients who presented with clinical features of small vessel vasculitis in association with PR3-ANCA positivity, who were subsequently diagnosed with bacterial endocarditis. The combination of cANCA on immunofluorescence (IIF) and anti-PR3 on ELISA is reported to be highly (99%) specific for Wegener's Granulomatosis versus diseased controls.

Aims: To identify the rate and clinical associations of PR3-ANCA positivity in patients without primary systemic vasculitis using current methods in our laboratory.

Methods: Retrospective review of all patients identified as cANCA and anti-PR3 antibody positive as determined by IIF and Luminex testing respectively in our laboratory over a 6 month period.

Results: 194 patients were positive for the combination of cANCA on IIF and anti-PR3 on Luminex. The majority (174 patients) had primary ANCA-associated vasculitis (AAV). Twenty patients (10%) who were PR3-ANCA positive but without a diagnosis of AAV were indentified. Clinical associations included bacterial endocarditis (2 patients), HIV (3), TB (2), other automimmune disorders (4), malignancies (3), osteoarthritis (2), cirrhosis (1), bronchiectasis (1), myelofibrosis (1), cyclical thrombocytopenia(1). Anti-PR3 titre ranged from 31-278 (normal range 0-25)

Conclusions: Clinicians should remember the rare but recognised association of bacterial endocarditis and PR3-ANCA. Our data suggests that PR3-ANCA may be found in association with other conditions, including infections, malignancy and autoimmune diseases.

The aetiology of these ANCA are unclear; a process of 'molecular mimicry' with microbial antigens has been suggested.

A recent study in healthy army recruits suggests the presence of PR3-ANCA may predate disease onset by 2 years. It remains to be seen if any of this cohort will develop AAV and ongoing follow-up is advised.

Our data suggest that application of ANCA testing to an unselected population, with a low clinical suspicion of vasculitis, is likely to increase "false-positive" rates. Reliance on detecting PR3-ANCA this population, without securing a tissue diagnosis, may lean to erroneous diagnoses and catastrophic treatment decisions.

**Anti-PLA$_2$R Autoantibodies in Recurrent Membranous Nephropathy** Laurence H. Beck,[1] Fernando G. Cosio,[2] Fernando C. Fervenza,[2] Fahim Malik,[1] Jean M. Francis,[1] Joel M. Henderson,[3] William S. Asch,[4] Reginald Y. Gohh,[5] David J. Salant.[1] *[1]Nephrology, Boston University Medical Center, Boston, MA; [2]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [3]Pathology, Boston University Medical Center, Boston, MA; [4]Yale New Haven Transplantation Center, New Haven, CT; [5]Rhode Island Hospital, Providence, RI.*

Antibodies to the phospholipase A2 receptor (PLA2R) are present in up to 80% of patients with primary membranous nephropathy (MN) and are associated with clinical disease activity. The aim of this study was to determine, in patients with recurrent MN after renal tansplantation, the prevalance of anti-PLA2R and the association with disease activity after treatment with rituximab.

Human PLA2R was immunoblotted with patient serum (1:25) and IgG4 anti-PLA2R was detected with appropriate secondary antibodies. Levels were semi-quantitatively assessed by densitometry.

7 of 12 patients (58%) with recurrent MN had anti-PLA2R antibodies. In those positive for anti-PLA2R, there was a disappearance of anti-PLA2R in many of those who responded to rituximab. Several patients who were negative for anti-PLA2R did not completely respond to rituximab.

The significance of these findings is underscored by the case of a young male diagnosed with MN in 2004. He progressed to ESKD and ultimately received a kidney transplant in 2010. This patient was found to have circulating anti-PLA2R antibodies 1 week post-transplantation; subsequent testing showed that he had also been positive immediately pre-transplantation. Although initially non-proteinuric, he developed 1.8 g/d proteinuria 1 month after his transplant. A renal biopsy performed at this time showed early recurrent MN, with tiny subepithelial deposits by EM. He has been treated with rituximab with initial improvement in proteinuria.

The proportion of anti-PLA2R positivity in patients with recurrent MN is similar to that found in those with primary MN. A disappearance of anti-PLA2R is associated with a clinical response to treatment with rituximab. Detection of circulating anti-PLA2R in the peri-transplantation period may be a useful tool in the monitoring of these patients.

**De Novo MGN Is Immunologically Distinct from Idiopathic MGN and Associated with C4d Deposition** A. Bernard Collins,[1] Laurence H. Beck,[3] Anjali A. Satoskar,[2] Daniel L. Karel,[3] Evan A. Farkash,[1] Tibor Nadasdy,[2] Robert B. Colvin.[1] *[1]Pathology, Massachusetts General Hospital, Boston, MA; [2]Pathology, Ohio State University Medical Center, Columbus, OH; [3]Nephrology, Boston University School of Medicine, Boston, MA.*

**Background**: De novo MGN is a significant complication of renal transplantation that occurs in HLA-identical and non-identical allografts. Beck et al have recently demonstrated that 70% of patients with idiopathic MGN have autoantibodies to phospholipase A2 receptor (PLA$_2$R). **Purpose:** To test whether de novo MGN is associated with autoantibodies to PLA$_2$R and features of alloantibody mediated rejection and whether IF studies can distinguish de novo and idiopathic MGN. **Methods:** Sera from 18 patients in which the diagnosis of de novo MGN was made at the MGH (n=4) or at OSU Medical Center (n=14) were tested for reactivity to PLA$_2$R by western blot analysis, using native or recombinant forms of the antigen. C4d was detected in frozen tissue sections using a sensitive 3-step IF technique to seek evidence of alloantibody reactivity. Double IF studies for IgG4-FITC and PLA$_2$R-Cy3 were performed on frozen sections for evaluation of colocalization by visual inspection and morphometry. **Results:** None of the sera (0/18) from de novo MGN were reactive to PLA$_2$R, in sharp contrast to the published prevalence of approximately 70% anti-PLA$_2$R in idiopathic MGN. The IF in renal biopsies revealed distinctive patterns in the two diseases. IgG4 and PLA$_2$R did not colocalize in glomeruli in de novo MGN, but did in idiopathic and recurrent MGN by both visual and morphometric analysis. C4d was positive in peritubular capillaries (PTC) in 72% (13/18) of the allograft biopsies from de novo MGN. Renal allograft biopsies with FSGS or IgA nephropathy had a low frequency C4d+ PTC (0/17)**. Conclusions:** De novo MGN has a distinct pathogenesis from idiopathic MGN. These morphologically similar conditions can be distinguished in renal biopsies by IF for IgG4 and PLA$_2$R. The high frequency of C4d$^+$ argues that de novo MGN is a form of chronic alloantibody mediated rejection, of unknown specificities, that affects PTC endothelium and glomerular podocytes.

**Variants in the Aquaporin-1 Gene Influence the Baseline Permeability and the Outcome of Peritoneal Dialysis** Céline Maréchal,[1] Marion Verduijn,[2] Raymond T. Krediet,[3] Pieter Evenepoel,[4] Friedo W. Dekker,[2] Olivier Devuyst.[1] *[1]Nephrology, UCL, Brussels, Belgium; [2]Epidemiology, Leiden UMC, Leiden, Netherlands; [3]Nephrology, AMC, Amsterdam, Netherlands; [4]Nephrology, KUL, Leuven, Belgium.*

Patients starting peritoneal dialysis (PD) show a significant variability in water transport across the peritoneal membrane (PM). The water channel aquaporin-1 (AQP1), the molecular counterpart of the ultrasmall pore, plays an essential role in the osmotic water flow across the PM. In this study we investigated whether variants in the *AQP1* gene influence the permeability of the PM and the outcome of PD. We sequenced the four exons, 2000 bp in the promoter and in the 3'UTR in the *AQP1* gene and investigated the influence of variants on baseline peritoneal equilibration test (PET) parameters and on mortality and technique failure (TF) in 165 incident Caucasian PD patients treated in Belgium (UCL and KUL). The Cox regression analysis was also performed for death and TF in a second, independent replication cohort (NECOSAD and AMC) (N = 576). Four SNPs (rs1476597, rs2075574, rs10253374 and rs1049305), with a minor allele frequency higher than 10%, were studied. In the Belgian cohort, patients with the T/T genotype of the rs2075574 in the promoter showed a significantly lower ultrafiltration (UF) ($p = 0.01$) than the C/C and C/T, whereas the D/P creatinine at 4 h was similar. Patients with the T/T genotype had an increased risk of death and TF (HR = 2.28, 95% CI 1.05 - 4.96). In the replication cohort, we also observed an influence of the T/T genotype on survival and TF (HR = 1.71, 95% CI 1.17 - 2.51). In vitro analysis showed that this variant resulted in a 61 % loss of activity relative to the wild type sequence for a luciferase reporter construct containing the proximal 1053 nucleotides of the *AQP1* promoter transfected into human erythroid k562 cells. Our data show that a promoter variant in *AQP1* influences the UF and the outcome of PD, in relation with a strong influence on the promoter activity. These results substantiate the influence of genetic factors on the transport parameters and the outcome of PD.

## TH-FC119

**High Glucose Levels Induce Endoplasmic Reticulum Stress in Peritoneal Mesothelial Cells** Junichi Nakamata,[1] Hiroyuki Morimoto,[2] Ryoko Baba,[2] Tetsu Miyamoto,[1] Tatsuya Shibata,[3] Ryota Serino,[1] Narutoshi Kabashima,[3] Yutaka Otsuji,[1] Yoshiaki Doi,[2] Masahito Tamura.[3] *[1]The 2nd Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyusyu, Japan; [2]Department of Anatomy, University of Occupational and Environmental Health, Kitakyusyu, Japan; [3]Kidney Center, University of Occupational and Environmental Health, Kitakyusyu, Japan.*

Background. It is important to maintain adequate peritoneal structure and function for long-term peritoneal dialysis (PD) therapy. Peritoneal dialysate, containing non-physiological materials such as glucose, is implicated in long-term damage of the peritoneal membrane. Endoplasmic reticulum (ER) stress is associated with the progression of hyperglycemia-associated atherosclerosis and kidney diseases; however, the involvement of ER stress in PD has yet to be elucidated. We investigated the role of high glucose as an inducer of ER stress in PD, and examined components of the ER stress pathways in rat peritoneal mesothelial cells (PMCs). Following the culture of primary PMCs obtained from the peritoneal parietal wall of Wistar rats, serum-starved PMCs were incubated with 2% d-glucose in culture medium for 0-72 hours. High glucose concentrations significantly increased both the expression and phosphorylation levels of eIF2 alpha, a key signaling molecule that attenuates general protein translation and induces apoptosis in the PERK pathway, in a time-dependent manner with a peak at 6 hours. The ratio of phosphorylated to total eIF2 alpha was also increased in the same manner. After a 6-hour incubation of PMCs with 0-4% glucose, the relative phosphorylation levels of eIF2 alpha were increased in a concentration-dependent manner up to 2% glucose. At concentrations greater than 2%, glucose suppressed both the cell viability examined by WST-1 assay. These results demonstrate that high glucose concentrations promote eIF2 alpha-mediated ER stress in PMCs, and suggest that ER stress might be involved in peritoneal damage in patients receiving PD therapy.

**TH-FC120**

**Peritoneal Macrophage Infiltration Is Correlated with Baseline Peritoneal Solute Transport Rate in Peritoneal Dialysis Patients** Akiho Sawai, Yasuhiko Ito, Masashi Mizuno, Yasuhiro Suzuki, Susumu Toda, Isao Ito, Waichi Sato, Naotake Tsuboi, Shoichi Maruyama, Enyu Imai, Yoshifumi Takei, Yukio Yuzawa, Seiichi Matsuo. *Department of Nephrology and Renal Replacement Therapy and Biochemistry, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

**Purpose:** High baseline peritoneal solute transport rate is reportedly associated with reduced patient and technical survival in peritoneal dialysis patients. However, the determinants of baseline peritoneal solute transport rate remain uncertain. The aim of this study was to investigate the relationship between peritoneal local inflammation, angiogenesis and systemic inflammation, and baseline peritoneal permeability.

**Methods:** Peritoneal biopsy specimens from 42 pre-dialysis uremic patients and 11 control individuals were investigated. Immunohistochemistry for CD68-positive macrophages, chymase- and tryptase-positive mast cells, interleukin-6 (IL-6)-positive cells, CD3-positive T cells , CD20-positive B cells, myeloperoxidase-positive neutrophils, and CD31- and pathologische anatomie Leiden-endothelium (PAL-E)-positive blood vessels in the peritoneum were performed. Clinical and laboratory parameters were measured at the time of peritoneal biopsy. Baseline dialysate-to-plasma ratio for creatinine (D/P Cr) was assessed after PD induction.

**Results:** Pre-dialysis uremic peritoneum showed infiltration by CD68-positive macrophages, IL-6-positive cells and mast cells, as compared to controls. Baseline D/P Cr was correlated with density of macrophages ($p<0.001$), IL-6-positive cells ($p<0.001$), CD31-positive ($p<0.05$) and PAL-E-positive blood vessels ($p<0.05$), and serum albumin ($p<0.05$). However, baseline peritoneal permeability was not correlated with infiltration by mast cells, T cells, B cells, neutrophils, CRP, age, gender, diabetes or other co-morbidities. On multiple linear regression analysis, the number of CD68-positive macrophages in peritoneum was an independent determinant for baseline peritoneal permeability ($p=0.009$).

**Conclusions:** Peritoneal macrophage infiltration is predominant in uremic patients and is an important factor in determining baseline peritoneal permeability.

**Atrial Natriuretic Peptide Prevents Peritoneal Adhesion Formation with Inhibiting Macrophage and CD3-Positive Cell Infiltration** Hideki Yokoi, Masato Kasahara, Kiyoshi Mori, Takashige Kuwabara, Hirotaka Imamaki, Tomoko Kawanishi, Kenichi Koga, Akira Ishii, Keita Mori, Yukiko Kato, Akira Sugawara, Masashi Mukoyama, Kazuwa Nakao. *Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Encapsulating peritoneal sclerosis is an infrequent, but most serious and refractory complication on continuous ambulatory peritoneal dialysis (CAPD). EPS is associated with high mortality in patients on CAPD. EPS is an intestinal obstruction syndrome caused by peritoneal deterioration and inflammation leading to intestinal adhesions with fibrin deposition. Treatment of EPS is total parenteral nutrition, steroid and surgery. We have already reported that natriuretic peptide inhibits extracellular matrix deposition in the kidney. To evaluate the therapeutic potential of atrial natriuretic peptide (ANP) on EPS, we treated chlorhexidine gluconate (CG)-induced EPS model mice with continuous intraperitoneal infusion of human ANP (carperitide). Next, CG was administered to develop EPS in brain natriuretic peptide (BNP)-transgenic (BNP-Tg) mice which overexpress mouse BNP in the liver with elevated level of plasma BNP, and in natriuretic peptide receptor GC-A deficient (GC-A KO) mice. Continuous intraperitoneal ANP infusion significantly prevents peritoneal adhesion. Inflammatory cytokines, TNF-$\alpha$ and IL-1$\beta$ were significantly reduced in ANP-treated mice. Surprisingly, the thickness of peritoneal membrane was not changed between ANP- and vehicle-infused CG-treated mice. Fibrosis-related gene expressions such as TGF-$\beta$1, CTGF, fibronectin and COL1A1 were not different. Infiltration of macrophages and CD3-positive cells was reduced with ANP treatment. BNP-Tg mice also showed reduced peritoneal adhesion with decreased expression of inflammatory cytokines and with reduced infiltration of macrophages and CD3-positive cells. In contrast, GC-A deficient mice exhibited increased peritoneal adhesion with augmented inflammation. These results indicate that natriuretic peptides prevent peritoneal adhesion, and that natriuretic peptides can be therapeutic drugs against EPS and peritoneal adhesion.

**Clinical Benefits of a CAPD Technique with One Icodextrin-Containing and Two Glucose-Containing Dialysates a Day in Incident CAPD Patients** Hye Eun Yoon,[1] Hyun Gyung Kim,[2] Yoon-Kyung Chang,[3] Young Soo Kim,[2] Seok Joon Shin,[1] Ho-Cheol Song,[4] Yong-Soo Kim.[5] *[1]Internal Medicine, The Catholic University of Korea, Incheon, Republic of Korea; [2]Internal Medicine, The Catholic University of Korea, Uijeongbu, Gyeonggi-do, Republic of Korea; [3]Internal Medicine, The Catholic University of Korea, Daejeon, Republic of Korea; [4]Internal Medicine, The Catholic University of Korea, Bucheon, Gyeonggi-do, Republic of Korea; [5]Internal Medicine, The Catholic University of Korea, Seoul, Republic of Korea.*

Icodextrin-based solutions have advantages over glucose-based solutions in fluid and metabolic management in continuous ambulatory peritoneal dialysis (CAPD) patients. We observed the clinical benefits of a three-exchanges-per-day CAPD technique using one icodextrin-containing and two glucose-containing dialysates in incident CAPD patients.

Sixty-eight incident CAPD patients completed the 12-month multicenter prospective randomized controlled trial. After one month of a CAPD schedule using four exchanges of glucose dialysates, patients were randomized to two groups; GLU group using four glucose-containing dialysates (n=33) and ICO group using one icodextrin-containing and two glucose-containing dialysates (n=35). The ICO group used icodextrin for the long-dwell (12h). Variables related to residual renal function (RRF), biocompatibility and dialysis adequacy were measured.

Weekly renal creatinine clearance and urine volume were significantly reduced during the 6 and 12 months in the GLU group ($P<0.05$), but not in the ICO group ($P>0.05$). The peritoneal glucose absorption was significantly less in the ICO group than the GLU group during 6 and 12 months ($P<0.05$). The ICO group showed a significant decrease in LDL-cholesterol and the GLU group showed a significant decrease in HDL-cholesterol ($P<0.05$). The weekly KT/Vurea, weekly creatinine clearance, and blood pressure did not differ between the two groups.

In conclusion, the CAPD technique using once icodextrin-containing and twice glucose-containing dialysates daily better preserved the RRF, was more biocompatible and showed comparable dialysis adequacy compared to the conventional CAPD technique in incident CAPD patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC123**

**A Randomized Controlled Trial Comparing Mupirocin to Polysporin Triple for the Prevention of Catheter Related Infections in Peritoneal Dialysis (PD) Patients** Rory F. McQuillan, Ernest Chiu, Charmaine E. Lok, Sarbjit Vanita Jassal. *Division of Nephrology, University Health Network, Toronto.*

**Aims**

Infectious complications remain a significant cause of PD technique failure. Topical ointments appear to reduce peritonitis, however concerns over resistance have led to a quest for alternative agents. We studied the effectiveness of Polysporin Triple ($P^3$) in a multi-centred, double blind randomized controlled trial.

**Methods**

PD patients aged ≥18 yrs were eligible. Exclusion criteria included recent infection or use of an antibiotic; known allergies to the study drugs; or planned transplant surgery. Ointments were prepared by a central trials pharmacy and dispensed in identical study jars. Stratified variable block randomization using computer-generated random-number list was used to allocate treatment. Patients were stratified on PD modality; PD vintage and study site. The primary outcome was defined as a catheter related infection (a composite endpoint of exit site infection, tunnel infection or peritonitis). All patients were followed for 18 months or until death, transplant or transfer to hemodialysis. The time to first catheter related infection was compared using time-dependent univariate analysis.

**Results**

201 of 304 eligible patients were recruited. Patients were mostly male (65%) aged 60.5+/-14.4 years and on PD for a median 9.5 months. 31% were incident PD patients. 4% had MRSA nasal carriage and 31% had >1 previous peritonitis episode. 43.6% were diabetic A total of 75 patients had an event (51 peritonitis episodes, 24 exit site infections). No difference in the time to first event was seen (13.2 ±0.7 and 14.0±0.7 months) for $P^3$ and mupirocin respectively p=NS). There were twice as many patients with redness at the exit site in the $P^3$ group (16 versus 8, p=NS). A higher number of patients using $P^3$ had positive fungal exit site cultures(7 vs 0, p= 0.01).

**Conclusion**

This study has shown that $P^3$ is not superior to mupirocin in the prophylaxis of catheter related infections. The higher risk of positive fungal cultures needs further investigation. As such we cannot advocate the use of $P^3$ over mupirocin in the prophylaxis of catheter related infections in peritoneal dialysis.

Disclosure of Financial Relationships: nothing to disclose

**A Costing Model for Use in Evaluating the Fiscal Impact of Home Versus In-Center Dialysis within Various Healthcare Systems** Paul Komenda,[1, 2] Susan Garfield,[3] Amy White Poret,[3] Manish M. Sood,[1, 2] Meghan B. Gavaghan.[3] *[1]Medicine, University of Manitoba, Winnipeg, MB, Canada; [2]Manitoba Renal Program, Seven Oaks General Hospital, Winnipeg, MB, Canada; [3]Bridgehead International, Boston, MA.*

**Purpose and Rationale:** An economic model was developed to calculate and contrast the costs to payers for providing three types of hemodialysis (HD) in Australia, Canada and the United States. The model was designed to provide decision-makers with a transparent tool for assessing the costs and cost drivers of hemodialysis modalities in the first year of treatment and beyond.

**Methods** Model inputs were derived from a literature review that yielded published cost input values as well as observational data from a clinical setting in Canada. The specific dialysis modalities used to develop the model comprised conventional in-center (ICHD), conventional home (CHHD), and nocturnal home hemodialysis (NHHD). Sensitivity analyses were conducted on all cost variables.

**Results** The model found that ICHD costs are stable over time and driven by staffing, renal medication, and infrastructure costs. CHHD and NHHD costs in year 1 are driven by renal medication costs, patient training costs, costs for machines, consumables, and home preparation. Subsequent year costs are driven by renal medication, consumables, and hospitalization costs. Costs for CHHD and NHHD were comparable to ICHD in year one and less than ICHD in subsequent years. (See table)

**Conclusions** These results reinforce findings from previous studies indicating that HHD modalities provide economic advantages over ICHD. As demand and associated costs for end-stage renal disease treatment increases in most countries, payers can use this model to better understand their hemodialysis costs. The model demonstrates the positive cost-impact from patients moving to home versus in-center hemodialysis modalities.

Costs for CHHD, NHHD and ICHD

| | Canada | | US | | Australia | |
|---|---|---|---|---|---|---|
| | Year 1 | Year 2 & Beyond | Year 1 | Year 2 & Beyond | Year 1 | Year 2 & Beyond |
| ICHD | $50,739 | $50,399 | $54,244 | $53,904 | $50,313 | $49,973 |
| HHD | $45,788 | $35,419 | $48,937 | $39,186 | $46,458 | $35,962 |
| NHHD | $47,174 | $36148 | $50,708 | $40,301 | $47,843 | $36,691 |

Disclosure of Financial Relationships: nothing to disclose

**TH-FC125**

**Determinants and Predictors of Successful Home Hemodialysis Training in a Multi-Center US Observational Cohort** Christopher T. Chan,[1] John E. Moran.[2] *[1]Toronto General Hospital, Torontao, Canada; [2]DaVita Inc., Denver, CO.*

**Background:** Frequent home hemodialysis (HHD) is a growing renal replacement modality in North America. Emerging data suggest that intensive hemodialysis offers multiple clinical advantages over conventional hemodialysis while providing improved quality of life. Yet, there has been a lack of studies examining the suitability and determinants of successful HHD candidates.

**Methods and Objectives:** This was a descriptive cohort study of all patients enrolled into an HHD program with a large, US dialysis provider from January 1 2004 to December 31 2009. Our primary objectives were to define the demographic characteristics of our HHD cohort and to assess the risk factors for patients unable to successfully undertake HHD therapy.

**Results:** From January 1 2004 to December 31 2009, 1222 were able to achieve HHD therapy after a mean training duration of 17.7 ± 0.2 days (mean ± SE). In contrast, 144 patients failed to graduate to HHD despite receiving 10.1 ± 0.6 training days. The demographics of the HHD cohort and the unsuccessful training group are summarized in Table 1. A multivariable model predicting HHD training success indicated that age (per 1 year increase) (odds ratio: 0.97, p<0.001) and diabetes status (odds ratio: 0.65, p=0.006) were significant risk factors for failure.

Table 1: Demographic Characteristics of Home Hemodialysis Patients vs. Patients unable to achieve HH

| | Home Hemodialysis (n=1222) | Training Failure (n=144) |
|---|---|---|
| Age (years)* | 52 ± 0.4 | 56 ± 1.1 |
| F:M | 421:801 | 49:95 |
| Diabetes (%)* | 29 | 40 |
| Body Mass Index (g/m$^2$) | 28.4 ± 0.2 | 28.7 ± 0.6 |
| Hypertension (%) | 24 | 16 |
| Charlson Co-morbidity Index* | 5.2 ± 0.1 | 5.6 ± 0.2 |
| Dialysis Vintage (years) | 3.1 ± 0.1 | 2.9 ± 0.3 |

**Conclusion:** This is the first US multi-center systematic analysis of the determinants of HHD patients. This study showed that advanced patient age and diabetes status are associated with HHD training failure. These data may be used to help predict which patients are likely to succeed or fail in training.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC126**

**A Longitudinal Follow-Up of Quality of Life amongst Patients on Nocturnal Haemodialysis** David T. Lau, John W. M. Agar. *Renal Medicine, Geelong Hospital, Barwon Health, Geelong, Victoria, Australia.*

Background: Studies have shown that nocturnal haemodialysis (NHD) improves quality of life (QOL) when compared with conventional dialysis regimens. However, to our knowledge, there is currently no published QOL data of NHD patients followed over a prolonged period. We report the QOL outcomes for NHD over an 8 year period.

Method: Using the KDQOL-36, a validated tool in assessing QOL in dialysis subgroups, QOL data was collected annually from 2001 to 2009; medical records were analyzed for factors confounding QOL. Patients were categorized by according to the number of years they had been on NHD.

Results: A total of 111 surveys were returned in the 8 years, with a total of 314 patient-years on NHD. The two QOL domains reflecting the 'prevalence of symptoms' and the 'individual restrictions placed on lifestyle by dialysis treatment' both scored similarly and were sustained at a consistently high level throughout the 8 year study. However, our NHD patients did still feel that the total burden of their kidney disease and its treatment requirements remained significant, as was reflected by their lower though also stable scores for the 'burden of kidney disease'. Physical and mental health composite scores compared favourably with the normal population.

Conclusion: This study reveals that the symptom impact and lifestyle limitations in the NHD group are broadly mild and do not deteriorate throughout an 8 year follow-up period. However, there was a pervasive perception of frustration at the interference kidney disease had on overall lifestyle. This impression persisted throughout the study period. This data suggests that despite the lack of major lifestyle limitations, and despite physical and mental stability, NHD patients are still dialysis-dependent – an unalterable, permanent, additional encumbrance in their daily lives.

Disclosure of Financial Relationships: nothing to disclose

**TH-FC127**

**Caregiver Burden among Nocturnal Home Hemodialysis Patients** Jean-Philippe Rioux, Christopher T. Chan. *Department of Medicine, Division of Nephrology, University Health Network, Toronto, ON, Canada.*

**Background:** Recent studies have suggested improvements in quality of life (QOL) in patients on quotidian dialysis compared with conventional hemodialysis. Few studies have focused on the burden and QOL in caregivers of patients with end-stage renal disease (ESRD) on nocturnal home hemodialysis (NHD). We aim to assess the caregiver burden, QOL and depressive symptoms and to compare these parameters with their patient counterparts.

**Methods:** Cross-sectional surveys were sent to 61 prevalent NHD patients and their caregivers. Surveys assessed demographics, general self-perceived health using the 12-Item Short Form Health Survey (SF-12) and the presence of depression using the Beck Depression Inventory. Subjective burden on caregivers was assessed by the Caregiver Burden scale and was compared with the perceived caregiver burden among patients on NHD.

**Results:** Thirty six patients and 31 caregivers completed the survey. The majority of caregivers were female (66%), spouse (81%) with no comorbid illness (72%). Their mean age was 51 ± 11 years. Patients were mostly male (64%) with a median ESRD vintage of 60 months (IQR, 18-136 months) and a mean age of 52 ± 10 years. Compared to caregivers, patients had lower perceived physical health score but had similar mental health score. Depression criteria were present in 47% of patients and 25% of caregivers. Total global burden perceived by either caregivers or patients is relatively low.

**Conclusion:** Although there is a relatively low global burden perceived by caregivers and patients undergoing NHD, a significant proportion of both groups fulfilled criteria for depression. Further innovative approaches are needed to support caregivers and patients performing NHD to reduce the intrusion of caring for a chronic illness and their risk of depression.

**Bone Microarchitecture in Hemodialysis Patients: A Disorder of Cortical and Trabecular Bone** Justine Bacchetta,[2] Solenne Pelletier,[1,2] Nicolas Vilayphiou,[2] Stephanie Boutroy,[2] Roland Chapurlat,[2] Denis Fouque.[1] *[1]Nephrology, Lyon, France; [2]Inserm U831, Lyon, France.*

Dual X-ray absorptiometry is the usual technique to analyze bone mineral density. Yet, measuring bone mass is not sufficient to define bone impairment: bone microarchitecture is also a major determinant of bone fragility. Here we hypothesize that volumetric bone mineral density (vBMD) and microarchitecture were impaired in maintenance hemodialysis (MHD) patients compared with control subjects.

56 MHD patients since 2.6±2.8 yrs were matched for age (51±16 yrs), BMI (25±4 kg/m²), gender and menopausal status for women, with 56 healthy subjects from epidemiological cohorts (STRAMBO and OFELY). A high-resolution peripheral quantitative computed tomography (HR-pQCT, XtremeCT, Scanco Medical AG) was used to assess cortical (Ct) and trabecular (Tb) vBMD and microarchitecture at the distal radius and tibia.

Compared to healthy subjects, MHD patients had a significant lower total vBMD at radius and tibia (respectively; -14% and -16% p<0.01), Ct vBMD (-6% and -3 % p<0.05), and Tb vBMD (-11% and -17% p<0.05). MHD patients had thinner cortex than controls at both sites (-16% and -17% p<0.01). Tb microarchitecture was also impaired in MHD patients. They had lowered Tb number (respectively at radius and tibia; -1% p=NS and -7% p<0.01), increased Tb separation (7% p=NS and 11% p<0.01) and heterogeneity of Tb network (7% p=NS and 16% p<0.01).

MHD patients presented an impairment of total, Tb and Ct vBMD, and Ct thickness at both sites compared to controls. However, Tb microarchitecture was significantly impaired at the tibia, but not at the radius. This suggests that Tb bone damage associated with MHD is more severe at lower limb than at radius, as already observed in CKD II-IV patients to a lesser extent.

HR-pQCT is a new non-invasive 3D-bone imaging technique and seems of interest in MHD. In this study, MHD patients had a greater bone impairment compared to healthy subjects. Longitudinal studies are required to confirm the differences observed between Tb microarchitecture of tibia and radius, and that this non-invasive technique allows improvement in the bone fracture prediction in this population.

**TGF-β Plays an Important Role in the Pathogenesis of High-Turnover Renal Osteodystrophy** Shiguang Liu, Joseph H. Boulanger, Wenping Song, Robert Fogle, Eric C. Roux, Mandy M. Smith, Hong Ling, Yves Sabbagh, Susan Schiavi. *Genzyme Corp., Framingham, MA.*

TGF-β1 plays a critical role in normal bone remodeling by regulating coupling of bone resorption and formation. In osteitis fibrosa, a high-turnover renal osteodystrophy (ROD), TGF-β1 protein is increased in both osteocytes and bone marrow. To assess the relevance of this increase on the pathogenesis of high-turnover ROD (HTO), we administrated a neutralizing anti-TGF-β antibody, 1D11, to adenine treated rats, a uremic model of HTO. Ten week-old Sprague Dawley rats were randomized into 3 groups (n> 6): (1) Control; (2) Adenine and (3) Adenine plus 1D11 (10 mg/kg, 3X /wk for wks 1-10). All adenine treated animals were fed standard chow containing 0.6% adenine for wk1, followed by 0.3% adenine for wks 2-6. Compared with the control group, adenine treatment was associated with a dramatic increase in serum BUN by week 3 (72.0 ± 4.6- vs. 19 ± 0.5 mg/dl) and serum creatinine (Cr) (0.31 ± 0.01 vs. 11 ± 0.12) that was sustained through the 10 week study. 1D11 had no significant influence on the progression of renal failure. Consistent with the presence of HTO, the serum bone formation marker, osteocalcin (OCN) and the bone resorption marker, C-terminal telopeptides of type I collagen (CTX) were significantly elevated in the adenine group at week 10 (1961 ± 341 vs. 272 ± 20.0 ng/ml and 239 ± 35.7 vs. 43 ± 9.1 ng/ml respectively). Importantly, 1D11 administration led to significant reductions in serum OCN (775 ± 68.2 ng/ml) and CTX (142 ± 11.6 ng/ml) independent of kidney function. MicroCT analysis revealed significant cortical porosity (typically associated with HTO) in femurs from adenine treated animals that were ameliorated by 1D11 treatment. Bone mineral density and volume were reduced in adenine treated relative to control animals.1D11 treatment promoted a trend toward increases in these parameters. These findings are consistent with a direct effect of 1D11 on bone rather than a secondary effect on improved renal function. Taken together, these data suggest that TGF-β1 contributes to the pathogenesis of renal osteodystrophy and anti-TGF- β1 antibody may provide a novel therapeutic approach to HTO.

**Indoxyl Sulfate as a Modulator of Bone Turnover in Pre-Dialysis Chronic Kidney Disease Patients** Fellype Barreto,[1,2] Daniela Veit Barreto,[1,2] Aluizio B. Carvalho,[3] Maria Eugenia F. Canziani,[3] Cristianne Tomiyama,[3] Andrea Higa,[3] Anais Mozar,[1] Griet Lrl Glorieux,[4] Raymond C. Vanholder,[4] Ziad Massy.[1,2] *[1]INSERM ERI-12 (EA 4292), Amiens, France; [2]Clinical Research Centre - Division of Clinical Pharmacology, Amiens University Hospital and the Jules Verne University of Picardie, Amiens, France; [3]Division of Nephrology, Department of Internal Medicine, Federal University of São Paulo, São Paulo, SP, Brazil; [4]The Nephrology Section, Department of Internal Medicine, University Hospital, Gent, Belgium.*

Pre-clinical evidence suggests that indoxyl sulfate (IS) may be involved in the development of low bone turnover in uremia. The present study sought to characterize renal osteodystrophy (ROD) in pre-dialysis chronic kidney disease (CKD) patients and evaluate the association between histomorphometric parameters and circulating IS levels. Bone biopsies were performed in 49 consecutive patients (mean±SD age: 52±10; 67% male; estimated glomerular filtration rate: 36±17 mL/min). Patients at CKD stages 2 and 3 presented remarkably low bone formation rate. Patients at CKD stages 4 and 5 presented significantly higher osteoid volume, osteoblast and osteoclast surface, bone fibrosis volume and bone formation rate and a lower mineralization lag time than CKD stage 2 and 3 patients. We observed a positive association between IS levels on one hand and the bone formation rate, osteoid volume, osteoblast surface and bone fibrosis volume on the other. Multivariate regression models confirmed that the associations between IS levels and osteoblast surface and bone fibrosis volume were both independent of demographic characteristics and other assayed circulating factors capable of affecting bone turnover (calcium, phosphorus, intact-PTH, FGF-23 and vitamin D). A similar trend was observed for the bone formation rate. Our findings suggest that the ROD in the initial phases of CKD may be characterized by a lower bone turnover state. Moreover, we demonstrated that IS is positively associated with bone formation rate, osteoid volume, osteoblast surface and fibrosis volume in a clinical CKD setting.

**Novel Mechanisms of Regulating Bone Formation in Chronic Kidney Disease (CKD)** Yifu Fang,[1] Suresh Mathew,[1] Richard Lund,[2] Keith A. Hruska.[1] *[1]Division of Pediatric Nephrology, Washington University School of Medicine, St. Louis, MO; [2]Division of Nephrology, Creighton University, Omaha, NE.*

The serum phosphorus has been established as a cardiovascular risk factor in CKD. Prospective studies *in vivo* demonstrate phosphorus stimulated vascular calcification (VC), and the stimulation of aortic osterix expression, which if inhibited stops VC. In several interventional studies, successful treatment of VC is associated with stimulation of bone formation. Human observational studies show inverse relationships between VC and bone formation in CKD, osteoporosis, and diabetes. A hypothesis tested in the studies reported here is that heterotopic mineralization inhibits orthotopic bone formation since osterix is a transcription factor for a circulating inhibitor of bone formation, Dkk1. In our hyperphosphatemic animal model of CKD stimulated VC and renal osteodystrophy/osteoporosis, we utilized a non-absorbable phosphorus binder that has no known systemic effects besides inhibition of phosphate absorption, reduction of the serum phosphorus and secondarily, PTH levels. In our model CKD induced VC and aortic osteoblastic gene transcription including osterix. We demonstrated increased aortic expression and serum levels of Dkk1 in the CKD animals. Treatment with LaCO3 1 and 3% added to the diet resulted in significant stimulation of bone formation rates and inhibition of FGF23 and VC. As a result, the osteoporosis of our animal model was corrected through an increase in bone volume. Lowering if the serum Pi was associated with decreased aortic osterix and Dkk-1 gene expression, but serum Dkk-1 was not decreased. The mechanism of LaCO3 stimulated bone formation was discovered by examining intestinal hormonal factors. We found that CKD stimulated an inhibitor of bone formation, serotonin, which LaCO3 diminished. We conclude that CKD stimulated serotonin levels are inhibited by LaCO3 contributing to the stimulation of bone formation and the inhibition of VC in CKD. Furthermore, that CKD stimulated Dkk-1 levels are of renal origin and not affected by changes in VC. LaCO3 may be a drug affecting intestinal epithelial functions other than binding luminal Pi.

**Bone Mass and Structure in Diabetic and Non-Diabetic CKD Versus Controls: A CRIC Study** Thomas L. Nickolas,[1] Matthew T. White,[2] Babette Zemel,[2] Takayuki Hamano,[3] Raymond R. Townsend,[3] Harold I. Feldman,[3] Lucy W. Kibe,[2] Michael Sulik,[2] Mary B. Leonard.[2] *[1]Medicine, Columbia Univeristy, NY, NY; [2]Pediatrics, Children's Hospital of Philadephia, Philadelphia, PA; [3]Medicine, University of Pennsylvania, Philadelphia, PA.*

CKD and diabetes mellitus (DM) increase fracture (FX) risk but effects on cortical (Ct) geometry and trabecular (Tb) and Ct volumetric bone mineral density (vBMD), determinants of bone strength, are not established.

305 CRIC subjects [MDRD eGFR median 46 (range 14-69)] were compared with 536 healthy, community controls. Tibia peripheral QCT (pQCT) scans were obtained for Tb/CtvBMD and Ct geometry [area, thickness, perimeter (CtArea, CtTh, CtPm)]. pQCT measures were converted to age-, sex-, race- specific Z-scores. iPTH and bone alk phos (BSAP; bone formation marker) were measured.

CKD vs. controls were older with higher BMI (Table). DM-CKD had higher BMI vs. NonDM-CKD. DM-CKD had greater TbvBMD, CtTh and CtArea vs. controls and NonDM-CKD, and greater CtPm vs. controls. After BMI adjustment group differences did not persist. CtvBMD was lowest in NonDM-CKD after BMI adjustment. CKD had higher iPTH levels than controls (both p<0.05). BSAP was highest in DM-CKD (p<0.05). CtvBMD was not associated with iPTH or BSAP.

DM-CKD was associated with greater TbvBMD and Ct dimensions, attributed to greater BMI. NonDM CKD was not associated with Tb deficits. NonDM-CKD was associated with lower CtvBMD. Mechanistically, increased bone turnover may result in lower CtvBMD. Greater bone formation (BSAP) in DM may offset this effect. Studies are needed to determine FX implications.

**VKORC1 Polymorphism Is Associated with CAC, CAC Progression and Survival in CKD Patients** Rachel M. Holden,[1,2] Alexander R. Morton,[1,2] Wilma M. Hopman,[3] Robert Louis Nolan,[4] Jocelyn S. Garland.[1,2] *[1]Medicine, Queen's University, Kingston, ON, Canada; [2]Queen's University Vascular Calcification Investigators; [3]Community Health and Epidemiology, Kingston General Hosptial; [4]Radiology, Queen's University.*

Polymorphisms in the vitamin K epoxide reductase complex subunit 1 (VKORC1), the enzyme target of warfarin, have been associated with an increase in cardiovascular disease (CVD) in the general population. Coronary artery calcification (CAC) is a prevalent form of CVD in the chronic kidney disease (CKD) population. We tested the hypothesis that the recessive *CC* VKOR genotype (G1542C SNP) would be associated with lower CAC, less CAC progression, and a lower incidence of mortality in a cohort of CKD patients over 5 years. In 2005, 171 stage 3-5 CKD patients had CAC quantified by MSCT scan. 12 % had *GG*, 49% had *GC* and 39% had *CC* genotypes. Considering the *CC* genotype versus the others, there were no differences according to sex, diabetes, age, or hypertension. Baseline CAC scores were lower in *CC* participants (median score 124 versus 302; p=0.051). In 2009, 86 patients had repeat CAC scores. Patients with the *CC* genotype were less likely to have progressive CAC. By logistic regression with increase of CAC score greater than 50 Agatston units over 5 years as the dependent variable, the *GG* or *GC* genotype was associated with an increased risk of progressive CAC (adjusted for age, diabetes, eGFR and hypertension). There was an interaction between baseline CAC score and VKOR genotype, such that the risk for progressive CAC was higher in individuals with the *GG* or *GC* genotype and baseline CAC score (OR 1.65; 95% CI 1.06 to 2.6; P=0.03). Survival analysis demonstrated increased all-cause mortality for patients with *GG* or *GC* genotype over five years, versus patients with the *CC* genotype (Log rank test p=0.001). By logistic regression mortality risk was four times higher for individuals with the *GG* or *GC* genotypes (OR 3.8; 95% CI 1.2 to 12.5; p=0.02) adjusted for age, gender, diabetes and micro-albuminuria. In summary, patients with the recessive VKOR *CC* genotype had lower baseline CAC levels, had a lower risk of CAC progression and a survival benefit over five years of follow-up.

**Bone Alkaline Phosphatase Is Strongly Associated with Mortality in Incident Dialysis Patients** Christiane Drechsler,[1,2] Marion Verduijn,[1] Stefan Pilz,[3] Raymond T. Krediet,[4] Friedo W. Dekker,[1] Christoph Wanner,[2] Markus Ketteler,[5] Elisabeth W. Boeschoten,[6] Vincent Brandenburg.[7] *[1]Dept of Clin Epidemiology, LUMC, Leiden, Netherlands; [2]Div of Nephrology, University of Wuerzburg, Germany; [3]Div of Endocrinology and Nuclear Medicine, Medical University of Graz, Austria; [4]Dept of Nephrology, AMC, Amsterdam, Netherlands; [5]Dept of Nephrology, Hospital Coburg, Germany; [6]Hans Mak Institute, Naarden, Netherlands; [7]Dept of Cardiology, RWTH University of Aachen, Germany.*

Background: Alkaline phosphatase (AP) has been found to be associated with vascular calcification and mortality in hemodialysis patients, but AP derives from various tissues of origin. The aim of this study was to assess the effect of bone-specific alkaline phosphatase (BAP) on morbidity and mortality in dialysis patients.

Methods: From a prospective cohort study of incident dialysis patients in the Netherlands (NECOSAD), we selected all patients with measured BAP at 12 months after the start of dialysis (baseline); n=800, mean age 59±15 years and BAP 18±13 U/l. By Cox regression analyses, we assessed the impact of BAP levels on mortality within 6 months (short term) and 4 years (longer term) of follow-up.

Results: Levels of BAP were positively correlated with levels of AP and parathyroid hormone. High levels of BAP strongly affected short-term mortality. After adjustment for confounders, patients of the highest BAP tertile had a 6 fold increased risk of death within 6 months (HR 6.1, 95% CI 2.2-17.0) compared to patients of the lowest tertile. The effects applied for both cardiovascular (HR 5.0, 95% CI 1.3-19.0) and non-cardiovascular mortality (HR 8.1, 95% CI 1.6-41.7). Furthermore, high levels of BAP were associated with increased cardiovascular mortality in the longer term (HR 1.7, 95% CI 1.1-2.6). In comparison with total AP, the effect sizes related to clinical outcomes were much higher for BAP.

Conclusions: High levels of BAP were strongly associated with short-term mortality in dialysis patients, pointing out the important impact of uncontrolled bone disease. Longitudinal assessments of BAP may be useful for the treatment monitoring in clinical practice in patients with end-stage renal disease.

**NFAT Activation Causes Podocyte Damage and Severe Proteinuria in Mice** Alexis J. Sloan,[1,2] Britta Sylvia Walter,[1] Ansel P. Amaral,[1,2] Wilhelm Kriz,[3] Jochen Reiser,[1] Christian Faul.[1,2] *[1]Department of Medicine, Division of Nephrology & Hypertension, University of Miami Miller School of Medicine, Miami, FL; [2]Department of Cell Biology & Anatomy, University of Miami Miller School of Medicine, Miami, FL; [3]Department of Anatomy and Developmental Biology, University of Heidelberg, Mannheim, Germany.*

Our previous work has shown that the activation of calcineurin, a calcium-dependent serine/threonine protein phosphatase, in podocytes causes the dephosphorylation of the actin-regulating protein synaptopodin. This is turn causes the cathepsin L-mediated degradation of synaptopodin leading to the loss of actin stress fibers in podocytes and the development of proteinuria in mice. In the present study we analyze the podocyte-specific function of NFAT (nuclear factor of activated T cells), a calcium/calcineurin-regulated transcription factor. To study consequences of NFAT activation in podocytes in vivo we utilized two mouse models. First, we expressed a constitutively active NFAT mutant form (NFATc1nuc) by generating an inducible, podocyte-specific double-transgenic mouse line (podocin-rtTA x tetO-CMV-NFATc1nuc-HA). Expression of NFATc1nuc led to severe proteinuria within 72 hours, which was homogenous and stable over several weeks. Ultra-structural analysis of podocyte morphology revealed podocyte damage which seemed non-progressive. Secondly, we used a transgenic NFAT/Luciferase reporter mouse line (NFAT-Luc) in order to identify stimuli that can induce NFAT activation in podocytes in vivo. Lipopolysaccharide (LPS) injections in mice have been previously used to generate rapid, reversible, calcineurin-dependent podocyte effacement resulting in proteinuria. When NFAT-Luc mice were injected with LPS, isolated glomeruli showed a significant increase in luciferase activity when compared to PBS injected animals. In summary, NFAT presents an additional important downstream target of calcineurin in podocytes. We hypothesize that NFAT is activated by certain stimuli that cause podocyte damage. Furthermore, once activated NFAT is sufficient to cause podocyte damage and proteinuria in mice.

**TH-FC136**

**Functional Calcium Permeable NMDA Receptors Are Expressed in Podocytes: Upregulation in Diabetic Mice and Their Effects on Nephrin Expression** Stuart E. Dryer. *Biology and Biochemistry, University of Houston, Houston, TX.*

NMDA receptors have been extensively studied in brain, where their activation by L-glutamate is essential for many forms of synaptic plasticity, and where their hyperactivation causes neuronal death. Systemic administration of NMDA antagonists is reported to cause acute proteinuria[1]. Here we show that functional NMDA receptors are expressed in podocytes. Using whole-cell recordings we observed inward currents evoked by NMDA in mouse and human podocyte cell lines and in primary cultures of mouse podocytes. These currents reversed at 0 mV, were highly reproducible, and were seen in 100% of cells tested. They do not desensitize with sustained or repeated exposure to NMDA. Responses were blocked by elevated $Mg^{2+}$ or by the antagonists D-APV or MK-801. Similar currents were evoked by D-aspartate and L-homocysteic acid, but responses to L-glutamate were surprisingly small. NMDA-evoked currents were potentiated by the modulatory ligand D-serine, but not by glycine. Responses to NMDA were completely inhibited by the glycine modulatory site antagonist L689,560. Sustained (2 hr) activation of NMDA receptors causese activation of Erk, Akt, but not RhoA in podocyte cell lines. However higher concentrations of NMDA also cause RhoA activation and a loss of nephrin expression in podocyte cell lines, but did not cause cell death even after 72 hr. In streptozotocin-treated mice we observed marked up-regulation of the NR1 subunit of NMDA receptors in some glomeruli. In segments of glomeruli with markedly elevated NR1 expression, we observed almost complete loss of nephrin. We also observed that NMDA receptors interact with other slit diaphragm proteins such as synaptopodin, and that stable knockdown of synaptopodin in podocyte cell lines causes marked reduction in the amplitude of NMDA-evoked currents. It is possible that NMDA receptors play a role in glomerularphysiology and pathophysiology. The properties of podocyte NMDA receptors are similar to those of neurons in broad outline, but their pattern of agonist responsiveness is somewhat unusual, especially the weak responses to L-glutamate and L-aspartate. 1. L. Giardino et al., J Am Soc Nephrol. 20:1929-40 (2009).

**Nephrin Endocytosis Is Mediated by a Tyrosine Based Endocytic Signal** Agnieszka Swiatecka-Urban. *Nephrology, Children's Hospital of Pittsburgh, Pittsburgh, PA.*

Nephrin is a transmembrane protein expressed at the slit diaphragm between the podocyte foot processes in the kidney glomerulus. Loss of nephrin expression reduces the integrity of the slit diaphragm and leads to proteinuria and nephrotic syndrome. The mechanisms that regulate the slit diaphragm integrity are incompletely understood. In particular, little is known about the role of nephrin endocytosis in the dynamic regulation of the slit diaphragm. The cytoplasmic tail of human nephrin contains several sequences that conform to the canonical tyrosine based endocytic motifs of the YxxØ type where x is any amino acid and Ø is an amino acid with a hydrophobic side chain. We hypothesized that the plasma membrane expression of nephrin is regulated by dynamic protein-protein interactions that control nephrin endocytosis. Studies were conducted in the T-SV40 immortalized human podocytes transiently transfected with human nephrin. YxxØ motifs

interact with the endocytic adaptor networks. Dynamin II provides intracellular vesicle transport by scission of the vesicles containing cargo proteins after endocytosis from the plasma membrane. Overexpression of the dominant negative, DynaminK44A increased the plasma membrane expression of nephrin indicating that nephrin undergoes endocytosis in our human podocyte cell model. Furthermore, nephrin co-immunoprecipitated with the small GTPases, Rab4 and Rab8 in the endocytic and recycling compartment. The Y1139RSL sequence in the nephrin cytoplasmic C-terminus is phosphorylated by Fyn and conforms to a canonical, tyrosine-based endocytic signal. Because the YxxØ motifs are activated as endocytic signals upon tyrosine de-phosphorylation we predicted that mutating the tyrosine to phenylalanine (non-phosphorylated tyrosine mimic) should activate nephrin endocytosis. The Y1139F mutant showed increased nephrin endocytosis compared to the WT-nephrin, examined by the glutathione protection assay and by immunofluorescence. Taken together our data demonstrate that the Y1139RSL sequence mediates nephrin endocytosis. Our data suggest that the Fyn mediated phosphorylation of Y1139 may control nephrin endocytosis and dynamically regulate the slit diaphragm integrity.

### TH-FC138

**The Role of wnt/β-Catenin Signaling in Podocytes** Hideki Kato,[1] Laura M. C. Barisoni,[2] Lawrence B. Holzman,[3] Katalin Susztak.[1] *[1]Medicine/Nephrology, Albert Einstein College of Medicine, Bronx, NY; [2]Pathology, New York University School of Medicine, New York, NY; [3]Division of Nephrology, University of Pennsylvania School of Medicine, Philadelphia, PA.*

We previously reported increased activity of the Wnt/β-catenin signaling in glomeruli of DKD patients. We created mice with podocyte specific stabilized β-catenin (by deleting exon3 the phosphorylation site) (NPHS2Cre/Ctnnb1Ex3/Ex3) and found GBM abnormalities, mild albuminuria and increased susceptibility to DKD. Podocyte specific β-catenin knockout mice (NPHS2Cre/Ctnnb1KO/KO) showed GBM abnormalities and increased susceptibility to DKD.

To understand the role of Ctnnb1, we performed microarray analysis of isolated glomeruli of these mice. We found 411 differentially expressed genes between WT and stabilized β-catenin expressing mice and 642 differentially expressed genes between WT and knockout mice. 270 transcripts were regulated in both animal models.

Phenotype analysis showed that glomerular podocyte number was decreased and urinary WT1 level was increased in NPHS2Cre/Ctnnb1Ex3/Ex3 mice, indicating a defect in cell adhesion. Therefore we generated immortalized podocyte lines from these mice by mating with the Immortomouse. Clones were established by limiting dilution method and cells were infected with Cre adenovirus. We confirmed in vitro Cre mediated recombination of Ctnnb1. In podocyte at baseline, Ctnnb1 showed membrane and perinuclear expression pattern, however, after Ad-Cre infection Ctnnb1 was expressed in the nuclei of Ctnnb1Ex3/Ex3 cells while its expression was diminished in Ctnnb1KO/KO cells. We analyzed podocyte adhesion to collagen IV. Cells expressing stabilized Ctnnb1 showed lower adherence and cells lacking Ctnnb1 showed higher adherence. Similar results were obtained when cells were treated with recombinant wnt3a. Gene expression analysis of the podocyte clones indicated Ctnnb1 controls the expression of podocyte cell marker (Nephrin, Podocin, WT1), cell adhesion molecules (β1integrin) in addition to Ctnnb1 target genes (axin, dkk).

Our results indicate that Ctnnb1 plays a key role in podocytes by controlling their gene expression, adhesion and motility.

### TH-FC139

**FSGS-Associated Mutations in TRPC6 Result in ERK Activation in a Calcineurin Dependent Manner** Johannes S. Schlondorff, Martin R. Pollak. *Renal Division, Beth Israel Deaconess Medical Center, Boston, MA.*

Gain-of-function mutations in the canonical transient receptor potential 6 (TRPC6) are a cause of autosomal dominant focal segmental glomerulosclerosis (FSGS), and increased TRPC6 expression has been linked to several acquired proteinuric renal diseases. The mechanism whereby abnormal TRPC6 activity results in proteinuria remains unknown. The ERK1/2 MAP kinases are activated in glomeruli and podocytes in several proteinuric disease models, including angiotensin II-mediated hypertension. We therefore examined whether FSGS-associated mutations in TRPC6 result in activation of these kinases.

In both 293T cells and cultured podocytes, overexpression of gain-of-function TRPC6 mutants resulted in increases in ERK1/2 phosphorylation, representing activation of these kinases. ERK1/2 activation was dependent on channel activity. Pharmacologic studies demonstrated that inhibition of either MEK1, the kinase responsible for activating ERK, or calcineurin abolished ERK phosphorylation due to mutant TRPC6 expression. Use of additional pharmacologic inibitors suggests that ERK activation downstream of mutant TRPC6 ALSO depends upon an atypical, not a calcium-dependent, protein kinase C (PKC), and is insensitive to inhibition of phospholipase C, Rho GTPase and Rho kinase (ROCK).

We next examined whether TRPC6 may form a complex with ERK. Endogenous ERK was found associated with immunoprecipitated TRPC6. This association was not appreciably altered by activation of TRPC6 via the muscarinic acetylcholine receptor, addition of the MEK inhibitor U0126 or calcineurin, or overexpression of Fyn, which induces the binding to PLC gamma to TRPC6.

In summary, we have found that FSGS-associated TRPC6 mutations lead to activation of the MEK-ERK signaling pathway, and that TRPC6 and ERK are capable of forming a complex. These results expand the list of potential downstream targets of TRPC6 and calcineurin to include ERK activation. These findings are intriguing as activation of the ERK MAP kinase pathway has been reported in several models of podocyte injury and proteinuria. The importance of ERK activation in TRPC6-mediated glomerular disease will require future studies in animal models.

**The Cytoplasmic Tail of Polycystin-1 Activates STAT3 and Is Cleaved to Differentially Regulate the Transcriptional Activity of STAT1 and STAT3** Jeffrey Talbot, Jonathan M. Shillingford, Thomas Weimbs. *Molecular Cellular and Developmental Biology, University of California Santa Barbara, Santa Barbara, CA.*

Autosomal-dominant polycystic kidney disease (ADPKD) is a common genetic disorder that frequently leads to renal failure. Mutations in polycystin-1 (PC1) underlie most cases of ADPKD, but the function of PC1 has remained poorly understood. Here, we show that PC1 regulates the transcriptional activity of STAT3 and that this occurs – surprisingly - by two different mechanisms. First, PC1 activates STAT3 by increasing its tyrosine-phosphorylation. The membrane-anchored PC1 tail is sufficient for this activation, which is JAK2-dependent and regulated by SOCS3. Second, PC1 undergoes proteolytic cleavage that releases its cytoplasmic tail, which undergoes nuclear translocation. The cleaved PC1 tail then strongly co-activates STAT3 in a manner that requires prior tyrosine-phosphorylation by cytokine signaling. The cleaved PC1 tail can also co-activate STAT1 and STAT6 in the same manner but in response to different cytokines.

We show that the cleaved PC1 tail accumulates in ADPKD kidneys and that patient mutations in the PC1 tail affect its ability to activate STAT3. Remarkably, STAT3 is strongly activated in cyst-lining cells in polycystic mouse models and human ADPKD compared to normal kidney in which it is barely detectable.

Altogether, these results indicate that PC1 can differentially regulate STAT1, STAT3 and STAT6 signaling depending on the state of PC1 cleavage, and on the cytokine environment. The cleaved PC1 tail hypersensitizes cells to STAT-dependent cytokine signaling. PC1 may integrate mechanical and chemical signals and direct the appropriate cellular response of renal epithelial cells.

**MicroRNA-21 (miR-21) Targets PTEN To Regulate Mesangial Cell Hypertrophy and Fibronectin Expression by High Glucose** Nirmalya Dey,[1] N. Ghosh-Choudhury,[2] Falguni Das,[1] Meenalakshmi M. Mariappan,[1] C. Mandal,[2] B. S. Kasinath,[1] Goutam Ghosh-Choudhury.[1] *[1]Medicine, UTHSCSA, San Antonio, TX; [2]Pathology, UTHSCSA, San Antonio, TX.*

We have shown recently that in mesangial cells (MC), decreased expression of the tumor suppressor protein PTEN contributes to hypertrophy and increased matrix protein fibronectin expression in response to high glucose (HG; 25 mM). The mechanism of PTEN expression by HG is not clear. MicroRNAs strategically control the mRNA translation. Analysis of 3'UTR of PTEN revealed the presence of a microRNA recognition element (MRE) for miR-21. HG significantly increased the expression of pre- and mature miR-21 in MC. Increased expression of pre- and mature miR-21 was also detected in the renal cortices of type 1 diabetic OVE26 transgenic mice. Plasmid-derived expression of miR-21 in MC reduced the expression of PTEN analogous to its downregulation by HG, resulting in increase in phosphorylation of Akt. In contrast, expression of miR-21 inhibitor (miR-in) significantly suppressed HG-induced decrease in PTEN expression, resulting in attenuation of Akt phosphorylation. To directly determine the involvement of miR-21 in PTEN regulation, we used a reporter containing 3'UTR of PTEN fused to luciferase. Expression of miR-21 significantly inhibited the luciferase activity similar to HG in MC. miR-21 additively reduced the HG-induced inhibition of luciferase activity. Conversely, miR-in significantly prevented the inhibition of luciferase activity in response to HG. Furthermore, miR-21 markedly increased the expression of fibronectin protein and its transcription similar to those with HG. In contrast, miR-in inhibited the HG-induced expression of fibronectin protein and its transcription. Finally, expression of miR-21 activated TORC1 kinase, resulting in protein synthesis and hypertrophy of MC, analogous to HG. miR-in significantly prevented HG-induced TORC1 activation, protein synthesis and hypertrophy. Together these results provide the first evidence for a functional role of miR-21 in targeting PTEN, which regulates matrix protein fibronectin expression and hypertrophy of MC, that contribute to complications of diabetic nephropathy.

### TH-FC142

**Hyperactivation of WNT-β-Catenin and PI3K/Akt Pathways in Monocytes and B Lymphocytes of IgA Nephropathy (IgAN) Patients Could Lead to a Defect in Antigen Handling** Francesco Paolo Schena,[1] Sharon N. Cox,[1] Fabio Sallustio,[1] Grazia Serino,[1] Francesco Pesce,[1] Nicola Ancona,[2] Patrizia Stifanelli,[2] Gianluigi Zaza.[1] *[1]Department of Emergency and Organ Transplantation, University of Bari, Bari, Italy; [2]ISSIA, CNR, Bari, Italy.*

A whole genomic screening was carried out to identify genes and pathways differently modulated in peripheral blood leukocytes isolated from 12 IgAN patients and 8 healthy subjects (HS). Bionformatic analysis revealed 210 genes discriminating IgAN pts from HS, these genes were also able to discriminate IgAN pts from other glomerular diseases. The identified set of genes generated highly significant networks involving WNT-b-catenin and PI3K/Akt. These pathways were further tested on peripheral blood mononuclear cells (PBMC) isolated from an independent group of 16 IgAN pts and 16 HS. Low protein levels

of inversin and phosphatase and tensin homolog, two modulators of the WNT-b-catenin and PI3K/Akt pathways, were found in IgAN pts suggesting a hyperactivation of these pathways. Furthermore, we found increased phospho-Akt protein levels, nuclear b-catenin accumulation with enhanced PBMC proliferation in IgAN pts.

Our next aim was to investigate which PBMC subpopulation of IgAN pts maybe principally involved in the WNT signaling alteration. We isolated T, B lymphocytes and monocytes and used a WNT pathway PCR Array to compare the transcript levels of 84 genes in IgAN pts and HS. Monocytes from IgAN pts showed an hyperactivation of the WNT pathway, in particular we found 24 significantly up regulated genes. B lymphocytes, showed a more blunt modulation since only 8 genes were found significantly up regulated, these genes overlapped with altered monocyte genes. T lymphocytes displayed only 5 deregulated genes. These findings highlight the emerging role of the WNT pathway in orchestrating the immune system in response to microbial stimulation of the immune cells in IgAN pts. Thus, the hyperactivation of this pathway could explain the abnormal systemic response to mucosal encountered antigens responsible for the onset of the disease. These newly identified pathways could be exploited for the identification of specific targets for the treatment.

## TH-FC143

**$GABA_BR2$-C-Terminal Tail Is a Novel Modulator of Renal Fibrosis** Madhavi J. Rane,[1] Shunying Jin,[1] Paul Johnson,[1] Michelle T. Barati,[1] Jon B. Klein.[1, 2] *[1]Medicine, University of Louisville, Louisville, KY; [2]Veterans Affairs Medical Center, Louisville, KY.*

$GABA_BR2$ agonists show beneficial effects on renal function by inhibiting fibrosis. However, mechanisms underlying such effects are largely unknown. Baclofen treatment induces Akt and CREB phosphorylation in renal proximal tubular cells (RPTCs) in a $GABA_BR2$-dependent manner. We documented Akt-$GABA_BR2$ -C-terminal tail association in granulocytes. Therefore, we hypothesized that active Akt promotes cleavage and nuclear translocation of the $GABA_BR2$- C-term tail in RPTCs. Over-expression of the $GABA_BR2$ with constitutively active Akt (AktCA) or TGF-b treatment of RPTCs induced cleavage of the $GABA_BR2$-C-term tail which was blocked by LY294002 pretreatment. AktCA but not AktDN (dominant negative) induced expression of $GABA_BR2$-C-term tail construct in RPTCs and stimulated its nuclear translocation. Because $GABA_BR2$ has been shown to bind the transcription factor CREB and contains a bZIP transcription factor domain, we examined if C-term tail acts as a transcriptional regulator. Luciferase assays demonstrated a significant increase in cyclic-AMP response element (CRE) luciferase activity by co-expression of AktCA and C-term tail. Co-expression of AktCA with C-term tail construct or 24 hr TGF-b treatment of RPTCs induced fibronectin expression which was blocked by LY294002 pretreatment. Furthermore, 30 kDa cleaved C-terminal fragment of $GABA_BR2$ was detected in 3 months STZ-diabetic kidneys a condition in which renal fibrosis is documented. Collectively, these data indicate that Akt plays a critical role in cleavage, expression, nuclear localization of the $GABA_BR2$-C-term tail and its action as a transcriptional regulator. Cleavage of $GABA_BR2$-C-terminal tail may prevent intact $GABA_BR2$-G-protein mediated inhibition of adenylate cyclase activity and may promote CRE activity with concomitant increase in fibronectin expression. Further investigation into how the $GABA_BR2$ C-term tail promotes fibrosis will provide insight into the renoprotective effects of GABA agonists in damaged kidneys and may identify targets for pharmaceutical intervention in renal diseases.

## TH-FC144

**Renal Fibrosis-Associated Gene IHG-1 Regulates Mitochondrial Biogenesis through Stabilisation of PGC-1a** Fionnuala B. Hickey,[1] James B. Corcoran,[1] Neil G. Docherty,[2] Brenda Griffin,[1] Fiona M. Furlong,[1] Finian Martin,[1] Catherine Godson,[1] Madeline Murphy.[1] *[1]Diabetes Research Centre, University College Dublin, Dublin, Ireland; [2]Department of Physiology, Trinity College Dublin, Dublin, Ireland.*

We have previously described IHG-1 as a highly conserved, glucose-regulated transcript associated with diabetic kidney disease. Here we report that IHG-1 is localised to the mitochondria. The transcriptional coactivator peroxisome proliferator-activated receptor gamma coactivator-1alpha (PGC-1a) plays a central role in the coordination of mitochondrial biogenesis. PGC-1a is a tightly regulated protein and its dysregulation has been implicated in the pathogenesis of several human diseases. We report that IHG-1 overexpression is associated with increased mitochondrial mass and stabilisation of PGC-1a protein. Consistent with increased mitochondrial mass we observe upregulation of PGC-1a-regulated transcription factors, including nuclear respiratory factor 1 (NRF-1) and mitochondrial transcription factor A (TFAM), a key activator of the transcription of mitochondrially encoded genes, along with increased expression of mitochondrial proteins. Conversely, inhibition of endogenous IHG-1 expression using shRNAmir resulted in reduced PGC-1a protein, decreased expression of NRF-1 and TFAM, and reduced expression of mitochondrial proteins. Mitochondrial dysfunction has recently been reported to be a major contributor to renal fibrosis. We demonstrate that PGC-1a protein is increased in an experimental model of tubulointerstitial fibrosis [rat unilateral ureteric obstruction] concomitant with increased expression of IHG-l. In summary these data identify IHG-1 as a novel regulator of PGC-1a and suggest that IHG-1-mediated stabilisation of PGC-1a may play a role in renal pathogenesis.

## TH-FC145

**Absence of TIM-1 Leads to Th-17 Mediated Rejection in a Model of Chronic Allograft Vasculopathy** Melissa Y. Yeung, Takuya Ueno, Mohamed H. Sayegh, Nader Najafian. *Transplant Research Center, Brigham & Women's Hospital, Boston, MA.*

We have previously reported the key role of TIM-1 molecule in differentiation of T helper cells in a model of acute cardiac rejection using a blocking monoclonal antibody. In this study, we sought to determine the role of TIM-1 in a chronic allograft vasculopathy (CAV) model (bm12 into B6) using a novel TIM-1deficient recipient (TIM1KO).

The absence of TIM-1 in B6 recipient mice led to accelerated rejection (MST=29d vs >60d, $p<0.01$) and severe vasculopathy. Intriguingly, rejection occurred despite a decrease in frequency of CD4+ effector-memory T cells (21.81± 1.2 vs 28.9 ± 1.8%, $p<0.01$) and alloreactive IFNg production (IFNg: 958 ± 176 vs 4278 ± 320 pg/ml, $p<0.001$) but was accompanied by an increase in IL-17 production (10.2 ± 2.7 vs 2.1 ± 0.3 pg/ml, $p=0.02$), suggesting a Th17-mediated rejection. Additionally, we observed a decrease in regulatory T cells (Tregs) (11.2 ± 0.7 vs 14.3 ± 0.6%, $p=0.03$) and alloreactive IL-10 (7.3 ± 1.0 vs 43.2 ± 7.1 pg/ml, $p<0.01$). To evaluate proliferation of nTregs in th absence of TIM-1, we utilized a GVH model. Whilst proliferation of CD4 (% divided: 24.0 ± 0.6 vs 29.6 ± 0.5, $p<0.001$) and CD8 (24.1 ± 0.5 vs 28.4 ± 0.6, $p<0.001$) T cells was reduced when TIM1KO splenocytes were injected as compared to WT splenocytes, proliferation of nTregs were comparable in both groups (42.1 ± 0.7 vs 40.7 ± 0.7, p=NS). To determine the role of TIM-1 in nTreg function, we first compared in vitro suppression by nTregs from TIM1KO mice with that of B6 WT counterparts and found no difference (IFNg suppression: 34.7 ± 2.7 vs 36.0 ± 2.1%, p=NS). Similarly, depletion of nTregs prior to transplantation led to similar degree of accelerated rejection in TIMKO recipient as well as WT mice (MST shortened by 38% in TIM1ko vs 30% in WT recipients) confirming similar functionality of nTregs in vivo.

These data suggest that in a class II mismatched Treg-dependent CAV model, the absence of TIM-1 does not affect proliferation or function of nTregs, but may impair the development/differentiation of "inducible" Tregs and shift CD4 differentiation towards a pathogenic Th17 milieu.

## TH-FC146

**Ratio of Th17 and Treg Is Significant Predictor for Renal Allograft Outcome after Acute Cellular Rejection** Byung Ha Chung, Hoon Suk Park, Jayoung Lee, Bumsoon Choi, Cheolwhee Park, Yong-Soo Kim, Chul Woo Yang. *Department of Internal Medicine, Seoul St. Mary's Hospital.*

**Background**: The aim of this study is to investigate whether the ratio between Th17 and regulatory T cell (Treg) in infiltration of allograft tissue could affect the allograft outcome after acute rejection episode.

**Patient and methods**: This study was done in cases with biopsy proven acute cellular rejection developed within 1 year after transplantation. We performed immunostaining for FoxP3 and IL-17 on infiltrating cells in renal allograft tissue and counted the number of stained cells. Treg rich group was defined when Treg / Th17 was more than 5 and the others were Th17 rich group. We compared both group in the frequency of steroid resistance, recovery after anti-rejection therapy, recurrent cellular rejection and renal allograft outcome.

**Results**: 57 cases of biopsy proven acute T cell mediated rejections from 33 patients were included in this study. Mean interval from transplantation to acute rejection episode was 3.2 ± 3.3 months. Treg rich group were 29 cases and Th17 rich group were 28 cases. Baseline characteristics such as age at transplantation or rejection episode, HLA mismatch number, gender, Serum creatinine level at rejection did not differ significantly between two groups. In Treg rich group, 89.7% responded well to steroid pulse therapy without secondary therapy. In contrast, only 32.1% responded to steroid therapy in Th17 rich group. ($p<0.05$) The proportion of recovered cases after acute rejection episodes was significantly higher in Treg rich group than in Th17 rich group.(93.1% vs. 74.1%, $P<0.05$) In recovered cases, the probability of recurrent rejection was significantly lower in Treg rich group compared to Th17 rich group. (28.7% vs. 48.7 %, $P<0.05$) The 1, 5 year graft survival rate after acute rejection was 81% and 62 % respectively in Treg rich group and those were only 48% and 37% in Th17 rich group. The graft outcome was significantly better in Treg rich group compared to Th17 group. ($P<0.05$)

**Conclusion**: Ratio of Th17 and Treg in infiltrating cell of renal graft tissue is significant predictor for allograft outcome after acute rejection episode.

## TH-FC147

**T-bet/Stat6 Double Knockout Recipients Experience Accelerated Rejection in a Chronic Rejection Model and Are Resistant to Transplant Tolerance Induction** Bara Sarraj,[1] Vishnupriya Samarendra,[1] Guodong Chen,[1] Omar A. Shah,[1] Zheng Jenny Zhang,[1] Mohamed H. Sayegh,[2] Mohammed Javeed Ansari.[1] *[1]Comprehensive Transplant Center, Northwestern University Feinberg School of Medicine, Chicago; [2]Brigham and Women's Hospital, Boston.*

INTRODUCTION: T-bet is the master regulator of Th1 immunity. We have previously shown T-bet-/- recipients experience accelerated rejection in a chronic rejection (CR) model and are resistant to tolerance (TOL) induction by costimulation blockade (CTLA4Ig+MR1). This resistance is believed to be due to excessive Th17 responses in the absence of Th1 responses in T-bet-/- recipients. The role of Th17 responses alone and the contribution of Th2 responses to resistance to TOL induction is unknown.

METHODS: We investigated the ability to induce TOL and mechanisms involved in the absence of Th1/Th2 immunity in T-bet/Stat6 double knockout (DKO) recipients, in 2 established models: 1) MHC-II mismatched (bm12-B6) CR model and 2) full MHC-mismatched (BALB/c into B6) cardiac allograft model of TOL with CTLA4Ig+MR1 treatment. Graft survival, histology, multi-parameter flow-cytomety (MFC) and cytokine bead array (CBA) assays were studied.

RESULTS: We generated DKO mice on B6 background and confirmed that DKO mice are immunologically normal except that they demonstrate attenuated Th1 and Th2 responses. In the CR model all grafts in DKO (n=6) and T-bet-/- (n=7) rejected in 14-28 days compared to graft survival of >42 in all WT (n=5) recipients ($p<0.05$). In TOL model all grafts in DKO (n=7) and T-bet-/- (n=7) recipients rejected in 10-14 days compared to graft survival of >30 days in all WT (n=5) recipients ($p<0.05$). Graft pathology showed predominantly granulocytic infiltration in DKO and T-bet-/- compared to WT. Increased RB6hi cells in grafts from DKO recipients. CD4 and CD8 memory T cells expressing IL-17 were increased in spleen and graft in DKO compared to WT and T-bet-/- recipients.

CONCLUSIONS: T-bet/Stat6 deficiency results in attenuated Th1/Th2 and Th17-skewed immunity which may be mediating resistance to tolerance induction by increased IL-17 CD4 and CD8 memory T cell generation and infiltration along with intense granulocytic infiltration in the grafts.

### TH-FC148

**Complement (C) Mediated Endothelial Cell (EC) Activation in a Swine Model of Renal Ischemia/Reperfusion (I/R) Injury** G. Castellano,[1] C. Curci,[1] T. Tataranni,[1] A. Loverre,[1] G. Lucarelli,[1] P. Ditonno,[1] M. Battaglia,[1] Beatrijs D. Oortwijn,[2] Edwin S. Van Amersfoort,[2] Francesco Paolo Schena,[1] G. Grandaliano.[1] *[1]Renal Unit, University of Bari, Bari, Italy; [2]Pharming Technologies, Leiden, Netherlands.*

I/R injury in transplanted kidney is the major cause of delayed graft function. The involvement of tubular endothelial cells (EC) in I/R injury has been widely investigated in rodents, with Complement (C) playing a major role in the induction of apoptotic and necrotic processes. On the contrary, renal EC seem not to be primary involved in the pathogenesis of C-mediated I/R renal injury.

By using a swine model of renal warm I/R injury, we found that 30' of ischemia was able to induce C4d and C5b-9 deposition on peritubular and glomerular EC, contrary to what has been described in rodents. By confocal microscopy analysis, we found the occurrence of AKT and NIK phosphorylation at 30' from reperfusion, which co-localized with EC markers, at peritubular and glomerular level. Interestingly, pAKT and pNIK co-localized with C4d on EC. pAKT and pNIK returned to basal level after 24 h from reperfusion, when C4d was also not detectable. Next, we stimulated EC in vitro with C3a and C5a. Western blotting analysis showed that C3a induced AKT phosphorylation at 15' (3.46±1.85 pAKT/AKT pixel ratio, ImageJ software) and 30' (5.01±2.11; control 1.82 ±0.23; $p<0.05$). Moreover, C3a induced NIK phosphorylation at 15' (1.97±0.63; pNIK/NIK pixel ratio) and 30' (6.10±1.10; control 1.10 ±0.38; $p<0.05$). Interestingly, also C5a induced pAKT and pNIK in cultured EC. To test the hypothesis of C-mediated EC activation in vivo, we injected 5 pigs with a C inhibitor, recombinant human C1-inhibitor (rhC1INH; Pharming). Pigs treated with rhC1INH showed dramatic reduction of C4d deposition on peritubular and glomerular EC. Interestingly, pAKT and pNIK were completely abrogated by C inhibition in vivo on pig glomerular and peritubular EC.

These data first indicate that C is primary involved in activation of renal EC in vitro and in vivo in a model of I/R injury, probably via C3a and C5a. Therefore, the use of C inhibitors might significantly limit EC activation with positive effects on graft survival.

Disclosure of Financial Relationships: nothing to disclose

### TH-FC149

**In Vitro Cytokine and HLA Antibody Stimulation of Glomerular Endothelial Cells Results in Complement Factor Synthesis** Rizwan A. Hamer,[1,4] Daniel Mitchell,[4] Simon C. Satchell,[2] David P. Lowe,[3] David Briggs,[3] Nithya Krishnan,[1] Simon Fletcher,[1] Robert Higgins,[1] Daniel Zehnder.[1,4] *[1]University Hospital Coventry and Warwickshire, United Kingdom; [2]University of Bristol, Bristol, United Kingdom; [3]NHS Blood and Transplant, Birmingham, United Kingdom; [4]University of Warwick, United Kingdom.*

Human microvascular endothelial cells (HMEC-1) and conditionally immortalised glomerular endothelial cells (ciGEnC), cultured under laboratory conditions, were stimulated for 12-48 h with IFN-γ (200-1000 IU/ml) and LPS (1-10 μg/ml). Western blot (WB) analysis of cell lysates showed C3 and C4 synthesis by both cell types on cytokine exposure. Amount of expression was proportional to both time and dose of cytokine stimulation. Unstimulated cells did not appear to synthesize complement. LPS was more effective than IFN-γ in causing expression of C3 (3 fold increase; $p<0.05$). C4 synthesis was seen only on treatment with IFN-γ (band density >30 times relative to control $p<0.05$). C4 mRNA and protein synthesis was inhibited by siRNA.

.After HLA typing both HMEC-1 and ciGEnC cells, effluent obtained during double filtration plasmapheresis (DFPP) treatment of our HLA antibody incompatible renal transplant patients containing HLA antibodies against cell HLA- type and "3rd party" antibodies were identified. Following extraction with sepharose columns, these antibodies were used to stimulate both HMEC-1 and ciGEnC cells. Confocal microscopy showed C4 on surface of cells treated with cell specific antibodies but not on cells treated with 3rd party antibodies. WB confirmed increased C4 expression by cells treated with cell-specific antibodies relative to cells treated with non cell-specific antibodies ( 89% increase; $p=0.08$).

We have shown, for the first time, C4 synthesis by glomerular endothelial cells and confirmed previously demonstrated C3 and C4 production by other endothelial cells. IFN-γ appeared to have the maximum stimulatory effect for C4 synthesis. Anti-HLA antibodies directed against the HLA type of these cells also resulted in C4 synthesis. These findings suggest the possibility of local complement synthesis playing a role in AMR of renal transplants.

Disclosure of Financial Relationships: nothing to disclose

### TH-FC150

**Development of De Novo Alloantibodies Post Transplantation Is Associated with Antecedent Change in Serum Cytokines and Subsequent Poorer Allograft Function** Ciara N. Magee,[1] Bechara G. Mfarrej,[1] Sacha A. De Serres,[1] Maninder K. Singh,[2] Barbara T. Murphy,[2] Nader Najafian.[1] *[1]Transplantation Research Centre, Brigham & Women's Hospital, Harvard Medical School, Boston, MA; [2]Dept. of Renal Transplant Medicine, Mount Sinai School of Medicine, New York, NY.*

Despite improvement in early allograft outcomes, long-term allograft survival remains suboptimal. A significant proportion of graft losses can be attributed to immune-mediated processes, highlighting the importance of developing clinically applicable methods of immune monitoring. We hypothesised that a detectable change in serum cytokines would precede the development of alloantibodies, thereby permitting antecendent monitoring.

Serum samples from 112 patients enrolled in the Genomics of Chronic Allograft Rejection (GoCAR) trial, a prospective longitudinal multicentre observational study of renal transplant recipients, were collected at predetermined study timepoints (baseline, 3, 6, 12, 18, 24 months); additional samples were taken at times of clinical indication. These samples were analysed by Luminex® for the presence of alloantibodies, including MICA; serum cytokines were assayed at concurrent timepoints to investigate the cytokine milieu associated with development of alloantibodies, in an attempt to identify potential sentinel markers of alloantibody conversion. Correlation with clinical outcome was made by comparison with allograft function using serum creatinine as a marker.

Of 112 patients analyzed, 57 were shown to have detectable alloantibodies, 42 at the time of transplantation, while 15 patients developed de novo alloantibodies at various timepoints post-transplantation. Several serum cytokines were shown to be temporally associated with alloantibody conversion, with levels of VEGF, TNFα, GMCSF, IL8 and IL1Ra shown to rise prior to conversion. Patients who developed de novo HLA antibodies had a trend towards higher serum creatinine.

We identified several serum cytokines which may have the potential to act as sentinel markers of alloantibody conversion; development of de novo HLA antibodies was associated with a trend towards poorer allograft function. These results need to be validated in the remaining study population.

### TH-FC151

**Regulatory B Cells Are Identified by TIM1 and Can Be Induced through TIM1 Ligation in an IL-4 Dependent Manner, To Promote Allograft Survival** David M. Rothstein,[1] Melissa Y. Yeung,[2] Mohamed H. Sayegh,[2] Nader Najafian,[2] Qing Ding.[1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Harvard Medical School, Boston, MA.*

TIM1 regulates immune responses by controlling T effector cell responses. For example, α-TIM1 mAb (RMT1-10) promotes long-term murine allograft survival (GS) through Th2 deviation. Yet, in vivo, TIM1 is expressed on <2% of CD4 cells. In contrast, 8% of B cells in naive mice express TIM1, which increases to 12% in transplanted mice and 25% after α-TIM1 (TIM1 on CD4 cells remains <2%). In diabetic BALB/c recipients of B6 islets, α-TIM1 increases MST from 12d to 28d (30% >120d GS). Yet, after B cell depletion (α-CD20) or in B-deficient JHD (BALB/c) recipients, α-TIM1 actually accelerates islet rejection (MST from 12d to 6d). Moreover, the Th2 shift normally induced by α-TIM1 requires B cells. Reconstituting JHD mice with wt B cells restores both prolonged GS and Th2 deviation mediated by α-TIM1. This suggests B cells are critical targets for α-Tim1 and promote Th2 responses. Accordingly, TIM1+ B cells are 10-20-fold enriched for IL-4 and IL-10 expression vs. TIM1- B cells. α-TIM1 not only induces TIM1+ B cells but doubles the % of these cells expressing IL-4 and IL-10. Transfer of TIM1+, but not TIM1-, B cells from BALB/c allograft recipients into otherwise untreated JHD recipients, markedly prolongs GS (MST >60d), indicating that TIM1+ B cells are regulatory. Breg have been previously defined as rare IL-10+ B cells with various phenotypes. TIM1 identifies B cells highly enriched for IL-10 in all B cell subsets including CD1dHiCD5+ ("B10") cells. IL-10 is essential for TIM1+ Breg function. In addition, IL-4-/- B cells do not restore α-Tim1-mediated GS in JHD recipients. However, IL-4-/- B cells exhibit markedly reduced TIM1 and IL-10 expression which is not induced by α-Tim1. IL-4R-/- B cells exhibit further reduction in TIM1 and IL-10 expression (20% of wt) and are even less effective at restoring α-TIM1-mediated GS in JHD mice. Thus, IL-4 signaling is required for TIM1 and IL-10 expression by Breg, and B cell IL-4 plays a predominant role. TIM1 represents the most inclusive marker yet for Breg which can be induced by TIM1 ligation, leading to prolonged allograft survival.

**TH-FC152**

**Rapamycin Induced Functionally Active Immunoregulatory CD8+Foxp3+ Cells Reside in Donor Skin Allograft and Facilitate Long-Term Engraftment**
Basset El Essawy,[1,2] Wenda Gao, Terry B. Strom.[1] *[1]Harvard Medical School, Boston, MA; [2]Medicine, Al-Azhar University, Egypt; [3]Beth Israel Deaconess Med Ctr, Boston, MA.*

Are the CD8+Foxp3+ regulatory T cells a component of the allograft protection? And home to long-term engrafted DBA/2 skin allografts? We generated a knock-in mouse(C57BL/6 background) (KI) with a Foxp3 promoter controlling down-stream bicistronic expression of Foxp3 and EGFP reporter introduced into the endogenous Foxp3 locus. Thus, EGFP(Foxp3)+ cells can be analyzed at the single cell level.

We injected 2x105 FACS-sorted CD8+ EGFP- T cells from the KI mouse into Rag-/- mice, followed by fully MHC-mismatched DBA/2 skin transplant. One group was treated with Rapamycin(RPM)(i.p.,3mg/kg) for 3 consecutive days, then alternate day for 2 weeks. The 2nd group was not-treated. FACS analysis at 3 months post-TX showed 2.8% GFP+(Foxp3+) cells in CD8+ population in the peripheral lymphoid organs in RPM-treated recipients as compared to 0.4% in the control(P 0.01). Histological analysis of skin grafts from RPM-treated recipients at 100 days post-TX (LTE) showed an abundance of graft-infiltrating CD8+ EGFP(Foxp3)+ cells. We investigated if the LTE graft-infiltrating CD8+EGFP+ T cells are active in protecting the allograft from rejection. DBA/2 skin grafts were harvested from (i) LTE RPM-treated Rag-/- mice(n=5) and (ii) autologous DBA/2 recipients(30 days after auto-transplantation)(n=5), and transplanted onto Rag-/- hosts to allow T cell expansion by homeostatic proliferation. Then we challenged the above 2 groups of mice with 0.2X106 CD8+ T cells from naive C57BL/6 mice. Survival of LTE DBA/2 skin allografts transplanted onto Rag-/- mice was significantly prolonged as compared to the control auto-transplanted DBA/2 skins onto Rag-/- mice(P 0.03).

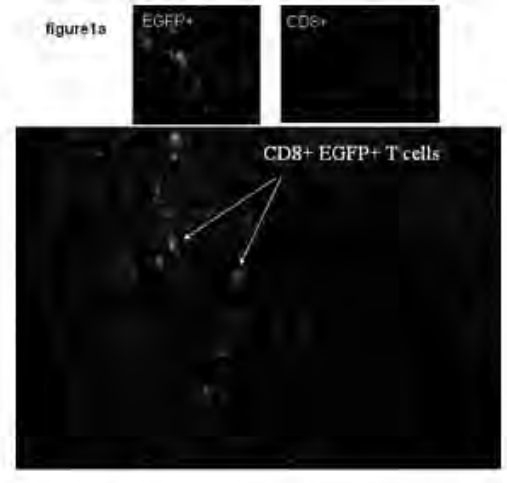

**figure 1b:** Survival after adoptive transfer of $2x10^5$ naive CD8+ cells onto Rag-/- bearing either the long term engrafted graft or the auto graft

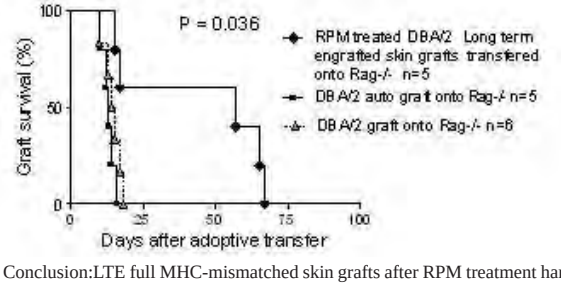

Conclusion:LTE full MHC-mismatched skin grafts after RPM treatment harbor graft-residing CD8+Foxp3+ regulatory T cells that actively prevent CD8-mediated rejection.

**Conversion to Sirolimus Increases Regulatory T Cell and NK Cell Numbers in Transplant Patients with Previous Squamous Cell Skin Cancer: Results of a Randomized Controlled Trial**
Robert Carroll,[1] Paul N. Harden,[2] Kathryn J. Wood.[3] *[1]Renal and Transplantation Services, Central North Adelaide Health Service, Adelaide, SA, Australia; [2]Oxford Transplant Centre, Oxford Radcliffe Hospitals NHS Trust, Oxford, Oxfordshire, United Kingdom; [3]Nuffield Department of Surgery, Oxford University, Oxford, Oxfordshire, United Kingdom.*

Kidney Transplant Recipients (KTR) are at increased risk of squamous cell cancer (SCC). The mTOR inhibitor sirolimus has been associated with reduced cancer rates post solid organ transplantation. The RESCUE study aims to determine whether conversion to sirolimus in KTR with SCC reduces new SCC development. Subjects were randomized to stay on current therapy or convert to sirolimus (levels 5-10 ng/ml) and 5mg of predisolone.

Within this study 31 KTR were enrolled in an immune phenotyping substudy, 13 KTR were randomized to sirolimus and 18 stayed on current therapy. Lymphocyte subsets were assessed prior to randomization and at 3 and 6 months post randomization by multiparameter flow cytometry. The laboratory investigator was blinded to the randomization status and dermatological outcome of the KTR's.

In the control arm $FOXP3^+$ T cell, $CD56^{bright}$ NK cell and $CD3^-CD56^+CD16^+$ NK cell numbers (cells/ul) were stable over time. KTR converted to sirolimus experienced increases in these cell numbers over time and at six months these increases were statistically significant: median (range) $FOXP3^+$ T cell number increased 21(7-71) to 45(14-98) p=0.017; median NK cells number increased 52(1-315) to 109(14-320) p=0.028 and $CD56^{bright}$ NK cells increased 6(1-54) to 16(1-40) p=0.006. In those KTR who did not tolerate sirolimus the immune phenotype returned to baseline values.

This is the first report demonstrating that conversion to sirolimus is associated with increased numbers of NK cells and when sirolimus is removed, NK cell numbers fall to baseline values.

The anti proliferative effect of sirolimus is thought to mediate its anti-cancer effects. However high numbers of NK cells have been shown to be associated with reduced SCC accrual in KTR, therefore sirolimus may mediate its anti cancer effect by inducing protective changes in KTR immune phenotype.

**Discovery and Validation of Differential Expression of MicroRNAs in Human Renal Allografts with Interstitial Fibrosis and Tubular Atrophy (IF/TA)**
Thangamani Muthukumar,[1] Franco Mueller,[2] Sylvia Ebalu,[1] Darshana M. Dadhania,[1] Manikkam Suthanthiran.[1] *[1]Cornell University; [2]The Foresight Group, New York.*

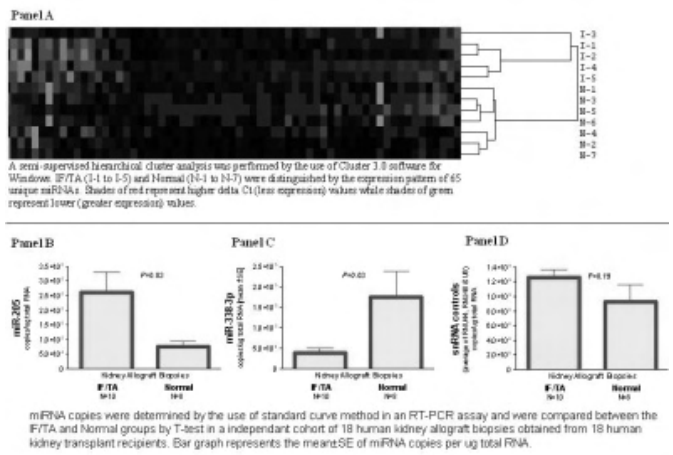
MicroRNAs (miRNA) are considered master regulators of adaptive & innate immunity. As both adaptive & innate immunity are implicated in the pathogenesis of IF/TA of human renal allografts, we tested the hypothesis that IF/TA is characterized by intragraft miRNA expression signatures.

In the discovery phase, we investigated the global expression pattern of miRNAs in human renal allograft biopsies using TaqMan® MicroRNA Array v2.0 containing primers/probes for the amplification of 667 human miRNAs. In the validation phase, we used our modified version of RT-PCR assay for absolute quantification of a subset of miRNAs found to be differentially expressed by global miRNA profiling. This selection was based on biological plausibility.

In the discovery phase we profiled 12 biopsies from 12 recipients; 5 IF/TA & 7 Normal. 70% of miRNAs were expressed in IF/TA & 69% in the Normal biopsies. 65 miRNAs were significantly different between the groups & a semi-supervised hierarchical clustering distinguished the two cohorts (Panel A).

Among the 65 miRNAs, we selected 2 based on their potential role in the pathogenesis of IF/TA for validation in an independent set of 18 biopsies from 18 recipients (10 IF/TA & 8 Normal).

miR-205, implicated in EMT was overexpressed in IF/TA (mean±SE 260103±70187 vs. 76650±16265 copies, P=0.03, Panel B). miR-338-3p, implicated in formation of epithelial cell polarity was under expressed in IF/TA (39144±10172 vs. 174395±63281, P=0.03, Panel C). The differential expression was miRNA specific as control snRNA was not different (Panel D).



A semi-supervised hierarchical cluster analysis was performed by the use of Cluster 3.0 software for Windows. IF/TA (I-1 to I-5) and Normal (N-1 to N-7) were distinguished by the expression pattern of 65 unique miRNAs. Shades of red represent higher delta Ct (less expression) values while shades of green represent lower (greater expression) values.

miRNA copies were determined by the use of standard curve method in an RT-PCR assay and were compared between the IF/TA and Normal groups by T-test in a independant cohort of 18 human kidney allograft biopsies obtained from 18 human kidney transplant recipients. Bar graph represents the mean±SE of miRNA copies per ug total RNA.

Our data demonstrates that intragraft miRNA expression patterns are diagnostic biomarkers of IF/TA & advance a new molecular basis for the pathogenesis of IF/TA.

**Macrophages Are Important Mediators of Recovery in a Novel Mouse Model of AKI with Targeted Injury of Proximal Tubule Cells** Bing Yao, Shilin Yang, Mingzhi Zhang, Raymond C. Harris. *Medicine, Vanderbilt University, Nashville, TN.*

We have previously reported the development of a model of selective proximal tubule injury in transgenic mice expressing the human diphtheria toxin receptor (hDTR) coupled to the γ-GT-I promoter. We determined that hDTR was selectively expressed in proximal tubules in adult kidney and was not expressed in adult liver. A single injection of DT caused reversible proximal tubule injury in DTR transgenic mice but not wild-type mice, and the injury was predominately due to tubular cell apoptosis, as indicated by increased TUNEL staining and caspase-3 and caspase-9 expression. Of note, during the recovery phase, there was marked infiltration of F4/80+ macrophages. In ischemia/reperfusion-induced AKI, numerous studies have indicated a detrimental role for infiltrating leukocytes, and previous studies have indicated that depletion of macrophages prior to ischemia lessens the degree of renal injury. Unexpectedly, in the DTR transgenic mice, macrophage depletion by clodronate either prior to, or after induction of injury by DT administration led to significantly greater histologic injury, increased and prolonged Kim-1 expression, increased apoptosis and delayed cell proliferation. At a concentration of DT that otherwise led to reversible injury without mortality in DTR-transgenic mice, clodronate-mediated macrophage depletion either before or after DT injection led to 60% mortality by 15 days (n=10 in each group). In response to DT, renal expression of markers of "M1" inflammatory macrophages (iNOS, CCl3, IL-23) were not changed, but "M2" wound healing macrophage markers (arginase, mannose receptor, IL4Ra) significantly increased; expression of these M2 markers was markedly inhibited by clodronate. In summary, these results demonstrate in this model of selective proximal tubule apoptosis induced by diphtheria toxin, M2 macrophage infiltration into the kidney increases in response to injury and is a crucial component of the reparative process.

**Flow Cytometric Characterization of Mitochondrial Subpopulations in the Kidney** Janet E. Saunders, Craig Cano Beeson, Rick G. Schnellmann. *Pharmaceutical and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

Mitochondria in the kidney experience periodic bouts of oxidative stress from metabolic demand and xenobiotic metabolism resulting in persistent damage to mitochondria. We hypothesize that damaged mitochondria slowly accumulate making the kidney more susceptible to failure when stressed by disease or xenobiotic exposure. While flow cytometric techniques have been developed to quantify features of individual mitochondria related to size, calcium concentration, mtDNA content, respiratory capacity and oxidative damage, the identification and characterization of mitochondrial subpopulations in kidneys is lacking. Mitochondria from rabbit kidneys were stained with molecular probes for cardiolipin content (nonyl acridine orange, NAO) and membrane potential (tetramethylrhodamine, TMRM) and analyzed using flow cytometry. Mitochondrial subpopulations were identified using NAO gates. Upon titration with uncoupler, carbonylcyanide-4-(trifluoromethoxy)-phenylhydrazone (FCCP), it was found that the high NAO content subpopulations were more resistant to uncoupling than lower NAO content populations. Calcium-induced swelling of mitochondria was measured as changes in light scattering at 540 nm and via flow cytometry. In cytometry, mitochondrial swelling was observed as changes in both SSC and FSC fluorescence. Swelling of distinct subpopulations was evaluated using probability binning (PB) analyses of SSC and FSC. Interestingly, when comparing controls to samples treated with calcium, the NAO-bright subpopulations are the most susceptible to swelling. When the mitochondria were pre-treated with cyclosporine A (CsA), less swelling was observed in all subpopulations. Our results demonstrate that flow cytometry combined with probability binning analyses can discriminate morphologically distinct mitochondrial subpopulations that have distinct stress-response characteristics.

**The Role of Proximal Tubular Socs-3 Expression in Acute Kidney Injury** Nathan D. Susnik,[1] Inga Soerensen,[1] Song Rong,[1] Lloyd G. Cantley,[2] Hermann G. Haller,[1] Roland Schmitt.[1] *[1]Hannover Medical School, Hannover, Germany; [2]Yale School of Medicine.*

In an attempt to identify new therapeutic targets for acute kidney injury (AKI), we found that suppressor of cytokine signaling 3 (Socs-3), a major negative regulator of the JAK/STAT and other receptor tyrosine kinase pathways, is up-regulated after ischemia reperfusion (IR) injury in mouse proximal tubules. To elucidate the specific role of Socs-3 in AKI, we created a proximal tubular conditional knockout mouse (Socs-3Δsglt2/Δsglt2). IR injury, induced through clamping of the renal pedicels for 20 min (medium damage) or 27 min(heavy damage), was used to induce AKI in Socs-3Δsglt2/Δsglt2 and Socs-3wt control mice. Renal function was monitored and kidneys were analysed by histology, immunohistochemistry, qPCR and immunoblot. Although there was no difference in mortality, Socs-3Δsglt2/Δsglt2 mice in the medium damage group did have significantly better renal function. Analysis of post-ischemic kidneys revealed marked differences in inflammation and repair processes. At 72 hours post clamping, when Socs-3 expression peaks in wild-type mice, Socs-3Δsglt2/Δsglt2 mice had less epithelial damage and Ki-67 staining revealed significantly more proximal tubular cell proliferation. Kidneys from Socs-3Δsglt2/Δsglt2 mice also had significantly higher expression of inflammatory markers such as interleukin-1 beta, greater TGF-β expression, and significantly more infiltrating leukocytes. In vitro analysis of migration and proliferation was performed by transfecting mIMCD3 cells with a Socs-3 plasmid or a GFP control plasmid. Proliferation assays were stimulated with either kidney protein homogenate from IR kidneys or from non-damaged control kidneys. These assays showed that IR kidney homogenate significantly increased cell proliferation but this effect was blocked by Socs-3 overexpression. Moreover, Socs-3 overexpression attenuated the rate of movement in migration assays. Our data illustrates the complex downstream effects of proximal tubular Socs-3 expression. While an increased Socs-3 level might attenuate post-ischemic inflammatory processes, it also suppresses reparative mechanisms such as epithelial proliferation and migration.

**F-FC158**

**MSCs Attenuate Ischemic Acute Kidney Injury by Modulating Dendritic Cells** Myung-Gyu Kim, Kichul Yoon, Eunjung Cho, Sang-Kyung Jo, Won-Yong Cho, Hyoung-Kyu Kim. *Division of Nephrology, Department of Internal Medicine, Korea University Hospital, Seoul, Republic of Korea.*

Previous studies demonstrated that inhibition of T cell activation or induction of immune tolerance by mesenchymal stem cells (MSCs) were partially mediated via monocytes or dendritic cells (DCs). The purpose of this study was to examine the role of DCs in MSCs induced beneficial effect in ischemia/reperfusion injury (IRI). C57/BL6 mice underwent bilateral ischemia and MSCs were administered before I/R injury. Twenty four hours after reperfusion, biochemical, histologic kidney damage as well as kidney inflammation were assessed. Percentage and immunophenotypes of DCs in kidney and spleen was performed by flow cytometry. Additional studies using in vitro splenocytes culture with or without MSC were also performed. To assess the effect of DC depletion on MSC induced in-vitro anti-proliferative effect, or also on MSC induced renoprotective effect, we used CD11c-DTR transgenic mice. Infused MSCs were not found in kidneys. However, pretreatment with MSCs attenuated kidney injury and also suppressed inflammation. In vitro MSC treated DC showed decrease of CD11c while increase of CD11b, and CD80 expression and in addition, relative expansion of spleen $CD11c^{low}$ $CD11b^{high}$ DC were also observed in MSC treated I/R mice, suggesting that MSCs might induce aberrant DC populations. In in-vitro experiment, MSCs showed IL-6 dependent antiproliferative property in PHA-ConA or anti-CD3 stimulation of CD4 cells from WT mice (MSC-lymphocytes). However, this immunosuppressive effect of MSCs was partially inhibited in lymphocytes from DC depleted mice (MSC-splenocytes with $DC^{dep}$; CD11c-DTR transgenic). Finally, systemic depletion of $CD11c^{+}$DCs using CD11c-DTR mice resulted in partial loss of the beneficial effect of MSCs on kidney injury and inflammation. These results suggest that effect of MSCs in suppressing inflammation and reducing kidney injury might be partially mediated by DC modulation. Further studies exploring precise immune-modulatory mechanisms of MSCs might be useful in developing various strategies that ultimately improve prognosis of AKI.

**HIF-1α Induction during Reperfusion Is Critical for Kidney Regeneration after Renal Ischemia** Elisa Conde,[1] Ignacio Blanco Sanchez,[1] Elia Aguado Fraile,[1] Marta Martinez,[1] Edurne Ramos,[1] Laura Alegre,[1] Jose-Antonio Sanchez-Tomero,[2] Rafael Selgas,[3] Laura Garcia-Bermejo.[1] *[1]Pathology, Hospital Univ Ramon y Cajal; [2]Nephrology, Hospital Univ La Princesa; [3]Nephrology, Hospital Univ La Paz.*

Mechanisms involved in kidney regeneration after ischemic damage are under deep investigation, with the aim to accelerate acute renal failure recovery and/or improve allograft outcome. Previous studies of our lab demonstrated a second induction of HIF-1α during

reperfusion (3-5days) suggesting that this accumulation contribute to tubular repair after renal ischemia. Here we injected a specific siRNA for HIF-1α to elucidate the role of HIF-1α in the response to renal ischemia by means of an in vivo model of ischemia/reperfusion (I/R) in rat. Initial experiments using 4 different siRNAs allowed us to choose the more effective one to inhibit HIF-1α in kidney. We demonstrate that rats interfered with HIF-1a agravated the proximal tubule damage, by PAS staining. In agreement, serum creatinine and urea levels were higher at 3 days of reperfusion in siRNA treated rats. Next, we assessed mechanisms underlying HIF-1α effects. Proximal tubular cells proliferation was evaluated by BRDU staining, finding a delay in cell proliferation in interfered rats in comparison with scramble rats. Furthermore, we evaluate HIF-1α relation with the inflammation response associated to ischemic injury, by qRT-PCR of proinflamatory mediators such as TNFα, IL-1β and MCP-1, finding higher levels of them in siRNA-treated rats vs scramble rats. Finally, since HIF-1α might regulate the expression of repairing genes, we studied the expression of EPO by RT-PCR and western blot, observing that EPO is only expressed at 3-5 days in scramble treated rats. Correlating with this, in human biopsies from renal transplantation, HIF-1α and EPO were expressed only in proximal tubules which exhibited non-damage structure, with a significant negative correlation between ATN and both gene expression. In summary, we demonstrate that HIF-1α is critical for proximal tubule epithelial cell recovery after ischemia, by promoting cell proliferation, expression of repairing genes and regulating inflammatory mediators.

**Tubular Regeneration after Ischemia/Reperfusion (I/R) Injury Originates from Dedifferentiated Proximal Tubular Cells** Katja Berger, Bart Smeets, Peter Boor, Peggy Jirak, Jurgen Floege, Marcus J. Moeller. *Department of Nephrology and Clinical Immunology, University Hospital of RWTH Aachen University, Aachen, Germany.*

Tubular cells are regenerated from intrinsic renal cells after ischemia/reperfusion injury (I/R). However, it is unknown, whether the source of regeneration is a distinct population of intra-renal (intra-tubular) progenitor cells or if it involves any surviving tubular cell.

We found previously that rare, individual tubular cells are genetically labeled in adult triple-transgenic PEC-rtTA/LC1/R26R mice, which we have used to trace parietal progenitor cells. In young and still growing transgenic mice, significantly more tubular cells were genetically labeled by administration of doxycycline for 14 days compared to adult mice.

To test whether the triple-transgenic PEC-rtTA/LC1/R26R mouse labels a progenitor population of tubular cells, adult mice were treated with doxycycline for 14 days to induce the irreversible genetic label. After a washout phase of one week, the mice were subjected to I/R injury of the left kidney. Within 2 weeks after I/R injury, regeneration was completed but the number of genetically labeled cells had not increased in the injured kidney compared to the right control kidney (n=15). This suggested, that the cells labeled by the PEC-rtTA/LC1/R26R mouse were not a distinct tubular progenitor population.

Next we tested the alternative hypothesis that any surviving tubular cell participates in the regeneration process. For this purpose, doxycycline treatment was applied during (instead of prior to) the I/R injury and the subsequent regeneration process. After 14 days, significantly more tubular cells (50% versus 5%) were labeled within the injured left kidney compared to the right control kidney (n=15).

These experiments show for the first time, that regeneration after I/R occurs from the bulk of the remaining tubular cells and not from a distinct intratubular progenitor population.

### F-FC161

**Small Molecule Mediated Augmentation of Kidney Regeneration** Chiara Cianciolo Cosentino,[1] Eric Degroh,[1] Lisa M. Swanhart,[1] Mark P. De Caestecker,[2] Neil A. Hukriede.[1] *[1]Developmental Biology, University of Pittsburgh, Pittsburgh, PA; [2]Medicine, Vanderbilt University, Nashville, TN.*

One of the first molecular hallmarks of vertebrate renal tubular regeneration is the reactivation of embryonic genes normally required during organogenesis. To identify chemicals that could enhance this reactivation event, we developed a high-content screen using zebrafish embryos to identify compounds that cause expansion of the embryonic renal progenitor cell population. One compound identified from this screen, PTBA, expanded expression domains of markers of kidney organogenesis by increasing the number of renal progenitor cells through a proliferation-dependent mechanism. PTBA exhibits structural similarity to the HDAC inhibitors phenylbutanoic acid and trichostatin A. Treatment with either of these HDAC inhibitors also elicited renal progenitor cell expansion, but unlike PTBA, these responses were associated with abnormalities in embryonic patterning indicative of increased toxicity. In addition to its low toxicity, PTBA has a unique thioether moiety in the connecting unit that has not been described in other HDAC inhibitors. Consequently, we utilized an automated fluorescence-based secondary screen using transgenic cdh17:eGFP zebrafish embryos to identify PTBA analogues that cause expansion of the renal progenitor cell population at lower concentrations than PTBA. One of these compounds, m4PTB, promotes expansion of renal progenitor cells at nanomolar concentrations. Moreover, administration of m4PTB post-injury increases the rate of renal recovery in a gentamicin model of acute kidney injury (AKI) in zebrafish larvae. In a mouse model of diphtheria-toxin induced AKI, m4PTB also reduces the severity of renal injury and post-injury fibrosis. These findings indicate that PTBA analogues cause an expansion of renal progenitor cells during embryonic development and increase renal tubular regeneration following AKI. Moreover, while other HDAC inhibitors also promote expansion of renal progenitor cells in zebrafish embryos, favorable efficacy and toxicity profiles of these PTBA analogues suggest they have unique properties to augment renal regeneration following injury.

### F-FC162

**Temporal and Site-Specific Trafficking Receptors Expression on Regulatory T Cells during Repair from Ischemic Acute Kidney Injury** Yuhong Tao, Jinxiang Yu, Qianmei Sun, Elizabeth M. Higbee, Yanfei Huang, Nada Alachkar, Karl L. Womer, Manchang Liu, Hamid Rabb. *Department of Medicine, Division of Nephrology, Johns Hopkins University School of Medicine, Baltimore, MD.*

**Background:** Foxp3$^+$ regulatory T cells (Tregs) infiltrate into kidneys and directly participate in repair during ischemic acute kidney injury(AKI). Distinct trafficking receptors likely regulate Treg trafficking during kidney repair, which is important for understanding mechanisms and accelerating tissue repair.

**Objective:** To identify candidate trafficking receptors that mediate Treg trafficking into kidney during repair from AKI.

**Methods:** The left renal pedicle was clamped in C57BL6 mice for 45 min, followed by reperfusion. Animals were sacrificed at baseline, day 1,3,10,21 after IRI. Blood, kidney, spleen, and draining lymph nodes were evaluated. Flow cytometry was used to quantify CCR2,CCR5,CCR6, CCR7 and CD103 on Tregs.

**Results:** Expression of CCR6 and CCR7 on Tregs in kidney was upregulated significantly with time(%CCR6 on Tregs at baseline,day1,3,10,21: 2.74±2.04, 32.06±12.76, 58.18±12.46, 24.28±12.42 and 48.75±11.93,respectively. %CCR7: 4.28±1.95, 19.61±5.33, 28.59±7.96, 17.64±3.59 and 17.64±3.59). Expression of CCR6 and CCR7 on Tregs in blood at day1,3 ,21 was significantly higher than that at baseline. Expression of CCR2 and CCR5 on Tregs in kidney and blood at day 1,3 was significantly higher than that at baseline. Expression of CCR2 on Tregs in spleen and renal draining lymph nodes decreased with time. Increased expression of CCR6 on Tregs in spleen on day 1,3,21 was observed. There was no significant change of CCR5 and CCR7 on Treg in spleen or draining lymph node at all times. Unlike in other studied tissues, CD103 expression on Tregs in kidney significantly increased from baseline at all time points(%CD103 on Tregs in kidney at baseline,day1,3,10,21: 22.07±3.67, 38.47±15.43, 60.68±9.55, 56.82±2.87 and 69.24±4.38, respectively).

**Conclusion:** A specific temporal and site-specific expression of CD103, CCR6 and CCR7 on Tregs occurs during repair from AKI. These trafficking receptors may play a vital role in mediating Tregs trafficking and function in kidney repair from AKI.

### F-FC163

**Exploring the Origin of the Cells Responsible for Regeneration and Fibrosis in the Kidneys** Tomomi Endo,[1] Tomohiko Okuda,[1] Jin Nakamura,[1] Atsuko Y. Higashi,[1] Atsushi Fukatsu,[1] Toru Kita,[2] Motoko Yanagita.[1] *[1]Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]Kobe City Medical Center, Kobe, Japan.*

Kidneys repair after acute kidney injury (AKI) with a rapid proliferative response, which leads to the restoration of nephron structure and function, however the origin of the proliferating cells after AKI remains controversial. There are three hypotheses to explain the origin of the proliferating cells: the bone marrow cells, the stem/progenitor cells in the kidney, and the intrinsic tubule cells. We hypothesized that the intrinsic epithelial cells, possibly the mature proximal tubule cells, proliferate and repair kidney injury. To test the hypothesis, we generated proximal tubule-specific inducible Cre mice (NDRG1-CreERT2 knock-in mice), in which CreERT2 is activated only after the administration of tamoxifen.

First, to determine the specificity and efficiency of the Cre recombination, we bred NDRG1-CreERT2 knock-in mice to Rosa26R indicator mice. The X-Gal staining showed that the Cre recombination was specifically achieved in almost 100% of proximal tubules without any leakage.

Second, to explore the origin of the proliferating cells after AKI, we operated ischemia-reperfusion injury (I/R injury) to the labeled mice, and administered BrdU. At day1 after I/R injury, more than 60% of the proliferating cells expressed LacZ, indicating that mature proximal tubule cells indeed proliferated. Furthermore, no dilution of genetic label was observed in the proximal tubules of the repaired kidney at day45, despite of extensive proliferation after I/R injury, indicating that mature proximal tubule cells repaired themselves by their own proliferation.

We further analyzed the contribution of epithelial-mesenchymal transition (EMT) of proximal tubule cells to renal fibrosis, which also remains controversial. We performed kidney fibrosis model in the genetically labeled mice. After UUO, LacZ positive cells were hardly detectable in the interstitium, suggesting that EMT of proximal tubule cells did not significantly contribute to renal fibrosis in our study.

Taken together, NDRG1-CreERT2 knock-in mice may provide a powerful tool to analyze "Proximal Tubule Biology".

**F-FC165**

**Regional Citrate Versus Systemic Heparin for Anticoagulation in Critically Ill Patients on Continuous Venovenous Hemofiltration: A Prospective Randomized Multicenter Trial** Gerd R. Hetzel,[1] Michael Schmitz,[1] Rainer Himmele,[3] Adelheid Gauly,[2] Bernd Grabensee,[1] Lars C. Rump.[1] *[1]Heinrich-Heine-University Duesseldorf; [2]Fresenius Medical Care Germany; [3]Fresenius Medical Care NA.*

Background:

Continuous veno-venous hemofiltration (CVVH) in the intensive care setting requires anticoagulation to prevent clotting of the extracorporeal circuit. Several protocols avoiding heparin and using regional citrate anticoagulation have been developed to diminish bleeding risks. However, data from randomized trials comparing citrate anticoagulation with systemic heparinzation are very limited.

Methods:

We randomly assigned 174 patients to either CVVH treatment with systemic heparinization or to CVVH treatment with a system that uses citrate as the only anticoagulant and buffering substance. All patients were on mechanical ventilation, therefore written informed consent was obtained from a patient's legal representative. The primary objective was to compare treatment efficacy represented by the patients' acid base status on day 3 and on each consecutive day. Several parameters of safety and efficacy were analyzed as secondary objectives.

Results:

Comparison of standard bicarbonate from day 3 until day 11 confirmed equal effectivity of both treatment modalities. Use of citrate resulted in less systemic anticoagulation, a lower risk of bleeding and a longer hemofilter patency. However, episodes of hypercalcemia, hypocalcemia as well as the need for additional bicarbonate infusions occurred more often under citrate. The patients' high mortality was not influenced by the mode of anticoagulation.

Conclusion:

Citrate may be used as a regional anticoagulant and as the only buffering agent in CVVH with adequate treatment efficacy and safety. However, neither citrate nor heparin anticoagulation should be regarded as a therapeutic standard, since there is no advantage of one of these substances with regard to the patients mortality.

Disclosure of Financial Relationships: nothing to disclose

**F-FC166**

**Regional Citrate Anticoagulation Reduces Polymorphonuclear Cell Degranulation in Critically Ill Patients Treated with Continuous Veno-Venous Hemofiltration (CVVH): A Randomized Controlled Trial** Khajohn Tiranathanagul,[1] Onanong Jearnsujitwimol,[1,2] Paweena Susantitaphong,[1] Narin Kijkriengkraikul,[3] Kearkiat Praditpornsilpa,[1] Somchai Eiam-Ong.[1] *[1]Division of Nephrology, Department of Medicine, Chulalongkorn Memorial Hospital, Thai Red Cross Society and Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [2]Phrapokklao Hospital, Chanthaburi, Thailand; [3]National Blood Center, Thai Red Cross Society, Bangkok, Thailand.*

Background: The high mortality in critical acute kidney injury (AKI) patients treated with CVVH is associated with increased oxidative stress and systemic inflammation which are induced by the blood-membrane reaction. This is the first study conducted to examine the effect of regional citrate anticoagulant (RCA) on PMN cells degranulation of myeloperoxidase (MPO) and inflammatory cytokine levels in patients with critical AKI undergoing CVVH treatment.

Methods: This prospective study was carried out in 20 critical AKI patients who were treated with pre-dilution CVVH and randomized into RCA group (n=10) and heparin group (n=10). The pre-filter and post-filter MPO and inflammatory cytokine (IL-6, IL-8, and TNF-$\alpha$) levels were measured at baseline, 6 hr and 24 hr after initiating CVVH.

Results: The baseline characteristics were similar between the two groups. In the heparin group, the pre-filter serum MPO levels were significantly increased at 6 hr (40.5 ± 21.3 vs. 66.0 ± 63.5 ng/mL, $p < 0.01$) and the post-filter serum MPO levels were also significantly higher than the pre-filter ($p<0.05$). Interestingly, citrate could significantly decrease pre-filter serum MPO (56.7 ± 51.0 vs. 27.7 ± 36.6 ng/mL, $p<0.01$) as well as TNF-$\alpha$ and IL-8 levels ($p<0.05$) at 6 hr. There were no significant differences between pre- and post-dialyzer MPO levels in the citrate group. The mean CVVH circuit survival in the citrate group was longer than the heparin group ($p=0.03$).

Conclusions: Treatment with CVVH caused PMN degranulation and increased oxidative stress which might be mediated by the blood-dialyzer membrane reaction. RCA could diminish the oxidative stress, prolonged the circuit survival time, and minimized bioincompatibility during on CVVH.

**F-FC167**

**Change in CRRT Dose Prescription after Recent Trials** Flavio Basso,[1] Zaccaria Ricci,[2] Claudio Ronco,[1] Dinna N. Cruz.[1] *[1]S Bortolo Hosp, Vicenza, Italy; [2]Bambino Gesù Hospital, Rome, Italy.*

Recent studies on RRT dose (RENAL, ATN, DoReMi) showed no difference in outcomes with higher CRRT dose. They also underlined that a delivered dose of at least 20 ml/kg/h was important, but to achieve this, a higher prescribed dose is usually needed. The impact of these studies on clinical practice is yet unknown.

**Methods**

We compared the results of practitioner surveys distributed during the International Course on Critical Care Nephrology held in Vicenza, Italy in 2004, 2007 and 2010 to evaluate trends in CRRT practice patterns. We limited this analysis to physician responses only.

**Results**

In 2010, the overall response rate was 64%. Of 377 completed questionnaires, 338 were from physicians. Most were nephrologists (60%) followed by intensivists (36%); majority were from Europe (80%).

The use of individualized dose prescription based on body weight increased from 28% to 61.5% in 2010, while indiscriminate "by the liter dose" prescription decreased from 33% to 20%. The CRRT dose most commonly considered appropriate was 21-35ml/kg/h (42%), similar to 2007 (see Figure). The proportion of respondents who are "not sure" about adequate dose was fallen from 38% (2004) to 18% (2010). Fifty four percent of responders said they did not change their practice after publication of RENAL and ATN. Of the remainder, 28% increased their prescribed CRRT dose, while 22.5% decreased it.

**Conclusion**

Awareness regarding RRT dose has progressively improved over the past 6 years; in 2010, <20% expressed uncertainty about an "appropriate" CRRT dose. Less than half of surveyed physicians changed their practice after publication of recent landmark studies on CRRT dose. Interestingly, 28% actually increased their prescribed CRRT dose, perhaps indicating better recognition of a "gap" between prescribed and delivered CRRT dose.

**An Updated Systematic Review of Extracorporeal Blood Purification in Prevention of Radiocontrast-Induced Nephropathy** Ching Yan Goh,[1,2] Valentina Corradi,[1] Claudio Ronco,[1] Dinna N. Cruz.[1] *[1]Nephrology Dialysis & Transplantation, S Bortolo Hosp., Vicenza, Italy; [2]Nephrology, Selayang Hosp., Selangor, Malaysia.*

**Background**: Radiocontrast induced nephropathy (RCIN) is an important cause of acute kidney injury, increasing in-hospital and long term mortality. It is controversial whether extracorporeal blood purification (EBP) reduces patient's risk of RCIN. A systematic review in 2006 showed that periprocedural EBP did not decrease the incidence of RCIN compared with standard medical therapy (SMT). We conducted an update of this review.

**Methods:** We searched through Pubmed and bibliographies of retrieved articles. Published studies of EBP for RCIN prevention in patients receiving radiocontrast were included. The primary endpoint was the incidence of RCIN, defined as an increase in serum creatinine ≥0.5mg/dL. Results were combined on the risk ratio (RR) scale. Random-effects models were used. Sensitivity analyses were defined *a priori* to evaluate the effects of EBP modality, study design, and sample size.

**Results**: Nine randomized controlled trials and 2 nonrandomized trials were included (n=1100 patients). Eight trials assessed IHD, 3 trials assessed CRRT. Nine studies had data for primary endpoint; RCIN incidence was 23.3% in the EBP group and 21.2% in the SMT group. EBP did not decrease the incidence of RCIN compared with SMT (RR1.02; 95%CI 0.54,1.93, see Figure); however, intertrial heterogeneity was high. In sensitivity analyses, limiting to only IHD studies significantly reduced heterogeneity. IHD appeared to increase RCIN risk (RR1.61; 95%CI 1.13,2.28) and had no effect on need for permanent RRT or progression to ESRD (RR1.47; 95%CI 0.56,3.89).

**Conclusion:** In this updated meta-analysis, periprocedural EBP does not decrease the incidence of RCIN compared with SMT. IHD appears to actually increase RCIN risk.

## F-FC169

**Cerebral Blood Flow Decreases during Hemodialysis in Patients with Acute Kidney Injury but Not in Patients with End-Stage Renal Disease** Carola Cademartiri,[1] Giuseppe Regolisti,[1] Aderville Cabassi,[1] Elena Cremaschi,[1] Stefano Tedeschi,[1] Elisabetta Parenti,[1] Caterina Maccari,[1] Alberto Guido Caiazza,[2] Enrico Fiaccadori.[1] *[1]Department of Internal Medicine and Nephrology, University of Parma, Parma, Italy; [2]Department of Diagnostic Medicine, AUSL Parma, Parma, Italy.*

**INTRODUCTION AND AIMS:** Hemodialysis (HD) can decrease cerebral blood flow (CBF) in patients (pts) with end-stage renal disease (ESRD). Pts with acute kidney injury (AKI) may be at higher risk for cerebral hypoperfusion during HD, as they often present with critical illness and hemodynamic instability. We studied CBF during HD in pts admitted for oliguric AKI and in pts with ESRD on regular HD thrice weekly. **METHODS:** CBF was examined by measuring middle cerebral artery mean flow velocity (mcaMFV, transcranial Doppler, 2-MHz probe, duplicate measurements) at start, at midtime and at the end of the first 4-h HD session *(Qb 200 ml/min, Qd 300 ml/min, co-current dialysis flow)* in 15 pts with AKI (median age 77 yrs, range 69-92, 8 males) and in 8 pts with ESRD (median age 81 yrs, range 36-89, 4 males), in whom mcaMFV was measured during the last HD session of the week *(Qb 300 ml/min, Qd 500 ml/min, counter-current dialysis flow)*. Data were analyzed using mixed models for repeated measurements. **RESULTS:** Mean blood pressure was similar at start HD in the pts with AKI or ESRD (87.8 [SD=20.1] *vs* 86.4 [SD=5.0] mmHg, P=0.799), and did not change significantly during the HD session in either group (group-averaged rate of change: P=0.368; time-averaged difference between groups: P=0.789). Mean weight loss at end HD (-1.5 [SD=0.8] *vs* -0.9 [SD=0.7] Kg, P=0.002) was greater in the pts with ESRD. Mean mcaMFV at start HD was higher in the pts with ESRD than in those with AKI (34.6 [SD 7.1] *vs* 26.4 [SD 9.0] cm/sec, P=0.037); after adjusting for different weight loss, mcaMFV decreased during the HD session in the pts with AKI (P=0.002) but not in those with ESRD (time-averaged difference between groups: P=0.026; rate of change difference between groups: P=0.045). **CONCLUSIONS:** Pts with AKI are at higher risk for cerebral hypoperfusion during HD than pts with ESRD, independently of changes in systemic arterial pressure.

Disclosure of Financial Relationships: nothing to disclose

## F-FC170

**Cefepime Clearance and Creatinine Generation during High Blood and Dialysate Flow Continuous Venovenous Hemodialysis (CVVHD)** Francis P. Wilson, Daniel A. Caroff, Becca Adler, Marcus A. Bachhuber, Jeffrey S. Berns. *Medicine, University of Pennsylvania Health System, Phialdelphia, PA.*

**Background**:

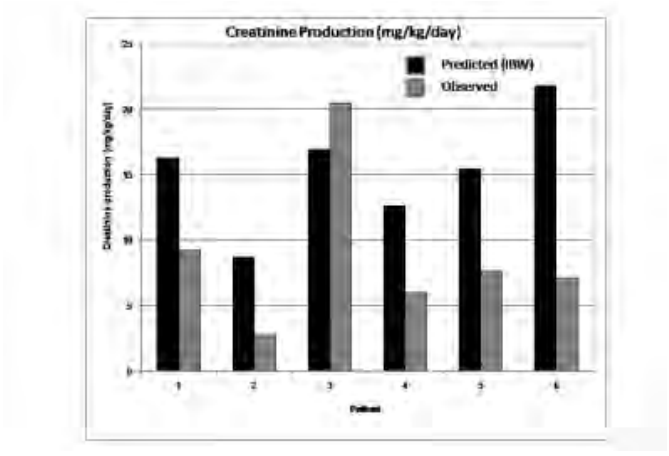
Guidelines for cefepime dosing during CVVHD were derived from studies using lower blood flow (Qb) and dialysate flow (Qd) than are used in our clinical practice. This study was designed to assess the pharmacokinetics of cefepime in CVVHD, and to determine creatinine generation rates in the critically ill population.

**Methods:**

All patients receiving CVVHD and cefepime at our institution from 12/2008 to 06/2009 were screened for potential enrollment. Six eligible patients gave informed consent and were included in the study. Pre- and post-filter blood and effluent samples were drawn at 0.5, 1, 2, 6, and 12 hrs after a cefepime dose and analyzed for cefepime concentration and creatinine concentration.

**Results:**

Cefepime dosages varied from 1-2g mg every 8 -12 hrs. Qb was 300 ml/min in all patients. Median Qd was 3000 ml/hr. All patients were anuric. The median sieving coefficient for cefepime was 0.34. Median half-life of cefepime was 7.55 hrs. With a cutoff of 8 ng/ml cefepime levels at 12 hrs after dosing were subtherapeutic in 3 of 6 patients, including both patients receiving 1000 mg every 12h. Median daily creatinine generation was 7.3 mg/kg. Estimated creatinine generation using the Jelliffe equation overestimated measured creatinine generation by a median 240%.



**Conclusions:**

There is significant clearance of cefepime during CVVHD using high blood and dialysate flow CRRT. We recommend dosing cefepime at least 2000 mg every 12 hrs to obtain sustained therapeutic serum levels of cefepime in this setting. Critically ill patients with oliguric AKI on CVVHD demonstrate reduced creatinine generation compared to expected levels for hospitalized patients. This finding has important implications for assessment of GFR in critically ill patients.

## F-FC171

**Fluid Overload (FO) Calculations in Pediatric Stem Cell Transplant (PSCT) Patients Requiring Continuous Renal Replacement Therapy (CRRT)** Rebecca M. Lombel,[1] Michael Heung,[2] Theresa Mottes,[1] Mallika Kommareddi,[2] Yong Y. Han,[1] Katherine L. Collins.[1] *[1]Pediatrics, University of Michigan, Ann Arbor, MI; [2]Internal Medicine, University of Michigan, Ann Arbor, MI.*

**Background:** FO>10% above baseline has been associated with poor outcome in PSCT patients who require CRRT. However, the optimal measure of %FO has not been established. We sought to compare published & novel methods for calculating %FO & to assess which method best correlates with patient outcomes.

**Methods:** We retrospectively analyzed all PSCT patients requiring CRRT from 2004-2009 at our hospital. We applied 7 different methods for calculating %FO that varied by "fluid balance" (weight difference or fluid [in - out]) & reference "dry weight" (pre-hospital clinic, hospital admission, PICU admission, or CRRT initiation). Differences between %FO calculation methods were determined by ANOVA-on-Ranks. The impact of %FO on mortality was assessed by logistic regression analysis. A mixed models approach was used to examine the relationship between %FO & Pediatric Logistic Organ Dysfunction (PELOD) scores (a surrogate outcome variable) over time. Data are presented as median [25%tile-75%tile].

**Results:** The median age of this study cohort (N=21) was 184 months [137-241]. Wide variations in %FO for the cohort were noted depending on the calculation method used (0.0% [-1.2%-2.9%] to 8.5% [0.5%-16.7%], $p$=0.170). %FO calculations among individual patients varied by a median of 11.3% [6.2%-17.1%] ($p$<0.001). Depending on the method used, as few as 3 (14%) patients & as many as 10 (48%) were identified as being FO>10% ($p$=0.109). No method was significantly associated with PICU or 6-month mortality. Increasing %FO was predictive of higher PELOD scores in 5 of 7 methods ($p$=0.003 to 0.038).

**Discussion**: Identification of patients with FO depends on the calculation method used. Although we did not see an association between %FO & mortality with any method (most likely due to limited cohort size), we observed that several %FO methods were predictive of PELOD scores over time. Future studies examining FO should include an assessment of multiple methods in order to determine the most clinically relevant approach.

## F-FC172

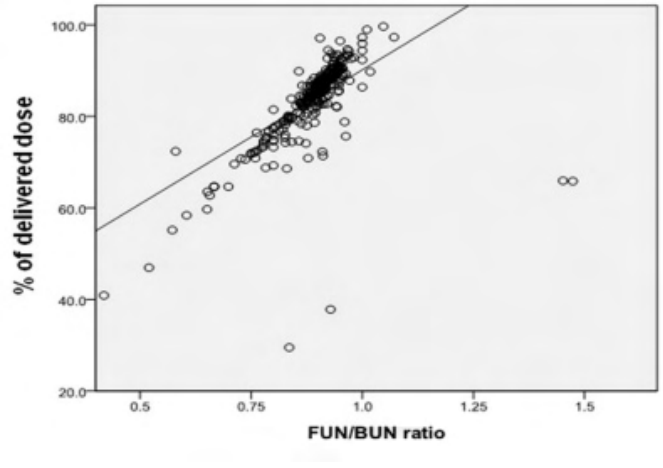
**The Impact of Down-Time and Filter Efficacy on Delivered Dose of Continuous Renal Replacement Therapy** Jiandong Wei, Rolando Claure-Del Granado, Rakesh Malhotra, Etienne Macedo, Yang Luo, Sharon Soroko, Ravindra L. Mehta. *Nephrology, University of California San Diego Medical Center, San Diego, CA.*

**Background:** Time off CRRT (down- time) and low filter efficacy due to clotting constitute important factors that lead to failure to deliver the prescribed dose in critically ill patients. We assessed the impact of down-time and filter efficacy on the difference between prescribed and delivered dose.

**Methods:** We prospectively analyzed data from 305 treatments in 54 critically ill patients treated with predilution continuous venovenous hemodiafiltration (CVVHDF), utilizing regional citrate anticoagulation, at the University of California San Diego Medical Center from September 2009 to March 2010. All patients were prescribed a 2700 ml/hr effluent rate. Delivered dose was calculated by actual mean urea nitrogen clearance with the formula (effluent urea nitrogen x effluent volume) / plasma urea nitrogen adjusted by

body weight. CRRT down-time was defined as the time off CRRT (hrs) per day. Filter efficacy is determined by filter clearance using effluent urea nitrogen (FUN)/plasma urea nitrogen (BUN) ratio. Percentage (%) of delivered dose was calculated by delivered dose/prescribed dose x 100%.

**Results:** 10% of all the treatments had down-time 2.0 (1.0-5.1) hrs/day. The mean FUN/BUN ratio was 0.9±0.1. Delivered dose by actual urea clearance was significantly lower than prescribed dose, 29.1±11.8 *vs* 34.5±13.2 ml/kg/hr, $p< 0.001$. A significant correlation was found between FUN/BUN ratio and % of delivered dose ($r =0.25$; $p < 0.001$) whereas the down-time did not affect % of delivered dose ($r =0.11$; $p = 0.062$).



**Conclusion:** Delivered dose of CRRT is lower than prescribed dose. Filter efficacy has significant impact on percentage of delivered to prescribed dose. We recommend monitoring solute clearances to optimize dose delivery in CRRT.

### F-FC173

**Comparison of Plasma Exchange and Hemodialysis Using a High Cut-Off Membrane (HCO) for Removal of Immunoglobulin Free Light Chains in Multiple Myeloma** Alain Wynckel, Vincent Vuiblet, Nathalie Schneider, Brigitte Kolb, Jean Pierre Melin, Julien Journet, Philippe Rieu. *University Hospital, Reims, France.*

Plasma exchange (PE) and hemodialysis with a high cut-off dialyzer (HCO-HD) have been tested for the treatment of acute renal failure (ARF) associated with multiple myeloma. Whether one technique is better than the other is not clearly evaluated in clinical practice. The aim of our study was to compare PE and HCO-HD for free light chains (FLC) removal in patients with dialysis-dependent ARF due to light chain multiple myeloma (LCMM). Seven patients with LCMM were included after informed consent. PE and HCO-HD (Gambro HCO 1100 dialyzer, surface area :1.1m²) were performed in each patient. Serum, plasma filtrate and dialysate FLC concentrations were measured by nephelometry (FREELITE, The Binding Site). Plasma filtrate was soustracted at a flow rate of 40 ml/min and collected entirely for measurement . During HCO-HD, serum and dialysate fluid samples were drawn simultaneously after 10 min (T10) then at T60, T120, T240 and T 360. Blood and dialysate flow rates were 250 ml/min and 750 ml/min respectively. Results: Mean plasma volume exchanged by PE session was 3842 ± 342 ml (46 ± 11 ml per kg of body weight). Mean PE duration was 94 ± 5 min. When considering serum FLC concentration before PE , cleared plasma volume was 3010 ± 423 ml per session; net FLC clearance was 31,4 ± 4,8 ml per min of PE. During HCO-HD, instantaneous clearances were 27,4 ± 11,1 ml/min, 29,3 ± 5,7 ml/min, 21,6 ± 8,2 ml/min , 21,0 ± 8,6 ml/min and 16,2 ± 5,2 ml/min at T10, T60, T120, T240 and T360 respectively. When considering serum FLC concentration before HCO-HD, cleared plasma volume was 1285 ± 534 ml between T0 and T60, 918 ± 348 ml between T60 and T120, 1272 ± 444 ml between T120 and T240, and finally 984 ± 288 ml between T240 and T360. In conclusion, 3.5 hours of HCO-HD (with a dialyzer surface area of 1.1 m²) are equivalent to one PE session. Prolonged HCO –HD session up to 6 h increased FLC removal by 50 %. The use of a dialyzer with a surface area of 2.1 m² should improve the performance of FLC epuration.

Disclosure of Financial Relationships: nothing to disclose

### F-FC174

**A Novel Program of Sustained Low Efficiency Dialysis (SLED) with Near-Automated Regional Citrate Anticoagulation (RCA) for 24-Hour ICU Renal Support: Improving Treatment Quality and Safety While Reducing Costs Compared to Traditional CRRT** Balazs Szamosfalvi, Stan Frinak, Lenar T. Yessayan, Jerry Yee. *Division of Nephrology and Hypertension, Henry Ford Health System, Detroit, MI.*

**Purpose:** Create an early start, large 24-h ICU renal support program of SLED-RCA to improve treatment quality and safety and lower costs.

**Methods:** We collected information from the literature and from dialysis personnel, renal and ICU physicians and nurses for desirable features of the new program. We developed a near-automated, simple RCA protocol for 24-h SLED to prevent blood clotting and to flexibly control dialysate Na, bicarbonate, potassium and phosphate. To eliminate errors and standardize therapy, RCA prescriptions are generated from a secure webserver which is also used to distribute protocol training materials and flowsheets. The delivered dose of effective ionic dialysance (OLC; small solute clearance) is monitored automatically. An optical hematocrit (Hct) sensor monitors blood volume and $O_2$ saturation. We use commercial dialysis equipment with available telemetry software.

**Results:** Standardized electronic order generation helped nephrologists write safe RCA prescriptions with a minimal learning curve. The RCA protocol completely prevented clotting and proved safe even in patients with severe liver dysfunction. Nurse satisfaction with modality effectiveness and simplicity has been very high. Nurse training was accelerated by the web-based document deployment and the simple, predictive calcium dosing. A 2:1 patient to nurse ratio could be maintained. Disposables cost savings are at least 200 dollars per day per patient compared to traditional CRRT. The delivered dose of dialysis monitor (OLC) and optical Hct and $O_2$ saturation sensors performed reliably and are quality improvements. Clearance with ultrapure dialysate is in the traditional CRRT range at 3 L/h with a convective component due to internal filtration on the dialyzers.

**Summary:** Our 24-hour SLED-RCA program has multiple quality and safety enhancements, costs less than traditional CRRT and helps expand the use of 24-h renal support, especially in combination with electronic order generation and telemetry.

### F-FC175

**The Generation of a Novel Murine Model of B Cell-Mediated Proteinuria with Pathologic Changes Similar to Minimal Change Disease** Alfred Hyoungju Kim,[1] Andrey S. Shaw.[2, 3] *[1]Rheumatology, Washington University School of Medicine; [2]Howard Hughes Medical Institute; [3]Pathology & Immunology, Washington University School of Medicine, Saint Louis, MO.*

**Purpose**: Minimal change disease remains the most common etiology for pediatric nephrotic syndrome. B cell depletion therapy has been efficacious in the treatment of steroid-resistant disease, but contributions of B cells to proteinuria and podocyte effacement remain unknown. The development of a murine model of B-cell induced proteinuria with pathologic characteristics similar to minimal change disease would enhance our understanding of this disease.

**Methods**: The well-characterized B cell model antigen hen egg lysozyme (HEL) was biotinylated and complexed to avidin. Following intravenous injection in mice, naive HEL-specific B cells were adoptively transferred and proteinuria assessed. Kidneys were processed for immunofluorescence, H&E staining, and transmission electron microscopy. Intravital two-photon microscopy was performed on exteriorized kidneys from live, anesthetized mice.

**Results**: HEL was embedded within the glomerular basement membrane within 30 minutes following injection. Induction of proteinuria occurred only after the transfer of HEL-specific B cells. This was associated with podocyte effacement as visualized on transmission electron microscopy. The absence of periglomerular infiltrates on H&E stained sections were noted in both proteinuric and control mice, indicating the absence of inflammation. There were no immune complex or complement deposits in the glomeruli of proteinuric mice. Intravital two-photon microscopy demonstrated that HEL-specific B cells were retained only within the antigen-bearing glomeruli and became activated in situ as measured by calcium flux.

**Conclusion**: We have demonstrated that B cells were activated within antigen-bearing glomeruli, and induced proteinuria and podocyte foot process effacement in the absence of immune complexes, complement deposition, or inflammation. These are observations similar to those found in minimal change disease. We hypothesize that B cell-derived cytokines are directly responsible for this phenotype, and this is currently being tested.

### F-FC176

**Culprit and Victim: Distinct Roles of α3/4/5(IV) and α5/6/5(IV) Collagen Networks in the Pathogenesis of X-Linked Alport Post-Transplant Nephritis** Florina Olaru,[1] Wentian Luo,[1] Billy G. Hudson,[1] Clifford E. Kashtan,[2] Xu-Ping Wang,[1] Dorin-Bogdan Borza.[1] *[1]Dept of Medicine (Nephrology), Vanderbilt University School of Medicine, Nashville, TN; [2]Dept of Pediatrics, Univ. of Minnesota, Minneapolis, MN.*

Alport post-transplant nephritis (APTN), affecting ~3-5% of Alport patients after a kidney transplant, is mediated by alloantibodies to collagen IV chains present in the renal allograft but absent from Alport tissues. In X-linked Alport syndrome (XLAS), APTN alloantibodies target accessible sites in the noncollagenous (NC1) domain of α5(IV) collagen. Because α5(IV) collagen is a constituent of two supramolecular networks with different tissue distribution, we addressed the involvement of α3/4/5(IV) and α5/6/5(IV) collagen in the pathogenesis of APTN. APTN alloantibodies reactive with α5NC1 monomers also targeted α3/4/5NC1 and α5/6/5NC1 hexamers, likely sharing common alloepitopes. In addition, sera and allograft eluates from affected patients contained a novel subset of alloantibodies targeting specifically α3/4/5NC1 hexamers, but not α5/6/5NC1 hexamers, nor α5NC1 monomer subunits. Hence, neo-epitopes formed by supramolecular assembly of α3, α4 and α5 NC1 domains in the GBM are novel targets of APTN alloantibodies from XLAS patients. Murine alloantibodies to α3/4/5NC1 neo-epitopes were produced in Col4a5-null mice immunized with NC1 hexamers from human or mouse GBM but not with α5NC1 monomers. These results suggest that NC1 hexamers of α3/4/5(IV)

collagen are the culprit antigen initiating alloimmunity and the primary target of all APTN alloantibodies, whereas α5/6/5NC1 hexamers become secondary targets due to sharing tertiary α5NC1 epitopes.

**MPO-Specific Plasma Cell Depletion by Bortezomib Protects from ANCA-Induced Glomerulonephritis** Julia Bontscho,[1] Adrian Schreiber,[1] Rudolf A. Manz,[2] Wolfgang Schneider,[1] Friedrich C. Luft,[1] Ralph Kettritz.[1] *[1]Department of Nephrology and Hypertension and Experimental and Clinical Research Center, Medical Faculty of the Charite, Berlin, Germany; [2]Institute for Systemic Inflammation Research, Lubeck, Germany.*

ANCA cause small vessel vasculitis and necrotizing crescentic glomerulonephritis (NCGN). Steroids combined with cytotoxic drugs reduced mortality, but added substantial treatment-associated adverse events. We hypothesized that a MPO-ANCA NCGN mouse model allows to test novel treatment protocols and specifically tested the proteasome inhibitor bortezomib (BTZ). Anti-MPO IgG-induced NCGN was established by transplanting wild-type bone marrow (BM) into irradiated MPO-deficient mice immunized with MPO. Three weeks after BM transplantation actively treated mice received a steroid/cyclophosphamide (S/CYC) combination or BTZ, respectively. All untreated control mice developed hematuria, proteinuria, and NCGN, with 38±9% crescents and 13±3% necrosis. S/CYC and BTZ significantly reduced the urine abnormalities, crescents (3.9±2.5% and 2.8±2.8% respectively), necrosis (2.3±1.7% and 1.1±1.1%, respectively), and PMN and macrophage infiltration. BTZ, but not S/CYC, significantly reduced anti-MPO titers by ELISA. We analyzed total and MPO-specific splenic and BM plasma cells, MPO-specific plasma cells, and B lymphocytes by flow cytometry and ELISPOT. The data indicate that BTZ significantly diminished MPO-specific plasma cells in spleen and BM, reduced total plasma cells by approximately 50% (n.s.), and spared B lymphocytes. In contrast, S/CYC caused strong spleen shrinkage with reduction in total cells, B lymphocytes, plasma cells, including MPO-specific plasma cells. Two fatalities within 36 h after BTZ administration occurred.

Conclusion: An ANCA mouse model can be used to compare efficiency and adverse events of new drugs to standard protocols. More specifically, we show that BTZ depletes anti-MPO-specific plasma cells, reduces anti-MPO titers and prevents NCGN in mice.

**F-FC178**

**Serine Proteases Activate IL-1β To Produce ANCA NCGN** Adrian Schreiber,[1] Christine Pham,[2] Sylvia Krueger,[1] Friedrich C. Luft,[1] Ralph Kettritz.[1] *[1]Experimental and Clinical Research Center (ECRC) at the MDC Berlin, Berlin, Germany; [2]Division of Rheumatology, Washington University School of Medicine, St. Louis, MO.*

ANCA-activated neutrophils and monocytes cause necrotizing crescentic glomerulonephritis (NCGN). ANCA induce respiratory burst and release serine proteases. Serine proteases are generated as inactive pro-forms that are processed by the dipeptidyl-peptidase I (DPPI). We tested the hypothesis that serine proteases are essential to the ANCA response and NCGN. We immunized MPO-deficient mice with MPO to induce NCGN followed by irradiation and bone marrow transplantation from either wild-type (WT) mice or DPPI-deficient animals. WT mice developed NCGN with 37.4±8.2% glomerular crescents, whereas DPPI-/- mice were protected (1.3±0.7% crescents). Furthermore, inflammatory cytokine assessment in whole kidney lysates showed sharply reduced IL-1β generation in DPPI -/-mice (103.0 ± 29.6 pg/ml versus 5.9±1.1 pg/ml). Extracellular IL-1β release requires cytokine pro-form cleavage involving the inflammasome and caspase-1. To test whether or not serine proteases are involved in IL-1β activation, we stimulated murine monocytes and neutrophils with murine anti-MPO IgG, respectively. We observed a strong IL-1β release in WT monocytes that was reduced in DPPI-/- cells (152±9.0 vs. 47.5±15.9 pg/ml). We then tested whether or not human neutrophils and monocytes generate IL-1β after ANCA stimulation. We found strong IL-1β generation in monocytes and a smaller effect in neutrophils by immunoblotting and ELISA. We also observed that serine protease inhibitors reduced ANCA-triggered IL-1β generation, whereas caspase-1 inhibition had only small effects. Finally, we treated mice with the specific IL-1β antagonist, Anakinra®. In this set of experiments, untreated mice developed NCGN with 16.7±6.0% crescents, whereas Anakinra®-treated mice were protected (2.4±1.7%). Thus, we demonstrated that serine proteases are essential to ANCA-induced NCGN via IL-1β processing. Furthermore, IL-1 β is an effective therapeutic target.

**F-FC179**

**Robust Efficacy of C5aR Antagonist CCX168 in a Mouse Model of ANCA Glomerulonephritis** Hong Xiao,[1] J. Charles Jennette,[1] Daniel Dairaghi,[2] Jay P. Powers,[2] Yu Wang,[2] Linda Ertl,[2] Trageen Baumgart,[2] Shichang Miao,[2] Lisa C. Seitz,[2] Peiqi Hu,[1] Ronald J. Falk,[1] Thomas J. Schall,[2] Juan C. Jaen.[2] *[1]Pathology and Laboratory Medicine, University of North Carolina, Chapel Hill, NC; [2]ChemoCentryx, Inc, Mountain View, CA.*

**Purpose**

CCX168 is an orally active antagonist of human C5a receptor(C5aR) that has completed Phase 1 characterization. We evaluated CCX168 efficacy in a mouse model of antineutrophil cytoplasmic antibody (ANCA) glomerulonephritis (GN) known to involve C5a in pathogenesis. We used the biomarker of C5aR blockade used in the Phase 1 trial to establish pharmacokinetic, pharmacodynamic and therapeutic endpoints in C5aR-humanized mice.

**Methods**

A model of ANCA GN was iduced in human C5aR knock-in (hC5aR KI) mice by injection of anti-MPO IgG. The potency of CCX168 for C5aR in hC5aR KI mice was assessed by $^{125}$I-C5a binding, chemotaxis and other assays. C5a-induced neutrophil CD11b expression was used to assess CCX168 C5aR blockade in mice and humans. CCX168 doses ranged from 0.1-30 mg/kg qd.

**Results**

CCX168 had similar C5aR antagonist potency on human and hC5aR KI mouse neutrophils (inh. C5a-mediated chemotaxis in blood, $IC_{50}$ 2 nM; inh. C5a-induced CD11b upreg. in blood, $IC_{50}$ 4 nM). 30 mg/kg CCX168 markedly reduced the severity of anti-MPO induced GN with reduced crescents (vehicle 29.3%, CCX168 3.3%; $p<0.0001$) and necrosis (vehicle 8.2%, CCX168 1.1%; $p<0.0001$), which correlated with reduced urine protein, leukocytes and RBCs, and reduced serum BUN and creatinine. 30% reduction in crescents occurred with 0.1 mg/kg/d CCX168. 4 mg/kg CCX168 bid was the lowest dose that produced a near-maximal therapeutic benefit with plasma levels from 35 to 200 ng/mL throughout the day. At these doses C5aR blockade ranged from 95 to 99% with a time-averaged level of 97%. Plasma CCX168 levels of 197 ng/mL (~ 400 nM) were reached with a 100-mg dose in a human Phase 1 trial (see related meeting abstract).

**Conclusions**

Orally active hC5aR antagonist CCX168 has robust efficacy in a mouse model of ANCA GN. The lowest dose that induces a near-maximal therapeutic benefit produces CCX168 plasma levels and C5aR blockade attainable and well tolerated in humans.

Disclosure of Financial Relationships: Research Funding: ChemoCentryx Inc, Mountain View, CA.

**Tripartate Motif Containing Protein 27 (TRIM 27) Negatively Regulates CD4 T Cell Activation Via the Ubiquination and Inhibition of Phosphatidlyinositol 3 Kinase** β Xinjiang Cai,[1] Shekhar Srivastava,[1] Jon Backer,[2] Edward Y. Skolnik.[1] *[1]Skirball Institute, Department of Internal Medicine, New York University Langone Medical Center, New York, NY; [2]Department of Molecular Pharmacology, Albert Einstein College of Medicine, New York, NY.*

The Ca2+-activated K+ channel KCa3.1 is required for Ca2+ influx and the subsequent activation of T cells. We previously showed that the class 2 phosphatidylinositol 3 kinase C2β (PI3KC2β) is activated by the T cell receptor (TCR) and functions upstream of Nucleoside Diphosphate Kinase Beta to activate KCa3.1 channel activity. A yeast 2-hybrid screen was performed using a T cell cDNA library to identify PI3KC2β interacting proteins. One of the proteins identified was TRIM27. TRIM27 is a member of a large family of proteins that are characterized by the presence of a tripartite motif, which consists of a RING finger, a zinc-binding domain named a B box, and a coiled coil (CC) domain. TRIM family members have been shown to regulate a plethora of cellular pathways and recent evidence indicates that some TRIM family members function as a novel class of RING finger ubiquitin E3 ligases.

We now show that TRIM27 functions as an E3 ligase and ubiquitinates PI3KC2β. TRIM27 and PI3KC2β also co-immunoprecipitated in mammalian cells. Overexpression of wild type TRIM27, but not TRIM27 mutant for either the RING finger or CC domain, led to ubiquitination of PI3KC2β. siRNA knockdown of TRIM27 led to inhibition of PI3KC2β ubiquitination indicating that endogenous TRIM27 is the primary E3 ligase for PI3KC2β. TRIM27 mediated the polyubiquitination of PI3KC2β via lysine 48 (lys48) linkages. One function of lys48 polyubiquination is to inhibit proteins by targeting them for proteosomal mediated degradation. While TRIM27 inhibited PI3KC2β, this inhibition was mediated by inhibition of PI3K enzyme activity and not by protein degradation. Consistent with these findings, we found that TRIM27 also functions to negatively regulate CD4 T cells by inhibiting PI3KC2β leading to decreased KCa3.1 channel activity and TCR-stimulated Ca2+ influx. Thus, these finding identify TRIM27 as new negative regulator of CD4 T cells.

**The TH17-Defining Transcription Factor RORγt Mediates Severe Experimental Glomerulonephritis** Oliver M. Steinmetz, Shaun Andrew Summers, Poh-Yi Gan, Stephen R. Holdsworth, A. Richard Kitching. *Centre for Inflammatory Diseases, Monash Medical Centre, Clayton, Victoria, Australia.*

While Th17 responses may play a role in the pathogenesis of glomerulonephritis, the role of RORγt, the key transcription factor in Th17 cell development, is unknown. Glomerulonephritis (GN) was induced by planting sheep anti mouse anti glomerular basement membrane globulin in glomeruli of wild type (WT) and RORγt deficient ($RORγt^{-/-}$) mice. $RORγt^{-/-}$ mice were protected from disease, with reduced histological (crescents 18.7±1.8 vs. 6.4±1.1%, $p<0.0001$; glomerular necrosis 35.6±6.1 vs. 12.4±6.0%, $p<0.05$) and functional injury, diminished renal leukocyte infiltration and decreased IL-17A and F production, but intact lymphocyte activation and proliferative responses. As $RORγt^{-/-}$ mice lack lymph nodes which may influence the development of nephritis, cell transfer studies were performed. $Rag1^{-/-}$ mice (lacking B and T cells) were reconstituted with different leukocyte subsets from naïve WT or $RORγt^{-/-}$ mice and GN was induced. Mice receiving unfractionated WT splenocytes showed high mortality caused by renal failure while $RORγt^{-/-}$ cell recipients were protected (mortality 6/9 vs. 2/12, $p<0.05$). Likewise, recipients

of WT CD4$^+$ T cells developed severe glomerulonephritis whereas disease was attenuated in RORγt$^{-/-}$ cell recipients (crescents 21.4±3.6 vs. 8.7±1.1%, p=0.0011; necrosis 48.5±9.2 vs. 5.7±3.6%, p<0.001; no cell transfer controls 0.3±0.2% crescents and 1.3±0.8% necrosis). To exclude effects of altered regulatory T cell (Treg) development caused by RORγt deficiency, naïve CD4$^+$ T cells depleted of Tregs were transferred into Rag1$^{-/-}$ mice. GN was severe in recipients of WT, Treg depleted, CD4$^+$ T cells, but mice receiving RORγt$^{-/-}$, Treg depleted, CD4$^+$T cells were protected (crescents 3.6±1.0 vs. 0.3±0.3%, p<0.01; necrosis 82.9±3.1 vs. 14.3±14.3% p<0.001; no cell transfer controls: 0% crescents and necrosis). Both systemic and renal Th1 responses were intact in recipients of RORγt$^{-/-}$ cells. These studies therefore show an important role for RORγt in the pathogenesis of severe glomerulonephritis by directing nephritogenic Th17 responses.

**Accumulation and Activation of T-Helper 17 (Th17) Cells in Obstructive Uropathy** Jana Pindjakova, Shirley Hanley, Michelle M. Duffy, Rhodri Ceredig, Matthew D. Griffin. *Regenerative Medicine Institute, College of Medicine, National University of Ireland, Galway, Galway, Ireland.*

**Background and Aims:** Intra-renal Th17 cells participate in experimental AKI and glomerulonephritis but remain incompletely characterized. Intra-renal Th17 cells were profiled in mouse unilateral ureteral obstruction (UUO) for chemokine receptor expression and activation. Th17-activating factors and their cellular sources were examined. **Methods:** Obstructed (Obs) and control (Ctr) kidneys were procured following 24-72 hr UUO. Th17 cells were identified by intracellular IL-17 staining of renal digests following brief activation *in vitro* with counterstaining for chemokine receptors. Renal CD4 T-cell subsets, dendritic cells (DC), monocytes and macrophages were purified by FACS for qRT-PCR. Conditioned media were prepared from MACS-enriched renal cell populations, analyzed by ELISA and added to *in vitro*-generated Th17 cells to detect Th17-activating factors. Blocking experiments were carried out with anti-IL-1R and/or IL-23R. **Results:** IL-17 mRNA increased progressively in cortex of Obs but not Ctr kidneys from 24-72 hrs. CD4+CCR6+ T cells ± CCR4 were identified as the primary source of IL-17. Numbers of these cells increased almost 100-fold in Obs vs Ctr kidneys. Ligands for CCR6 and CCR4 (CCL20, CCL17, CCL22) were selectively secreted by DCs from Obs kidneys. Conditioned media from the total leukocytes (CD45+) and DCs (CD11c+) but not CD45- cells of Obs kidneys augmented IL-17 production by *in vitro*-generated Th17 cells. This effect was inhibited by anti-IL-1R but not anti-IL-23R. IL-1α, IL-1β and IL-23 were detected in Obs kidneys and were secreted both by DCs and non-DC leukocyte fractions. FACS purification of multiple myeloid populations from 72-hr obstructed kidneys revealed a hierarchy of IL-1α/β expression: Ly6C-hi monocytes > F4/80+ DCs > F4/80- DCs > Ly6C-lo/CD11c- macrophages. **Conclusions:** Th17 cells are progressively activated following UUO and preferentially express CCR6 ± CCR4. During UUO renal DCs are a potent source of chemokine ligands for CCR6 and CCR4. Monocytes and DCs are the primary source of Th17-activating factors of which IL-1α and/or IL-1β are the most significant.

## F-FC183

**CD14 Mediates Inflammation and Kidney Injury of MPGN in the TSLP Model Cryoglobulinemic Glomerulonephritis Independent of TLR4** Takahisa Kobayashi, Tomasz A. Wietecha, Kelly L. Hudkins, Warangkana Pichaiwong, Kelly D. Smith, Shunhua Guo, Ichiro Kojima, Charles E. Alpers. *Dept. of Pathology, Univ. of Washington, Seattle, WA.*

Toll-like receptors (TLRs) are key proteins in innate immunity. We have reported upregulation of TLR4 in podocytes of TSLPtg (thymic stromal lymphopoietin transgenic) mice, a model of cryoglobulinemia associated MPGN (JASN,19:704,2008). To investigate the role of TLR4 in this model, we crossed the TSLPtg mice with mice deficient for TLR4 or CD14 (a major accessory molecule for TLR4). Renal disease was assessed in female mice after 50 days.

TSLPtg/TLR4-/- mice had a high mortality rate of 52.4% compared to 7.7% for TSLPtg/CD14-/- at 50 days. TSLPtg/CD14-/- mice had significantly reduced glomerular macrophage infiltration compared with TSLPtg and TSLPtg/TLR4-/- (% staining area/ glomerular tuft area (%GTA): TSLPtg 1.76±0.35, TSLPtg/CD14-/- 0.67±0.29 (p<0.05 vs TSLPtg), TSLPtg/TLR4 1.88±0.24). Despite similar levels of cryoglobulinemia and glomerular immune complex deposition, TSLPtg/CD14-/- mice had less glomerular hypercellularity, mesangial matrix expansion as measured by silver stained matrix (%GTA: TSLPtg 12.90±0.83, TSLPtg/CD14-/- 8.82±1.19 (p<0.05 vs TSLPtg), TSLPtg/ TLR4-/- 14.84±0.45), and mesangial cell activation as measured by smooth muscle actin (%GTA:TSLPtg 0.75±0.17, TSLPtg/CD14-/- 0.19±0.06 (p<0.05 vs TSLPtg), TSLPtg/ TLR4-/- 0.58±0.17). Proteinuria decreased in TSLPtg/CD14-/- mice compared with TSLPtg while it was not changed in TSLPtg/TLR4-/- (albumin/creatinine ratio (ug/mg): TSLPtg 100.4±15.3, TSLPtg/CD14-/- 43.9±17.6 (p=0.053)).

CD14 deficiency results in significant improvement in renal structure and function in TSLPtg mice, whereas deficiency of TLR4 does not. CD14 appears to mediate glomerular monocyte/macrophage infiltration, which may contribute to the development of kidney injury. In addition to LPS recognition by TLR4, CD14 also has been demonstrated to enhance recognition of some TLR2 ligands, and the TLR3 ligand, dsRNA. The clear beneficial effects of CD14 deficiency in the TSLPtg mice demonstrates TLR4 independent pathways of activity previously unrecognized as mediators of glomerulonephritis.

**Regulatory T Cells Suppress Kidney Ischemia Reperfusion Injury through Autocrine and Paracrine Adenosine Signaling** Gilbert R. Kinsey, Liping Huang, Mark D. Okusa. *Division of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia Health System.*

Regulatory T cells (Tregs) suppress the inflammation and injury associated with kidney ischemia-reperfusion injury (IRI). Activation of adenosine $A_{2A}$ receptors ($A_{2A}$Rs) on bone marrow-derived cells also blocks inflammation and prevents renal injury after IR. Tregs express $A_{2A}$Rs and CD39 and CD73, which are the membrane bound enzymes necessary for conversion of extracellular ATP to adenosine (ADO). Production of ADO is a recognized mechanism of suppression of adaptive immune responses by Tregs, but the contribution to suppression of innate immune pathology, such as early kidney IRI is unknown. We hypothesized that both the production of adenosine by, and $A_{2A}$R signaling in Tregs are required to block innate immune responses in kidney IRI. The ability of Tregs from WT, CD73KO and $A_{2A}$RKO mice to protect WT mice from kidney IRI was compared in terms of renal function, tubular necrosis and kidney infiltrating leukocytes. WT Treg cells protected WT mice from kidney IRI, but in the absence of adenosine generation (CD73KO) or $A_{2A}$Rs ($A_{2A}$RKO), the functional capacity of Tregs to block kidney IRI was impaired (plasma creatinine 18hr post ischemia: +non-Tregs: 1.3±0.3; +WT Tregs: 0.4±0.1*; +CD73KO Tregs: 1.2±0.4; +$A_{2A}$RKO Tregs: 0.8±0.3; *p<0.05 vs. IRI+non-Tregs). Furthermore, WT Tregs offered significant protection to $A_{2A}$RKO mice, although protection was not complete. Real-time PCR analysis revealed no difference in activation-induced expression of FoxP3, IL-10, TGF-β or CD73 in WT vs. $A_{2A}$RKO Tregs; however CD39 and CTLA-4 expression was significantly inhibited in $A_{2A}$RKO Tregs. Taken together these findings demonstrate that ADO production is vital for the protective effects of Tregs in IRI and suggest Treg-generated ADO acts in an autocrine manner to enhance the suppressive function of Tregs and paracrine manner to inhibit innate immune cell responses in kidney IRI.

**Low Dose Atrasentan Safely Reduces Albuminuria in Subjects with Type 2 Diabetic Nephropathy (DN) on Renin-Angiotensin System (RAS) Inhibitors** Donald E. Kohan,[1] Mark E. Molitch,[2] Yili Pritchett,[3] Utpaul Audhya,[3] Shihua Wen,[3] Bo Yan,[3] Dennis L. Andress.[3] *[1]Univesity of Utah; [2]Northwestern University Feinberg School of Medicine; [3]Abbott.*

INTRODUCTION: DN is the leading cause of ESRD. RAS inhibitors only slow CKD progression due to incomplete inhibition and/or RAS-independent mediators of disease. Endothelin (ET)-1 is elevated in patients with DN and promotes glomerulosclerosis by activation of the ETA receptor. This study tested if low dose atrasentan, a highly selective ETA antagonist, could safely reduce residual albuminuria in subjects with DN on RAS inhibitors.

METHODS: A double-blind, placebo-controlled study of 89 subjects with DN on stable doses of RAS inhibitors for ≥2 months with UACR 100-3000 mg/g, eGFR >20 mL/min/1.73m$^2$, and NT-pro-BNP ≤500 pg/mL who were equally randomized to placebo, atrasentan 0.25, 0.75, or 1.75 mg daily for 8 weeks. The primary endpoint was change from baseline (BL) in first morning void UACR.

RESULTS: Mean age (64 years), mean eGFR (range 48-60 mL/min/1.73m$^2$) and median BL UACR (range 351-514 mg/g) were similar among groups. Repeated measures analysis showed early and sustained UACR reductions for the 0.75 mg (P=0.001) and 1.75 mg (P=0.011) groups, while the 0.25 mg dose had no significant effect. Change in UACR, SBP, DBP, and weight are shown in Table 1. ~15%-20% of the UACR lowering effect was related to SBP reduction. There were no significant changes in eGFR from BL. Peripheral edema (primarily mild) was the most common adverse event (14%, 18% and 46% for 0.25, 0.75 and 1.75 mg with p=0.007 for 1.75 mg vs. 9% in placebo). No deaths and only 1 treatment-related serious adverse event were reported.

CONCLUSIONS: Low dose atrasentan safely and effectively reduces residual albuminuria in subjects with type 2 diabetes receiving treatment with RAS inhibitors, mostly independent of reductions in SBP.

**Long-Term Renal Outcomes of Patients with Type 1 Diabetes and Microalbuminuria** Ian H. de Boer,[1] Tessa Rue,[1] Patricia A. Cleary,[2] John M. Lachin,[2] Mark E. Molitch,[3] Michael Steffes,[4] Wanjie Sun,[2] Bernard Zinman,[5] John D. Brunzell.[1] *[1]University of Washington; [2]The George Washington University; [3]Northwestern University; [4]University of Minnesota; [5]University of Toronto.*

In type 1 diabetes, long-term clinical outcomes after the development of microalbuminuria are variable. Frequencies of and risk factors for subsequent renal events are not clear. We evaluated long-term renal outcomes of 325 persons with type 1 diabetes who developed incident persistent microalbuminuria (albumin excretion rate [AER] ≥ 30 mg/24hr on two consecutive study visits) at a clearly defined time point in the Diabetes Complications and Control Trial (DCCT) and its observational follow-up (EDIC Study). In this group, we quantified the incidence of and risk factors for subsequent long-term renal events, including progression to macroalbuminuria (sustained AER ≥ 300 mg/24hr), impaired glomerular filtration rate (sustained estimated GFR < 60 mL/min/1.73m²), ESRD, and regression to normoalbuminuria (sustained AER < 30 mg/24hr). Median follow-up after microalbuminuria diagnosis was 13 years (maximum 23 years). 10-year cumulative incidences of macroalbuminuria, impaired GFR, and ESRD were 28%, 15% and 3% respectively, whereas 40% regressed to normoalbuminuria. Albuminuria outcomes were more favorable (decreased risk of progression to macroalbuminuria and increased probability of regression to normoalbuminuria) with randomly assigned intensive diabetes therapy, lower hemoglobin A1c, lack of retinopathy, female gender, lower blood pressure, and lower concentrations of LDL cholesterol and triglyceride (each p<0.05). Lower hemoglobin A1c, lack of retinopathy, and lower blood pressure were also associated with decreased risk of impaired GFR (p<0.05). In conclusion, the development of persistent microalbuminuria does not necessarily represent the start of an inexorable downhill course for diabetic nephropathy, since regression is as common as progression of kidney disease. Intensive glycemic control, lower blood pressure, and a more favorable lipid profile are associated with improved long-term renal outcomes after the development of persistent microalbuminuria.

**Serum Placental Growth Factor (PlGF) Predicts All-Cause and Cardiovascular Mortality but Not Deterioration of Kidney Function in Type 1 Diabetic Patients with Diabetic Nephropathy** Simone Theilade,[1] Maria Lajer,[1] Anders Jorsal,[1] Lise Tarnow,[1] Hans-Henrik Parving,[2] Peter Rossing.[1] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Dept. of Medical Endocrinology, Copenhagen University Hospital, Rigshospitalet, Denmark.*

**Objective**

Placental growth factor is a vascular endothelial growth factor involved in angiogenesis, vascular inflammation and plaque formation. The aim of this analysis is to evaluate the predictive value of PlGF in relation to all-cause and cardiovascular mortality, and decline in kidney function in type 1 diabetic patients.

**Design**

A prospective, observational follow-up study with 8(0-13) years (median(range)) of follow-up.

422 patients with longstanding type 1 diabetes and normoalbuminuria (223 men; age 45±11 years[mean±SD], diabetes duration 28±10 years) and 440 type 1 diabetic patients with diabetic nephropathy (DN) (267 men; age 42±10 years, diabetes duration 28±9 years, glomerular filtration rate ((GFR) 76±34 ml/min/1.73m²).

**Results**

PlGF levels were lower in normoalbuminuric patients vs. patients with DN (median(range) 11(7-131) vs. 15(4-68)pg/L (p<0.001).

In the normoalbuminuric group the patients were divided according to the median PlGF level. PlGF levels did not predict all-cause mortality (adjusted for sex, age and systolic BP) hazard ratio (HR) 1.0[0.5–1.9].

Patients with DN were divided according to tertiles of PlGF levels, and 61(41%) patients with the highest vs. 29(20%) patients with the lowest PlGF levels died during follow-up ($p$<0.01).

High levels of PlGF was predictive of all-cause mortality HR 1.9[1.1-3.2] (p=0.018) and cardiovascular mortality HR 2.9[1.5-5.9] ($p$<0.01), (adjusted for sex, age, smoking, systolic BP, $HbA_{1c}$, cholesterol, GFR, UAER, antihypertensive treatment and previous CVD).

High levels of PlGF did not predict development of end stage renal disease or rate of decline in GFR, $p$=0.49 and $p$=0.56, respectively.

Evaluating PlGF as a continuous variable introduced only minor changes in the statistical output.

**Conclusion**

In type 1 diabetic patients with DN higher levels of PlGF predict all-cause and cardiovascular mortality, but not deterioration of kidney function.

PlGF was measured by Roche Diagnostics, George Hess and Dietmar Zdunek

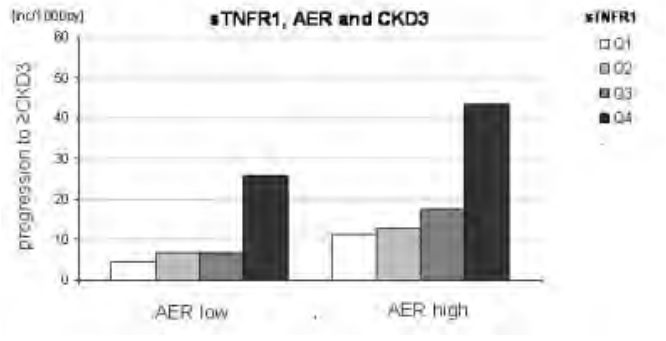
**Tumor Necrosis Factor Receptors 1 and 2 Are Early Serum Markers of Progressive Loss of Renal Function in Type 1 Diabetes** Tomohito Gohda, Monika A. Niewczas, Linda Hanna Ficociello, William Walker, Amanda Johnson, Gordon S. Crabtree, Jan Skupien, Adam Smiles, James Warram, Andrzej S. Krolewski. *Research Division, Joslin Diabetes Center, Boston, MA.*

Objective: To examine serum markers of the TNF pathway as determinants of early progressive renal function loss in patients with type 1 diabetes (T1D).

Methods: The study group comprises 629 patients with T1D and microalbuminura (MA) or high-normal albuminuria recruited between 1991 and 2005 and followed for 4-12 years. Concentrations of TNFα, soluble TNF receptor 1 (sTNFR1) and receptor 2 (sTNFR2), soluble Fas (sFas) were measured in baseline serum, and cystatin C was measured in serial samples for estimating the glomerular filtration rate (GFRcystatin) and determining two renal outcomes: "early GFR loss" (at least 3.3% decline in GFRcystatin per year) and onset of chronic kidney disease (CKD) ≥3 (GFRcystatin<60 ml/min/1.73 m²).

Results: While GFRcystatin was normal in all patients at baseline, both outcomes were significantly associated with baseline TNF receptors' concentrations, grouped into quartiles (p<0.0001). The odds ratios of early GFR loss were 1.4 [95% CI:1.1, 1.8] per quartile of sTNFR1 and 1.7 [95% CI:1.3, 2.3] per quartile of sTNFR2 after adjustment for HbA1c, urinary albumin excretion and initial GFRcystatin. Similarly, the hazard ratios for onset of CKD ≥3 were 1.8 [95% CI:1.3, 2.3] and 1.7 [95% CI:1.3, 2.3] per quartile. This effect was independent from albuminuria.



Renal outcomes were unrelated to TNFα and sFas.

Conclusions: The risk of early progressive renal function loss in patients with T1D and MA is strongly and independently associated with serum concentrations of sTNFR1 and sTNFR2. While the underlying mechanisms are unclear, a single determination of one of these receptors in serum may identify patients at high risk of early progressive renal function loss.

Disclosure of Financial Relationships: nothing to disclose

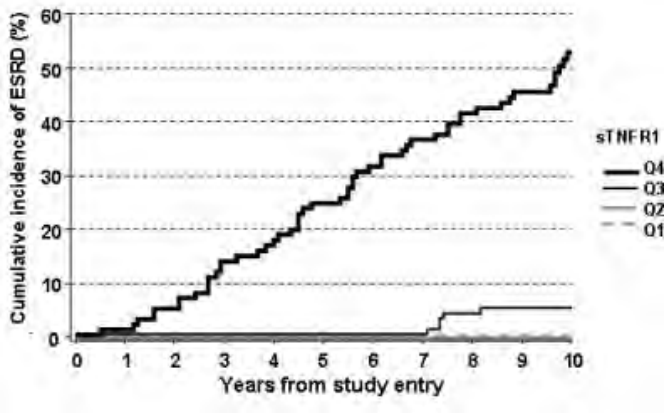
**F-FC189**

**Serum Markers of Tumor Necrosis Factor Pathway and Risk of End-Stage Renal Disease in Type 2 Diabetes** Monika A. Niewczas,[1,2,] Tomohito Gohda,[1,2,] Jan Skupien,[1,2,] Adam Smiles,[1] William Walker,[1] Linda Hanna Ficociello,[1,2] James Warram,[1] Andrzej S. Krolewski.[1,2] *[1]Research Division, Joslin Diabetes Center, Boston, MA; [2]Department of Medicine, Harvard Medical School, Boston, MA.*

Objectives: Incidence of end-stage renal disease (ESRD) due to type 2 diabetes (T2D) has increased during the last 20 years in the US. Better understanding of its etiology is needed to arrest this trend. In this study we explore the role of serum markers of inflammation as determinants of ESRD in T2D.

Methods: 410 patients attending the Joslin Clinic (211 normoalbuminuria, 119 microalbuminuria, 80 proteinuria) were recruited in the 1990s. We recorded characteristics at enrollment and measured markers of the TNF pathway, endothelial dysfunction and systemic inflammation in baseline serum. Onset of ESRD and deaths within 12 years of follow-up were ascertained.

Results: ESRD developed in 59 patients (1.7/100 p-years), and 84 patients died without ESRD (2.4/100 p-years). The risk of ESRD was associated with all TNF pathway markers and none of the others. Association with sTNFR1 was strongest. Ninety percent of ESRD cases were in the highest quartile of its distribution, giving that quartile a 10-year cumulative risk of 52% and leaving a risk of only 5% for the remaining quartiles (P<0.0001).



This effect of sTNFR1 was independent of other clinical characteristics. Deaths unrelated to ESRD were only moderately associated with TNF receptors. When examined as a predictor of ESRD, sTNFR1 outperformed estimated glomerular filtration rate, urinary albumin excretion, glycohemoglobin and their combination.

Conclusions: The activation of TNF pathway plays a major role in development of ESRD in T2D. A single determination of serum sTNFR1 predicts accurately the subsequent 10-year risk of ESRD.

**Systemic Transcriptome Analysis for Extraction of Specific Gene Clusters in Diabetic Nephropathy – Reduced Expression of Insulin Regulated Aminopeptidase Angiotensin IV Receptor (IRAP/AT4) in Diabetic Renal Tissue** Tadashi Konoshita. *Third Department of Internal Medicine, Fukui University School of Medicine, Eiheiji, Fukui, Japan.*

The renin-angiotensin system (RAS) plays pivotal roles on progression of diabetic nephropathy. However, much remains unknown about the molecular mechanisms involved. The aim of the study was to obtain novel insights into processes by systemic transcriptome analysis by DNA microarray technology. RNA was extracted from a small part of renal cortical biopsy specimens. A total number of 54,675 transcripts expression levels were analyzed systemically with GeneChip Human Genome U133 Plus 2.0 Array (Affymetrix). Specific gene clusters involved in diabetic nephropathy was analyzed by hierarchical clustering method. Extracted candidate genes were analyzed by real-time PCR method with LightCycler (Roche). Hierarchical clustering analysis with 18 samples showed cluster formation considerably distinct by each original renal condition. By a hierarchical clustering analysis with 3 samples each from minor abnormality and diabetic nephropathy, we divided the transcripts to 12 clusters. By ontology and pathway analysis from the 11th cluster, the renin-angiotensin system was selected as a diabetic nephropathy specific pathway implying the reduction of ACE2, C9orf3, ENPEP and IRAP/AT4, which are thought to exert the effects for degradation of angiotensin II. Further analysis of 78 subjects with real-time PCR method revealed a significant reduction of IRAP/AT4 expression in diabetics renal tissues compared to non-diabetics (p=0.01). Recently AT4 (angiotensin IV receptor) was identified as IRAP (insulin regulated aminopeptidase). The IRAP/AT4 was originally identified from GLUT4 vesicles and thought to be involved in insulin sensitivity. On the other hands, IRAP/AT4 is thought to degrade angiotensin III to angiotensin IV and to further degraded fragments. Thus, the results suggest that reduction of IRAP/AT4 in renal tissue might be involved in formation and progression of diabetic nephropathy.

**Progression of Kidney Dysfunction and Its Association with Cardiovascular Outcomes in Patients with Type 2 Diabetes Mellitus and Coronary Artery Disease in the BARI 2D Study** Barry M. Wall,[1] Phyllis August,[2] Mark E. Molitch,[3] Regina Hardison,[4] Janet B. McGill,[5] Michael Steffes,[7] Fadi G. Hage,[9] Oscar C. Marroquin,[6] Yves Rosenberg.[8] *[1]VAMC/Univ TN; [2]New York Hosp Queens; [3]Northwestern Univ. Feinberg School of Med; [4]Univ of Pittsburgh; [5]Washington Univ/Barnes Jewish Hosp; [6]Univ. of Pittsburgh Med Ctr; [7]Univ of MN; [8]NHLBI; [9]Univ of AL.*

We determined the progression of kidney disease and its association with cardiovascular outcomes Death\MI\Stroke (DMS) in 1937 patients with type 2 DM and coronary artery disease enrolled in the Bypass Angioplasty Revascularization Investigation 2 Diabetes (BARI 2D), a trial comparing 5 yr outcomes in patients randomized to revascularization and medical therapy vs medical therapy, and 2 glycemic control strategies: insulin providing (IP) vs insulin sensitizing (IS). Definitions: Reduced eGFR (< 60 ml/min/1.73m$^2$ ) and eGFR progression (reduction of ≥15 ml/min/1.73m$^2$ or ≥25%); albuminuria: micro-(ACR>30, ≤ 300 mg/g,), or macro (ACR>300 mg/g) and progression as ≥ doubling of ACR to > 100 mg/g or to ≥ 2 visits with worsened ACR status. eGFR decreased over time. Patients with baseline macro or micro albuminuria had larger decreases in eGFR than those with normal albuminuria. During the study, the prevalence of eGFR's < 60 doubled, from 21.9 to 39.8%. The prevalence of micro- and macroalbuminuria increased minimally. The IS strategy had increased risk for albuminuria progression (IS vs IP OR 1.27, p=0.021). Other significant factors for ACR progression were being Hispanic and elevated HbA1c. Significant factors for eGFR progression were baseline ACR, female sex, systolic and diastolic BP. Progression of eGFR did not differ between randomized treatment groups. Reduced eGFR was related to higher risk of DMS (HR 1.7, p < 0.001). Macro (HR 2.2, p <0.001) and micro albuminuria(HR 1.4, p 0.006) also increased risk of DMS compared to normal albuminuria. We conclude that in subjects enrolled in BARI 2D 1) reduced eGFR and albuminuria were prevalent, 2) worsening of eGFR was more common than progression of albuminuria, and 3) eGFR and ACR were significant predictors of Death/MI/Stroke.

**Hypophosphatemic Effect of Niacin in Patients with Type 2 Diabetes: A Randomized Trial** Andrew G. Bostom,[1] Alexandra Maclean,[2] Darbie Maccubbin,[2] Diane Tipping,[2] Hilde Giezek,[2] William A. Hanlon.[2] *[1]Division of Kidney Diseases and Hypertension, Rhode Island Hospital, Providence, RI; [2]Merck and Company, Rahway, NJ.*

Niacin lowers serum phosphorus (P) concentrations in patients with stage 5 chronic kidney disease (CKD), an estimated glomerular filtration rate [eGFR] < 15 ml/min/1.73 m$^2$. We expanded upon these data with a post-hoc evaluation of the impact of extended release niacin (ERN), in fixed-dose combination with laropiprant (L), a specific inhibitor of prostaglandin-mediated, niacin-induced flushing, versus placebo (PBO), on serum P concentrations measured serially (at weeks 0,4,8,12,18,24,30, and 36) during a 36-week randomized, placebo-controlled trial. All subjects had a confirmed diagnosis of type 2 diabetes (n=446 niacin/laropiprant; n=339 placebo). Their eGFR ranged from 36-184 ml/min/1.73 m$^2$, with n=111 (14.1%) having an eGFR <60 ml/min/1.73 m$^2$. Subjects received 1 tablet daily of ERN-L (ERN 1g/ L 20 mg) for the first 4-weeks, and 2 tablets once daily, thereafter, or matched PBO. Repeated measures analysis demonstrated ERN-L lowered serum P concentrations by 0.36 mg/dl (95% CI: -0.40, -0.31; p < 0.001), relative to PBO, expressed as the treatment difference between the Week 12-36 average changes from baseline values of 3.57 and 3.56 mg/dl in the ERN-L and PBO groups, respectively. There was no evidence for P-lowering effect modification by these baseline variables: eGFR < 60 (n=111; 14.1%) vs. ≥ 60 ml/min/m$^2$ (n=674; 85.9%); P ≤ 3.5 mg/dl (n=392; 49.9%) vs. >3.5 mg/dl (n=393; 50.1%); or prior statin use (n=618; 78.7%) vs. non-use (n=167; 21.3%). Specifically, among the large (i.e., 50%) subgroup of patients (n=224 ERN-L; n=169 PBO) whose baseline serum P was > 3.5 mg/dl, ERN-L lowered serum P concentrations from baseline means of 3.98 and 3.97 mg/dl (for ERN-L and PBO, respectively) by 0.39 mg/dl (95% CI: -0.46, -0.31; p <0.001), relative to PBO.These data confirm that niacin's phosphorus-lowering effects—which may have therapeutic implications for the management of hyperphosphatemia in renal disease—extend across a broad spectrum of renal function (eGFR) in type 2 diabetics *without* stage 4 or 5 CKD (an eGFR ≥ 30).

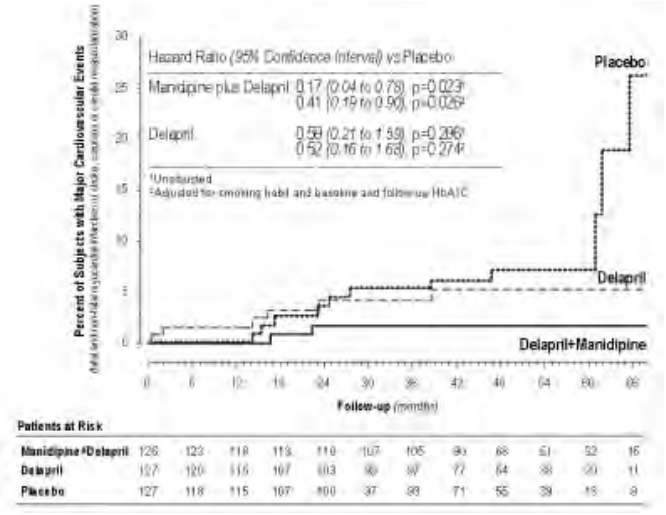
**Effects of Manidipine and Delapril on Chronic Complications of Type 2 Diabetes: DEMAND Study** Piero Ruggenenti,[1] Giuseppe Lauria,[2] Jelka Zaletel,[3] Giuseppe Remuzzi.[1] *[1]Mario Negri Institute for Pharmacological Research and Ospedali Riuniti di Bergamo, Italy; [2]Carlo Besta Neurological Institute, Milan, Italy; [3]University Medical Center, Ljubljana, Slovenia.*

Background: DElapril and MAnidipine for Nephroprotection in Diabetes (DEMAND) was a multicenter, double-blind, placebo-controlled, randomized trial to assess whether ACE inhibitors and third-generation dihydropyridine CCBs ameliorate complications of type 2 diabetes.

Methods: 380 hypertensive patients with albuminuria <200 µg/min were randomized to >3-year treatment with manidipine (10 mg/day) plus delapril (30 mg/day), delapril (30 mg/day), or placebo. Glomerular filtration rate (GFR, primary outcome) and glucose disposal rate (GDR) were measured by iohexol plasma clearance and hyperinsulinemic euglycemic clamps.

Results: Median monthly GFR decline (interquartile range) was 0.32 (0.16-0.50), 0.36 (0.18-0.53) and 0.30 (0.12-0.50) ml/min/1.73m$^2$ on combined therapy, delapril or placebo, respectively. Combined therapy decreased the incidence of major cardiovascular events vs placebo. Delapril had no significant effect.



Among 192 subjects without retinopathy at inclusion, three on combined therapy developed retinopathy vs nine on placebo [HR (95%CI): 0.27 (0.07-0.99), p=0.048]. Among 200 subjects with centralized neurological evaluation, 24 on combined therapy and 26 on delapril had peripheral neuropathy at 3 years vs 39 on placebo. Odd Ratios (95%CI): 0.45 (0.24-0.87), p=0.017, and 0.52 (0.27-0.99), p=0.048, respectively. GDR decreased on delapril or placebo, but was stable on combined therapy. No patient withdrew for treatment adverse events.

Conclusions: In hypertensive type 2 diabetic patients combined manidipine and delapril therapy failed to slow renal function loss, but ameliorated cardiovascular disease, retinopathy and peripheral neuropathy, stabilized insulin resistance, and was safe.

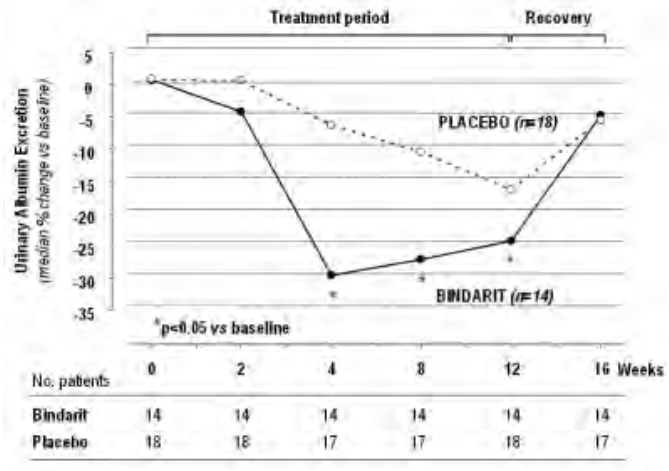
**Effects of MCP-1 Inhibition by Bindarit Therapy in Type 2 Diabetes Subjects with Micro- or Macro-Albuminuria** Piero Ruggenenti. *Mario Negri Institute and Azienda Ospedaliera Ospedali Riuniti di Bergamo, Italy.*

Background: Monocyte chemoattractant protein-1 (MCP-1 or, more recently, CCL2) is a cytokine with chemotactic activity toward monocytes involved in the development and progression of albuminuria in subjects with diabetes. Whether MCP-1 inhibition may reduce albuminuria in this population is not known

Methods: In this prospective, randomized, double-blind, placebo-controlled trial we evaluated urinary albumin excretion (UAE) in 41 micro (UAE: 20 to 200 µg/min) and 32 macro- (UAE: 200 to 2000 µg/min) albuminuric type 2 diabetes patients on stable irbesartan (300 mg/day) therapy randomized to 12-week therapy with the MCP-1 synthesis inhibitor bindarit (600 mg twice daily) or placebo and followed-up to 4 weeks after treatment withdrawal. Treatment was titrated to systolic/diastolic blood pressure <120/80 mmHg and HbA1C<7%. Within patient changes were assessed by paired t-test.

Results: Baseline characteristics of the two treatment groups were comparable. In those with macroalbuminuria at inclusion, UAE decreased significantly at 4, 8 and 12 weeks of bindarit therapy, but did not change appreciably on placebo.



UAE recovered to baseline values after treatment withdrawal. Blood pressure and metabolic control were similar throughout the study in both treatment arms. No significant treatment effect was observed in the 21 subjects on bindarit and the 20 on placebo who were microalbuminuric at inclusion. Treatment was well tolerated in all patients

Conclusions: Bindarit significantly and safely reduced albuminuria compared to placebo in type 2 diabetes patients with residual macroalbuminuria despite optimized blood pressure and metabolic control and background full-dose angiotensin II receptor blocker therapy. Prospective trials may help addressing the long-term renoprotective effect of bindarit therapy in this population.

**(1-34) PTH Infusion Acutely Lowers FGF23 Levels in Healthy Volunteers** Orlando M. Gutierrez, Tamara Isakova, Myles S. Wolf. *University of Miami.*

**Purpose:** Previous studies showed that (1-34) parathyroid hormone (PTH) infusions stimulate increased fibroblast growth factor 23 (FGF23) secretion in healthy volunteers and dialysis patients over 24-48 hours, however the acute effects of (1-34) PTH infusion on FGF23 are less clear. Specifically, little is known about the change in FGF23 levels in relation to decreases in serum phosphate levels that occur early after the initiation of (1-34) PTH infusion and prior to the rise in calcitriol levels. Accordingly, we examined the acute changes in FGF23 levels in response to (1-34) PTH infusion.

**Methods**: 26 healthy volunteers underwent (1-34) PTH infusion at a rate of 0.055 mcg/kg/hr for six hours. Serum phosphate, (1-84) PTH, FGF23, and urinary $FE_{Pi}$ were measured every 30 minutes for the first two hours and than every hour for the remaining 4 hours.

**Results:** The mean age of the population was 36 ± 11, 19% (5/26) were female and 38% (10/26) were black. As depicted in the figure, mean serum phosphate levels decreased while mean $FE_{Pi}$ increased during the course of the 6 hour infusion. In addition, (1-84) PTH levels gradually decreased over 6 hours. FGF23 levels decreased early after initiating the infusion in parallel with the decrease in serum phosphate, with both analytes reaching their nadir after 6 hours.

**Conclusion:** In healthy volunteers, FGF23 levels acutely decrease after initiation of (1-34) PTH infusion in parallel with concurrent decreases in serum phosphate levels. Whether this reflects an effect of decreasing serum phosphate levels on FGF23 synthesis or a direct inhibitory effect of (1-34) PTH on FGF23 requires further study.

**PTH Increases FGF23 Gene Expression through PKA-Wnt Signaling and Mediates the High FGF23 Levels of CKD: A Bone Parathyroid Feedback Loop** Tomer Meir, Vardit Lavi-Moshayoff, Gilad Wasserman, Tally Naveh, Justin Silver. *Nephrology, Hadassah Hebrew University Medical Center, Jerusalem, Israel.*

PTH and FGF23 target the kidney to cause a phosphaturia. FGF23 also acts on the parathyroid to decrease PTH expression, but in CKD there are high serum PTH and FGF23 levels and resistance of the parathyroid to FGF23. We now report that PTH acts on bone to increase FGF23 expression and characterize the signal transduction pathway whereby PTH increases FGF23 expression. Remarkably, we show that PTH is necessary for the high FGF23 levels of early CKD. In CKD rats due to an adenine high phosphorus diet, parathyroidectomy totally prevented the 5-fold increase in FGF23 levels. Moreover, in rats with established experimental CKD, PTX corrected the high FGF23 levels. Therefore, in CKD the high FGF23 levels are dependent on the high PTH levels. PTH infusion for 3 days to mice with normal renal function increased serum FGF23 and calvaria FGF23 mRNA levels. To demonstrate a direct effect of PTH on FGF23, we added PTH to rat osteoblast like UMR106 cells. PTH ($1x10^{-7}$ M) increased FGF23 mRNA levels (4-fold) and this effect was mimicked by a PKA activator, forskolin. Both PTH and forskolin also decreased SOST mRNA levels (3-fold). SOST codes for sclerostin, a Wnt pathway inhibitor, which is a PTH receptor (PTH1R) target. The effect of PTH was prevented by added sclerostin (5 microg/ml). Therefore, PTH increases FGF23 expression in vivo and in vitro through the PKA and Wnt pathways. The effect of PTH on FGF23 completes a novel bone-parathyroid endocrine feedback loop whereby FGF23 decreases PTH expression and PTH in turn increases FGF23 expression in bone. Importantly, we demonstrate that secondary hyperparathyroidism is essential for the high FGF23 levels in CKD.

**Fibroblast Growth Factor 23 Predicts Cardiovascular Mortality in Elderly Men** Per-Anton Westerberg,[1] Claes Ohlsson,[2] Åsa Tivesten,[3] Tobias Larsson,[4] Torbjorn Linde,[1] Osten Ljunggren.[1] *[1]Department of Medical Sciences, Uppsala University, Uppsala, Sweden; [2]Center for Bone Research at the Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [3]Wallenberg Laboratory for Cardiovascular Research, University of Gothenburg, Gothenburg, Sweden; [4]Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden.*

Objectives. Fibroblast growth factor 23 (FGF23) decreases renal phosphate (Pi) reabsorption and vitamin D activation, and the level of circulating FGF23 is associated with atherosclerosis, endothelial dysfunction and left ventricular hypertrophy in the general population, and with mortality in dialysis patients. It is unknown if FGF23 is associated with cardiovascular mortality when the renal function is normal or slightly reduced.

Methods. The prospective population-based MrOS Sweden study included 3014 Swedish men (age 69 -81 years). On inclusion, among other factors related to mineral metabolism, intact FGF23 was measured using an ELISA (Kainos, Japan) in 2837 of the participants. Estimated glomerular filtration rate (eGFR) was calculated from cystatin C levels. 763 (27%) had eGFR< 60 ml/min. Mortality data for the whole cohort were collected after a mean of 4.5 years follow-up, 352 deaths occurred, 132 of cardiovascular cause. Using Cox proportional hazards regression, we examined if FGF23 was independently associated with all-cause and cardiovascular death.

Results. There was a significant association between FGF23 level and all-cause mortality with a hazard ratio (HR) of 1.13; 95.0 % confidence interval (CI) 1.01-1.27 per standard deviation increase in FGF23. For cardiovascular death HR was 1.44, CI 1.20-1.75. In multivariate analysis, including age, eGFR, 25OH vitamin D, albumin-corrected calcium, Pi and intact PTH, the association remained significant only for cardiovascular death: HR 1.26, CI 1.02-1.56. Conclusion. The serum level of FGF23 is associated with increased risk of cardiovascular death in elderly men. Whether FGF23 is a useful marker or a modifiable risk factor for cardiovascular mortality that can be affected by Pi-reduction or other methods are areas of further research.

**Genetic Variants That Modify the Association of Vitamin D Deficiency with Clinical Outcomes: A Candidate Gene Study** Gregory Levin,[1] Cassianne Robinson-Cohen,[1] Bryan R. Kestenbaum,[1,2] Ian H. de Boer,[1,2] Thomas J. Wang,[3] Bruce M. Psaty,[1] David Siscovick.[1] *[1]University of Washington; [2]Kidney Research Institute; [3]Massachusetts General Hospital Heart Center.*

Consistent data from prospective health studies link lower serum 25-hydroxyvitamin D concentrations with incident cardiovascular disease, fracture, cancer, and premature death. 25-hydroxyvitamin D represents available vitamin D substrate, which requires a series of metabolic steps for activation. In this study, we investigated whether variation within 6 genes involved in 25-hydroxyvitamin D metabolism modifies the association of 25-hydroxyvitamin D deficiency with the composite outcome of myocardial infarction, hip fracture, cancer, or death (gene x environment interaction). Our cohort consisted of 1,509 Caucasian participants (mean age 74 years) from the Cardiovascular Health Study. We tested 141 single nucleotide polymorphisms (SNPs) genotyped by the Illumina 370CNV BeadChip platform from genes encoding the vitamin D receptor (VDR), cubilin (CUBN), 1-alpha hydroxylase (CYP27B1), 24-alpha hydroxylase (CYP24A1), megalin (LRP2), and the vitamin D-binding protein (GC). We used Cox proportional hazards models to test for multiplicative interactions of 25-hydroxyvitamin D and SNP on the risk of composite outcome, using a false discovery rate threshold of 0.25 to account for multiple testing (no more than 25% of our reported discoveries are expected to be false positives). There were a total of 944 events during 14 years of follow-up (median 11 years). We found 6 SNPs located within CYP27B1, CUBN, and VDR that significantly modified the association of 25-hydroxyvitamin D with the combined endpoint. Each additional copy of the minor allele in these 6 SNPs was associated with an estimated 30-40% difference in the hazard ratio (all q-values <0.25, p-values between 0.002 and 0.009). These findings suggest that known associations of vitamin D deficiency with clinical outcomes vary according to genetic differences in 25-hydroxyvitamin D metabolism. If confirmed, specific genetic variants may identify individuals for whom vitamin D deficiency is associated with greatest risk of adverse events.

**The Use of Inhibitors of CYP24 To Control Secondary Hyperparathyroidism in an Adenine Induced Rat Model of CKD** Martin P. Petkovich,[1] Dominic Cuerrier,[1] Gary H. Posner,[2] Aza Kharebov,[1] Christopher Hosfield,[1] Christian Helvig.[1] *[1]Research and Development, Cytochroma Inc., Markham, ON, Canada; [2]Department of Chemistry, The Johns Hopkins University, Baltimore, MD.*

Recently, we have shown that CYP24, the cytochrome P450 enzyme responsible for catabolism of both 1,25-dihydroxyvitamin $D_3$ ($1,25(OH)_2D_3$) and its prohormonal form, 25-hydroxyvitamin $D_3$ ($25(OH)D_3$), is aberrantly over-expressed in kidney from adenine induced uremic rats, as well as, in kidney biopsy specimens from patients with chronic kidney disease (CKD) (1). These findings strongly indicate that CYP24 over-expression may contribute to the prevalence of vitamin D deficiency in CKD. Furthermore, they raise the possibility that such elevated expression of CYP24 may block kidney exposure

to vitamin D, thereby depriving it of crucial anti-inflammatory and anti-fibrotic activities, leading to accelerated progression of CKD. Current therapies, which are readily catabolized by CYP24, may be impaired in their ability to reach tissues expressing high levels of CYP24. Alternatively, we have developed and characterized a series of vitamin D-based inhibitors which target CYP24. *In vitro* studies indicate that these vitamin D analogs are potent CYP24 inhibitors ($IC_{50}$< 23 nM), that they are highly specific for CYP24 and do not activate or antagonize the vitamin D receptor. Several promising compounds, CTA091, CTA056, CTA102, CTA112 and CTA156 were evaluated in a rat adenine induced model of CKD. In single or repeat dose studies with these inhibitors, efficient reductions in parathyroid hormone could be achieved without significant increases in blood calcium levels. These studies demonstrated that blocking CYP24 activity effectively facilitated 1) the activity in target tissues of existing $1,25(OH)_2D_3$ and/or 2) the activation of $25(OH)D_3$ by residual kidney 1α-hydroxylase (CYP27B1) by increasing substrate availability. These studies show that CYP24 is a feasible therapeutic target for the treatment of secondary hyperparathyroidism associated with CKD.

**F-FC200**

**Regional Up-Regulation of 25-Hydroxyvitamin D 1a-Hydroxylase (CYP27B1) Gene Is Associated with the Pathogenesis of Ectopic Calcification in the alpha Klotho Mutant Mice** Ayako Otani, Hironori Yamamoto, Yuichiro Takei, Mina Kozai, Masashi Masuda, Shoko Ikeda, Otoki Nakahashi, Yutaka Taketani, Eiji Takeda. *Dept. Clinical Nutrition, Inst. Health Biosciences, Univ. Tokushima, Tokushima, Japan.*

Fibroblast growth factor (FGF) 23 is a critical regulator in the phosphate and vitamin D metabolism. Recent studies have revealed that alpha klotho plays an essential role in FGF23 signaling. Alpha klotho mutant (kl/kl) mice have hyperphosphatemia, hypercalcemia and hypervitaminosis D, and develop arteriosclerosis, osteoporosis and ectopic calcifications, together with short lifespan and infertility. It has been thought that these disorders are caused by high level of serum 1, 25-dihydroxyvitamin D through the up-regulation of key active vitamin D-metabolizing enzymes, 25-hydroxyvitamin D 1 alpha-hydroxylase (CYP27B1), in the kidney of kl/kl mice because these phenotypes are reversed by normalizing vitamin D homeostasis. However, it is still unclear how high-expressed CYP27B1 gene associate with the pathogenesis of ectopic calcification in kl/kl mice. In present study, we investigated the relationship between the expression of CYP27B1 and the pathogenesis of ectopic calcification in kl/kl mice. Real-time PCR and western blot analysis indicated renal cortex CYP27B1 mRNA and protein expressions were increased in 6 week old kl/kl mice compared with wild-type mice. Interestingly, immunohistochemical analysis and von Kossa staining using kl/kl tissue serial sections identified the regional high-expressed CYP27B1 in kidney cortex from 3 week old mice without ectopic calcification, in other hand, in 6 week old mice, its localization merged with calcifying renal arterioles and tubular cells in kl/kl mice. Importantly, we also found that the CYP27B1 protein accumulates in cardiac and aortic calcifying cells. In conclusion, the expression of CYP27B1 was regionally up-regulated and co-localized with calcified lesions in kl/kl mice. These results suggest that the regional overproduction of 1, 25-dihydroxyvitamin D through the up-regulation of CYP27B1 gene expression by abnormality of FGF23-klotho signaling may be implicated in the pathogenesis of ectopic calcification.

**Lack of PTH Receptor Phosphorylation Alters the Temporal Profile of the Acute Calcemic Response to PTH Analogs** Akira Maeda,[1] Makoto Okazaki,[1] Hiroko Segawa,[1] Abdul Abou-Samra,[2] Harald Jueppner,[1] John T. Potts,[1] Thomas J. Gardella.[1] *[1]Endocrine Unit, Massachusetts General Hospital, Boston, MA; [2]Wayne State University, Detroit, MI.*

Serine phosphorylation of the C-terminal of the PTHR1 plays a key role in controlling the receptor signaling and internalization responses induced by PTH ligands. A phosphorylation-deficient mutant PTHR1 (PD) exhibits defective internalization in cells, and PD-knock-in mice exhibit prolonged increases in blood cAMP after single PTH(1-34) injection, as well as frank hypercalcemia upon continuous PTH infusion (Bounoutous, 2006, Endo.). In separate work, we have developed high-affinity, N-terminally modified PTH analogs, e.g. M-PTH(1-28), that induce prolonged cAMP and robust internalization responses via the wild-type (WT) PTHR1 in cells, and prolonged calcemic and phosphaturic responses upon single injection in WT mice (Okazaki, 2008, PNAS). To explore further the relationships between PTHR1 phosphorylation/internalization and down-stream functional responses, we assessed the acute effects of PTH(1-34) and M-PTH(1-28) in PD knock-in mice. As expected, PD mice, vs. WT controls, exhibited enhanced/prolonged blood cAMP responses to both ligands. Surprisingly, however, the ionized(i)Ca response induced by either ligand was not prolonged, as compared to that induced in WT mice, and, in fact, was blunted, in that the onset of the response was delayed by 1-2h, vs. WT, and the maximum level attained was about half that attained in WT mice. For each ligand, the later-phase, 4-8h, of the iCa response induced in PD mice was similar to that observed in WT mice. The results suggest that PTHR1 phosphorylation, and potentially internalization, play key roles in mediating the rapid-phase of the iCa response induced by PTH ligands. The apparent discrepancy between the PTH-induced increases in blood iCa and cAMP, as revealed in PD mice, may be a manifestation of altered receptor internalization responses. The acute, calcium-homeostatic actions of PTH thus appear to involve multi-phasic and multi-component mechanisms of receptor signaling and trafficking, which may differ in different target tissues.

**History of Parathyroidectomy and Survival among Hemodialysis Patients with Secondary Hyperparathyroidism: Results from a Nationwide Registry in Japan** Hirotaka Komaba,[1] Masatomo Taniguchi,[2] Atsushi Wada,[2] Masafumi Fukagawa.[1] *[1]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Kanagawa, Japan; [2]Patient Registration Committee, Japanese Society for Dialysis Therapy, Tokyo, Japan.*

**Background.** Parathyroidectomy (PTx) for severe secondary hyperparathyroidism (SHPT) can dramatically reduce PTH levels and ameliorate clinical symptoms related to the disease. However, the effect of PTx on future mortality has not been adequately investigated.

**Methods.** We compared 1-yr all-cause and cardiovascular (CV) mortality between patients who underwent PTx for severe SHPT and those who did not undergo PTx despite severe SHPT (>500 pg/ml), using data on 108,151 patients on hemodialysis on December 31, 2004 obtained from the nationwide registry of the Japanese Society for Dialysis Therapy (JRDR-08001). Analysis was done using multivariate Cox regression model, adjusted for patient demographics, body mass index, serum albumin, calcium, phosphate, CRP, history of CV disease, Kt/V, dialysate calcium, and use of active vitamin D.

**Results.** Among patients without a history of PTx, higher intact PTH levels were associated with an increased risk for all-cause and CV mortality. By contrast, patients with a history of PTx (N = 5104) had a significantly lower risk for all-cause and CV mortality as compared with those who had not underwent PTx despite severe SHPT (N = 5455) (hazard ratio [HR], 0.58 [95% CI, 0.42 to 0.80] and 0.46 [95% CI, 0.29 to 0.74], respectively). The trend for lower non-CV mortality was not statistically significant (HR, 0.70 [95% CI, 0.45 to 1.08]). We also compared survival in a subcohort of patients who did (N = 3041) and did not undergo PTx despite severe SHPT (N = 3041) individually matched by patient demographics. Compared with the matched controls, patients with a history of PTx had a significantly lower risk for all-cause and CV mortality (HR, 0.68 [95% CI, 0.54 to 0.85] and 0.61 [95% CI, 0.44 to 0.85], respectively), but not significant for non-CV mortality (HR, 0.76 [95% CI, 0.55 to 1.04]).

**Conclusion.** PTx for severe SHPT may reduce the risk for all-cause and CV mortality among patients undergoing hemodialysis.

**Serum Mineral Metabolism Markers and Risk of Incident Hip Fracture: The Cardiovascular Health Study** Cassianne Robinson-Cohen,[1] Ronit Katz,[2] Ian H. de Boer,[3] David Siscovick,[4] Bryan R. Kestenbaum.[3] *[1]Epidemiology, University of Washington, Seattle, WA; [2]Biostatistics, University of Washington, Seattle, WA; [3]Nephrology, University of Washington, Seattle, WA; [4]Medicine and Epidemiology, University of Washington, Seattle, WA.*

Mineral metabolism disturbances are highly prevalent among people with chronic kidney disease. Vitamin D deficiency and hyperparathyroidism are associated with fractures in the general population. However, associations of these disturbances with long-term fracture risk are unknown in the setting of CKD. We evaluated associations of intact parathyroid hormone (PTH), 25-hydroxyvitamin D (25(OH)D) and bone-specific alkaline phosphatase (BAP, an enzyme anchored to osteoblasts that indicates bone formation), with incident hip fracture among older adults with and without CKD. We studied 2284 ambulatory participants from the Cardiovascular Health Study (mean age 74 years) who were free of known cardiovascular disease and hip fracture at baseline; 413 subjects (18.1%) had CKD defined by an estimated glomerular filtration rate <60 ml/min/1.73m2. We measured serum 25(OH)D, PTH, and BAP concentrations from previously collected samples. We used Cox proportional hazards models to evaluate associations of mineral markers with incident hip fracture. There were a total of 242 incident hip fractures during up to 14 years of follow-up (9.7 fractures per 1000 person-years). After adjustment for traditional fracture risk factors and kidney function, 25(OH)D levels <15 ng/ml were associated with increased risks of incident hip fracture among participants who had CKD (HR 2.8, 95% CI 1.2, 7.0) and those who did not (HR 1.6, 95% CI 1.0, 2.4); p-for-interaction = 0.28. PTH concentration >65pg/ml was associated with a trend to increased risk of hip fracture only among participants who had CKD (HR 1.8, 95% CI 0.8, 4.0). BAP was not associated with hip fracture. Lower 25(OH)D levels are associated with increased long-term fracture risk among older adults with CKD, suggesting that supplementation with substrate forms of vitamin D may reduce fracture risk in this population.

**Molecular Mechanism of Vitamin D Regulation of Nephrin Gene Expression** Dilip K. Deb, Zhongyi Zhang, Youli Wang, Yan Chun Li. *Medicine, The University of Chicago, Chicago, IL.*

Prolonged diabetes often damages the glomerular filtration barrier leading to proteinuria. Nephrin plays a key role in maintaining the structure of the slit diaphragm, and reduction of nephrin leads to the development of proteinuria. Our previous studies demonstrated that 1,25-dihydroxyvitamin D (1,25-VD) has renoprotective activity and is able to up-regulate nephrin expression. The aim of this study is to understand the molecular mechanism. Nephrin mRNA expression was down-regulated in podocytes exposed to high glucose (HG, 30 mM), but 1,25-VD treatment increased nephrin expression by 8-10 fold over the basal level. Vitamin D up-regulation of nephrin was confirmed by immunostaining with anti-nephrin antibodies in podocyte cultures and in kidney sections from diabetic mice

treated with vitamin D analog. In mouse nephrin gene promoter, a putative VDRE was identified at -313 bp. EMSA showed that this putative VDRE could be bound by VDR/RXR. ChIP assays with anti-VDR antibody confirmed that VDR binds to the VDRE in podocytes. Transfection of podocytes with a luciferase reporter construct containing the nephrin promoter region from -0.427 to -0.127 kb showed induction of luciferase activity upon 1,25-VD treatment, but luciferase activity was not induced by 1,25-VD with the construct containing a mutant VDRE. Together these data demonstrate that 1,25-VD up-regulates nephrin gene expression in podocytes by acting on a VDRE in the nephrin promoter. Up-regulation of nephrin contributes to the renoprotective activity of vitamin D against renal injury in diabetes.

**National Kidney Foundation Education Survey Results** Michael J. Choi,[1] Kerri L. Cavanaugh,[2] Chester H. Fox,[3] Mark A. Perazella,[4] Sandeep S. Soman,[5] Bernard G. Jaar.[1] *[1]Johns Hopkins University; [2]Vanderbilt University; [3]State University of New York at Buffalo; [4]Yale University; [5]Henry Ford Hospital.*

The National Kidney Foundation (NKF) is recognized for disseminating best available evidence-based clinical practice guidelines. The purpose of the Kidney Disease Outcomes Quality Initiative (KDOQI) Education Committee is to disseminate of kidney disease guidelines by determining educational needs, developing effective tools and identifying barriers to guideline implementation. The KDOQI Education Committee conducted an online survey to physicians and allied health professionals to assess use and opinions regarding current KDOQI guidelines, NKF educational tools, and Clinical Action Plans. Responders were asked demographic questions including profession (physician, physician extender, nurse, social worker, dietitian, pharmacist, dialysis technician, or other) and specialty. **Results:** A total of 607 nephrology providers completed the survey. Main results are outlined in the table. More non-physicians acknowledged using KDOQI guidelines in practice ($p<0.001$) and also reported satisfaction with the current density of information ($p=0.001$) than physicians/extenders. Few respondents were aware of the NKF Clinical Action Plans. **Conclusion:** This is the first national survey to assess the impact and utilization of the KDOQI guidelines by all health care professionals. Specific barriers to implementation, especially among physicians, need to be identified and addressed. A prospective study is needed to determine if improved dissemination and application of KDOQI guidelines translate into better clinical care of CKD patients.

## F-FC206

**Chronic Kidney Disease Education in the Primary Care Setting Improves Disease Prevention, Detection and Management** Cynthia R. Christiano, Melanie I. Hames, Tejas P. Desai, Hsiao L. Lai, Rachel Ward, Jessica Caroline Collins, Matthew Hojatzadeh, Karen R. Parker, Paul Bolin, Jr. *Division of Nephrology and Hypertension, Brody School of Medicine at East Carolina University, Greenville, NC.*

**Background**: The increasing prevalence of chronic kidney disease (CKD) and risk factors for CKD in the southeastern U.S. demands strategic efforts for addressing prevention and management. We hypothesize that an educational intervention targeting primary care providers will result in improved management of patients at risk or diagnosed with CKD, with the ultimate goal of reducing the number of patients who progress to end-stage renal disease (ESRD).

**Methods:** A federally funded primary care clinic was selected for educational intervention addressing kidney disease screening, prevention, and management. Nephrologists from a regional academic medical center provided educational sessions covering topics based on KDOQI clinical practice guidelines to clinic staff. Site visits were conducted weekly for 6-months and were tapered over a 3-year period. Outcome measures consisted of kidney-related prescription filling and lab ordering practices. Relevant prescriptions and laboratory tests were categorized based on their role in CKD treatment and detection. Electronic medical records were queried for data regarding the outcome measures over 18-months. Descriptive statistics were used to highlight trends in prescription filling and lab ordering practices. Paired sample t-tests were used to compare the mean filling and ordering rates between the pre-intervention and post-intervention periods.

**Results:** Preliminary data indicated a statistically significant ($p<0.05$) increase in prescription filling and in lab tests ordered for anemia, vitamin D and diabetes. Further analysis is needed to determine the impact of confounding factors on the selected outcome measures. Longitudinal observation is needed to demonstrate whether the impact on CKD prevention and management is sustainable.

## F-FC207

**Effective Chronic Kidney Disease Training Tool for Physicians** Michelle M. Estrella, Stephen Sisson, Jennifer Roth, Michael J. Choi. *Medicine, Johns Hopkins School of Medicine, Baltimore, MD.*

**Purpose:** To determine if an online module used by several U.S. training programs improved knowledge in recognition and management of chronic kidney disease (CKD). **Methods:** An online education intervention was administered yearly from July 1, 2006 to June 31, 2009 to participating U.S. internal medicine training programs. To assess baseline skills in CKD recognition and management, participants completed a pre-test. A didactic module reviewing the diagnoses and management of CKD based on the National Kidney Foundation K/DOQI guidelines and more than 30 publications was completed. The effectiveness of this module was evaluated by a post-test made available only if the didactic module was completed. Participants who did not complete the module were excluded. Pretest scores by level of training were compared using the $X^2$ test while the pre- and post-test scores were compared by paired t-tests. Two-sided P-values were calculated. **Results:** The number of participating programs and residents increased annually (see Table 1). The baseline knowledge of CKD was poor and did not differ significantly by training level (Figure 1A). Completion of the online didactic module led to an average improvement of 25-33% each year (Figure 1B). **Conclusion:** Physicians are unfamiliar with the diagnosis and management of CKD. Web-based training can be effective in the education of physicians on CKD recognition and management. A prospective study is needed to determine if knowledge gained from such an intervention translates to improved clinical care of CKD patients

## F-FC208

**Validating Peer Chart Audit in a Nephrology Fellow Continuity Clinic Setting** Leslie Thomas, Suzanne Norby. *Nephrology & Hypertension, Mayo Clinic, Rochester, MN.*

**Background:** Peer chart audit is a method of assessing the Practice-Based Learning and Improvement competency used in our nephrology training program to evaluate the ability of nephrology fellows to identify complications of chronic kidney disease (CKD). However, the accuracy of data collection by fellows had not been systematically evaluated. The purpose of this study was to determine the accuracy of data collected by nephrology fellows performing peer chart audits of continuity clinic patient records. **Methods:** Each of 12 nephrology fellows was assigned to review medical records of 10 consecutive non-dialysis patients with CKD stage 3, 4, or 5 cared for by another fellow. Seven data points were abstracted from laboratory data and visit notes: presence of a medication list and BP measurement; whether a plan was documented for BP >130/80 mmHg; whether Hgb and PTH were measured within 6 months or at the time of the visit; whether iron studies were checked if Hgb <11 g/dL; and whether total 25(OH)D2+3 levels were checked if PTH > normal. Chart audits were then repeated by the program director. **Results:** Of 120 patient records reviewed, 3 patients treated with dialysis were excluded. Collections yielded 819 data points from 117 patient records. Overall, 91% of fellow data points were accurate

although individual fellow accuracy ranged from 77-100%. Mean accuracy did not differ among 1st year fellows (90%), 2nd year fellows (93%), and 3rd year fellows (89%). Accuracy varied depending on the type of data abstracted. Accuracy of data collected on documentation of a medication list (99%) and BP measurement (100%) as well as recent Hgb measurement (100%) was high. Data abstraction for presence of a plan for BP >130/80 and recent PTH measurement were each 92% accurate. The least valid data points were determination of whether iron studies were checked if Hgb <11 g/dL and whether total 25(OH)D2+3 were checked if PTH > normal, with accuracies of 83% and 70% respectively. **Conclusions:** Use of peer chart audit appears to yield valid results (91% mean accuracy), and validity was not affected by year of training. Validity differed among the parameters assessed, with accuracy rates ranging from 70% to 100%.

Disclosure of Financial Relationships: nothing to disclose

**F-FC209**

**A Description of Nephrologist Training, Beliefs, and Practices from the National Nephrologist Dialysis Practice Survey (2010)** Dorian R. Schatell,[1] Jennifer L. Bragg-Gresham,[1] Rajnish Mehrotra,[2] Joseph R. Merighi,[3] Beth Witten.[1] *[1]Medical Education Institute, Inc., Madison, WI; [2]Los Angeles Bio Medical Research Unit, CA; [3]Boston University, MA.*

Large variation exists in nephrologists' beliefs, training, and practices for treating dialysis patients. The National Nephrologist Dialysis Practice Survey was sent to all ASN member nephrologists to better understand and quantify this variation. One goal was to elucidate areas (such as Nephrology Board exam items, training, and modality preference) where educating nephrologists could lead to better care of dialysis patients.

A 1-page fax-back survey was mailed to 6,800 U.S. nephrologists and 669 responded. An incentive of $2 per survey was donated to the American Kidney Fund. Ninety-six percent (629) of responding nephrologists reported that clinical practice as their major focus; these respondents were used in the analysis. All analysis was done using SAS 9.2.

Most (79.8%) respondents were male. Other characteristics and responses from this sample were as follows:

| | | | |
|---|---|---|---|
| *Years in nephrology practice (%):* | | *Received additional training in dialysis after completing fellowship (%)* | 16.0 |
| <4 | 12.4 | | |
| 5 - 10 | 24.0 | | |
| 11 - 20 | 25.0 | *To prepare NEW nephrologists for dialysis, how many Board exam items should focus on:* | |
| 21+ | 38.6 | Hemodialysis | 20 |
| | | PD | 12 |
| *% of week dealing with these concerns:* | | CKD | 24 |
| Acute kidney injury | 18.8 | Diabetes | 12 |
| Fluid & electrolyte disorders | 14.3 | | |
| Predialysis CKD | 31.2 | | |
| Dialysis (all types) | 28.2 | *Dialysis Modality Nephrologists would choose for themselves if they had kidney failure and a 5-year wait for transplant (%):* | |
| Transplant | 7.5 | | |
| | | Standard *in-center* HD | 6.4 |
| *How prepared did nephrologists feel to care for patients after passing Nephrology Boards (%)?* | | Nocturnal *in-center* HD | 3.0 |
| | | PD | **45.4** |
| Not at all | 2.3 | Daily *home* HD | **24.8** |
| Somewhat | 35.8 | Nocturnal *home* HD | **17.5** |
| Very well | 61.1 | Standard *home* HD | 2.9 |

Approximately 60% of nephrologists' work week was spent on dialysis and pre-dialysis CKD care. 38.1% of respondents felt somewhat or not at all prepared to care for dialysis patients after passing the Board exam; respondents recommended, on average, that a total of 68 items (28%) of Board exam items cover clinical CKD or dialysis care. Just 6.4% of nephrologists stated a preference for standard in-center HD for themselves if they had kidney failure and expected to wait 5 years for a transplant. PD was their preferred modality, though only 7.1% of US patients currently receive it (US Renal Data System: USRDS 2009 Annual Data Report. The National Institutes of Health, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD, 2009).

**F-FC210**

**Correlates with Nephrologist Beliefs about Patient Job Retention from the National Nephrologist Dialysis Practice Survey (2010)** Jennifer L. Bragg-Gresham,[1] Dorian R. Schatell,[1] Rajnish Mehrotra,[2] Joseph R. Merighi,[3] Beth Witten.[1] *[1]MEI, Inc., Madison, WI; [2]Los Angeles Bio Medical Research Unit, CA; [3]Boston University, MA.*

The Medicare ESRD Program was funded in 1972 based on the promise that dialysis patients would be employed, tax-paying citizens. This promise remains largely unfulfilled. The ESRD Networks reported that only 23% of prevalent patients ages 18-54 were employed in 2007. Nephrologists' knowledge of and attitudes toward maintaining patient employment has rarely been studied. This study was conducted to provide insights that may help to improve patient job retention.

The National Nephrologist Dialysis Practice Survey is a 1-page fax-back survey and was mailed to 6,800 U.S. nephrologists with 669 respondents. An incentive of $2 per survey was donated to the American Kidney Fund. After limiting the responses to Nephrologists in clinical practice (n=629) and removing 40 surveys with missing data, a total of 589 responses were analyzed. Logistic regression was used to assess the association between nephrologists' beliefs about job retention and: gender, years of practice, patient modalities treated, knowledge of income replaced by Social Security disability insurance (SSDI), and who requests disability forms. Analyses were done using SAS 9.2.

Just over 80% of respondents were male, and more than 99% treat in-center hemodialysis (HD) patients, either solely or in addition to other modalities. Only 6.5% of respondents knew that SSDI replaces on average 35% of prior income.

| Measure | N (%) | Agree job retention is "Very Important" (%) | Odds Ratio (p) | |
|---|---|---|---|---|
| | | | Unadjusted | Adjusted |
| *Gender (F/M)* | 117 (19.9) | 76.1 / 63.1 | 1.86 (**0.009**) | 2.08 (**0.004**) |
| *Practice Years:* | | | | |
| < 4 years | 75 (12.7) | 49.3 | 1.00 (ref) | 1.00 (ref) |
| 5 to 10 years | 143 (24.3) | 67.1 | 2.10(**0. 011**) | 1.85 (**0.04**) |
| 11-20 years | 149 (25.0) | 66.7 | 2.05(**0. 013**) | 1.89 (**0.03**) |
| 21 + years | 231 (38.0) | 69.6 | 2.36 (**0.002**) | 2.33 (**0.003**) |
| *Nephrologist sees patients with Treatment Modality (Y/N):* | | | | |
| Daily Home HD | 240 (40.7) | 68.3 / 63.9 | 1.04 (0.26) | 1.15 (0.46) |
| Nightly Home HD | 48 (8.1) | 66.7 / 65.2 | 1.01 (0.88) | 0.97 (0.93) |
| PD (all) | 498 (84.6) | 67.1 / 58.2 | 1.09 (0.10) | 1.27 (0.34) |
| Standard Home HD | 139 (23.6) | 67.3 / 65.1 | 1.03 (0.59) | 1.06 (0.79) |
| In-center HD | 585 (99.3) | 65.5 / 100.0 | 0.71 (0.15) | 0.00 (na) |
| Nightly in-center HD | 126 (21.4) | 66.7 / 65.4 | 1.01 (0.80) | 0.97 (0.91) |
| *Knew SSDI $ (Y/N)* | 38 (6.5) | 79.0 / 64.8 | 2.04 (0.08) | 1.84 (0.15) |
| *Disability forms requested by:* | | | | |
| Don't sign | 71 (12.1) | 64.8 | 0.56 (0.24) | 0.65 (0.40) |
| Patient | 333 (56.5) | 65.1 | 0.57 (0.21) | 0.55 (0.19) |
| Social Worker | 155 (26.3) | 64.2 | 0.57 (0.22) | 0.60 (0.27) |
| Other | 30 (5.1) | 76.7 | 1.00 (ref) | 1.00 (ref) |

Female nephrologists and nephrologists with more years in practice had significantly higher odds of seeing job retention as important; dialysis modalities seen and who requested disability forms were not significant. Teaching the value of job retention during nephrologist training may help dialysis patients maintain their income and lifestyle.

**F-FC211**

**Kidney Disease Screening and Awareness Program (KDSAP): A Model for Potentially Increasing Workforce in Nephrology** Eric C. Shieh,[1] Jingshing Wu,[1] Albert C. Yeh,[2] Ang Li,[1] Li-Li Hsiao.[3] *[1]Harvard College, Cambridge, MA; [2]Harvard Medical School, Boston, MA; [3]Renal Division, Brigham and Women's Hospital, Boston, MA.*

The high prevalence of chronic kidney disease (CKD) in underserved populations and the shortage of nephrologists nationwide create a gap in health care provisioning that demands attention. Solutions must aim at raising community awareness of kidney disease and increasing the renal health care workforce. Kidney Disease Screening and Awareness Program (KDSAP), a kidney health initiative started by Harvard University undergraduates, offers a promising solution. With the key objectives of providing free health screenings, increasing awareness of CKD, and providing mentorship, career, and leadership opportunities for college students, KDSAP recruits undergraduate volunteers to organize health screenings free of charge to at-risk populations. Since its founding in Nov. 2007, KDSAP has screened 1000+ people in 13 Greater Boston neighborhoods. Under the guidance of nephrologists and in collaboration with medical and high school students, KDSAP provides a needed service to local communities, while offering college students an opportunity to explore medicine and the field of nephrology. The study's aim was to assess KDSAP's potential to impact the field of nephrology from a recruitment perspective. A one-year follow-up survey completed by 27 of KDSAP's current membership of 36 students indicated that the program significantly increased students' exposure and knowledge of nephrology ($p<0.008$, 0.001, respectively). KDSAP also had a strong influence on students' perceptions of nephrology, medicine, research, public health, clinical practice, and serving the underserved. Personal interviews with members showed the program's highly positive influence on personal development in areas of leadership and teamwork. The results suggest that KDSAP can serve as a model organization to increase interest in nephrology among college students, develop student leadership skills, and enhance public awareness of CKD. Our hope is that the KDSAP model of service learning can be replicated in universities nationwide to increase workforce in nephrology and improve community renal health.

Disclosure of Financial Relationships: nothing to disclose

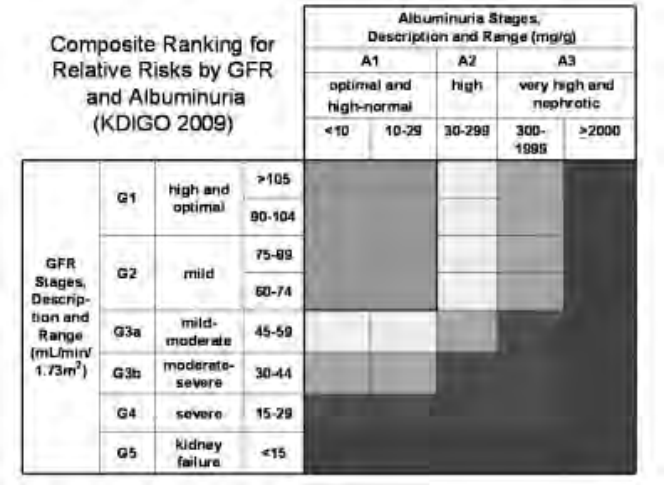
**F-FC212**

**Grouping eGFR and Albuminuria Stages into "Risk Categories" for CKD Clinical Practice Guidelines: Summary of Initial Results for the CKD Prognosis Consortium** Andrew S. Levey,[1] Ron T. Gansevoort,[2] Kunihiro Matsushita,[3] Brad C. Astor,[3] Josef Coresh,[3] Paul E. de Jong.[2] *[1]Nephrology, Tufts Medical Center, Boston, MA; [2]Nephrology, University Medical Center, Groningen, Netherlands; [3]Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

**Background:** Risk categories are often used to communicate risk and guide clinical management for chronic conditions. KDIGO initiated a collaborative meta-analysis and sponsored a Controversies Conference in October 2009 to examine the relationship of

eGFR and albuminuria to mortality and kidney outcomes. Based on analyses of 45 cohorts including 1,555,332 participants from general, high-risk and CKD populations, Conference attendees reached consensus to retain the current definition of CKD as GFR <60 ml/min/1.73 m² or ACR ≥30 mg/g, and to modify the classification by adding albuminuria stages, subdividing CKD stage 3, and emphasizing clinical diagnosis in addition to stage. Prognosis of CKD could then be assigned based on the clinical diagnosis, stage, and other key factors relevant to specific outcomes.

**Results:** Relative risks for all-cause mortality, cardiovascular disease (CVD) mortality, ESRD, AKI, and CKD progression were adjusted for demographic factors, CVD risk factors and history of CVD, and were ranked from lowest to highest. The rank was then grouped into four risk categories. Distribution of eGFR and albuminuria stages among risk categories was similar across five outcomes and three populations. The composite average ranking is shown below. Categories are identified by color (dark red for data from CKD cohorts).



**Conclusions:** The usefulness of risk categories in communication of risk and clinical management in CKD should be evaluated. Other methods of aggregating risks across outcomes and including additional outcomes of CKD should be considered.

Disclosure of Financial Relationships: Research Funding: Amgen (clinical trial agreement); Scientific Advisor: American Journal of Kidney Disease (NKF).

## F-FC213

**Differences in the Prevalence of Concurrent CKD Complications by Estimated GFR Using the CKD-EPI and MDRD Study Equations: The National Health and Nutrition Examination Survey III and 1999-2006** Lesley A. Stevens,[1] Josef Coresh,[2] Andrew S. Levey,[1] Paul Muntner.[3] *[1]Tufts Medical Center; [2]Johns Hopkins University; [3]University of Alabama at Birmingham.*

**Background** The CKD-EPI equation improves accuracy of estimation of measured GFR and mortality risk prediction compared to the Modification of Diet in Renal Disease (MDRD) Study equation. However, whether it better discriminates individuals with and without concurrent CKD complications is not well established.

**Methods** Using data from 30,528 participants, ≥ 20 years of age and eGFR 15-120 ml/min per 1.73 m² in the National Health and Nutrition Examination Survey 1988-1994 and 1999-2006, we compared the prevalence of anemia (hemoglobin < 12 g/dL for women, <13.5 g/dL for men), acidosis (bicarbonate < 22 mmol/L), hyperphosphatemia (phosphate ≥ 4.5 mg/dL) , hyperuricemia (uric acid > 8.3 mg/dl), hypoalbuminemia (albumin < 3.5 mg/dl) and hypertension ( ≥ 140/90 mmHg or antihypertensive medications) using eGFR categories from the CKD-EPI ($eGFR_{CKDEPI}$) versus the MDRD Study ($eGFR_{MDRD}$) equations .

**Results** Using $eGFR_{CKD-EPI}$ 39.1%, 26.5%, 8,4% and 3.6% participants with $eGFR_{MDRD}$ levels of 60-89, 45-59, 30-44, and < 30 ml/min/1.73m², respectively, were re-classified into higher $eGFR_{CKD-EPI}$ levels. Analogously, 1.6%, 0.4%, 1,5%, and 4.3% were re-classified into lower $eGFR_{CKD-EPI}$ levels. The table shows the prevalence of CKD complications in people with $eGFR_{MDRD}$ of 45-59 ml/min per 1.73 m² who were reclassified into a higher or lower $eGFR_{CKD-EPI}$ category. Results were consistent for reclassification from other categories.

**Conclusion** Compared to the MDRD Study equation, the CKD-EPI equation was better able to discriminate individuals with anemia, hyperuricemia, hypoalbuminemia and hypertension, but not hyperphosphatemia or acidosis.

Reclassification from $eGFR_{MDRD}$ 45-59 ml/min/1.73m²

| | eGFR -CKD-EPI ml/min/1.73m² | | | |
|---|---|---|---|---|
| | 60–89 | 45–59 | 30–44 | p-trend |
| Anemia, % | 7.7 | 13.9 | 34.7 | 0.008 |
| Hyperuricemia % | 4.5 | 9.1 | 28.1 | 0.003 |
| Hypoalbuminemia % | 0.8 | 2.6 | 6.3 | 0.013 |
| Hypertension % | 45.8 | 72.1 | 76.2 | <0.001 |
| Hyperphosphatemia% | 9.5 | 6.8 | 1.7 | 0.123 |
| Acidosis % | 10.2 | 6.4 | 1.8 | 0.063 |

## F-FC214

**NGAL Is a Differential Marker of Pediatric Nephrotic Syndrome and Its Severity** Michael R. Bennett, Kimberly Czech, Mark Mitsnefes, Prasad Devarajan. *Cincinnati Children's Hospital.*

Idiopathic nephrotic syndrome (NS) is the most common glomerular disorder of childhood. Pathology on invasive biopsy, including minimal change disease and focal segmental glomerulosclerosis (FSGS), remains the diagnostic method of choice for NS. Prognosis correlates with steroid responsiveness, from sensitive (SSNS) to resistant (SRNS). SRNS is the most common acquired cause of end stage renal disease (ESRD) in children. NGAL has shown great promise as an early diagnostic marker of AKI and has been demonstrated to be a powerful risk marker of CKD progression.

Objective: We set out to determine if urine NGAL can distinguish between patients with SRNS (FSGS), SSNS and healthy controls.

Methods: Urine and clinical data were collected from patients at Cincinnati Children's Hospital that were recently diagnosed with active nephrotic syndrome as well as healthy controls. Patients with a history of gross hematuria, active/recurrent UTI or nephrotic syndrome secondary to systemic disease were excluded. Urinary NGAL measurements were performed with a commercially available ELISA kit and normalized to urine creatinine.

Results: This study included subjects in the following three groups: biopsy-proven FSGS and steroid resistant clinical course (n=16), steroid sensitive clinical course (n=18), and normal controls (n=10). Median NGAL levels were calculated and subjected to Kruskal-Wallis One Way Analysis of Variance on Ranks and Dunn's multiple comparison test. Median NGAL was significantly ($p < 0.001$) higher in FSGS (114 ng/ml, IQR 25-571) than both SSNS (5.9 ng/ml, IQR 4.9-9.3) and healthy controls (6.5 ng/ml, IQR 4.9-9.1). NGAL was not different between SSNS and healthy controls. In FSGS patients, NGAL also demonstrated a significant ($p < 0.001$) negative correlation with glomerular filtration rate (GFR – R= -0.5), though NGAL was similar in SSNS whether patients were in relapse (n=8; NGAL 5.5 ng/ml, IQR 3.9-6.6) or remission (n=10; NGAL 7.8 ng/ml, IQR 4.8-12.6). Results did not change with NGAL corrected for urine creatinine.

Conclusion: Urine NGAL levels reliably differentiate SSNS from SRNS patients and correlate with disease severity in SRNS, but not with remission/relapse in SSNS.

Disclosure of Financial Relationships: nothing to disclose

## F-FC215

**Effecting Whole Population Improvement in Blood Pressure Control in CKD in the UK** Hannah Kilbride, Paul E. Stevens, Kushan Karunaratne, Jean Irving, Helen Hobbs, Richard W. C. Kingston, Christopher K. T. Farmer. *Kent Kidney Care Centre, East Kent Hospitals, Canterbury, Kent, United Kingdom.*

Introduction

The aims of implementation of national eGFR reporting and the inclusion of renal specific indicators in primary care incentive payments, the Quality and Outcomes Framework (QOF), were to promote identification of CKD and improved management of risk factors, especially hypertension.

Aim

To evaluate the effectiveness of renal indicators in the QOF on the management of hypertension in patients with CKD in primary care in the UK.

Methods

The study cohort comprised 7474 patients with stage 3-5 CKD identified from a primary care population of 36519 people with serum creatinine data 2 y pre- and 2 y post-QOF. Patients were separated into pre- and post-QOF groups (Pre-QOF: 1/4/2004-1/4/2006; Post-QOF: 1/4/2006-1/4/2008). Mean systolic (SBP) and diastolic (DBP) blood pressure (BP) together with antihypertensive medication were analysed in each group.

Results

Mean age was 74.5 y, 62.1% were female. 78.6% (n=5871) of the cohort were hypertensive. Diabetes mellitus and cardiovascular disease was present in 10.9% (n=811) and 16.9% (n=1264) of patients respectively. The table details BP control and prescribed antihypertensives.

| | All (n=7474) | | Hypertensive (n=5871) | |
|---|---|---|---|---|
| | Pre-QOF | Post-QOF | Pre-QOF | Post-QOF |
| Mean SBP (mmHg) | 139 ± 29 | 137 ± 25* | 147 ± 14 | 140 ± 22* |
| Mean DBP (mmHg) | 76 ± 16 | 75 ± 14* | 79 ± 8 | 76 ± 12* |
| ACE-I/ARBs (n,%) | 3766 (50) | 4697 (63)† | 3766 (64) | 4242 (72)† |
| Diuretics (n,%) | 630 (8) | 2075 (28)† | 630 (11) | 1712 (29)† |
| Betablockers (n,%) | 394 (5) | 1441 (19)† | 394 (7) | 1135 (19)† |
| Ca channel blockers (n,%) | 408 (5) | 1244 (17)† | 408 (7%) | 1059 (18)† |

* p<0.001, Student's T-Test. †p <0.001, Chi-squared test. Hypertension = BP>140/85 mmHg or on antihypertensive medication (during the pre-QOF period)

Conclusion

Population BP control markedly improved following introduction of renal indicators in the QOF, associated with a significant increase in the use of antihypertensives. Longer term follow up will establish whether or not this translates to improved outcomes in terms of progression of CKD, cardiovascular disease and mortality.

**F-FC216**

**Vitamin D Deficiency Is Associated with Renal Function Decline and with Circulating Markers of Bone and Mineral Metabolism in Chronic Kidney Disease Patients** Pablo A. Urena,[1] Marie Metzger,[2] Pascal Houillier,[3] Alexandre Karras,[3] Benedicte Stengel,[2] Marc C. Froissart.[2,3] *[1]Clinique du Landy, Saint Ouen, France; [2]INSERM U1018, Villejuif, France; [3]HEGP, Paris, France.*

Several epidemiological studies have pointed out the high incidence of vitamin D deficiency in CKD patients. However, none of these studies have assessed the factors associated with serum vitamin D levels using measured glomerular filtration rate (mGFR) in CKD patients, nor in an European population of CKD patients. We therefore used data from the NephroTest cohort, including 1026 adult patients with nondialysis-dependent CKD stages 1 to 5 and free from vitamin D supplementation, to assess occurrence and determinants of vitamin D deficiency (<15 ng/ml), as well as its association with circulating markers of bone and mineral metabolism. GFR was measured by the renal clearance of 51Cr-EDTA. As mGFR decreased from ≥60 ml/mn/1.73 m2, to 45-59, 30-44, 15-29 and <15, the percentage of vitamin D deficiency progressively increased from 28% to 39%, 39%, 46%, and 51%, respectively. The percentage of vitamin D deficiency in CKD stages 1-2 was twice as high that of a referent Parisian population. Obesity, African origin, diabetes, macroalbuminuria, hypoalbuminemia, systolic hypertension, and winter season were strongly associated with vitamin D deficiency. After ajusting for age, sexe and the above confounders, the OR(95%CI) for vitamin D deficiency significatively increased from 1.4(0.9-2.3) to 1.4(0.9-2.1), 1.7(1.1-2.7), and 2.0(1.1-3.7) with decreasing mGFR from 45-59, 30-44, 15-29, and <15 as compared with ≥60 ml/mn/1.73 m2. After excluding patients using vitamin D analogs, those with deficiency were at higher risk of ionized hypocalcemia, hypocalcitriolemia, secondary hyperparathyroidism, and high CrossLaps® levels, with OR of 2.6(1.2-5.9), 1.8(1.3-2.4), 2.8(2.0-3.9), 1.6(1.0-2.6), respectively, independent of age, sex, center, and mGFR. In conclusion, in this cohort of European CKD patients, there was a high prevalence of vitamin D deficiency, which was independently associated with mGFR levels and with higher risk of abnormalities in circulating markers of mineral metabolism.

**The Risk for Advanced Chronic Kidney Disease in Patients with Heart Diseases: A 7-Year Follow-Up in a Cohort Study in Taiwan** Jiung-Hsiun Liu,[1] Chiu-Ching Huang,[1] Shih-Yi Lin,[1] Chung-Lin Hsieh,[1] Fung-Chang Sung.[2] *[1]Divison of Nephrology and Kidney Institute, Department of Internal Medicine, China Medical University Hospital, Taichung, Taiwan; [2]Department of Public Health, China Medical University, Taichung, Taiwan.*

The incidence of chronic kidney disease (CKD) is constantly increasing in the world. There is limited information of incidence of new CKD onset with a longitudinal follow-up in patients with heart diseases. This study investigated the risk of developing CKD among patients with heart disease. From universal insurance claims data, we retrospectively identified a cohort of 26005 insured people with newly diagnosed heart disease and 52010 people with no such disease both in the 2000-2001 claims. We observed prospectively both cohorts until the end of 2007 to measure CKD incidences in both cohorts and hazard ratios (HRs) by comparison of event rates. The incidence of CKD in the cohort with heart disease was 4.1 times greater than that in the comparison cohort (39.5 vs. 9.65 per 10,000 person-years). However, the HR changed into 2.37 (95% confidence interval (CI) = 2.05 - 2.74) in the multivariate Cox proportional hazard model after controlling for sociodemographic characteristics and comorbidities. Compared with individuals aged < 40 years, the HRs for CKD ranges 2.70 to 4.99 in other age groups. Significant estimated relative risks of CKD observed in heart disease patients independently associated with hypertension (HR=2.26, 95% CI = 1.94 - 2.63) and diabetes mellitus (HR=2.44, 95% CI = 2.13 - 2.80), but not with hyperlipidemia (HR=1.13, 95% CI =0.99-1.30). This population study provides strong evidence that patients with heart disease are at an elevated risk of developing CKD. Hypertension and diabetes mellitus are also comorbidities associated with increased risk of CKD independently.

**F-FC218**

**Novel Risk Factors for Peripheral Arterial Disease (PAD) among Patients with Chronic Kidney Disease: Results from the CRIC Study** Jing Chen, Emile Mohler, Dawei Xie, Michael Shlipak, Raymond R. Townsend, Lawrence J. Appel, Dominic S. Raj, Akinlolu O. Ojo, Martin J. Schreiber, Louise Frances Strauss, Xin Wang, Jiang He, L. Lee Hamm. *Medicine, Tulane School of Medicine, New Orleans, LA.*

Patients with chronic kidney disease (CKD) have an increased risk of developing PAD compared to those with normal kidney function. We examined the cross-sectional association between novel risk factors and PAD among 3,747 participants in the Chronic Renal Insufficiency Cohort (CRIC) study. CKD patients aged 21 to 74 years with an estimated glomerular filtration rate (eGFR) of 20-70 mL/min/1.73 $m^2$ were recruited from 7 clinical centers in the US. PAD was defined as an ankle-brachial index <0.9 or history of arm or leg revascularization. Compared to those without PAD, patients with PAD (n=694) were older (62.4 vs. 57.2 years, p<0.0001), more likely to be black (49.1% vs. 40.8%, p=0.0002) and less likely to have graduated from high school (70.5% vs. 81.8%, <0.0001). PAD patients were also more likely to be current smokers (19% vs. 12%, p<0.0001), to have hypertension (93.4% vs. 84.3%, p<0.0001) and diabetes (64.7% vs. 42.5%, p<0.0001), and less likely to be alcohol drinkers (28.1% vs. 40.7%, p<0.0001) or physically active (163.1 vs. 206.8 METs/week, <0.0001). PAD patients on average had lower levels of HDL-cholesterol (45.2 vs. 48.1 mg/dL, p<0.0001) and eGFR (38.4 vs. 44.0, ml/min/1.73$m^2$, p<0.0001), but higher pulse pressure (65.6 vs. 54.5, mmHg, p<0.0001). After adjustment for these traditional risk factors, the following novel risk factors were associated with PAD (odds ratios and 95% confidence interval for one standard deviation higher level): hemoglobin A1c (1.16, 1.04-1.29), HOMA-insulin resistance (1.11, 1.02-1.20), high-sensitivity C-reactive protein (1.11, 1.03-1.20), uric acid (1.14, 1.03-1.25), fibrinogen (1.19, 1.08-1.08), and cystatin C (1.37, 1.19-1.57). These data indicate that novel cardiovascular risk factors are associated with PAD independent of traditional risk factors among patients with CKD.

**Intima and Media Thickening, Calcification and Inflammation of Different Vascular Beds in Patients with Early and Late Stages of Renal Failure** Kerstin Benz,[1] Ildiko Varga,[2] Daniel Neureiter,[3] Kerstin U. Amann.[2] *[1]Pediatrics, University of Erlangen-Nürnberg, Erlangen, Germany; [2]Pathology, University of Erlangen-Nürnberg, Erlangen, Germany; [3]Pathology, Paracelsus Medizinische Privatuniversität, Salzburg, Austria.*

Introduction:

Death from cardiovascular causes is the major cause of death in chronic renal failure (CRF) patients. While these patients have a high prevalence of classical risk factors, there is increasing evidence that atherosclerosis is different in CRF than in non-renal patients. There is a lack of data concerning the morphological characteristics of vascular changes in patients with different stages of CRF. The present study compares changes in different arterial and venous vessels between patients with early and late stages of CRF and non-renal control patients.

Methods:

Fifty patients undergoing cardiac bypass surgery were divided into 3 groups: (i) 24 control patients (creatinine <1.3 mg/dl), (ii) 14 patients with moderate CRF (creatinine 1.3-2.0 mg/dl, CKD1/2), (iii) 12 patients with endsatge CRF (creatinine >2.0 mg/dl, CKD3-5). Different vessels (A. mammaria int., aorta, subcutaneous arterioles, V. saphena) were

analysed using morphometry and immunohistochemistry for markers of inflammation (CRP,CD40,CD154) followed by univariate analysis and correlation analyses.

Results:

Media thickness and inflammation score of A. mammaria int. and aorta were sig. higher in CKD3-5 patients than in controls. Significant vascular inflammation and aortic media calcification was already present in CKD1/2 whereas calcification of aortic intima and of V. saphena was significantly more pronounced in CKD3-5 patients than in and controls. Of note, CaxP product correlated well with markers of inflammation, but not with calcification itself.

Discussion:

Early stages of CRF are already associated with local upregulation of proinflammatory molecules in the vascular wall and calcification of aortic media. These findings point to the importance of microinflammation and may shed new light on the possibly overestimated role of the CaxP for vessel calcification in CRF .

## F-FC220

**Additive Value of Renal Risk Markers in the Decision To Initiate Cardiovascular Protective Treatment** Paul Smink, Hiddo Jan Lambers Heerspink, Ron T. Gansevoort, Stephan J. L. Bakker, Dick De Zeeuw. *Clinical Pharmacology and Nephrology, University Medical Center, Groningen, Netherlands.*

*Introduction*

Guidelines recommend treatment of individuals if 10 yrs risk for cardiovascular (CV) disease is >20%, based on traditional CV risk factors. However, renal risk markers albuminuria and eGFR also predict CV disease. Aim of this study was to assess the additive value of renal risk markers beyond classical, as well as recent novel CV risk factors.

*Method*

Data from the prospective community based cohort study PREVEND, comprising 8592 subjects, were used. Risk factors were measured at baseline. Endpoints, first occurrence of CV morbidity and all cause mortality, were measured during median 7.5 years follow up. Calculated risks were extrapolated to 10 years predictions.

*Results*

During follow-up 917 events occurred. Micoalbuminuria and eGFR <60 ml/min/1.73m$^2$ predicted CV disease (HR 3.61 (95%CI 3.02-4.31) and 2.41 (95%CI 1.79-3.26), respectively). Microalbuminuria identified subjects above the threshold for treatment, irrespective of normal or elevated classical or even novel (CRP and proBNP) CV risk factors.

| | Total N=8592 | alb≤30 mg/day N=8062 | alb>30 mg/day N=503 | eGFR>60 ml/min/ 1.73m2 N=8037 | eGFR≤60 ml/min/ 1.73m2 N=464 |
|---|---|---|---|---|---|
| Total | 10.5 | 9.3 | **31.1** | 9.9 | **22.6** |
| systolic BP | | | | | |
| ≤140 | 8.1 | 7.6 | **22.9** | 7.8 | 17.6 |
| >140 | **20.3** | 17.1 | **38.6** | 19.3 | **29.4** |
| Cholesterol | | | | | |
| ≤6.5 | 9.0 | 7.9 | **29.5** | 8.2 | **26.2** |
| >6.5 | 17.2 | 15.9 | **35.5** | 17.5 | 14.9 |
| BMI | | | | | |

| non smoker | 5.5 | 4.8 | **23.4** | 5.1 | 14.4 |
| smoker | 13.0 | 11.5 | **33.4** | 12.2 | **26.4** |
| proBNP | | | | | |
| ≤125 | 8.3 | 7.7 | **21.3** | 8.2 | 12.9 |
| >125 | **29.7** | **24.9** | **60.9** | **27.7** | **41.7** |
| CRP | | | | | |
| ≤3 | 8.1 | 7.4 | **24.3** | 7.6 | 18.7 |
| >3 | 18.5 | 15.9 | **42.5** | 17.8 | **27.8** |

The additive value of low eGFR was limited to normal cholesterol ranges, BMI, smokers and elevated CRP levels.

*Conclusion*

Measurement of renal biomarkers, especially albuminuria, has additive value beyond the set of current classical and even novel biomarkers to identify those who have indication for CV protective treatment.

Disclosure of Financial Relationships: nothing to disclose

## F-FC221

**Elevated Urinary Markers of Glomerular, Proximal Tubular and Distal Tubular Injury during RAAS Inhibition Can Be Reduced by Dietary Sodium Restriction in Proteinuric Renal Disease** Maartje C. J. Slagman,[1] Ferdinand L. Nauta,[1] Femke Waanders,[1] Marc H. Hemmelder,[2] Gerjan Navis,[1] Ron T. Gansevoort,[1] Gozewijn Dirk Laverman.[1] *[1]Nephrology, UMCG, Groningen; [2]Nephrology, MCL, Leeuwarden, Netherlands.*

**Background:** High dietary sodium intake blunts the antiproteinuric response to renin-angiotensin-aldosterone-system inhibition (RAASi). This results in residual proteinuria (UP) and consequent proteinuria-induced tubulo-interstitial damage, allegedly elicited by proximal tubular uptake of leaked proteins. Dietary sodium restriction can reduce residual UP during RAASi. Whether this is accompanied by a reduction of urinary markers of glomerular, proximal tubular and distal tubular injury, is unknown.

**Methods:** In a cross-over RCT we treated 52 non-diabetic CKD patients with glomerular nephropathies (83% male, age 51±2 years, CrCl 83±6 mL/min) during two 6-week periods with lisinopril 40 mg/d (LIS), combined with a normal (189±8 mmol $Na^+$/d) and a low sodium diet (LS; 106±7 mmol $Na^+$/d; p<0.001), in random order.

**Results:** During LIS with a normal diet, UP was 1.7 [1.3-2.1] g/24h. Albuminuria and urinary excretion of glomerular markers (IgG, IgG4), proximal tubular markers (β2-microglobulin, NAG), and a distal tubular marker (H-FABP) were elevated compared to age- and sex-matched controls (n=52), and positively correlated with UP (UAE: ρ 0.98, p<0.001; IgG: ρ 0.76, p<0.001; IgG-4: ρ 0.59, p<0.001; β2MG ρ 0.42, p=0.003; NAG: ρ 0.66, p<0.001; H-FABP: ρ 0.58, p<0.001). Addition of LS diet to LIS significantly reduced UP (1.9-fold), albuminuria (2.0-fold), and all of the glomerular markers (13-23 fold), proximal tubular markers (1.2-2.9 fold), and the distal tubular marker (1.9 fold).

**Discussion:** In glomerular nephropathy patients on RAASi, UP is paralleled by elevated urinary markers of glomerular, proximal tubular and, remarkably, also of distal tubular injury. All markers decreased when dietary sodium restriction was added to RAASi. This suggests that not only the glomerulus and the proximal tubule, but also the distal tubule benefits from antiproteinuric intervention by sodium restriction.

**Relationship between Waist Circumference and Pulse Pressure in Children: National Health and Nutrition Survey (NHANES) 1988-1994 Data** Gangadarshni Chandramohan,[1,2] Kamyar Kalantar-Zadeh,[1,2] Keith C. Norris,[3] Sheena Cecille Marie Go,[1] Dulcie Kermah.[3] *[1]Pediatric Nephrology, Harbor-UCLA Medical Center, Torrance, CA; [2]Los Angeles Bio-Medical Research Institute, Torrance, CA; [3]RCMI, Charles Drew University School of Medicine, Los Angeles, CA.*

Pulse pressure (PP) is an independent predictor of cardiovascular (CV) disorders. Prevalence of obesity has been increasing steadily over the past few decades along with various CV risk factors in children. This study evaluated the association between waist circumference (WC) and pulse pressure (PP) in children. Methods: High waist circumference: WC >75th percentiles for age and gender. Wide PP: 4th quartile PP. Results: We studied clinical and laboratory data in 4667 children in the third NHANES; 6 -17 years of age, 48% males, 74% White, 36% Hispanic, 36% Black, 11% obese and 27% had high WC. PP varied with age, gender and blood pressure. Mean PP was significantly high in children with high WC compared to those with normal WC (49cm Vs. 46cm, p=<.001). Odds ratio for wide PP was significantly increased in high WC, but not with obesity as assessed by body mass index (>90th percentile for age and gender).

Odd Ratio for Wide (4th Quartile) Pulse Pressure

| Variables | Odd Ratio | 95% Confidence Interval |
|---|---|---|
| Sex (Female=1.0) | | |
| Male | 1.4 | 1.1 - 1.8 |
| Races (White=1.0) | | |
| Black | 1.2 | 1.0 - 1.6 |
| Hispanic | 0.9 | 0.7 - 1.3 |
| Waist Circumference (Normal - 1.0) | | |
| High | 1.5 | 1. 2- 1.9 |
| BMI (<95th percentile = 1.0) | | |
| ≥95th percentile | 1.2 | 1.0 - 2.2 |
| Height (<50th percentile = 1.0) | | |
| ≥50th percentile | 0.9 | 0.7 - 1.2 |
| Blood pressure (Normal = 1.0) | | |
| *High | 2.5 | 1.6 - 3.8 |

* Systolic and/or Diastolic blood pressure > 90th percentile

Conclusion: There was a significant association between high WC and PP. Since WC has a better correlation to CV risk factors, the standard guidelines for routine physical examination in children might incorporate this parameter to identify those who are at risk for CV disease. Further studies needed to substantiate this finding and its long-term cardiovascular consequences in children as they age.

Disclosure of Financial Relationships: nothing to disclose

## F-FC223

**An Early Pregnancy Urinary Proteomic Fingerprint Accurately Predicts Later Pre-Eclampsia** Matt Hall,[1,2] Paul M. Bosio,[3] Jonathan Barratt,[1,2] Karen Molyneux,[2] Susan Carr,[1] Nigel J. Brunskill.[1,2] *[1]John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom; [2]Department of Inflammation, Infection and Immunity, University of Leicester, Leicester, United Kingdom; [3]Department of Maternal Medicine, Sandwell and West Birmingham NHS Trust, Birmingham, United Kingdom.*

**Background**

Pre-eclampsia affects approximately 5% of pregnancies and is a leading cause of maternal and fetal morbidity and mortality worldwide. Abnormal placentation or placental insufficiency is central to the disease pathogenesis. Given that placentation is complete by 18 weeks gestation and proteinuria is a diagnostic criterion for the disease, we hypothesised that changes in the urinary proteomic profile early in pregnancy may be predictive of disease development.

**Methods**

We performed a prospective longitudinal study of urinary proteomics in pregnancy. Pregnant women were recruited prior to 20 weeks gestation from a high risk obstetric outpatient clinic. Urine samples were centrifuged to remove cellular debris within 30 minutes of micturition, and placed on ice until analysed by SELDI TOF MS the same day. Following delivery, patients were categorised as pre-eclampsia or normal pregnancy according to ISSHP 2001 criteria. A training sample of spectra obtained prior to 20 weeks

gestation were analysed between pre-eclampsia and normal pregnancies using an artificial neural network algorithm and multivariate non-linear regression. The model was validated by random sampling of 50 test datasets.

**Results**

Of 145 patients recruited to the study, 11 (7.6%) developed pre-eclampsia; 10 at >37 weeks gestation and one at 31 weeks. Spectral analysis of samples obtained prior to 20 weeks gestation identified a panel of 5 peaks which correctly predicted pre-eclampsia with 92% accuracy. Validation of the test datasets revealed a sensitivity of 87% and specificity of 82%.

**Conclusion**

Pre-eclampsia can be predicted by urinary proteomic profiling of spot urine samples in early pregnancy with high accuracy, before the development of any of the usual diagnostic criteria or symptoms. Early prediction of pre-eclampsia will allow focussed monitoring and tailoring of therapy to optimise maternal and fetal outcomes.

Disclosure of Financial Relationships: nothing to disclose

## F-FC224

**The Significance of Urinary Podocyte and Renin Angiotensin System in Preeclampsia Patients's Proteinuria** Gu Yong,[1] Chen Guixiang,[2] Niu Jianying.[2] *[1]Division of Nephrology, Huashan Hospital, Fudan University, Shanghai, China; [2]Division of Nephrology, The Fifth People Hospital of Shanghai, Fudan University, Shanghai, China.*

The mechanisms of proteinuria in preeclampsia is still enigmatic. We hypothesized that RAS may play an role in the regulation of podocyte injury in preeclampsia.

**Methods:** 14 preeclampsia and 14 gestational hypertension as well as 13 normal pregnant women were enrolled. Immunofluorescence microscopy using anti-podocalyxin(PCX) monoclonal antibody quantificated the urinary podocyte numbers. RAS components including Ang(1-7), Ang II and AGT in maternal serum and urine were quantified by enzyme-linked immunosorbent assay (ELISA). Urine albumin/creatinine ratio (ACR) was examined .The correlation among podocyturia, RAS components, and proteinuria were investigated. Receiver operating characteristic (ROC) curves were used to indicate reciprocal impact on sensitivity and specificity.

**Results:** Urinary levels of podocytes were significantly higher in preeclampsia than gestational hypertension [3.093(2.367, 5.658) vs. 1.405(0.71, 3.728) ] and normal pregnant women [0.523(0.012, 1.489)cells/ml of urine]. In preeclamsia group, prepartal urinary podocytes was higher than postpartum[3.093(2.367, 5.658) vs. 0.45 (0, 1.794)]. Serum and urinary Ang(1-7) in preeclampsia(53.88 ± 17.97 vs 69.99 ± 19.09 pg/ml)was significantly decreased compared to gestational hypertension (70.96 ± 19.83 vs 98.78 ± 23.99 pg/ml) and normal pregnant women(72.50 ± 20.59 vs 92.91 ± 18.04 pg/ml).Serum AGT had no difference among three groups. Urinary AGT in preeclampsia and gestational hypertension was lower than normal control (212.37 ± 35.13,193.24 ± 21.61 vs 317.10 ± 77.63 ng/L). There were positive correlation among prepartal urinary podocyte number to ACR and blood pressure. Negative correlation between prepartal urinary podocyte number and serum Ang1-7 was found. ROC curves of serum and urinary Ang(1-7) as well as podocyturia confirmed that they were useful in identifying preeclampsia.

**Conclusions:** Direct injury of podocyte may lead to proteinuria development in preeclampsia. Decreased Ang(1-7) and the renal local RAS may contributed to podocyte injury.

Disclosure of Financial Relationships: nothing to disclose

## F-FC225

**Podocyte Specific mRNA Levels Measured in Urine of Patients with Preeclampsia Are Increased Compared to Healthy Pregnant Controls** Hans J. Baelde,[1] Tim Peter Kelder,[1] Maria Elisabeth Penning,[1] Sicco Scherjon,[2] Jan A. Bruijn.[1] *[1]Pathology, Leiden University Medical Center, Leiden, Netherlands; [2]Obstetricx and Gynaecology, Leiden University Medical Center, Leiden, Netherlands.*

Preeclampsia affects 5% of all pregnancies, and is an important cause of maternal and perinatal morbidity and mortality worldwide. Podocyturia, detected with immunohistochemistry, has been noted as a specific marker for preeclampsia. The aim of this study was to quantify podocyturia in preeclamptic women using Q-PCR to detect podocyte specific mRNA transcripts.

Clean catch urine samples were collected from preeclamptic (n=34), healthy pregnant (n=34), and healthy non-pregnant (n=12) women. Preeclampsia was defined as new-onset hypertension (>140/90 mmHg) with proteinuria (>300 mg/ 24u urine) after at least 20 weeks of gestation. Patients and controls were matched for parity, amenorrhea duration, and age. mRNA was isolated and Q-PCR reaction was carried out for nephrin, VEGF, podocin, GAPDH, and GP330. mRNA levels were corrected for urine creatinine concentration. A Receiver Operating Characteristic (ROC) curve analysis was performed.

Significantly elevated mRNA expression levels of nephrin ($p<0,01$), podocin ($p<0,01$) and GAPDH ($p<0,01$) were detected in preeclamptic women compared to healthy pregnant and non-pregnant controls. Nephrin, podocin and VEGF were significantly higher in pregnant women, compared to healthy non-pregnant controls. The areas under the curve, distinguishing between preeclamptic and non-preeclamptic patients, were 0.735 for nephrin, 0.689 for VEGF, and 0.735 for podocin. GP330 expression was very low and did not show significant differences between all three groups. A positive correlation was found between nephrin and VEGF in both preeclamptic (R=0,899) and healthy pregnant women (R=0.861).

The podocyt specific slit diaphragm molecules, nephrin and podocin, seem to be reliable markers to detect podocyturia in urine samples of preeclamptic women. A strong correlation between nephrin and VEGF suggests no differential expression in podocytes between both genes in preeclamptic women. Measuring podocyturia with qPCR constitutes a novel sensitive marker to predict and detect preeclampsia.

Disclosure of Financial Relationships: nothing to disclose

## F-FC226

**Expanded Medullary Kidney Volume in Hypertensive African-Americans Is Associated with Increased Blood Flow but Reduced Medullary Oxygenation Related to Solute Transport** Stephen C. Textor,[1] Monika L. Gloviczki,[1] Michael F. Flessner,[2] David A. Calhoun,[3] James Glockner,[1] Joseph P. Grande,[1] Michael A. Mckusick,[1] Lilach O. Lerman.[1] *[1]Mayo Clinic, Rochester, MN; [2]National Institutes of Health, Bethesda, MD; [3]University of Alabama, Birmingham, AL.*

**Background:** Hypertension develops earlier and is more frequently associated with kidney disease in African-Americans (AA) than in Caucasians (C), but little is known about regional kidney volumes and oxygen (O2) consumption for these groups. **Methods:** Hypertensive subjects were treated with ACE-I/ARB and 150 mEq Na+ intake. 21 C and 16 AA subjects underwent Blood O2 Level Dependent (BOLD) 3T MR to measure R2* (deoxyhemoglobin) before and after IV furosemide. Cortical and medullary volumes and blood flows were measured with multidetector CT. GFR (iothalamate), renin (PRA) and urinary isoprostanes were also determined. **Results:** AA were younger (53±3 vs 68±3, $p<.01$) and had higher BMI (31.1±1.8 vs 27.5±0.8, $p<.05$). BP, creatinine, urinary Na+ and BP medications did not differ.

| | AA (32 kidneys) | Caucasians (42 kidneys) | |
|---|---|---|---|
| GFR/kidney (ml/min/1.73m2) | 55±3 | 46±2 | p=.02 |
| Cortical volume (cc/m2) | 50.3±2.8 | 49±2 | NS |
| Medullary volume (cc/m2) | 35.6±1.9 | 25.2±1.4 | p<.001 |
| Cortical blood flow: ml/min | 394±24 | 315±21 | p<.01 |
| Medullary blood flow:ml/min | 98±6 | 62±4 | p<.01 |
| Cortical R2* (/sec) | 17.5±0.8 | 17.9±0.3 | NS |
| Medullary R2* (/sec) | 40.4±1.1 | 36.8±1 | p<0.02 |

Basal medullary R2* values were higher in AA, but fell to similar levels after furosemide in both groups. Isoprostanes for AA correlated directly with blood flow (R=.67, p<. 02). Venous O2 did not differ between ethnic groups. Increased medullary volume and R2* persisted after allowing for age and BMI. **Conclusion:** These data demonstrate for the first time expanded medullary volume in AA subjects with higher blood flow and O2 consumption. Higher basal R2* values in AA reflected increased medullary, but not cortical, deoxyhemoglobin due to O2 consumption from loop solute transport, since furosemide eliminated the R2* difference. Increased medullary volume and O2 consumption in hypertensive, obese AA subjects may predispose to oxidative stress injury.

Disclosure of Financial Relationships: nothing to disclose

## F-FC227

**Intrarenal RAAS Activity Can Modify Circadian Blood Pressure Rhythm in Patients with IgA Nephropathy** Michio Fukuda,[1] Maki Urushihara,[2] Tamaki Wakamatsu,[1] Hiroyuki Kobori,[2] Genjiro Kimura.[1] *[1]Department of Cardio-Renal Medicine and Hypertension, Nagoya City University, Japan; [2]Department of Physiology, and Hypertension and Renal Center of Excellence, Tulane University Health Sciences Center.*

To address renal mechanism for non-dipper circadian blood pressure (BP) rhythm, we have postulated that both reduced glomerular ultrafiltration coefficient and enhanced tubular sodium reabsorption cause high sodium-sensitivity resulting in the defect in sodium excretory capacity. This in turn makes BP elevated during the night (non-dipper) in order to compensate for diminished natriuresis during daytime, thereby causing enhanced pressure natriuresis during the night. In fact, for patients with insulin resistance, diabetes mellitus, metabolic syndrome, and primary aldosteronism, non-dipper BP rhythm was noted despite preserved renal function. We also reported in patients with biopsy-proved glomerular diseases, as renal function deteriorated, nighttime BP was elevated. However, among these patients, some showed non-dipper BP rhythm even with preserved renal function. We previously showed that the intrarenal activation of renin-angiotensin-aldosterone system (RAAS), which may stimulate tubular sodium reabsorption, could be caused by the augmentation of proximal tubular angiotensinogen (AGT) expression. Therefore, this study was performed to examine whether subjects with non-dipper BP rhythm showed increased AGT expression in renal proximal tubules in patients with IgA nephropathy (n = 41, 23 females/18 males, 31 ± 11 years old). AGT protein levels in biopsied kidney samples were quantified in a semi-automatic manner by a robotic system using immunohistochemistry. The AGT expression had significant relationships with the night/day ratios of BP ($r = 0.38$, $p = 0.02$) and natriuresis ($U_{Na}V$) ($r = 0.34$, $p = 0.03$). As AGT expression was augmented in patients with IgA nephropathy, sodium reabsorption, which was reflected as a decrease in $FE_{Na}$, was enhanced ($r = 0.22$, $p = 0.20$). These data suggest that in addition to the reduced filtration capacity, the enhanced tubular sodium reabsorption may also contribute to non-dipper circadian BP rhythm in patients with IgA nephropathy.

**Uric Acid Level and Hypertension in U.S. Adolescents** Lauren F. Loeffler,[1] Edgar R. Miller,[2] Tammy M. Brady,[1] Jeffrey J. Fadrowski.[1] *[1]Pediatric Nephrology, Johns Hopkins University; [2]Internal Medicine and Epidemiology, Johns Hopkins University, Baltimore, MD.*

**Background:** Multiple studies have demonstrated an association between uric acid and cardiovascular disease in adults, and a small number of studies have examined the relationship in children. We sought to examine the association between uric acid and hypertension in a large, nationally representative cohort of U.S. adolescents.

**Methods:** We examined 6,036 adolescents 12-17 years of age who participated in the National Health and Nutrition Examination Survey (NHANES), a cross-sectional survey of non-institutionalized U.S. civilians, from 1999-2006. Using logistic regression, we analyzed the association between uric acid and hypertension, defined as a systolic (SBP) or diastolic blood pressure (DBP) ≥ the 95$^{th}$ percentile for age, gender, and height. Age, gender, race/ethnicity, BMI percentile and glomerular filtration rate (eGFR) estimated by the Schwartz formula were also included in the regression analyses.

**Results:** Cohort charteristics: mean age (SD) 14.52 (0.04) years; 49% female; 63% non-Hispanic White, 14% non-Hispanic Black, 11% Mexican American, 6% other Hispanic; mean serum uric acid (SD) 5.03 (0.03) mg/dL; 17% obese (BMI ≥95$^{th}$ percentile); mean eGFR (SD) 144.7 (0.7) mL/min/1.73m$^2$; 2.5% SBP ≥95$^{th}$ percentile, and 0.8% DBP ≥95$^{th}$ percentile. Thirty-four percent of participants had a uric acid level ≥5.5 mg/dL, which has been shown in other studies to have a high predictive value for hypertension. In fully adjusted analyses, for each increase of 0.1 mg/dL in uric acid level, participants had a 1.39 times higher odds of being hypertensive (95% CI, 1.15 to 1.60). Participants with a uric acid level ≥5.5 mg/dL had a 2.02 times higher odds of being hypertensive (95% CI, 1.37 to 3.00).

**Conclusions:** Increasing levels of serum uric acid are associated with hypertension in this large, nationally representative sample of healthy adolescents in the U.S. Uric acid may play a role in the early development of hypertension in adolescents and young adults, which may have important implications for screening and treatment in this population to prevent future cardiovascular disease.

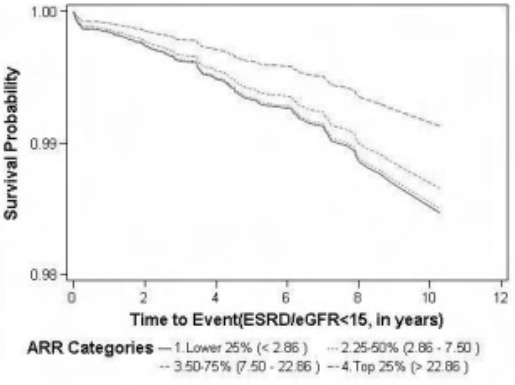
**Aldosterone to Renin Ratio (ARR) as a Predictor of Mortality and End Stage Renal Disease (ESRD)** John J. Sim,[1] Jiaxiao Shi,[1] Federico Calara,[2] Kamyar Kalantar-Zadeh,[3] Scott A. Rasgon.[1] *[1]Nephrology - Hypertension Research & Evaluation, Kaiser Permanente LAMC, Los Angeles, CA; [2]Novartis Corporation, Hanover, NJ; [3]Nephrology & Hypertension, Harbor UCLA Medical Center, Torrance, CA.*

BACKGROUND: Higher ARR is associated with resistant and refractory hypertension. We hypothesized that ARR is a predictor of death and ESRD.

METHODS: We conducted a historical cohort study within a large ethnically diverse outpatient population (>17 yrs) with minimum 1 yr follow-up and documented ARR calculated from plasma aldosterone and renin activity levels. Patients were categorized into 4 ARR quartiles based on population distribution. Medicare and hospitalization data were used to determine death, and ESRD defined as need for dialysis, renal transplantation, or eGFR<15 mL/min/ 1.73 m. Cox regression was employed to estimate hazard ratios (HR) at 2 and 5yrs after adjustment for age, gender, medication usage, hypertension, diabetes, and Charlson's comorbidity index.

RESULTS: 4,665 subjects with documented ARR had a median follow-up of 3.4yrs and an overall 10.0% mortality. Compared to the lowest quartile of ARR, the multivariate adjusted HR (95% CI) for mortality alone at 5 yr followup was 0.79 (0.61-1.02), 0.67 (0.51-0.87), and 0.71 (0.54-0.92); and HR (95% CI) for ESRD were 0.98 (0.61-1.58), 0.88 (0.55-1.42), and 0.57 (0.34-0.94) for quartiles 2, 3, and 4 respectively. Survival estimates showed a similar trend toward increased renal survival with higher ARR.



CONCLUSIONS: Higher ARR appears associated with lower mortality and a trend towards fewer ESRD outcomes. This was most pronounced in the population with high suspicion for hyperaldosteronism. Additional studies are to examine whether these associations are due to appropriate renin suppression or whether hyperaldosteronism is a disorder more amenable to treatment.

**Trends in Albuminuria under RAS Suppression** Julian Segura,[1] Cesar Cerezo,[1] Jose R. Banegas,[2] Juan J. De la Cruz,[2] Jose A. Garcia-Donaire,[1] Ton J. Rabelink,[3] Manuel Praga,[1] Luis M. Ruilope.[1] *[1]Hypertension Unit, Department of Nephrology, Hospital 12 de Octubre, Madrid, Spain; [2]Department of Preventive Medicine & Public Health, Universidad Autónoma, Madrid, Spain; [3]Department of Nephrology and Hypertension, Leiden University Medical Center, Leiden, Netherlands.*

Introduction- RAS suppression is considered as the therapy of choice, together with a strict BP control, to prevent the development and to impede the progression of albuminuria.

Objective- We have reviewed the evolution of albuminuria in a group of 1433 patients (mean age 60.5 yr; 50.3% male), arriving in our unit as a consequence of arterial hypertension with varying degrees of associated cardiovascular risk factors. All had in common the existence of previous therapy with an ACEi or an ARB for a minimum of two years before arrival in the Unit.

Results- When first seen 67.7% were normoalbuminuric (albumin-to-creatinine ratio [ACR] <10 mg/g for male, <15mg/g for female), 11.9% exhibited high-normal values of albuminuria (ACR 10-20 mg/g for male, 15-30 mg/g for female), 16.4% were microalbuminuric (ACR 20-200 mg/g for male, 30-300 mg/g for female) and 4% had macroalbuminuria (ACR >200 mg/g for male, >300 mg/g for female). At that time measured creatinine clearance was 96.8+/-49.6 and 54.1% had BP values below 140/90 mmHg. All of them were followed for three years during which RAS suppression was maintained, while BP control improved. At the end of follow-up, only 54.9% were normoalbuminuric, 16.1% presented high-normal albuminuria, 21.6% were microalbuminuric and 7.4% macroalbuminuric ($p<0.004$). The changes were seen in non-diabetic ($p<0.005$) but were more marked in diabetics with only 37.5% of patients being normoalbuminuric.

Conclusions- These results indicate that albuminuria develops in the presence of chronic RAS suppression at adequate doses and progresses continuously. Long-term RAS suppression needs to be revisited in order to control this alteration.

**F-FC231**

**Prevention of Microalbuminuria: Predictors for a Good Response to Olmesartan Treatment (ROADMAP Trial)** Hermann G. Haller,[1] Luis M. Ruilope,[4] Lars C. Rump,[3] Ton J. Rabelink,[5] Eberhard Ritz.[2] *[1]Medical School Hannover; [2]University of Heidelberg; [3]University of Düsseldorf; [4]Hospital 12 de Octubre; [5]Leiden University Medical Center.*

*Background* Microalbuminuria (MAU) is an early sign of diabetic nephropathy and increased cardiovascular risk. We investigated whether early treatment with an angiotensin receptor blocker (ARB) in diabetic subjects with normal albumin excretion delays the occurrence of MAU and analysed subgroups that would benefit most from treatment.

*Methods* We studied 4,447 subjects with type 2 diabetes and at least one additional cardiovascular risk factor in a randomized, double-blind, multicentre, controlled, and event-driven (MAU) trial. They received either 40 mg olmesartan medoxomil (OM) or placebo (Pb) od. for a median duration of 3.2 years. In both groups, additional antihypertensive treatment (except ACE inhibitors or ARBs) was used to reach the target BP of <130/80 mmHg.

*Results* Baseline UACR, eGFR, blood pressure and cardiovascular disease (CVD) risk profiles were comparable in both groups. During the double blind period, 178 (8.2%) subjects in the OM group and 210 (9.8 %) subjects in the Pb group developed MAU (time-to-onset: HR: 0.770; 95.1% CI: 0.630 to 0.941, p: 0.0104). To identify factors influencing the response to OM treatment, explorative post-hoc subgroup analysis using the corresponding median at baseline as a cut-off were performed. This analysis revealed that the treatment effect on time to onset of MAU was better in subjects with a SBP >135 mmHg than with SBP values ≤135 mmHg. The treatment effect in subjects with DBP < or > 80.3 mmHg was comparable. A baseline HbA1c ≤7.3% and an eGFR ≤83.79 ml/min. were predictors for a better response to OM treatment. Furthermore, less than 5% of patients with a baseline UACR ≤4 mg/g developed MAU during the study and the rate was similar between the OM and Pb treated patients.

*Conclusions* In subjects with type 2 diabetes olmesartan showed a significant 23% risk reduction regarding time to onset of microalbuminuria. Patients with a baseline eGFR ≤83.79 ml/min., or an UACR >4mg/g benefit most from olmesartan treatment.

**Mild Hyponatremia as a Risk Factor for Fractures: The Rotterdam Study** Ewout J. Hoorn, Robert Zietse, M. Carola Zillikens. *Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.*

INTRODUCTION: Recent studies suggest that mild hyponatremia is associated with fractures, but prospective studies are lacking. Our aim was to study whether hyponatremia is associated with fractures and, if so, whether this is mediated through falls and/or bone mineral density (BMD).

METHODS: 5208 elderly (> 55 years) with available serum sodium at baseline were included from the prospective, population-based Rotterdam Study. The following data were analyzed: BMD, vertebral fractures (mean follow-up 6.4 years), non-vertebral fractures (mean follow-up 7.4 years), recent falling, co-morbidity, medication, and mortality.

RESULTS: Hyponatremia (serum sodium < 136 mmol/L) was detected in 399 community subjects (7.7%, 133.4 ± 2.0 mmol/L). Subjects with hyponatremia were older (73.5 ± 10.3 vs. 70.0 ± 9.0 years, P<0.001), had more recent falls (23.8% vs. 16.4%, P<0.01), higher type 2 diabetes mellitus prevalence (22.2 vs. 10.3%, P<0.001), and more often used diuretics (36.9% vs. 21.3%, P<0.001). Hyponatremia was not related to BMD, but was associated with increased risk of incident non-vertebral fractures (HR=1.39, 95% CI 1.11-1.73, P=0.004) after adjustment for age, sex and body mass index. Further adjustments for disability index, use of diuretics or psycholeptics, recent falls and prevalent diabetes did not modify results. Subjects with hyponatremia also had increased risk of vertebral fractures after adjustment for all covariates (OR=1.61, 95% CI 1.00-2.59, P=0.049). Finally, all-cause mortality was higher in subjects with hyponatremia (HR=1.21, 95% CI 1.03-1.43, P=0.022).

CONCLUSION: Mild hyponatremia in the elderly is associated with increased risk of vertebral fractures and incident non-vertebral fractures but not with BMD. Increased fracture risk in hyponatremia was also independent of recent falls, pointing towards a possible effect on bone quality. This study adds to the growing body of evidence that chronic hyponatremia is not a benign condition, and suggests the need for monitoring and treatment.

**Use of Vasopressin Receptor Antagonists for Treatment of Hyponatremia: A Meta-Analysis** Leena Almarzouqi,[1,2] Lea Borgi,[1,2] Victor F. Seabra,[1,2] Ethan M. Balk,[2,3] Bertrand L. Jaber,[1,2] Nicolaos E. Madias.[1,2] *[1]Department of Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Department of Medicine, Tufts University School of Medicine, Boston, MA; [3]Center for Clinical Evidence Synthesis, Tufts Clinical and Translational Science Institute, Tufts University, Boston, MA.*

**Background:** Several clinical trials have examined the efficacy of vasopressin receptor antagonists (VRAs) for the treatment of hyponatremia.

**Methods:** We performed a meta-analysis of randomized placebo-controlled trials (RCTs) to assess the efficacy and safety of VRAs among patients with normovolemic or hypervolemic hyponatremia. We searched MEDLINE for RCTs that evaluated the use of VRAs for treatment of hyponatremia. Using a random-effects model, the primary efficacy outcome of interest was the pooled net serum sodium correction on day 2 and day 4 in the treatment group compared to the placebo group. A pooled odds ratio was also compiled for the rate of overly rapid sodium correction.

**Results:** We identified 9 RCTs (4 conivaptan, 2 tolvaptan, 2 satavaptan, 1 lixivaptan) with 933 analyzable patients. Use of VRAs achieved a pooled net increase in serum sodium concentration of 4.6 mEq/L at day 2 (95% CI 3.9, 5.6) and of 5.4 mEq/L at day 4 (95% CI 4.3, 6.4) compared to placebo. The weighted incidence rate of overly rapid sodium correction among patients treated with VRAs was 11.5% (95% CI 8.3, 15.8). Use of VRAs was associated with a 2.9-fold increased odds of overly rapid sodium correction (95% CI 1.6, 5.3) compared to placebo.

**Conclusion:** This meta-analysis indicates that VRAs for the treatment of hyponatremia are effective at raising serum sodium concentration on day 2 and day 4, but are associated with a nearly 3-fold increased risk of overly rapid sodium correction.

**Comparison of Vaptans to Urea for Long-Term Treatment of Patients with SIADH. A Prospective Study** Alain Soupart, Guy Decaux. *General Internal Medicine, Erasme University Hospital, Bruxelles, Belgium.*

**Aim of the study**

Usual treatments of hyponatremia related to SIADH consist in water restriction, oral furosemide plus NaCl or Urea. A new therapeutic option is now available with selective AVP renal V2 receptors antagonists (Vaptans). We compare the efficacy and tolerance of Vaptans to Urea in patients with SIADH during a 2 years consecutive period. Twelve patients with chronic hyponatremia of were treated first with oral Vaptans (Satavaptan 5 to 25 mg/day or Tolvaptan 30-60 mg/day) for one year. After an 8 days drug-holiday, they received urea (15-30 g/day) for one additional year.

| | TREATMENT | DURATION | ONE | YEAR | 8 DAYS | ONE | YEAR |
|---|---|---|---|---|---|---|---|
| | Basal (n=2) | Basal | Vaptans | Vaptans | Drug Holiday | Urea | Urea |
| N | SNa | SUrea | SNa* | SUrea* | SNa | SNa* | SUrea* |
| 1 | 124 | 41 | 131 +/- 3 | 52 +/- 5 | 123 | 133 +/- 4 | 106 +/- 35 |
| 2 | 122 | 23 | 136 +/- 0.4 | 29 +/ - 2 | 120 | 138 +/- 2 | 93 +/- 15 |
| 3 | 125 | 23 | 133 +/- 1 | 48 +/- 5 | 131 | 134 +/- 2 | 52 +/- 9 |
| 4 | 121 | 25 | 139 +/- 1 | 34 +/- 2 | 130 | 135 +/- 1 | 41 +/- 9 |
| 5 | 120 | 23 | 134 +/- 2 | 40 +/- 8 | 116 | 131 +/- 1 | 101 +/- 25 |
| 6 | 131 | 41 | 136 +/- 1 | 63 +/- 2 | 126 | 137 +/- 1 | 56 +/- 6 |
| 7 | 123 | 18 | 134 +/- 1 | 22 +/- 4 | 125 | 131 +/- 6 | 42 +/- 3 |
| 8 | 129 | 28 | 137 +/- 1 | 52 +/- 4 | 130 | 138 +/- 2 | 74 +/- 5 |
| 9 | 130 | 28 | 140 +/- 2 | 36 +/- 6 | 132 | 134 +/- 4 | 49 +/- 6 |
| 10 | 128 | 21 | 141 +/- 1 | 24 +/- 1 | 133 | 137 +/- 2 | 44 +/- 17 |
| 11 | 125 | 25 | 129 +/- 0.8 | 31 +/- 1 | 131 | 133 +/- 2 | 48 +/- 6 |
| 12 | 124 | 19 | 141 +/- 1 | 23 +/- 4 | 124 | 135 +/- 4 | 35 +/- 2 |
| Mean values | 125 +/- 3 | 26 +/- 7 | 135 +/- 3 | 37 +/- 13 | 126 +/- 5 | 135 +/- 2 | 61 +/- 25 |

*Mean value of 6 data collected over one year. SUrea: mg/dl (+/-SD)

**Results**

One patient treated with Urea develops one episode of hypernatremia (155 mEq/l) when admitted for pneumonia and completely recovered. Another patient falled during the drug-holiday period and broke her wrist. One patient stopped Vaptan because of excessive thirst. Urea shows similar efficacy than Vaptans for treatment of chronic SIADH. Tolerance is good in both groups.

Disclosure of Financial Relationships: nothing to disclose

**KCNJ10: Report of a New Family with SeSAME Syndrome and Potential Role in the Maturing Tubule** Ute I. Scholl,[1] Haatal B. Dave,[2] Ming Lu,[1] James Listman,[2] Richard P. Lifton.[1] *[1]Genetics, Yale University School of Medicine, New Haven, CT; [2]Pediatrics, SUNY Upstate Medical University, Syracuse, NY.*

We have recently reported four families with a novel autosomal recessive Mendelian disorder characterized by seizures, sensorineural deafness, ataxia, mental retardation, and electrolyte imbalance (SeSAME, Scholl et al. 2009). Independently, this disease was described as EAST syndrome in two kindreds (Bockenhauer et al. 2009). All patients had mutations in the *KCNJ10* gene, which encodes an inward rectifier potassium channel (Kir4.1) expressed in brain, inner ear, and kidney.

We here report a seventh family with four siblings clinically diagnosed with SeSAME syndrome. Using DNA sequencing, heterologous expression, electrophysiology and confocal microscopy, we identify and characterize a novel *KCNJ10* mutation (T57I). This residue is conserved from invertebrates to humans. Heterologous expression of the mutant channel in *Xenopus* oocytes revealed that is was non-functional despite adequate surface expression. We studied the clinical presentation of the four affected children to refine the spectrum of abnormalities resulting from *KCNJ10* mutations. Only two children showed evidence of sensorineural hearing loss. One subject developed brain MRI findings consistent with excitotoxicity following a seizure event.

The electrolyte abnormalities in SeSAME syndrome (hypokalemic alkalosis, hypomagnesemia) closely resemble that of Gitelman syndrome. This syndrome is caused by mutations in the NaCl cotransporter NCCT in the distal convoluted tubule (DCT). Kir4.1 is essential for DCT salt reabsorption; it recycles $K^+$ for the $Na^+$-$K^+$-ATPase. While patients with Gitelman syndrome typically manifest symptoms in early adolescence, it is unclear whether electrolyte imbalance is present earlier. Seizures in our SeSAME patients necessitated early electrolyte studies. Interestingly, hypokalemic alkalosis and hypomagnesemia were absent or mild early in life and deteriorated with age, raising the question whether the relative impact of DCT salt reabsorption increases with age.

Our report describes a novel *KCNJ10* mutation in SeSAME syndrome and points to a potential change of DCT function in the maturing tubule.

**F-FC236**

**Long-Term Neutralization of Diet-Induced Acid Load by Kcitrate Increases Bone Density in Elderly Subjects with Normal Bone Mass: Results of a 2 Year Placebo-Controlled Trial** Sigrid Jehle, Reto Krapf. *Department of Medicine, Kantonsspital Bruderholz, University of Basel, Bruderholz/Basel, Switzerland.*

The dietary acid-loads typical of the Western diet are postulated to decrease bone mass in humans and to contribute to the current osteoporosis epidemy. However, human intervention studies (long-term neutralization of dietary acid loads) on bone mineral density by DEXA (BMD) have yielded controversial results. To resolve this issue, 201 subjects healthy, elderly subjects [69.1 ± 3.3 yrs] of both genders [female 61 %, male 39 %)] with normal baseline BMD (t-score L2-L4 = -0.6) were enrolled in a DBPRT and received either 60mmol Kcitrate as base or placebo daily for 2 yrs. The 2 groups did not differ in any of the baseline parameters. Primary endpoint was the intergroup difference in bone density by DEXA (Lunar DPXL) and by quantitative CT (uCT, SCANCO Medical) at 24 mo. Results are summarized in table 1.

% Changes in bone density by DXA and μCT at different sites

| | Month 12 | | Month 18 | | Month 24 | |
|---|---|---|---|---|---|---|
| | %ΔPlacebo | %ΔKcitrate | %ΔPlacebo | %ΔKcitrate | %ΔPlacebo | %ΔKcitrate |
| Lumbar BMD | -0.4 | +1.2 | -0.2 | +1.5 | -0.04 | +1.8** |
| Hip BMD | -0.6 | +0.5* | -0.7 | +0.5* | -1.3 | +0.7** |
| Tot Body BMD | -0.5 | +0.3* | -0.7 | +0.3** | -0.8 | +0.6** |
| Radius R BMD | -0.8 | +1.0* | -1.0 | +1.4** | -1.0 | +1.6* |
| Radius L BMD | -1.2 | +1.0** | -1.2 | +1.1* | -1.3 | +1.5** |
| Radius R μCT | -0.8 | +1.1** | -0.7 | +1.1** | -0.7 | +1.4** |
| Radius L μCT | -0.02 | +1.1** | -0.1 | +1.2** | -0.1 | +1.3** |

*p<0.05, ** p<0.001 for intergroup comparison

Kcitrate induced a significant and sustained increase of bone density at all sites by either method. Furthermore, the increases in density analysed by the 2 methods were of the same magnitude at comparable sites (radius).

In conclusion, long-term neutralization of diet-induced acid loads by K citrate significantly increased bone density in this elderly population.The increase occurred in subjects with normal bone mass and, therefore, is evidence for a quantitatively important role of K citrate in preventing and even treating age-associated decreases in bone mass.

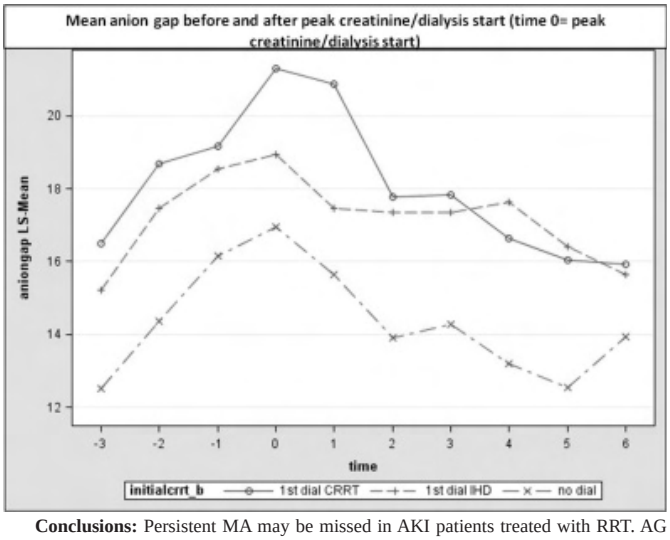
**Assessment of Metabolic Acidosis in Critically Ill Patients with Acute Kidney Injury (AKI)** Rolando Claure-Del Granado,[1] Etienne Macedo,[1] Sharon Soroko,[1] Glenn M. Chertow,[2] Jonathan Himmelfarb,[3] T. Alp Ikizler,[4] Emil P. Paganini,[5] Ravindra L. Mehta.[1] *[1]University of California, San Diego; [2]Stanford University School of Medicine; [3]Kidney Research Institute, University of Washington; [4]Vanderbilt University Medical Center; [5]Cleveland Clinic Foundation.*

**Background:** RRT is often used to manage complex acid base disorders particularly metabolic acidosis (MA) in critically ill pts with AKI. $HCO^3$ and pH values are commonly used to assess response and evaluate effectiveness of RRT, however may not recognize persistence MA. We assessed the utility of anion gap (AG) to characterize MA in ICU pts with AKI. We hypothesized that AG would identify persistent MA despite correction of pH and $HCO^3$. **Methods:** We analyzed data from 363 critically ill pts with AKI from 5 centers included in the PICARD study. We assessed the presence of MA using the pH, $HCO^3$, the anion gap (AG) during the first 7 days of ICU admission. The course of MA was compared between patients who did and did not require RRT. **Results**: Day of peak creatinine (time 0) values of $HCO_3$ were 23.3±5.3 (no RRT) , 20.3±5.4 (CRRT), and 20.3±5.5 (IHD); pH 7.38±0.1 (no RRT), 7.34±0.1 (CRRT) and 7.34±0.1 (IHD); AG 17.1±5.5 (no RRT), 19.8±6.4 (CRRT), IHD 19.3±4.8 (IHD). CRRT and IHD were equally effective in correcting levels of pH, $HCO^3$, and AG at 48hrs, 72hrs and at day 6 after RRT initiation ($p > 0.05$) (Figure 1). pH and $HCO^3$ levels normalized at 48 and 72hrs respectively; while AG showed improvement after 24 hours of therapy, but still did not reach normal values after 72hrs of treatment.



**Conclusions:** Persistent MA may be missed in AKI patients treated with RRT. AG provides a simple method to evaluate the effectiveness of RRT to correct MA and should be calculated as part of the assessment of dialyzed patients.

## F-FC238

**Prevalence of Acidosis in Intensive Care Unit (ICU) Patient's on Continuous Renal Replacement Therapies (CRRT): Classical Versus Stewart's Approach?** Paolo Lentini,[1-2] Vincenzo Catena,[1] Monica Baccarin,[1] Luca Zanoli,[1] Alexandra Chronopoulos,[3] Massimo De Cal,[2-3] Valentina Pellanda,[1] Claudio Ronco,[3] Marco Baiocchi,[1] Roberto Dell'Aquila.[1] *[1]Nephrology-Intensive Care, St. Bassiano Hospital, Bassano Del Grappa, Italy; [2]University of Padua, Padua, Italy; [3]Nephrology, St Bortolo, Vicenza, Italy.*

Acid-base disorders are common in the ICU and are indications for CRRT. If the perturbations are unrecognized they may result in poor outcomes. The Stewart approach may be superior for acid-base analysis in the critically ill. AIM: Assessment of correlation and agreement between Classical versus Stewart approaches for the analysis of acid-base disturbances during CRRT. Materials and Methods: We enrolled 19 consecutive adult patients on CVVH and mechanical ventilation. All patients received a ≥35 ml/Kg/h infusion of a standard buffer [5 Litres (mmol/L): [HCO-3]35, [Na+]140, [K+]2, [Ca2+]1,75, [Mg+]0.5, pH 7,4]. We calculated [HCO-3] and SBE with the Henderson- Hasselbach and Siggaard-Andersen equations. Based on the SBE, metabolic status was classified as acidosis (SBE -5.0), normal (SBE -4.9 to 4.9) or alkalosis (SBE +5.0). Physicochemical analysis was performed using the Stewart equations modified by Figge et al. The apparent strong ion difference was calculated: SIDa =[Na+]+[K+]+[Mg+]+[Ca2+]-[Cl-]-[lactate](mEq/L). The normal variation for SIDa was defined as 40–42 mEq/L. The effective SID (SIDe) was then calculated: SIDe = 1000x 2.46 x 10-11 xPaCO2/(10-pH)+[alb]x(0.123 x pH-0.631)+[PO4-] x(0.309xpH-0.469)(mEq/L). Normal variation for SIDe was defined as 38–42 mEq/L. Chi square test was used at 0,6,12,and 24h after CVVH to compare the prevalence of acidosis detected with pH vs. SIDe and BE vs.SIDe. RESULTS: The prevalence of acidosis after CVVH, as assessed by pH vs. SIDe, was [36.8% vs. 94.7% ($p<0.001$)] at 6h, 21.1% vs. 73.7% ($p<0.05$)] at 12h, and [21.1% vs. 98.6% ($p<0.001$)] at 24h. The prevalence of acidosis after CVVH, as assessed by SBE vs.SIDe, was [57.9%vs.94.7%($p<0.05$)] at 6h,[63.2% vs.73.7% (p=NS)]at 12 h,and [63.2% vs.98.6%($p<0.05$] at 24h. CONCLUSION: Stewart approach seems to be more sensitive than Classical approach for detection of acidosis in ICU patients on CRRT.

**Role of KLF15 in Podocyte Differentiation** Ruijie Liu,[2] Sandeep K. Mallipattu,[1] John C. He.[1, 2] *[1]Medicine/Nephrology, Mount Sinai School of Medicine, New York, NY; [2]Medicine, James J. Peters VA Medical Center, Bronx, NY.*

We have shown previously that retinoic acid (RA) induces podocyte differentiation via stimulation of cAMP/PKA/CREB pathway. However, it remains unknown what are the transcription factors mediating the effects of RA on the expression of podocyte differentiation markers. To address this, we performed microarray studies in podocytes incubated with or without RA for 6 hours. By computational analysis, we found that KLF15 was highly stimulated by RA in podocytes and is a CREB-target gene. KLF15 is known as a kidney-enriched Kruppel-like factor and was found to mediate differentiation of adipocytes. We confirmed that RA stimulates 2-3 fold increase of KLF15 by both real-time PCR and western blot in conditionally immortalized murine podocytes. We have reported previously that HIV infection induces podocyte dedifferentiation. Here, we found that HIV-infection suppressed KLF15 expression and over-expression of KLF15 stimulated expression of synaptopodin in HIV-infected murine podocytes. KLF15 expression was also suppressed in glomeruli of HIV-1 transgenic mice where podocytes undergo significant dedifferentiation. In addition, we confirmed these findings in human podocytes. We found that RA stimulated KLF15 expression in conditionally immortalized human podocytes with a peak level of 2 hours indicating that KLF15 is an early inducible gene. Expression of KLF15 was low at 33oC when podocytes were de-differentiated and high at 37oC when podocytes were differentiated. Finally, KLF15 knockout mice exhibited 2 fold increase of albuminuria with significant mesangial expansion and focal foot process effacements under EM. These data suggest a critical role of KLF15 in mediating podocyte differentiation.

**Primary HIV Injury in a Fraction of Podocyte Population Triggers Secondary Injury in the Remaining Population throughout the Whole Glomerulus, Leading to Global Sclerosis: Evidence from a Mosaic Murine Model** Taiji Matsusaka,[1] Iekuni Ichikawa.[2,3] *[1]Department of Internal Medicine, Tokai University School of Medicine, Isehara, Kanagawa, Japan; [2]Department of Pediatrics, Vanderbilt University Medical Center, Nashville, TN; [3]Department of Bioethics, Tokai University School of Medicine, Isehara, Kanagawa, Japan.*

In female placental mammals, one of the two copies of X chromosome, either of paternal or maternal origin, is randomly inactivated. Using HIV-1 transgenic mice, which carry nephrin-vpr gene on X chromosome, we tested the hypothesis that progression of glomerulosclerosis involves spread of injury from podocytes targeted by a primary insult into non-targeted podocytes. As expected, all hemizygous male vpr mice (n=13) developed moderate to severe nephropathy at 8 weeks of age. Nephrin immunostaining was markedly downregulated with scores averaging 3.47±2.29 on 0 (complete loss) to 8 (normal) scale. Immunostaining revealed that all podocytes express the transgene in intact glomeruli. In contrast, biopsy specimens obtained from heterozygous female vpr mice at 6 weeks (n=27) showed no injury. At this time point, approximately 50% of podocytes randomly expressed the transgene within each glomerulus. At 9 weeks of age, heterozygous female

vpr mice (n=7), showed only mild nephropathy with nephrin scores averaging 7.18±0.97. Later, 17 out of 28 female heterozygotes died at 13-25 wks. Histological analysis in the remaining surviving mice showed that 6 had extensive global sclerosis with near complete loss of nephrin staining, and the other 5 showed only moderate sclerosis. In the non-sclerotic glomeruli, the number of WT-1 positive, i.e., intact, podocytes (7.7±3.0) was not largely changed from that at 6 wks of age (8.6±3.1); however, unlike at 6 wks, none of the podocytes showed transgene expression. These indicate that vpr expression in 50% of podocyte population is mostly sufficient to induce global sclerosis by spreading damage into the entire podocyte population. However, through mechanisms yet to be identified, under certain circumstances, the glomerulus, hence the mouse, is capable of escaping from sclerosis by suppressing transgene expression in podocytes.

**Activated PECs Are Crucially Involved in the Segmental Scar Formation in Classical FSGS** Bart Smeets,[1,2] Christoph Kuppe,[1] Eva Maria Sicking,[1] Peggy Jirak,[1] Wilhelm Kriz,[5] Jack F. Wetzels,[3] Jurgen Floege,[1] Marcus J. Moeller.[1] *[1]Nephrology and Clinical Immunology, Univerity Hospital Aachen, RWTH, Aachen, Germany; [2]Patholoy, RUNMC, Nijmegen, Netherlands; [3]Nephrology, RUNMC, Nijmegen, Netherlands; [4]Cellular and Molecular Pathology, DKFZ, Heidelberg, Germany; [5]Anatomy and Developmental Biology, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany.*

Focal and segmental glomerulosclerosis (FSGS) is a common histopathological finding in human biopsies and a major cause for end-stage renal disease. Loss of podocytes beyond a certain threshold triggers the formation of a classical FSGS lesion. So far, the pathogenesis of the formation of a classical FSGS lesion is not completely resolved.

Previously, we have made the observation that activated parietal epithelial cells (PECs) invade the glomerular tuft in a segmental pattern. To resolve whether PECs play a critical role in the pathogenesis of FSGS lesions, PECs or podocytes were specifically tagged in experimental mice in an irreversible fashion. Subsequently, the mice were uninephrectomised and treated with DOCA/salt to induce FSGS lesions within the remnant kidney.

Analysis of the histological findings revealed the following sequence of events: 1. A primary injury results in the formation of an adhesion between the glomerular tuft and Bowman's capsule. 2. PECs are focally activated. Subsequently, PECs proliferate and migrate onto the glomerular tuft via the adhesion. 3. PECs invading the glomerular tuft migrate onto the glomerular podocytes destroying the microanatomy of the affected glomerular segment and depositing extracellular matrix. Podocytes are displaced in this process and disappear from the lesion. The adhesion as an entry site for activated PECs also explains the focal and segmental character of the classical FSGS lesion.

Genetic tagging of PECs allowed to identify the origin of these cells even after prolonged periods of time or trans- or dedifferentiation. The sequence of events resulting in a segmental glomerular scar was also verified in other FSGS models as well as in human biopsy material.

In summary, we propose a novel theory for the pathogenesis of FSGS.

**F-FC242**

**Aggravated Phenotype of Preeclampsia in Mice Lacking eNOS** Nobuyuki Takahashi,[1] Feng None Li,[1] Nobuyo Maeda,[1] Oliver Smithies,[1] S. Ananth Karumanchi,[2] J. Charles Jennette.[1] *[1]Pathology, University of North Carolina at CH, Chapel Hill, NC; [2]Department of Medicine and the HHMI, Harvard Medical School, Boston, MA.*

Preeclampsia is pregnancy-associated hypertension with proteinuria. Excess sFlt-1, an endogenous VEGF inhibitor of placental origin has been implicated to cause hypertension, proteinuria and glomerular endotheliosis, all features of preeclampsia. sFlt-1 antagonizes VEGF and induces endothelial dysfunction via several pathways including decreased eNOS. Human eNOS polymorphisms leading to low NO production are associated with preeclampsia. We tested whether a decrease in eNOS causes aggravation of preeclampsia using eNOS knockout mice. eNOS-/- mice have higher systolic blood pressure (BP) than wild type (WT) mice (144.2 ± 3.3 mmHg vs. 126.0 ± 2.6 in WT). Adenoviral mediated sFlt-1 overexpression to the non-pregnant female mice increased BP of both eNOS-/- and WT mice (171.5 ± 7.9 mmHg vs. 153.2 ± 5.2 in WT). eNOS-/- sFlt-1 mice showed higher daily urinary albumin excretion (490.1 ± 73.1 mg/day vs. 180.4 ± 67.8 in WT sFlt-1) and lower GFR (129 ± 34 ml/min vs. 405 ± 125 in WT sFlt-1). eNOS-/- sFlt-1 mice had less glomerular open capillary volume (13.5 ± 2.4 % vs. 34.7 ± 8.5 % in WT sFlt-1 mice), and lost fenestration of glomerular capillary endothelial cells, suggesting eNOS-/- sFlt-1 mice have more severe endotheliosis than WT sFlt-1 mice. eNOS-/- sFlt-1 mice also show podocyte effacement. Expression of endothelin-1 and $ET_A$ receptor in the kidney was higher in eNOS-/- sFlt-1 mice than in WT sFlt-1 mice. An $ET_A$ receptor antagonist sulfisoxazole (1g/kg/day) decreased urinary albumin excretion, and increased glomerular open capillary volume more in eNOS-/- sFlt-1 mice than in WT sFlt-1 mice. Sulfisoxazole also improved endothelial fenestration and corrected podocyte effacement in eNOS-/- sFlt-1 mice. We conclude that reduced maternal eNOS/NO exacerbates preeclampsia through activation of ET system.

**Bacterial CpG-DNA Accelerates Alport Glomerulosclerosis by Inducing a M1 Macrophage Phenotype and TNF-α-Mediated Podocyte Loss** Mi Ryu,[1] Oliver Gross,[1] Hans J. Anders.[1] *[1]Medizinische Poliklinik, University of Munich, Munich, Germany; [2]Department of Nephrology, University of Goettingen, Goettingen, Germany.*

Loss of function mutations in the a3 or α4 chain of type IV collagen (COL4) cause Alport nephropathy which is characterized by progressive glomerulosclerosis. The mechanisms that determine disease progression remain unclear. We found that the progression of kidney disease in *Col4a3*-deficient mice is associated with an influx of immune cell subsets including non-activated macrophages. We hypothesized that immune recognition of bacterial products would accelerate Alport nephropathy by enhancing intrarenal inflammation.

Exposure to bacterial endotoxin from week 4 to 6 of age did not affect disease progression while an equipotent dose of cyrosin-guanosin (CpG)-DNA accelerated all aspects of Alport nephropathy and reduced the overall life span of *Col4a3*-deficient mice. This effect of CpG-DNA was associated with a significant increase of renal CD11b+/$Ly6C^{high}$ macrophages, intrarenal production of iNOS, TNF-α, IL-12, and CXCL10, and loss of podocytes. TNF-α was essential for acceleration of Alport nephropathy because etanercept entirely abrogated the CpG-DNA effect.

Together, non-activated macrophages accumulate during Alport nephropathy. Systemic exposure to CpG-DNA induces classically-activated (M1) macrophages which enhance intrarenal inflammation and disease progression, e.g. via the secretion of TNF. Thus, factors that modulate the phenotype of renal macrophages can affect the progression of Alport nephropathy, and potentially of other types of chronic kidney diseases.

**Inducible Expression of Constitutively Active TGF-beta Receptor Type 1 Transgene in Tubular Epithelia Causes Progressive Tubular Degeneration and Tubulointerstitial Fibrosis** Shaolin Shi, Taoran Zhang, Erwin P. Bottinger. *Nephrology/Medicine, Mount Sinai School of Medicine, New York, NY.*

TGF-β is considered a key mediator for renal tubular injury in various kidney diseases, however, the initiating pathomechanisms and cellular targets remain poorly understood. To define precisely the consequences of ligand-independent, epithelial-restricted activation of TGF-β receptor type 1 (Tgfbr1) signaling in mouse nephrons, we generated bi-transgenic Pax8-rtTA/Tgfbr1(AAD) mice carrying mutant Tgfbr1(AAD) (constitutively active form of Tgfbr1) and Pax8-rtTA (reverse tetracycline-depedent transactivator under control of Pax8 promoter) transgenes for doxycycline-inducible expression of Tgfbr1(AAD) in renal tubules. The bi-transgenic Pax8-rtTA/Tgfbr1(AAD) mice manifested rapid loss of body weight, anuria, and death within 10 days of doxycycline treatment. Renal histopathology revealed global loss of tubules and massive tubulointerstitial fibrosis, demonstrating that TGF-β signaling in tubular epithelia is sufficient to trigger progressive nephron loss and tubulointerstitial fibrosis. Detailed experiments to characterize the time course and reversibility of molecular signals and cellular responses in nephrons of Pax8-rtTA/Tgfbr1(AAD) mice are in progress and will provide novel insights into signaling networks and cellular mechanisms that mediate tubular injury and tubulointerstitial fibrosis induced by epithelial TGF-β signaling.

**F-FC245**

**Conditional Knock Down of Renal Epithelial ADAM17 Reduces Ischemia/Reperfusion Injury in Mice** Gemma M. Mulder,[1] Wynand B. W. H. Melenhorst,[1] Johanna Wam Celie,[2] Niels H. Huizing,[1] Jan-Luuk Hillebrands,[1] Marc Seelen,[3] Dorien J. M. Peters,[4] Lydia Visser,[1] Harry Van Goor.[1] *[1]Pathology, UMC Groningen, Groningen, Netherlands; [2]Pathology, AMC, Amsterdam, Netherlands; [3]Nephrology, UMC Groningen, Groningen, Netherlands; [4]Human Genetics, Leiden UMC, Leiden, Netherlands.*

Ischemia/reperfusion injury (IRI) plays a major role in the pathophysiology of interstitial fibrosis and tubular atrophy (IF/TA). EGF receptor is crucially involved in the response to ischemia, and knock down of its ligand HB-EGF protects against early IRI. ADAM17 (TACE) sheds various EGF receptor ligands. We investigated ADAM17 in human IF/TA and in experimental IRI.

We studied expression of ADAM17 mRNA in IF/TA and control kidneys by RT-PCR and in situ hybridization. Moreover, we assessed ADAM17-mediated HB-EGF shedding in cultured human kidney (HK2) cells. Using Cre-Lox technology, we selectively knock down ADAM17 in renal tubular epithelial cells to examine its contribution to IRI.

ADAM17 mRNA was seven-fold upregulated in IF/TA when compared with control kidneys ($P<0.001$). In normal kidneys, ADAM17 mRNA was weakly expressed in proximal tubules, peritubular capillaries, glomerular endothelium and parietal epithelium. In IF/TA, tubular, capillary and glomerular ADAM17 expression was strongly enhanced with *de novo* expression in the mesangium. Furthermore, we observed colocalization of ADAM17 protein with HB-EGF protein in interstitial fibrotic lesions.

*In vitro*, PMA stimulation induced a 4-fold increase in HB-EGF shedding compared with baseline conditions. Inhibition of ADAM17 with TNF484 resulted in a dose-dependent reduction of HB-EGF shedding, up to 82% in PMA-stimulated cells ($P<0.005$) and 53% in non-stimulated cells ($P<0.005$). Compared with WT mice, conditional ADAM17 KO

mice showed strong reduction in cortical tubular ischemic damage after 6h (4.05±1.55 vs 11.24±2.80, KO vs WT resp), 1d (6.25±3.67 vs 23.6±5.95, KO vs WT resp) and 3d of reperfusion (12.24±5.55 vs 30.97±5.62, KO vs WT resp, P<0.05).

In conclusion, ADAM17 inhibition reduces cortical tubular damage in experimental IRI, indicating a modulating role for ADAM17. Pharmacological ADAM17 inhibition might be a future therapy in renal transplantation.

**N-Terminal Truncated Intracellular Matrix Metalloproteinase-2 Induces Renal Injury** David H. Lovett,[1] Rajeev Mahimkar.[2] *[1]Medicine, University of California San Francisco, San Francisco, CA; [2]BioMarin Pharmaceuticals, Novato, CA.*

Modulation of renal structure and function by members of the matrix metalloproteinase (MMP) gene family is an area of intense interest. Much effort has been focused on the role of a specific MMP, matrix metalloproteinase-2 (MMP-2).Transgenic expression of active MMP-2 in the proximal tubule (PT) (Cheng, et al. FASEB J (2006) 20:1898) is sufficient to induce glomerulosclerosis, tubular atrophy and interstitial fibrosis. In this model PT cells acquire a mixed mesenchymal/epithelial phenotype with limited TBM penetration. To examine the mixed EMT phenotype further we developed an in vitro model by gradient expression of MEK in epithelial LLC-MK2 cells. Proteolytic targets of MMP-2 were assessed by in LLC-MK clones with a mixed phenotype by 2-D DIGE-LC/MS/MS and identified mitochondrial voltage-dependent anion channel-2 as a target. Western blot of isolated mitochondria identified a unique 65 kDa N-terminal isoform of MMP-2 generated by use of an alternative translational start site at $M^{77}$. This isoform lacks a secretory sequence and prodomain and is intracellular and enzymatically active. Microarray analysis after transfection with a N-terminal truncated MMP-2 (NTT-MMP2) cDNA indicated induction of genes characteristic of an innate immune response regulated primarily by NF-κB and NFAT. These genes included chemokines, pro-apoptotic factors and viral stress response genes, thereby defining a novel mitochondrial-nuclear signaling cascade. To assess the in vivo activity of NTT-MMP2 transgenic mice were developed with proximal tubule-specific expression of this isoform. NTT-MMP2 transgenic mice develop normally and have normal structure and function at 3 months: by six months there was evidence for PT cellular dedifferentiation, with mitochondrial structural abnormalities. By nine months there was severe glomerulosclerosis, tubular atrophy, TBM thickening and interstitial infiltration with mononuclear cells. We conclude that an NTT isoform of MMP-2 is generated during EMT, triggers mitochondrial-nuclear stress signaling and directly contributes to progressive renal injury independent of superimposed injury.

Disclosure of Financial Relationships: nothing to disclose

**F-FC247**

**Monoclonal Light Chain Deposition in Proximal Tubule Cells Induces Oxidative Stress and Defective Receptor-Mediated Endocytosis in Mouse** Sara Terryn,[1] Christophe Sirac,[2] Frank Bridoux,[3] Olivier Devuyst.[1] *[1]Nephrology, UCL, Brussels, Belgium; [2]Immunology, CNRS, Limoges, France; [3]Nephrology, CHU, Poitiers, France.*

Renal involvement is a common complication of multiple myeloma, associated with a worse prognosis. In particular, the storage of monoclonal immunoglobulin light chain (LC) within the endo-lysosomal compartment of proximal tubule cells (PTC) may lead to LC-associated Fanconi syndrome (FS). We have now used a transgenic mouse model overexpressing a pathogenic human monoclonal κ chain (CHEB mice) to investigate the cellular mechanisms involved in PTC dysfunction after LC-deposition. CHEB mice showed a low-molecular weight proteinuria as evidenced by the selective urinary loss of CC16 and transferrin, in absence of overt albuminuria. They also presented glucosuria and phosphaturia, indicating a general PTC dysfunction, whereas glomerular filtration rate, BUN and plasma creatinine were unchanged. Electron microscopy of CHEB kidneys revealed crystalline inclusions in PTC of predominantly the S3 segment. Immunostaining for megalin and cubilin showed a decreased expression of both receptors in S3 segments of CHEB kidneys. To gain insight in the cellular mechanisms, we established well-differentiated, polarized primary cultures of PTC from micro-dissected S3 segments. qRT-PCR analysis revealed a decreased expression of genes involved in endocytosis (megalin, cubilin, NHE3, amnionless), which resulted in a reduced endocytic uptake of transferrin but not of albumin in CHEB PTC. The defective endocytosis in CHEB PTC coincided with an increased expression of genes related to oxidative stress (HO-1, CAIII, SOD1/2, catalase, Trx) and proliferation (PCNA, Ki67). The state of oxidative stress of CHEB PTC was confirmed by carboxy-$H_2$DCFDA staining.

These results show that transgenic CHEB mice display a LC-associated FS which faithfully reflects the human pathology. The accumulation of LC within PTC results in defective endocytosis through the loss of megalin and cubilin and cellular responses including oxidative stress and proliferation. The interplay between lysosomal accumulation of LC, defective endocytosis and oxidative stress in PTC provides targets for intervention studies.

Disclosure of Financial Relationships: nothing to disclose

**F-FC248**

**MicroRNA Profiles of Tubular Cells under Hypoxia-Reoxygenation and Endoplasmic Reticulum Stress** Shiyo Muratsu, Masaomi Nangaku, Tetsuhiro Tanaka, Chih-Kang Chiang, Takehiko Wada, Toshiro Fujita, Reiko Inagi. *Div of Nephrol and Endocrinol, Univ of Tokyo Sch of Med, Tokyo, Japan.*

Both hypoxia and endoplasmic reticulum (ER) stress orchestrate the tubular damage via the stress signalings. Meanwhile, various physiologic and pathologic processes are regulated by microRNA (miR). We thus hypothesize that the crosstalk of these stress signalings in damaged tubules may be modulated by miRs at mRNA level.

To address this, we assessed the change in miR expression in cultured human tubular cells (HK-2) exposed to 16hr hypoxia (0.1% $O_2$) followed by 3hr (HR3) or 10hr (HR10) reoxygenation or ER stress inducers, tunicamycin (2ug/ml TUN) or thapsigargin (0.5ug/ml THG), by miR microarray analysis.

In 821 miRs we tested, we identified the miRs that showed the significant change in their expression under HR (11 miRs) or ER stress (10 miRs) (P<0.05). They included the miRs that are well-known to be regulated by oxygen tension (miR-21, miR-210), or that regulate the gene expression for cell proliferation or apoptosis (miR-886-3p, miR-923). Of note, we identified one miR, miR-205, whose expression was markedly decreased both under HR and ER stress. These findings were confirmed by real-time qRT-PCR followed by the sequence analysis: 0.73- in HR3, 0.45- in HR10, 0.55- in TUN, 0.57-fold in THG compared to control (P<0.05). In addition, the decrease in miR-205 expression was induced by hypoxia alone. While miR-205 is predicted to be a tumor-suppressor-miR or regulator for epithelial- mesenchymal differentiation (EMT), miR-205-overexpressed HK-2 did not change the cell morphology or cell growth. When these cells were exposed to 500uM $H_2O_2$ or 5ug/ml TUN, the cell survival was markedly increased (71.3 or 78.2 v.s. 46.4% in control miR transfectant). Augmented intracellular ROS induced by $H_2O_2$ was not declined by miR-205 overexpression, suggesting the contribution of miR-205 in modulation of these stress signals independent of oxidative stress.

These results strongly suggest that certain miRs may contribute to both signalings triggered by hypoxia-reoxygenation and ER stress in tubular cells and influence the tubular pathological phenotypes.

**A New Strategy for Preventing CKD-Induced Muscle Atrophy: Manipulation of Muscle Progenitor/Stem Cells Using a microRNA-29 Technique** Xiaonan H. Wang,[1] William E. Mitch.[2] *[1]Emory University, Atlanta, GA; [2]Baylor College of Medicine, Houston, TX.*

In a mouse model of CKD, we have found (JASN, 2010) that the functions of muscle progenitor cells (MPC) are impaired and since these cells are involved in regulating muscle mass, the impairment could contribute to muscle wasting. We investigated how CKD changed the function of MPC in a mouse model of CKD. We found: 1) increased expression of YY1, a protein that inhibits MPC differentiation; and 2) a 3-fold decrease in miR29, a microRNA that is complementary to a sequence in the 3' un-translated region (3'-UTR) of the YY1 mRNA. Therefore, we tested whether impaired differentiation of MPC results from an excess of YY1 because miR29 is suppressed. Alternatively, an increase in miR29 would suppress YY1 stimulating differentiation and increasing muscle mass when MPC grow. First, we used a lentivirus strategy to stimulate YY1 expression in cultured C2C12 myoblasts. In these myoblasts, embryonic myosin heavy chain (eMyHC) expression decreased sharply indicating that myoblast differentiation into myotubes was inhibited. Next, we transduced miR29 (Ad-miR29) into C2C12 myoblasts using adenovirus-mediated microRNA transfer. There was a significant (n=6, p<0.05) decrease in the YY1 protein. This response was accompanied by increased expression of markers of muscle cell maturation. Thus, miR29 regulates YY1 expression, promoting muscle cell maturation. Third, we cloned the YY1 3'-UTR sequence complementary for miR29 binding and inserted it into a pMir-Luciferase vector. C2C12 myoblasts expressing this pMir-luciferase-3UTR-YY1 were treated with an adenovirus expressing miR29 (Ad-miR29). Luciferase activity decreased (P<0.05; n=4) indicating that miR29 suppressed YY1 expression. Conclusions: expression of YY1 impairs muscle progenitor cell maturation and YY1 expression can be suppressed by miR29. These results identify a new mechanism regulating muscle mass and identify a mechanism for CKD-induced loss of muscle mass. Methods resulting in increased miR29 expression could lead to strategies for treating the muscle atrophy of CKD and possibly other catabolic conditions.

**Mechanisms Reducing Skeletal Muscle Mass in Chronic Kidney Disease (CKD): Studies in β1 Hom and Podocin Gene Knock-Out (β1 HOM-POD) Mice** Haiming Li,[1] Feng Sha,[1] Roy Zent,[1] Zhaoyong Hu,[2] William E. Mitch,[2] T. Alp Ikizler.[1] *[1]Vanderbilt; [2]Baylor.*

A substantial body of evidence implicates activation of the ubiquitin-proteasome system (UPS) as the principal cause of skeletal muscle atrophy. Triggers activating muscle catabolism in CKD include chronic inflammation. We found that β1 HOM-POD mice develop progressive CKD with proteinuria (Zent et al Development 2009) and used this model to examine the contributions of UPS and chronic inflammation in the development of skeletal muscle protein degradation in CKD. The β1 Hom-Pod mice were generated by crossing integrin $\beta\ 1^{flox/flox}$ with the podocin-Cre mice. Blood samples and muscle tissue were obtained from 6 HOM-POD and 6 control mice. IL-1, IL-6, and TNF-a were measured in serum by CBA and in muscle tissue by real-time PCR. Akt/pAKT, Ubiquitin (Ub)-

Conjugates and 20s proteasome subunits α1,2,3,5,6,&7 were measured by immunoblotting and mRNA expression of Ub, E1, E214K, E3aI, E3aII, atrogin-1 and MurF-1 were measured by real time PCR in muscles.

Results: β1 HOM-POD mice developed massive proteinuria and elevated BUN. They also had severe edema, smaller, pale kidneys, skeletal atrophy and weighed less (22.66+-8.9 g vs 17.96+-1.78 g) compared to HOM mice. Ub-conjugates and 20s proteasome subunits α1,2,3,5,6,&7 were significantly increased in muscle in HOM-POD mice and pAKT (a major regulator of UPS activity) was decreased. mRNA expressions of Ub and the E3 Ub-conjugating enzymes, E3aI, E3aII, atrogin-1 and MurF-1 were significantly elevated in β1 HOM-POD mice. Likewise, IL-6 and TNFa were elevated in serum and IL-1α and IL-6 were elevated in muscle of β1 HOM-POD mice (Data not shown).

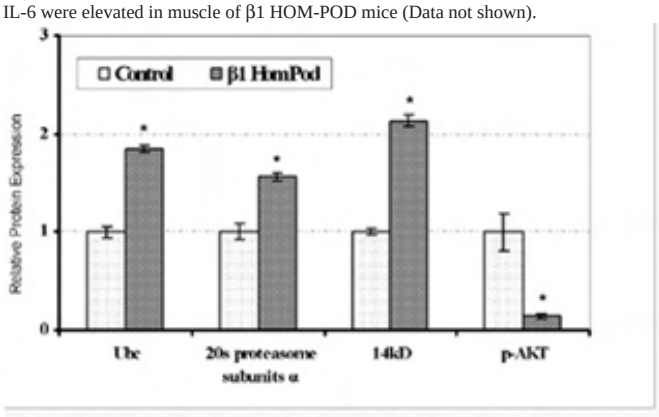

Figure 1:The Ub-Conjugates , 20s proteasome subunits <1,2,3,5,6,&7 and 14KD by immunoblotting show significant increase in Hom-Pod mice, while the pAKT decreased

*: p<0.05

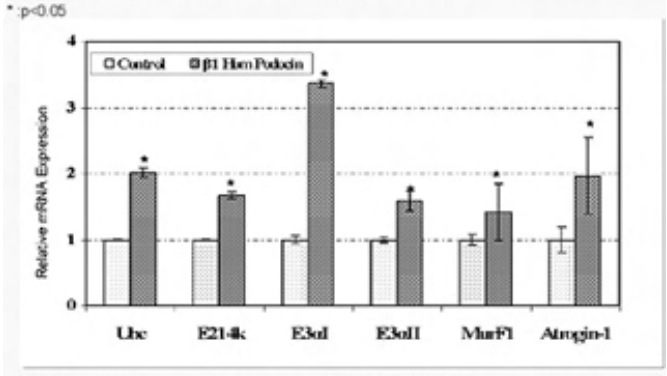

Figure 2: The mRNA expression of Ubc, E3aI, E3aII, atrogin-1 and MurF-1 are found to be significantly elevated in Hom-Pod mice

*: p<0.05

Conclusion: In the β1 HOM-POD mouse model of CKD, stimulation of the UPS causes loss of skeletal muscle. Besides depressed pAkt, stimulation of the UPS could be augmented by chronic inflammation.

Disclosure of Financial Relationships: nothing to disclose

## F-FC251

**Elucidation of the Anti-Fibrotic Mechanism of a Novel HIF-Regulated Globin, Cytoglobin, with Molecular Genetics** Imari Mimura, Hiroshi Nishi, Tetsuhiro Tanaka, Reiko Inagi, Toshiro Fujita, Masaomi Nangaku. *Division of Nephrology and Endocrinology, University of Tokyo School of Medicine, Tokyo, Japan.*

Cytoglobin (Cygb) is a novel member of the globin superfamily expressed by splanchnic fibroblasts in various organs under the control by HIF. In light of experimental evidence that tubulointerstitial hypoxia plays a critical role in chronic kidney disease, a role of Cygb was investigated in the rat remnant kidney (RK) model, focusing on its potential impact on fibrogenesis. Quantitative evaluation revealed an increase in expression of Cygb mRNA and protein, in parallel with the disease progression. Transgenic overexpression of Cygb significantly ameliorated fibrosis of the kidney, with improvement of renal functions. Histological improvement in the transgenic rat kidney was corroborated by immunohistochemical analysis of α-smooth muscle actin and ED-1 showing less severe myofibroblast changes and macrophage infiltration, respectively. Double-immunostaining studies clarified that Cygb was expressed in the interstitial area with collagen IV accumulation. Additionally, nitrotyrosine staining and urinary 8-OHdG measurement revealed that oxidative stress was less in Cygb-Tg rats. In vitro studies utilizing Cygb-overexpressing cells, as well as ex vivo studies using primary cultured fibroblasts from Cygb-Tg rats, demonstrated that overexpression of Cygb inhibited collagen synthesis at both mRNA and protein levels. Antifibrotic properties of Cygb were offset by introducing mutation in the heme moiety and disallowing its binding to molecular oxygen. Furthermore, flow cytmetric analysis clarified that the fibroblast cell line NRK49F overexpressing Cygb suffered from milder intracellular ROS, following acute challenge with hydrogen peroxide. Results of the present study identify Cygb as a critical antifibrotic molecule that plays an important role in protection against renal fibrogenesis, via reduction of oxidative stress.

## F-FC252

**Adipose-Specific Deletion of Angiotensin Type 1 Receptor Protects Against Obesity-Induced Proinflammatory Injury and Albuminuria** Li-Jun Ma,[1] Bridgette Corsa,[1] Dan Gao,[1,2] Valentina Kon,[3] Agnes B. Fogo.[1,3] *[1]Department of Pathology, Vanderbilt University; [2]Department of Nephrology, First Affiliated Hospital of ZhengZhou University, China; [3]Department of Pediatrics, Vanderbilt University.*

Background: Activation of the renin-angiotensin system is implicated in the pathogenesis of both obesity and CKD. We investigated the effects of deletion of angiotensin type 1a receptor (AT1a) in adipocytes on obesity and kidney injury.

Methods: AT1aflox/flox mice and aP2-Cre transgenic mice were crossed to generate adipose-specific AT1a knockout mice (KO). Littermates lacking the aP2-Cre transgene were used as wild-type controls (WT). Adult (age 8-10 wks) male KO and WT mice were fed with high-fat diet (HFD) for 24 weeks (KO+HFD, n=6; WT+HFD, n=6), and compared to baseline. Metabolic parameters, kidney morphology and albumin/creatinine ratio (ACR) were assessed. P-JNK protein expression was examined by Western blot. Data are expressed as mean±SE.

Results: Adipose tissue AT1 receptor protein level was markedly reduced by 82% in lean KO vs WT mice while AT1 levels in liver and kidney were not altered. When challenged with HFD, KO mice and WT mice showed similar body weight (47.2±1.2 vs 49.3±1.1 g) and adipose tissue mass (1.1±0.2 vs 1.1±0.1 g). Obese KO and WT mice had comparable blood glucose (187.5±4.0 vs 189.8±8.0 mg/dl) and blood pressure (BP, 102.3±3.6 vs 104.1±3.6 mmHg). Surprisingly, fat tissue p-JNK protein expression was dramatically inhibited in obese KO vs obese WT (p-JNK/GAPDH ratio 0.10±0.05 vs 0.42±0.05, p<0.01). Although obesity-induced renal structural injury (mesangial expansion, tubular vacuolization) was similar in KO vs WT, ACR was much less in obese KO vs obese WT (KO+HFD 42.4±8.8 vs baseline 6.6±1.5, WT+HFD 158.6±63.6 vs baseline 6.1±1.1 ug/mg, p<0.05 KO+HFD vs WT+HFD, p<0.01 WT+HFD vs WT baseline).

Conclusions: Adipose-specific AT1 deletion has no effect on obesity, BP, or glucose in response to HFD. However, adipose AT1 deletion resulted in decreased adipose p-JNK and albuminuria. These results suggest that AT1 is key for adipose tissue JNK activation, and that adipose-derived factors are crucial in driving obesity-induced kidney dysfunction.

## F-FC253

**Mechanisms of Uremia-Induced Down Regulation of ApoA-I Expression** Hamid Moradi,[1] Hamid M. Said,[2] Nosratola D. Vaziri.[1] *[1]Nephrology, Univ of California, Irvine, Irvine, CA; [2]Medicine, LBVA Med Ctr, Long Beach, CA.*

Atherosclerotic cardiovascular disease is a major cause of mortality in CKD patients. HDL deficiency and defective HDL-mediated reverse lipid transport contribute to atherogenic diathesis in this population. The primary cause of HDL deficiency in CKD is reduction of apoliprotein A-I which is the principal component of HDL. Plasma ApoA-I is reduced in dialysis patients and hepatic ApoA-1 mRNA expression is decreased in uremic rats. This study explored the mechanism/s by which uremia decreases ApoA-I expression. HepG2 cells were incubated for 48 hours in media containing whole serum or serum subfractionation (using Amicon filters with different size selectivities) from normal control subjects and ESRD patients before and after hemodialysis. Cells and culture media were then separated and used for measurement of ApoA-I protein (ELISA) and ApoA-I mRNA (real-time PCR). The effect of the test sera on ApoA-I promoter activity was measured using transfection with a luciferase promoter construct containing the -2096 to +293 segment of ApoA-I gene. RNA stability was assessed in presence of actinomycinD. Exposure to uremic serum resulted in a 5-6 folds reduction in the ApoA-I mRNA expression and significant reduction of ApoA-I level in the culture media (137±40 vs. 38±5).This effect was fully reversed when uremic serum was replaced with control serum. Transfection studies revealed no difference between uremic and normal sera on ApoA-I gene promoter activity. However exposure to uremic serum significantly reduced RNA stability. Fractionation studies revealed that the negative effect of uremic serum on ApoA-I mRNA abundance resides in the fraction containing molecules larger than 30 Kd. This supposition was supported by the observation that post-dialysis serum exerted equal inhibitory effect on ApoA-I mRNA abundance as that found with pre-dialysis serum samples. Uremia causes a significant reduction in ApoA-I mRNA abundance by lowering RNA stability without altering ApoA-I promoter activity. The negative effect of uremic milieu on ApoA-I mRNA stability resides in the fraction containing molecules larger than 30 Kd which are not removable by hemodialysis.

## F-FC254

**Fibrinogen Promotes Kidney Fibrosis by Activating Renal Interstitial Fibroblasts** Inga Soerensen, Nathan D. Susnik, Therese Inhester, Hermann G. Haller, Roland Schmitt. *Department of Nephrology, Hannover Medical School, Hannover, Germany.*

Studies in animal models have identified fibrinogen (fbg) as an important player in inflammation, tissue repair and regeneration. Here, we focused on the role of fbg in the development of renal tubulointerstitial fibrosis using the unilateral ureteral obstruction

(UUO) model. UUO was induced in fbg-/- and fbg +/- mice, which were sacrificed at 1 and 2 weeks to analyze kidneys using histology, immunohistochemistry, qPCR and immunoblot. For in vitro studies we used rat renal fibroblasts (NRK-49F) that were stimulated with fbg in the presence and absence of neutralizing antibodies and siRNA. We found that UUO kidneys from fbg +/- mice are characterized by massive deposition of tubulointerstitial fbg at 1 and 2 weeks. Fbg deficiency significantly attenuated UUO-dependent changes such as the deposition of collagen I and de novo expression of alpha smooth muscle actin. In parallel fbg-/- mice had significantly less S100A4 positive interstitial fibroblasts. In vitro we found that exposure of NRK-49F cells to fbg resulted in rapid ERK phosphorylation and in a significant increase in cell proliferation. As fbg can interact with a variety of cell surface receptors we first tested for integrin-dependent signalling. However, the mitogenic effect of fbg was unchanged in the presence of RGD or β1-integrin neutralizing antibody. Instead we found that NRK-49F cell proliferation was significantly reduced if binding of fbg to ICAM-1 was blocked using a neutralizing antibody and/or if TLR signalling was inhibited by siRNA knockdown of MyD88. The role of MyD88 was corroborated in primary renal fibroblasts from MyD88-/- mice where the proliferative response upon fbg was significantly reduced. Blocking of ICAM-1 receptor sites and knockdown of MyD88 reduced fbg-induced NRK-49F cell proliferation in an additive fashion. In summary, we demonstrate that fbg is an important activator of renal interstitial fibroblasts in vivo and in vitro. Its mitogenic effect is at least partially mediated through binding of ICAM-1 which is expressed on the surface of tubulointerstitial fibroblasts and secondly through the TLR signalling pathway as shown by MyD88 knockdown.

### F-FC255

**MYH9 Expression in Podocytes Is Reduced by HIV Infection** Thomas Hays, Marc E. Trubin, Deborah P. Hyink, Paul E. Klotman. *Department of Medicine, Mount Sinai School of Medicine, New York, NY.*

Recent genetic mapping studies demonstrated that MYH9 gene variants in African Americans are strongly linked to development of focal segmental glomerulosclerosis (FSGS), including HIV-associated nephropathy (HIVAN). Additionally, MYH9 mutations are known to cause rare autosomal dominant end stage renal disease with a variably penetrant glomerulosclerosis. To explore whether the pathogenesis of HIVAN involves a loss of MYH9 function, we analyzed the expression of MYH9 in several models of the disease. In the HIV transgenic mouse model, we observed by immunohistochemistry that MYH9 expression is dramatically reduced in the glomeruli. To determine what role podocytes played in the reduced glomerular expression, we next analyzed MYH9 levels in conditionally immortalized podocytes derived from the HIV transgenic mouse. Western analysis revealed that MYH9 expression was indeed reduced in these cells (75% reduction, p=0.02). Finally, to determine whether HIV infection directly reduced MYH9 expression, we infected wildtype conditionally immortalized podocytes with VSV.G pseudotyped HIV. Here too, western analysis showed that MYH9 expression was reduced (90%, reduction, p=0.01). These results demonstrate that a reduction in MYH9 expression is a component of the host response to HIV podocyte infection. Given the strong genetic link of MYH9 to HIVAN, these data provide an important insight into the mechanism of HIVAN and FSGS in African Americans.

### F-FC256

**The Transcription Factor ETS-1 Is a Critical Mediator of the Pro-Fibrotic and Pro-Inflammatory Effects of Ang II in the Glomerulus** Wenguang Feng,[1] Phillip H. Chumley,[1] Ping Hua,[1] Gabriel Rezonzew,[1] Dongqi Xing,[1] Edgar A. Jaimes.[1 2] *[1]Department of Medicine, University of Alabama at Birmingham, AL; [2]VA Medical Center, Birmingham, AL.*

The renin-angiotensin system (RAS) plays a major role in the pathogenesis of end-organ injury in hypertension. The transcription factor ETS-1 is an important mediator of growth-related responses and inflammation in different models of injury. We have previously shown that Angiotensin II (Ang II) increases cortical ETS-1 expression *in vivo* and that ETS-1 is required for fibronectin production in mesangial cells. In these studies we tested the hypothesis that ETS-1 mediates pro-inflammatory and pro-fibrotic effects of Ang II *in vivo*. C57B/L6 mice (n=6 per group) were infused with vehicle (Veh), Ang II (1.4mg/kg/day), Ang II and an ETS-1 dominant negative peptide (DN,10mg/kg/day) or Ang II and an ETS-1 mutant peptide (MU, 10 mg/kg/day) for 4 weeks. Mean blood pressure (MBP) was measured by radio-telemetry weekly until sacrifice. MBP (mmHg) was significantly increased by Ang II and was not modified by DN or MU: Veh 96±3.1, Ang II 168±3.8*, Ang II + DN 163±4.8*, Ang II + MU* 164±3.2 (* P <0.05 vs vehicle). By morphometric analysis we determined that Ang II induced mesangial expansion (% of glomerular PAS): Veh 15.4±0.3 vs Ang II 19.2±0.4, (p<0.05 vs control) which was partially prevented by DN: 17.1 ± 0.4 (P<0.05), but not by MU: 19.2 ± 0.6 (P =NS). Ang II increased macrophage infiltration (F4/80, cells/mm$^2$): Veh 25.8 ± 12.1 vs Ang II 52.1 ± 6.8, P<0.05) and cell proliferation (ki67, cells/mm$^2$): Veh 16.0 ± 7.2 vs Ang II 128.2 ± 23.9, P < 0.05) which were prevented by DN: 36.9 ± 4.3 (F4/80) , 76. 8± 10.2 (ki67) (P<0.05 vs Ang II). Ang II induced a 22 fold increase in nitrotyrosine expression as assessed by immunofluorescence (AFU): Veh 39 ± 35 vs Ang II 863 ± 194 (P<0.05) that was significantly reduced by DN: 206 ± 123 (P<0.05 vs Ang II) but not by MU: 579 ± 228 (P = NS). In conclusion, ETS-1 plays a major role as mediator of the pro-fibrotic and pro-inflammatory effects of Ang II in the kidney cortex. These findings may result in the development of novel strategies in the treatment and prevention of end-organ injury in hypertension.

### F-FC257

**Indoxyl Sulfate Reduces Klotho Expression and Promotes Senescence in the Kidney of Hypertensive Rats** Toshimitsu Niwa,[1] Ayinuer Adijiang,[1] Yuusuke Higuchi,[2] Fuyuhiko Nishijima,[2] Hidehisa Shimizu.[1] *[1]Department of Advanced Medicine for Uremia, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan; [2]Biomedical Research Laboratories, Kureha Co., Tokyo, Japan.*

Administration of indoxyl sulfate, a uremic toxin, promotes progression of chronic kidney disease (CKD) in CKD rats. Klotho, an anti-aging gene, is expressed in the kidney, and its renal expression is decreased in CKD. This study aimed to clarify if indoxyl sulfate could reduce Klotho expression, and contribute to cell senescence in the kidney of hypertensive rats.

The rat groups consisted of 1) Dahl salt-resistant normotensive rats (DN), 2) Dahl salt-resistant normotensive indoxyl sulfate-administered rats (DN+IS), 3) Dahl salt-sensitive hypertensive rats (DH), and 4) Dahl salt-sensitive hypertensive indoxyl sulfate-administered rats (DH+IS). After 32 weeks, their kidneys were excised for histological and immunohistochemical analysis for Klotho, senescence-associated b-galactosidase (SA-beta-gal), p16$^{INK4a}$, p21$^{WAF1/CIP1}$, p53 and retinoblastoma protein (Rb).

DH+IS rats showed decreased expression of Klotho, increased expression of SA-beta-gal, p16$^{INK4a}$, p21$^{WAF1/CIP1}$, p53 and Rb in renal tubular cells, and increased tubulointerstitial fibrosis and mesangial expansion as compared with DH rats. Further, DN+IS rats showed decreased expression of Klotho as compared with DN rats.

Thus, administration of indoxyl sulfate to hypertensive rats reduced renal expression of Klotho, and promoted cell senescence with expression of senescence-related proteins such as p16$^{INK4a}$, p21$^{WAF1/CIP1}$, p53 and Rb accompanied by renal fibrosis.

### F-FC258

**Combined Losartan (L) and Hydrochlorothiazide (H) Arrests Renal Injury Consequent to L Consumption during Lactation** Camilla Fanelli, Bianca H. Ventura, Flavia G. Machado, Elizabete P. Poppi, Denise M. Malheiros, Claudia R. Sena, Clarice K. Fujihara, Roberto Zatz. *Renal Division, Dep Clin Med, Univ of Sao Paulo, Brazil.*

We previously described (AJP F1345) a model of severe CKD ($L_{LAC}$) based on L teratogenesis during lactation. Here we sought to 1-Verify if L+H treatment, highly effective in the remnant kidney (Nx), would afford equal renoprotection in $L_{LAC}$. 2-Gain further insight into injury mechanisms. Twenty Munich-Wistar dams, each nursing 6 pups, were divided into: Control, untreated, and $L_{LAC}$, given L, 250 mg/kg/d, until weaning. Male pups went untreated until 7 mo of age, when tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/d), serum creatinine ($S_{Cr}$, mg/dL), glomerulosclerosis index (GSI) and interstitial expansion (INT), PCNA+ cells, α-actin (αACT) and matrix metalloproteinase 2 activity (MMP2) were measured in 17 rats ($L_{LAC}$Pre). The remaining 68 rats were divided into groups: $L_{LAC}$+V, untreated, $L_{LAC}$+L, given L, 50 mg/kg/d and $L_{LAC}$+LH, given L+H, 6mg/kg/d. Results after 3 months:

| | C | $L_{LAC}$Pre | $L_{LAC}$+V | $L_{LAC}$+L | $L_{LAC}$+LH |
|---|---|---|---|---|---|
| TCP | 149±4 | 146±6 | 187±4$^{abc}$ | 130±19$^{abc}$ | 126±3$^{abc}$ |
| ALB | 32±7 | 105±14$^{a}$ | 106±26$^{ab}$ | 59±9$^{c}$ | 32±5$^{bc}$ |
| $S_{Cr}$ | 0.68±0.04 | 0.78±0.07 | 1.12±0.07$^{ab}$ | 1.05±0.06$^{ab}$ | 0.96±0.05$^{a}$ |
| GSI | 6±2 | 35±17 | 94±26$^{ab}$ | 22±5$^{c}$ | 24±4$^{c}$ |
| INT | 0.4±0.1 | 0.6±0.6$^{a}$ | 5.8±0.9$^{ab}$ | 4.2±0.5$^{a}$ | 4.8±0.4$^{ab}$ |
| αACT | 0.5±0.1 | 1.9±0.3$^{a}$ | 4.1±0.6$^{ab}$ | 2.5±0.4$^{ac}$ | 2.1±0.2$^{ac}$ |
| PCNA | 20±3 | 71±12$^{a}$ | 107±12$^{ab}$ | 59±7$^{ac}$ | 50±6$^{c}$ |
| MMP2 | 1.0±0.1 | 1.1±0.3 | 2.7±0.4$^{ab}$ | 2.5±0.3$^{a}$ | 3.5±1.3$^{ab}$ |

$^{a}$p<0.05 vs. C, $^{b}$p<0.05 vs. $L_{LAC}$Pre, $^{c}$p<0.05 vs. $L_{LAC}$+V, $^{d}$p<0.05 vs. $L_{LAC}$+L

Progression of renal injury in $L_{LAC}$+V was associated with worsening of hyperplasia and αACT. No MMP deficiency was noted, suggesting that fibrosis resulted from enhanced matrix production. L and L+H arrested GS, INT and αACT but only L+H normalized TCP and ALB, prevented further rise of $S_{Cr}$, and increased MMP2 activity. In $L_{LAC}$ rats, L treatment provides renoprotection even if started at an advanced CKD stage, while L+H affords subtle but definite additional protection.

### F-FC259

**Reversibility of Diabetic Nephropathy and Podocyte Loss in the BTBR *ob/ob* Mouse** Warangkana Pichaiwong,[1] Kelly L. Hudkins,[1] Tomasz A. Wietecha,[1] Bardia Askari,[1] Takahisa Kobayashi,[1] Stuart J. Shankland,[2] Jeffrey W. Pippin,[2] Charles E. Alpers.[1] *[1]Pathology, Univ. of Washington, Seattle, WA; [2]Nephrology, Univ. of Washington, Seattle, WA.*

Podocytes (podos), with limited replicative capacity, are injured or lost early in diabetic nephropathy (DN). Inability of podos to regenerate may be a key limiting factor for reversal of DN.

We have developed a murine model of Type II DN, the BTBR mouse strain with the ob/ob leptin deficiency mutation (JASN 2010; in press). We tested whether interventions that cause restoration of a normoglycemic milieu (leptin replacement) or inhibit the renin angiotensin system (RAS) by angiotensin converting enzyme inhibitor (enalapril) or angiotensin II type 1 receptor blocker (losartan) can induce reversal of established DN and do so by restoration of podo density.

Development of DN was preceded by significantly diminished podo density quantified as WT-1 expressing cells divided by mean glomerular volume (cells/10$^6$ μm$^3$). Leptin replacement via minipump infusion, beginning at age 18 weeks and continued until 24

weeks resulted in reversal of morphologic features of DN and restored podo density (leptin 231.9±14 vs. 24wks untreated mice 129.2±15.5, $p<0.001$). Treatment with enalapril or losartan for 6 weeks resulted in no significant change in podo density vs. untreated mice. Leptin replacement resulted in return to normoglycemia, reduced body weight and reduced albuminuria (leptin 175±74.8 vs. 24wks untreated mice 740.7±167 µg/24hr., $p=0.01$). Normalization of glomerular morphology in leptin treated mice was characterized by significant reduction of extracellular matrix accumulation (% of Type IV collagen/ glomerulus: leptin 14.9±0.7 vs. 24wks untreated mice 22.5±1.2, $p<0.001$) and decreased mesangiolysis. Treatment with enalapril and losartan reduced mesangiolysis and decreased albuminuria, but had no effect on extracellular matrix accumulation.

We demonstrated structural and functional reversal of DN is accompanied by full restoration of podo density, proof of podo regeneration. The lack of podo restoration by RAS inhibition, despite improvement in albuminuria, may underlie limitations of this therapy for treating human DN.

Disclosure of Financial Relationships: nothing to disclose

## F-FC260

**Systems Analysis of Circulating Leucocytes of Patients with Type 1 Diabetes (T1D), Microalbuminuria and Early Progressive Renal Function Loss Suggests Activated Inflammatory Pathway** Wenjun Ju,[1] Monika A. Niewczas,[2] Viji Nair,[1] William Walker,[2] Felix H. Eichinger,[1] Ann Randolph,[1] James Warram,[2] Andrzej S. Krolewski,[2] Matthias Kretzler.[1] *[1]Internal Medicine/Nephrology, University of Michigan, Ann Arbor, MI; [2]Research Division of Joslin Diabetes Center, Harvard Medical School, Boston, MA.*

In patients with T1D, progressive loss of renal function leading to ESRD is associated with an intra-renal inflammatory response. We tested the hypothesis that presence of this inflammatory activity associated with progressive renal function loss is detectable in circulating leucocytes of patients with T1D and early diabetic nephropathy (DN). Leucocytes were harvested at study entry from 33 T1D patients with microalbuminuria. They were followed for 4-6 years to obtain serial measurements of serum cystatin C for tracing the trajectory of GFR loss using estimates of GFRcystatin. Changes over time were summarized as the percent change in GFRcystatin per year using a mixed effects model. All patients had GFRcystatin >60 ml/min at entry. During follow-up, the annual percent change in GFRcystatin varied among patients between -13.3 to +0.2 (median -2.32). The gene expression profile of leukocyte RNA was obtained with the GeneChip Human Genome U133 Plus 2.0 Array and correlated with percent change in GFRcystatin. The expression values of 1213 genes correlated significantly with percent change (Pearson correlation>0.4, FDR q<0.02). Transcripts correlated with GFRcystatin loss were significantly enriched in canonical pathways associated with DN, including: mitochondrial dysfunction, retinoic acid mediated apoptosis signaling, oxidative phosphorylation, and TNF-alpha /NF-KB. Interestingly, the gene expression of TNF receptors correlated with GFRcystatin loss (r=-0.4, P=0.02 for TNFRSF1B, and r=-0.33, p=0.06 for TNFRSF1A). In conclusion, inflammatory pathways are activated in circulating leucocytes in T1D patients who are at risk of early GFRcystatin loss, supporting the notion of a systemic inflammatory state being important for early as well late renal function loss in T1D.

Disclosure of Financial Relationships: nothing to disclose

## F-FC261

**Monocyte/Macrophage Chemokine Receptor CCR2 Mediates Diabetic Renal Injury** Alaa S. Awad,[1,2] Gilbert R. Kinsey,[2] Konstantine Khutsishvili,[2] Ting Gao,[1] Kline Bolton,[2] Mark D. Okusa.[2] *[1]Medicine, Penn State College of Medicine, Hershey, PA; [2]Medicine, University of Virginia, Charlottesville, VA.*

**Introduction:** Monocyte/macrophage recruitment correlates strongly with the progression of renal impairment in diabetic nephropathy (DN). CC chemokine receptor (CCR)2 regulates monocyte/macrophage migration into injured tissues. However, the direct role of CCR2 in the progression of DN remains unknown. We hypothesize that deficiency or blockade of CCR2 confers kidney protection in DN.

**Methods:** Experiments were conducted in CCR2 deficient mice ($CCR2^{-/-}$) and their wild type littermates ($CCR2^{+/+}$) following STZ induced diabetes (80 mg/kg iv injection; n=8 each group) or $Ins2^{Akita}$ mice (n=5-8 each group).

**Results:** $CCR2^{-/-}$ mice significantly attenuated diabetic albuminuria to normal range (5.5-fold reduction; $p<0.0001$) compared to $CCR2^{+/+}$ mice despite comparable blood glucose levels after 6 wks of diabetes. The kidneys of diabetic $CCR2^{-/-}$ had less diabetes-mediated histological changes (interstitial fibrosis: 5-fold; $p<0.005$ and mesangial expansion: 4-fold; $p<0.05$), kidney fibronectin mRNA expression (3-fold; $p<0.005$), and inflammatory cytokine production (TNF-α: 3-fold; $p<0.001$ and IFN-γ: 4-fold; $p<0.01$) reduction compared to $CCR2^{+/+}$ mice. Diabetic $CCR2^{+/+}$ mice showed significant increases in kidney macrophages ($p<0.05$) compared with control mice using flow cytometry and immunohistochemistry. In contrast, kidney macrophages in control and diabetic $CCR2^{-/-}$ mice were similar to control $CCR2^{+/+}$ mice. Bone-marrow derived monocytes from $CCR2^{+/+}$ mice adoptively transferred into $CCR2^{-/-}$ mice reversed the renal tissue protective effect in diabetic $CCR2^{-/-}$ mice. Furthermore, blocking CCR2 using the selective CCR2 antagonist, RS504393 (2 mg/kg/day via osmotic minipump) for 12 wks in $Ins2^{Akita}$ mice mimicked CCR2 deficiency by reducing diabetic albuminuria (3-fold; $p<0.005$) and kidney macrophage recruitment (2-fold; $p<0.005$) compared to $Ins2^{Akita}$ + vehicle.

**Conclusion:** These findings provide evidence that CCR2 is necessary for monocyte/ macrophage-induced diabetic renal injury and suggest that blocking CCR2 could be a novel therapeutic approach in the treatment of DN.

## F-FC262

**Kidney-Specific Sirt1 Tg Mice Protects Against Albuminuria in Diabetic Nephropathy by Inhibiting Claudin-1 Ectopic Overexpression** Kazuhiro Hasegawa, Koichi Hayashi. *Keio University School of Medicine.*

**Aims**

Although it has been reported that whole body Sirt1 induction by calorie restriction or specific Sirt1 activators increases insulin secretion or attenuates insulin resistance, the role of kidney Sirt1 in diabetic nephropathy has not been elucidated. We created kidney-Specific Sirt1 Tg mice and investigated its effect on diabetic nephropathy.

**Methods**

WT or Sirt1 Tg mice were subjected to intraperitoneal injection of saline (control) or streptozotocin with 50mg/kg/day for 5 days (WT+Sal, WT+STZ, Tg+Sal, Tg+STZ). After 2 or 6 months, we measured various blood and urine parameters, and kidney histology (PAS, PHA-E staining) focusing on the morphology of parietal (PECs) or visceral (VECs) Bowman's capsule epithelial cells.

**Results**

At 2 months, WT+STZ represented increased blood glucose, albuminuria, proliferation of flat PECs accompanied by decreased body weight and blunted cuboid PECs. At 6 months, WT+STZ mice manifested kidney hypertrophy and mesangial cell proliferation. Additionally, WT+STZ mice also manifested claudin-1 overepression in the PECs and VECs. All these findings were attenuated in Tg mice. The expressions of other molecules involved in tight junction, adherent junction, or foot process which are supposed to be related with albiminuria were not different between WT and Tg. Immunostaining of Sirt1 revealed that Sirt1 was expressed in proximal tubules and glomerulus in WT+Sal, which expressions were decreased in WT+STZ. In Tg+Sal, Sirt1 expressions were dominat in proximal tubles reflecting on promoter usage, Npt2, in Tg mice, which were retained also in Tg+STZ.

**Conclusions**

These results indicate that kidney Sirt1 rescues albminuria through the suppression of claudin-1 overproduction in PECs and VECs, which findings precedes typical findings of diabetic nephropathy, such as glomerular hypertrophy or mesangial cell proliferation. Since claudin-1 is expressed physiologically only in flat PECs and functions as a tight junction protein, it is postulated that DM-induced claudin-1overexpression may cause junctional imbalance in foot processes leading to albuminuria. Renal Sirt1 can be a potential therapeutic target for the treatment of diabetic nephropathy.

## F-FC263

**Identification of microRNA-93 as a Novel Regulator of Vascular Endothelial Growth Factor (VEGF) in Hyperglycemic Conditions** Jianyin Long, Yin Wang, Wenjian Wang, Farhad R. Danesh. *Department of Medicine/Nephrology, Baylor College of Medicine, Houston, TX.*

Vascular endothelial growth factor (VEGF) is a dimeric glycoprotein which plays a crucial role in microvascular complications of diabetes, including diabetic nephropathy. However, the precise regulatory mechanisms governing VEGF expression in the diabetic milieu are still poorly understood. Here we provide evidence that microRNA-93 (miR-93) regulates VEGF expression in experimental models of diabetes both *in vitro* and *in vivo*. Comparative miRNA arrays from high glucose-exposed (25 mM) podocytes and kidney microvascular endothelial cells, as well as in the kidney glomeruli obtained from diabetic db/db mice identified miR-93 as a "signature miRNA" in hyperglycemic conditions. We identified VEGF-A as a putative target of miR-93 in the kidney with a perfect complementarity between miR-93 and the 3'-UTR (untranslated region) of *vegfa* in several species. miR-93 repressed the transcription of luciferase reporter construct of the mouse *vegfa* 3'-UTR, but not the mutant form where the potential miR-93 binding site was abolished, indicating that miR-93 acts as a negative regulator of VEGF by binding to the *vegfa* 3'-UTR. Forced expression of miR-93 abrogated VEGF protein secretion. Conversely, anti-miR-93 inhibitors increased VEGF release. Transfection of miR-93 also prevented the effect of high glucose on VEGF downstream targets, including a3 collagen IV and fibronectin. Using transgenic mice containing VEGF/LacZ bicistronic transcripts, we found that inhibition of glomerular miR-93 by peptide-conjugated morpholino oligomers elicited increased expression of VEGF. Our findings also indicate that high glucose decreases miR-93 expression by downregulating the promoter of its host *MCM7* gene. Taken together, our findings provide new insights into the role of miR-93 in VEGF signaling pathway, and offer a potentially novel target in preventing the progression of diabetic nephropathy.

Disclosure of Financial Relationships: nothing to disclose

## F-FC264

**MicroRNA-29c Targets Sprouty1, Promotes Apoptosis and Fibrosis, and Its *In Vivo* Inhibition Prevents Progression of Diabetic Nephropathy** Jianyin Long, Yin Wang, Wenjian Wang, Farhad R. Danesh. *Department of Medicine/ Nephrology, Baylor College of Medicine, Houston, TX.*

While several recent publications have suggested that miRNAs contribute to the pathogenesis of diabetic nephropathy (DN), the role of these miRNAs in animal models of diabetic kidney disease in vivo remains poorly understood. To systemically explore the role of miRNAs in the diabetic milieu, we generated comparative miRNA expression profiles from high glucose-exposed (25 mM) podocytes and kidney microvascular endothelial cells for 24hrs, as well as in the kidney glomeruli obtained from diabetic *db/db* mice. We identified upregulated miR-29c expression as a "signature miRNA" in the diabetic environment. Following validation of miR-29c expression *in vivo* and *in vitro* by using

RT-PCR and Northern blot analysis, we injected miR-29c antisense oligos intraperitoneally into 8-weeks old *db/db* mice (115mg/kg body weight every other week for 8-10 weeks, n=5). Compared to control *db/db* mice, miR-29c-treated animals exhibited significant reduction in albuminuria (161.233±40.93 vs. 407.60±140.21, p<0.01). Furthermore, inhibition of miR-29c led to a significant decrease in glomerular apoptosis, as shown by TUNNEL assay and caspase-3 activity analyses. The *in vivo* miR-29c silencing also suppressed glomerular fibrosis as evident by immunohistochemistry staining of glomerular collagen IV, 24hr urinary collagen excretion, and decreased glomerular mesangial matrix index. *In vitro*, overexpression of miR-29c led to elevated apoptosis as shown by FACS analysis. We also identified Sprouty1 (Spry1) as a direct target of miR-29c. Expression of miR-29c repressed the luciferase activity of Spry1 3'-UTR (untranslated region), but not that of the mutant form where the miR-29c binding site was abolished. Importantly, we found that overexpression of miR-29c decreased the protein level of Spry1, which in turn led to increased Rho kinase activity. Taken together, these findings reveal a previously unrecognized signaling cascade involved in the pathogenesis of diabetic nephropathy, and highlights a novel molecular interaction between miR-29c, Spry1, and Rho kinase activation.

**MicroRNA Expression Analysis in Angiotensin II-Stimulated Human Podocytes and Its Glomerular Expression in Diabetic Mice** Kenichi Koga,[1] Masashi Mukoyama,[1] Hideki Yokoi,[1] Kiyoshi Mori,[1] Masato Kasahara,[1] Takashige Kuwabara,[1] Yoshihisa Ogawa,[1] Hirotaka Imamaki,[1] Tomoko Kawanishi,[1] Akira Ishii,[1] Keita Mori,[1] Yukiko Kato,[1] Moin Saleem,[2] Akira Sugawara,[1] Kazuwa Nakao.[1] *[1]Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Academic and Children's Renal Unit, University of Bristol, Bristol, United Kingdom.*

MicroRNAs (miRNAs) are small non-coding RNAs that regulate gene expression by inhibiting protein translation or by inducing mRNA degradation of their target genes. Previous studies have shown that miRNAs regulate the expression of key genes relevant to the kidney disease. We have already reported that connective tissue growth factor (CTGF) is involved in the progression of diabetic nephropathy, and that the natriuretic peptide/guanylyl cyclase-A (GC-A) pathway has a protective role against diabetic nephropathy. In this study, we focused on the expression of miRNAs which target CTGF and GC-A genes. We studied expression of miRNAs in immortalized human podocytes with the stimulation of angiotensin II ($10^{-6}$ M). Using miRNA microarray analysis for 939 miRNAs, we revealed that 11 miRNAs showed > 2-fold change in its expression. Then we selected 7 miRNAs as candidate miRNAs in podocytes by using miRNA database, which target CTGF and/or GC-A genes. Three of them were miR-30c, miR-26a and miR-379. miR-30c expression was significantly increased by 3.5-fold after angiotensin II stimulation with real-time PCR analysis ($p = 0.029$). Next we examined these 7 miRNA expressions in glomeruli in type 2 diabetic db/db mice. In glomeruli of db/db mice, miR-30c, miR-26a and miR-379 were significantly increased by 9.2-, 20.8- and 10.6-fold compared with db/m mice, respectively ($p < 0.05$). Database shows that GC-A is a direct target of miR-379 and that CTGF is a target of miR-30c and miR-26a. These results suggest that these miRNAs may be involved in the progression of diabetic nephropathy and that function of GC-A and CTGF might be regulated by these miRNAs.

**Forced Deletion of ROCK1 Ameliorates Progression of Diabetic Nephropathy by Modulating Mitochondrial Fragmentation** Wenjian Wang,[1,2] Yin Wang,[1] Jianyin Long,[1] Farhad R. Danesh.[1] *[1]Medicine/Nephrology, Baylor College of Medicine, Houston, TX; [2]Nephrology, Guangdong General Hospital, Guangzhou, Guangdong, China.*

We have previously shown that pharmacological inhibition of Rho kinase (ROCK) activity ameliorates progression of diabetic nephropathy (DN). In the current study, we used a genetic approach to further examine the specific role of ROCK1 in the progression of DN. We observed a significant reduction of the urine albumin excretion and the mesangial matrix expansion in ROCK1$^{-/-}$ STZ-induced diabetic mice and ROCK1$^{-/-}$ *db/db* double gene knockout mice compared with wild-type (*wt*) diabetic mice. Furthermore, ROCK1$^{-/-}$ diabetic mice demonstrated a significant decrease in glomerular apoptosis compared to *wt* diabetic mice. The reduced frequency of apoptosis in ROCK1$^{-/-}$ diabetic mice correlated with a significant reduction in mitochondrial reactive oxygen species (ROS) and mitochondrial fragmentation as assessed by electron paramagnetic resonance spectroscopy and aspect ratio assay. *In vitro*, using a domain negative (dn) or constitutively activated (ca) mutants of ROCK1, we found that ca-ROCK1 significantly increased mitochondrial fragmentation, mitochondrial ROS generation, and apoptosis in podocytes and mouse kidney vascular endothelial cells. Interestingly, the use of dn-ROCK1 or si-ROCK1 reversed the increased mitochondrial fragmentation, mitochondrial ROS production and apoptosis induced by high glucose (25 mM). We further observed that ROCK1 modulated the mitochondrial fragmentation by phosphorylating the dynamin-related protein 1(Drp1) at S637. Our data indicate that deletion of ROCK1 ameliorates progression of DN by improving hyperglycemia-induced mitochondrial fragmentation.

**Bone Marrow Derived Endothelial Progenitor Cells Ameliorate Experimental Diabetic Nephropathy: Therapeutic and Mechanistic Implications** Yanling Zhang, Darren A. Yuen, Andrew Advani, Kim Connelly, Richard E. Gilbert. *St. Michael's Hospital, Toronto, Canada.*

Diabetic nephropathy is a leading cause of chronic kidney disease that continues to progress in a substantial proportion of patients despite the widespread use of agents that block the renin-angiotensin system. Given the reported beneficial effects of cell therapy in acute kidney injury, we considered whether bone marrow-derived progenitor cells, known to be reduced in patients with either diabetes or CKD, might also be useful in diabetic nephropathy. Methods: We used a well-established model of type 2 diabetic nephropathy, the db/db mouse, that develops albuminuria, mesangial expansion, glomerular hypertrophy and tubular apoptosis/atrophy. Eight week old BKS.Cg-m +/+ Leprdb/J (db/db) mice were randomised to receive a single injection of saline or 0.5 x $10^6$ endothelial progenitor cells (EPCs), administered intravenously. Cells were obtained from the bone marrow of db/m mice and cultured according to well-established techniques to yield a population enriched for so-called, early outgrowth EPCs. Outcome parameters, assessed 4 weeks after cell infusion, included urinary albumin, mesangial expansion, glomerular hypertrophy and tubular apoptosis. Results: Untreated db/db mice underwent a progressive increase in urinary albumin, mesangial sclerosis, glomerular hypertrophy and tubular epithelial cell apoptosis. In contrast, and without affecting blood glucose, EPC treatment not only attenuated the rate of rise in albuminuria but also significantly decreased mesangial type IV collagen deposition, glomerular enlargement, tubular basement membrane thickening and the number of apoptotic tubular epithelial cells (all p<0.05). In tracking experiments, exogenous EPCs were found predominantly within the reticulo-endothelial system, rather than in the kidney. Conclusions: This study shows firstly that early-outgrowth, culture modified, bone marrow derived cells (EPCs) preserve kidney structure and function in experimental diabetic nephropathy. Additionally, the benefits of this cell-type appear not to be a consequence of engraftment into the kidney, but rather suggest a systemic effect, as described in other disease settings.

Disclosure of Financial Relationships: nothing to disclose

**F-FC268**

**Inhibition of the Epidermal Growth Factor Receptor Preserves Podocytes and Attenuates Albuminuria in Experimental Diabetic Nephropathy** Andrew Advani,[1] Alison Joy Cox,[2] Yuan Zhang,[2] Richard E. Gilbert,[1] Darren J. Kelly.[2] *[1]Department of Medicine, St. Michael's Hospital, Toronto, ON, Canada; [2]Department of Medicine, St. Vincent's Hospital, Melbourne, Victoria, Australia.*

Epidemiological studies suggest an association between early renal enlargement and the subsequent development of nephropathy in patients with diabetes. The epidermal growth factor (EGF)-EGF receptor (EGFR) system plays a pivotal role in mediating renal hypertrophy, where it may act to regulate cell growth and proliferation and also to mediate the actions of angiotensin II through transactivation of the EGFR. The present study sought to investigate the effect of long-term (16 weeks) inhibition of the EGFR tyrosine kinase in a model of diabetes, the diabetic TGR(mRen-2)27 rat, that is characterized by angiotensin II dependent hypertension. Treatment of TGR(mRen-2)27 rats with the EGFR inhibitor, PKI 166 (Novartis), attenuated the increase in kidney size (kidney weight:body weight [%] control 0.55±0.02, diabetes 1.13±0.04, diabetes + PKI 166 1.01±0.03 [p<0.01]), glomerular hypertrophy ([volume x$10^6$μm$^3$] 1.18±0.06, diabetes 1.87±0.11, diabetes + PKI 166 1.41±0.05 [p<0.001]) and albuminuria (AER [mg/day, geometric mean ×/÷ tolerance factor] control 0.90×/÷1.39, diabetes 12.88×/÷1.42, diabetes + PKI 166 3.37×/÷1.36 [p<0.01]) that occurred with diabetes. The reduction in albuminuria in diabetic TGR(mRen-2)27 rats treated with PKI 166 was associated with preservation of the number of glomerular cells staining positively for the podocyte marker, WT1 (p<0.01). WT1 immunostaining inversely correlated with glomerular volume in diabetic rats ($r^2$=0.35, p<0.05). In contrast to agents that block the renin-angiotensin system (RAS), EGFR inhibition had no effect on either the quantity of mesangial matrix or the magnitude of tubular injury in diabetic animals. Taken together, these observations indicate that inhibition of the tyrosine kinase activity of the EGFR attenuates kidney and glomerular enlargement in association with podocyte preservation and reduction in proteinuria in diabetes. Targeting the EGF-EGFR pathway may represent a therapeutic strategy for patients who continue to progress despite RAS-blockade.

**Bone Morphogenetic Protein (BMP) Signaling Inhibitors for the Treatment of Anemia Due to Hepcidin Excess** Jodie L. Babitt, Elena Corradini, Delphine Meynard, Chia Chi Sun, Herbert Y. Lin. *Program in Membrane Biology, Nephrology Division, Center for Systems Biology, Massachusetts General Hospital, Harvard Medical School, Boston, MA.*

Dysregulated iron homeostasis contributes to the anemia of chronic kidney disease (CKD). In particular, many CKD patients have functional iron deficiency or reticuloendothelial cell iron blockade, characterized by low levels of circulating iron that limit erythropoiesis despite normal or high body iron stores. Recent research suggests that hepcidin excess may play a role in the dysregulated iron homeostasis and anemia of CKD. A peptide hormone secreted by the liver, hepcidin downregulates the iron exporter ferroportin, thereby inhibiting iron release into the bloodstream from dietary sources and body storage

sites. Hepcidin may accumulate in CKD patients due to reduced renal clearance and/or stimulation by inflammatory cytokines. Here, we explore the development of hepcidin lowering agents as a new therapeutic strategy to treat dysregulated iron homeostasis and anemia due to hepcidin excess.

We recently demonstrated that the BMP signaling pathway plays a key role in regulating hepcidin expression and systemic iron balance. Mutations in the BMP co-receptor hemojuvelin (HJV) lead to hepcidin deficiency and the iron overload disorder hereditary hemochromatosis. BMP ligands transcriptionally upregulate hepcidin expression and reduce serum iron levels, while BMP inhibitors decrease hepcidin expression, mobilize iron stores, and increase serum iron in normal mice. Notably, BMP inhibitors selective for BMP6 are the most effective hepcidin lowering agents *in vivo*, and *Bmp6* null mice develop hepcidin deficiency and iron overload similar to the phenotype of *Hjv* null mice, suggesting that BMP6 is a major endogenous ligand for hepcidin regulation *in vivo*. Here, we demonstrate that the small molecule BMP inhibitor LDN-193189 and a neutralizing BMP6 antibody inhibit hepcidin expression, mobilize iron stores, increase serum iron, and improve anemia in two different animal models of anemia due to hepcidin excess. These data support the possible utility of BMP inhibitors as hepcidin lowering agents to treat iron homeostasis disorders such as anemia of CKD.

### F-FC270

**Erythropoiesis Sustained 12 Months by the EPODURE Biopump in Patients with Chronic Kidney Disease: Further Results of Phase I/II Proof of Concept Trial** Anatole Besarab,[1] Allen R. Nissenson,[2] Doron Schwartz,[3] Andrew L. Pearlman,[4] Philip Ng,[5] Michal Elhalel.[6] *[1]Henry Ford Hospital, Detroit, MI; [2]UCLA School of Medicine, LA, CA; [3]Sourasky Medical Center, Tel Aviv, Israel; [4]Medgenics, Inc., Misgav, Israel; [5]Baylor College of Medicine, TX; [6]Hadassah Hospital, Jerusalem, Israel.*

The need for better hemoglobin (Hb) control during EPO therapy is paramount in view of studies linking hemoglobin variability with increased mortality, and concerns from supraphysiologic erythropoietin concentrations. Sustained delivery of EPO within the therapeutic window could reduce these risks and increase patient compliance. We are developing EPODURE to provide > 6 months of sustained EPO delivery from a single treatment. Autologous 30mm x 2mm dermis core biopsies excised from the patient's skin under local anesthetic are converted in days into "biopump" tissue EPO production units by introducing the EPO gene into cells of the intact explant. After a week the requisite dose is given by reimplanting the explants units subcutaneously into the patient. Dose can be varied by ablation or addition of more units.

We reported (ASN 2008) the first month's results of the first two patients following treatment using low dose EPODURE Biopumps delivering 20 IU/kg/day in an open label, single-center, Phase I-II study in anemic CKD patients.

We now report results in 7 patients treated up to 12 months: 4 EPO-naïve, 3 EPO-dependent (last EPO injection 4-6 wks before EPODURE treatment). 6 received EPODURE 20 IU/kg/day, 1 received 40 IU/kg/day: no adverse events reported to date. In 3 of 3 EPO-dependent, Hb decline following ESA cessation was reversed, Hb remained between 9.8-11.5 g/dl for > 3-12 months, some 1.7 – 2.4 g/dl above projected nadir. In 2 of 3 EPO-naïve, Hb was increased 0.5 – 0.7 g/dl above baseline and remained between 10-12 g/dl for > 5-7 months. One had minimal response. In the EPO-naïve treated at 40 IU/kg/day Hb remained 10-10.7 g/dl for 4.5 months.Conclusions: a single EPODURE treatment can provide up to 12 months sustained ESA therapy in CKD patients. Now treating additional patients at higher doses, results to be presented.

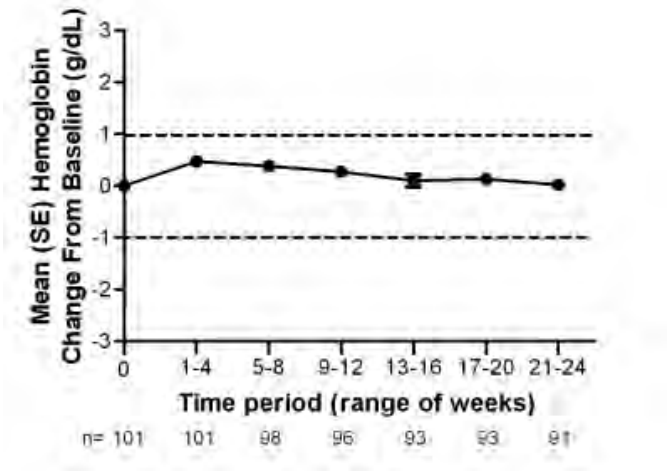
**A Phase 2 Study of the Safety and Effectiveness of Hematide™/Peginesatide for the Maintenance Treatment of Anemia in Patients Who Were Previously Treated with Darbepoetin Alfa** Steven Fishbane,[1] Francesco Locatelli,[1] Simon D. Roger,[1] Edouard R. Martin,[1] Grant S. Runyan,[2] Ping Qiu.[2] *[1]Peginesatide AFX01-202 Study Group; [2]Takeda Global Research & Development Center, Inc., IL.*

Background: Peginesatide is a PEGylated, investigational, peptide-based erythropoiesis-stimulating agent (ESA) that was designed and engineered to stimulate specifically the erythropoietin receptor that governs erythropoiesis.

Objective: To demonstrate that once-monthly peginesatide can maintain hemoglobin (Hb) levels in patients after conversion from darbepoetin alfa.

Methods: This phase 2 study included CKD patients who were receiving maintenance treatment with darbepoetin alfa and were either on hemodialysis (HD) or not on dialysis (CKD-ND). Starting peginesatide doses were determined with the use of a tiered weight-based darbepoetin alfa–to-peginesatide conversion table. Patients received Q4W peginesatide treatment for 24 weeks (Titration, Weeks 0-18; Evaluation, Weeks 19-24).

Results: A total of 101 patients were included (HD, n=52; CKD-ND, n=49). Mean (SD) baseline ferritin levels for the HD and CKD-ND groups were 448.1 (323.0) and 206.2 (132.9) ng/mL, respectively. Mean change in Hb from baseline by 4-week interval is presented in the Figure. Across both groups, 70.7% of patients maintained mean Hb within target (10-12 g/dL) during Evaluation. The most common adverse event (AE) was diarrhea (13.9% of patients). Four patients withdrew from the study because of AEs; 1 patient withdrawal was considered drug related (nausea, vomiting, decreased appetite).



Conclusions: In this study, once-monthly peginesatide treatment maintained mean Hb levels in CKD patients after converting from darbepoetin alfa, and the safety profile of peginesatide appeared consistent with those of marketed ESAs.

### F-FC272

**Use of the Mayo Clinic Anemia Management System (MCAMS) Decreases Darbepoetin Use by 30% in Chronic Hemodialysis (CHD) Patients** James T. McCarthy,[1] James L. Rogers,[2] Craig L. Hocum,[1] Edward J. Gallaher,[2] Stephen F. Gudgell,[1] Robert C. Albright.[1] *[1]Division of Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [2]Advance Management Group, Rochester, MN.*

MCAMS is a proprietary application to determine therapeutic dosing regimens (TDR) for erythropoietic stimulating agents (ESA's) in CHD patients to keep Hgb in a target range. MCAMS determines TDR using an individual's historical Hgb response, physiologic and pharmacokinetic parameters, and conditions such as hemorrhage or illness. In 2007-2009, darbepoetin, given IV once weekly, was the only ESA used by Mayo Clinic Dialysis Services (MCDS). In 2007 (Control=C), ESA was administered following a protocol based on 2006 NKF K/DOQI Guidelines with target Hgb of 10.0-12.9 gm/dL. MCAMS was validated in 2007 by comparing actual Hgb values to those predicted by MCAMS, using doses of darbepoetin given with the 2007 protocol. In 2008 (Transition=T), MCAMS was used in a single facility of 60 patients. In 2009 (Implementation=I), MCAMS was introduced into all other MCDS facilities. Monthly, we recorded darbepoetin use, and the percentage of MCDS patients with Hgb values of 10.0-12.9. The years 2007-2009 were divided into 6 month intervals (1=Jan-Jun; 2=Jul-Dec.), and the average monthly values for each 6 month period was compared.

| **Darbepoetin** | **2007** | **2007** | **2008** | **2008** | **2009** | **2009** |
|---|---|---|---|---|---|---|
| **Administered** | **C-1** | **C-2** | **T-1** | **T-2** | **I-1** | **I-2** |
| **Total in MCDS (mcg)/ month** | 93214± 7783 | 94544± 10403 | 80553± 9011 a | 83985± 8983 | 74668± 6742 a | 61322± 7418 b c |
| **mg/patient/ month** | 301±25.5 | 300±29.6 | 251±24.2 a | 258±28.5 a | 228±21.2 b | 183±19.4 b c |
| N - all MCDS patients | 310 | 315 | 320 | 325 | 327 | 334 |
| **% of patients with Hgb 10.0-12.9** | 62.0±3.0% | 63.1±4.6% | 69.9±3.9%a | 70.8±3.3%a | 72.5±4.0%a | 77.9±2.0%b |

Mean ± SD. T-test. a=p<0.05 vs. C-1 & C-2; b=P <0.001 vs. C-1 & C-2; c=P <0.001 vs. I-1.

MCAMS decreased darbepoetin use by over 30% in MCDS and increased the percent of patients achieving Hgb of 10.0-12.9 gm/dL. MCAMS will be an important tool for dialysis providers as CMS introduces bundling of dialysis payments in 2011.

Disclosure of Financial Relationships: nothing to disclose

**F-FC273**

**Clearance of Circulating Hepcidin during Haemodialysis and after Transplantation** Damien Ashby,[1] Mitul Palan,[1] Georgina Henrietta Aldous,[1] Mark Busbridge,[2] Kevin G. Murphy,[2] Stephen R. Bloom,[2] Neill D. Duncan,[1] Frederick W. K. Tam,[1] Peter Choi.[1] *[1]Imperial College Kidney and Transplant Institute, Hammersmith Hospital, London, United Kingdom; [2]Investigative Medicine, Imperial College, London, United Kingdom.*

The hepatic peptide hepcidin is the master regulator of iron absorption and transport. Inappropriate elevation of hepcidin in renal failure is thought to contribute to anaemia and erythropoietin resistance. Reduced levels of hepcidin have been observed following haemodialysis, but the factors influencing hepcidin clearance are unknown.

Plasma hepcidin was measured by radioimmunoassay in a group of haemodialysis patients before and after a single dialysis session, and in a group of patients undergoing renal transplantation.

In 96 haemodialysis patients (aged 23-89) median plasma hepcidin was 138ng/ml (IQR 82-175ng/ml), and levels were strongly correlated with ferritin (R=0.531, p<0.001). Significant hepcidin removal occurred during haemodialysis, with a median reduction of 53.4% (IQR 33.4-64.8%, p<0.001). By multiple linear regression, hepcidin reduction was found to be independently predicted by albumin, litres processed during dialysis and weight (table 1). There was no correlation with Kt/V, and neither was any significant relationship between hepcidin reduction and high vs low membrane flux observed (45.9 vs 48.7%, p=0.6).

Predictors of hepcidin reduction

| | Adj R sq | Beta | Sig |
|---|---|---|---|
| Albumin | 0.272 | 0.355 | <0.001 |
| Litres | 0.309 | 0.340 | 0.001 |
| Weight | 0.366 | -0.281 | 0.005 |

In 4 patients undergoing renal transplantation, plasma hepcidin levels were measured before, and 2-4 weeks after surgery. Hepcidin levels after transplantation were lower in all patients (mean reduction 25.2%, p=0.02) despite higher ferritin levels (mean increase 155%).

Substantial reductions in hepcidin are achieved by haemodialysis or renal transplantation. Clearance of hepcidin by haemodialysis is related to litres processed during dialysis and weight, but not to small solute clearance as measured by Kt/V. Hepcidin reduction may be an important therapeutic target in renal patients.

Disclosure of Financial Relationships: nothing to disclose

**F-FC274**

**Implementation of a Novel IV Iron for Iron Deficiency Anemia in Patients Undergoing In-Center Hemodialysis (HD)** Brigitte Schiller, Andrea Neitzer, Sheila Doss, Sumi Sun. *Satellite Healthcare, Mountain View, CA.*

Feraheme (ferumoxytol) is a new iron product recommended as initial 510 mg rapid IV push followed by a repeat after 3-8 days to treat iron deficiency anemia in patients with CKD. Ferumoxytol was introduced in an iron maintenance protocol to be given after routine monthly lab draws as a one time 510 mg IV push administration if TSAT < 30% OR ferritin < 500 ng/mL in both incident and prevalent patients on in-center HD. Contraindications were iron hypersensitivity, ferritin ≥ 800 ng/mL, TSAT ≥ 50% or Hb > 12.5 g/dL.

A total of 3,222 patients were given 7,134 doses of ferumoxytol following the Dec 2009 monthly labs until the end of May 2010. 1.3% of patients had one or more adverse events (38 gastrointestinal symptoms, 8 allergic reactions, and 7 hypotension), reflecting a rate of 0.6% (41/7,134 doses). Four serious adverse events occurred - 2 anaphylactoid reactions and 2 adjudicated as unrelated (sepsis, stroke).

The 2,822 patients treated exclusively with ferumoxytol (no other iron products) required an average of 2.2 doses (range 1-7) over 6 months. 33% of patients received one dose only, 33% two doses, 20% three, and 14% 4+ doses. Laboratory results (mean ± SD) for these patients during the 5 months prior to and after ferumoxytol introduction are shown:

| | Pre-ferumoxytol | Ferumoxytol |
|---|---|---|
| Hb (g/dL) | 11.7 ± 0.9 | 11.5 ± 0.9 |
| TSAT (%) | 28.5 ± 9.4 | 28.6 ± 11.4 |
| Ferritin (ng/mL) | 697 ± 212 | 715 ± 264 |

Clinical performance measures showed that Hb target (10-12g/dL) was reached in 67%, TSAT (20-50%) in 78%, and ferritin (200-800 ng/mL) in 53% of the patients while on ferumoxytol therapy.

A simple iron replacement protocol adjusted to TSAT or ferritin with 510 mg ferumoxytol given once after monthly blood work achieved stable iron stores and confirmed the drug's published safety profile in this large patient cohort. A favorable utilization profile was noted; evaluation of its effect on ESA usage is pending due to recent anemia protocol changes. Less frequent and rapid IV push administration of iron with this protocol will allow nurses to spend more time on direct patient care.

**F-FC275**

**Hepcidin Levels in Prevalent Non-Selected Hemodialysis Patients** Peter F. Barany,[1] Peter Stenvinkel,[1] Olof Heimburger,[1] Soheir Beshara.[2] *[1]Renal Medicine, CLINTEC, Karolinska Institutet, Stockholm, Sweden; [2]Division of Clinical Chemistry, Department of Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden.*

Hepcidin (Hep) is an important regulator of iron metabolism. Assays for assessment of plasma levels of Hep have recently been introduced but the role of Hep assays in clinical research and practice has not been established.

Hep-25 was measured in 219 prevalent hemodialysis (HD) patients using an ELISA method from Bachem (USA). Information about anemia treatment (210 treated with ESA), medications, comorbidity were recorded. Hb and ferritin, hypochromic RBC, CRP and IL-6 levels measured before a HD session. Results are presented as median (25-75 percentiles).

Hep levels in the HD patients, 111 (61-174) ng/ml, were higher than in healthy subjects (men 10-75 ng/ml, women 5-30 ng/ml). Age, sex and comorbidity did not affect Hep. Male patients with statin treatment had lower hepcidin 85 (31-144) ng/ml than those without statins 121 (73-218) ng/ml (p<0.01). Hep correlated strongly with ferritin levels (Spearman rho 0.58, p<0.001) but not with other anemia or inflammatory variables. In Table 1 the patients are grouped according to tertiles of Hep levels.

Anemia and inflammatory variables according to Hep tertile groups

| | Tertile 1 | Tertile 2 | Tertile 3 | p |
|---|---|---|---|---|
| Hep, ng/ml | 38 (22-61) | 110 (96-129) | 221 (170-267) | |
| Hb, g/dL | 11.9 (10.9-12.7) | 11.8 (11.0-12.7) | 12.0 (11.3-12.7) | 0.7 |
| Ferritin, µg/L | 216 (120-380) | 422 (296-610) | 630 (427-834) | <0.001 |
| Hypochromic RBC, % | 1.6 (0.75-4.1) | 1.1 (0.5-2.7) | 1.3 (0.8-4.0) | 0.12 |
| CRP, mg/L | 6.4 (2-18) | 6.3 (2.6-19) | 7.4 (3.0-24.3) | 0.5 |
| IL-6, pg/ml | 8.7 (4.7-14.5) | 8.8 (5.5-25.7) | 8.2 (5.5-47.7) | 0.8 |
| ESA, IU/kg per week | 168(106-240) | 119, (71-265) | 121 (78-209) | <0.05 |

Median (25-75 percentiles)

Unexpectedly, patients with the lowest Hep had the highest doses of ESA. However, ESA may down-regulate Hep expression. Several other factors such as iron overload, BMP, inflammation and anemia have been implicated in the regulation of Hep expression and the complexity of this signaling network affects the clinical usefulness of Hep assays.

**F-FC276**

**Efficacy of an Anemia Management Strategy Targeting Higher Transferrin Saturation (TSat) and Ferritin Levels Using Ferumoxytol** Premila Bhat, Joesan A. Gabaldon, Jodumutt Ganesh Bhat. *Atlantic Dialysis Management Services, LLC, Ridgewood, NY.*

Ferumoxytol, a novel intravenous iron formulation, was approved for treatment of anemia in chronic kidney disease (CKD) in June 2009. Ferumoxytol has been shown to improve iron indices in CKD and ESRD patients in comparison with oral iron. We report here our experience implementing an iron management protocol targeting TSat≥30% and ferritin≥500ng/mL using ferumoxytol. ESRD patients receiving hemodialysis at a regional chain of for-profit dialysis centers were treated with ferumoxytol (510 mg injection) if they had Hemoglobin<13 g/dL; TSat<30% or Ferritin<500ng/mL; and no documented allergies or intolerance to other intravenous irons. Prior to implementation of the ferumoxytol-based strategy, patients were treated with iron sucrose or sodium ferric gluconate at the discretion of their nephrologists. Primary outcome measures were changes in Hb and iron indices three months after ferumoxytol therapy was initiated. Secondary outcomes will include change in epoetin alfa dose, total iron dose, and overall costs. During the period from 9/15/2009 through 12/31/2009, 609 patients at 10 dialysis centers started treatment with ferumoxytol and 1379 doses of ferumoxytol were administered at three-month follow-up. Patients receiving ferumoxytol had a mean age of 64.07 years (SD 14.52); 57.7% were male and 42.2% were African-American. Patients were excluded from analysis if baseline or follow-up laboratory data was missing. Significantly improved Hb and iron parameters were observed with the ferumoxytol-based strategy (Table 1). In conclusion, a ferumoxytol-based anemia management strategy targeting TSat≥30% and Ferritin≥500ng/mL resulted in higher mean Hb values.

| | Baseline Mean (SD) | 3-Month Post Baseline (SD) | Change from Baseline (SD) |
|---|---|---|---|
| Hemoglobin (g/dL) (n=529) | 11.00 (1.318) | 11.33 (1.219) | 0.34 (1.662) p<0.0001 |
| Ferritin (ng/mL) (n=515) | 355.63 (267.16) | 541.25 (411.27) | 185.62(332.16) p<0.0001 |
| TSat (%)(n=530) | 23.82 (10.23) | 30.65 (13.07) | 6.83 (15.67) p<0.0001 |

Table 1. Hb and Iron Indices at baseline and 3 months after ferumoxytol.

**The Mayo Clinic Anemia Management System (MCAMS) Improves Achievement of Target Hemoglobin (Hgb) Values and Decreases High Hgb Values in Chronic Hemodialysis (CHD) Patients** James T. McCarthy,[1] James L. Rogers,[2] Craig L. Hocum,[1] Edward J. Gallaher,[2] Stephen F. Gudgell,[1] Robert C. Albright.[1] *[1]Division of Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [2]Advance Management Group, Rochester, MN.*

MCAMS is a proprietary application to determine therapeutic dosing regimens (TDR) for erythropoietic stimulating agents (ESA's) in CHD patients to keep Hgb in a target range. MCAMS determines TDR using an individual's historical Hgb response, with physiologic and pharmacokinetic parameters, and conditions such as hemorrhage or illness. We implemented MCAMS in Mayo Clinic Dialysis Services (MCDS) in 2008-2009. In 2007-2009, darbepoetin, given IV once weekly, was the only ESA used in MCDS. In 2007 (Control=C), ESA was administered according to a protocol based on 2006 NKF K/DOQI Guidelines with target Hgb of 10.0-12.9 gm/dL. MCAMS was validated in 2007 by comparing actual Hgb values to those predicted by MCAMS, using the doses of darbepoetin administered with the 2007 protocol. In 2008 (Transition=T), MCAMS was used in a single facility of 60 patients. In 2009 (Implementation=I), MCAMS was introduced into all other MCDS facilities. Monthly, we recorded the percentage of MCDS patients with Hgb < 10.0; Hgb 10.0-12.9; or Hgb > 12.9. The years 2007-2009 were divided into 6 month intervals (1=Jan-Jun; 2=Jul-Dec), and average monthly Hgb performance for each 6 month period was compared.

| | 2007 | 2007 | 2008 | 2008 | 2009 | 2009 |
|---|---|---|---|---|---|---|
| **Percent Patients** | **C-1** | **C-2** | **T-1 a** | **T-2 a** | **I-1 a** | **I-2 ab** |
| **Hgb < 10.0** | 7.6±0.8% | 6.3±1.2% | 9.2±1.3% | 9.1±1.3% | 11.3±2.4% | 11.1±2.1% |
| **Hgb 10.0-12.9** | 62.0±3.0% | 63.1±4.6% | 69.9±3.9% | 70.8±3.3% | 72.5±4.0% | 77.9±2.0% |
| **Hgb > 12.9** | 30.4±3.2% | 30.6±4.2% | 20.9±3.5% | 20.1±2.3% | 16.2±4.1% | 11.0±1.1% |
| N - all patients | 310 | 315 | 320 | 325 | 327 | 334 |

Mean ± SD. T-test. a=all p<0.05 vs. C-1 & C-2; b=all p<0.01 vs. T-1 & T-2

MCAMS decreased patients with Hgb > 12.9 gm/dL and increased patients with Hgb in range of 10.0-12.9 gm/dL. The use of MCAMS leads to significant improvement in anemia control when compared to the prior protocol.

**Oncostatin M Receptor β and Cysteine/Histidine-Rich 1 as Candidate Biomarkers of Erythropoietin Response** Michael Brier,[1,2] Michael Merchant,[2] Adam Gaweda,[2] Brad H. Rovin,[3] Jon B. Klein.[1,2] *[1]Robley Rex VA Medical Center, Louisville, KY; [2]University of Louisville, Louisville, KY; [3]The Ohio State University, Columbus, OH.*

Current biomarkers of hemoglobin (Hb) response to erythropoietic agents (ESA) primarily are measures of inflammation and iron availability. While these are important factors in modifying an individual's response to an ESA, they do not address all aspects of poor response. We tested the hypothesis that peptides present in the serum of hemodialysis patients are predictive of ESA response. Our objective was to identify biomarkers of ESA response. Serum from 15 good responders and 20 poor responders was collected and evaluated. Ninety-one candidate biomarker targets were identified and characterized using mass spectrometry (MS). Analysis of tandem MS data provided partial amino acid sequence information of 17 different peptides for 16 peptide masses whose serum abundance significantly differed between poor and good responders for further analysis.

| Peptide | m/z | p value | ROC |
|---|---|---|---|
| OSMR | 1273 | <0.0001 | 0.95 |
| OSMR | 1549 | <0.0001 | 0.96 |
| OSMR | 1664 | <0.0001 | 0.99 |
| CYHR1 | 1488 | <0.0001 | 0.089 |
| Fibrinogen B | 1552 | 0.005 | 0.20 |
| Factor XIII | 1210 | 0.015 | 0.25 |
| Complement C3 | 1504 | 0.07 | 0.26 |

ROC > 0.5 poor response, < 0.5 good response

The analysis concluded the 3 serum peptides associated with poor erythropoietin response were derived from the oncostatin M receptor β chain (OSMRβ). The 13 serum peptides associated with good erythropoietin response were derived from fibrinogen α chain, fibrinogen β chain, coagulation factor XIII A chain, complement C3 and cysteine/histidine rich 1(CYHR1). Poor response was most strongly associated with the largest molecular weight OSM fragment (ROC=0.99) while good response was most strongly associated with CYHR1 (ROC=0.91 (1-0.089)). Immunoblot experiments demonstrated that intact OSMRβ and CYHR1 abundance significantly differed between good and poor responders. Two novel biomarkers of ESA response are presented along with the first published association of CYHR1 and biological activity.

**Insulin Is a Positive Modulator of NCC Activity through a PI3K Dependent Mechanism** María Chávez Canales,[1] Norma Hilda Vázquez,[1] Juan Pablo Arroyo,[1] Maria Castañeda-Bueno,[1] Benjamin S. Ko,[2] Norma Bobadilla,[1] Robert S. Hoover,[2] Gerardo Gamba.[1] *[1]Molecular Physiology Unit, INNSZ-INCICH-IIB, UNAM, Mexico City; [2]University of Chicago, Chicago.*

One potential mechanism that has been advanced to explain the obesity-induced hypertension is the effect that insulin may have upon renal salt reabsorption. In this study we assessed the effect of insulin on the activity of the renal NaCl cotransporter, NCC, using the heterologous expression system of *Xenopus* oocytes and mDCT15 cells. NCC activity was measured as the thiazide-sensitive tracer $^{22}Na^+$ uptake. Three days after injection of NCC cRNA, we observed that NCC activity was increased by 2 or 3-fold when oocytes were exposed to insulin for 15 minutes before the uptake. The positive effect of insulin on NCC activity was also observed in mDCT15 cells endogenously expressing NCC. In oocytes, addition of wortmannin, an inhibitor of phosphatydil-inositol 3-kinase (PI3K) completely abrogated the positive effect of insulin on the transporter's activity, without affecting the basal function. The effect of insulin was also abolished by the specific AKT inhibitor IV. MAP or mTOR kinases inhibitors had no effect. Coinjection of NCC cRNA with wild type or catalytically inactive WNK4, WNK3, or SPAK cRNA did not affect the activation of NCC by insulin. Western blot analysis using anti-FLAG monoclonal antibodies with proteins extracted from oocytes revealed that FLAG-NCC level of expression was not affected by insulin. We also assessed the phosphorylation of NCC at residue T58 using a specific phosphoantibody. Although NCC phosphorylation was increased by co-injection with WNK3 or by intracellular chloride depletion, no increased signal was observed after insulin treatment. We conclude that insulin is a powerful activator of NCC in *Xenopus* oocytes by its threonine/serine phosphorylation mediated by PI3K-AKT pathway. However, the WNK4-SPAK-T58 phosphorylation does not seem to be involved. The insulin effect on NCC is also present in mDCT15 cells. Our observations have implications to explain the association between obesity and diabetes mellitus with arterial hypertension.

**SPAK Knockout Causes a Gitelman-Like, but Not Bartter-Like, Phenotype** James A. McCormick,[1] Joshua H. Nelson,[1] Kerim Mutig,[2] Turgay Saritas,[2] Sebastian C. Bachmann,[2] Eric J. Delpire,[3] David H. Ellison.[1] *[1]Division of Nephrology & Hypertension, Oregon Health & Science University, Portland, OR; [2]Department of Anatomy, Charité Universitätsmedizin, Berlin, Germany; [3]Department of Anesthesiology, Vanderbilt University School of Medicine, Nashville, TN.*

SPAK (Ste20-related Proline Alanine rich Kinase) is a protein kinase that phosphorylates and activates members of the cation chloride cotransporter family (NCC, NKCC2, NKCC1). SPAK is expressed in neurons and in many epithelia. In kidney, its expression is highest along the thick ascending limb (TAL) and distal convoluted tubule (DCT). WNK (With No Lysine (K)) kinases phosphorylate SPAK, which would be expected to phosphorylate and activate transporters along the TAL and DCT. To test the physiological significance of SPAK interaction with renal ion transporters, we evaluated the renal phenotype of SPAK knockout (KO) mice. Immunofluorescence showed that SPAK was absent along both the TAL and DCT in KO mice. Baseline plasma electrolytes were similar in wild type (WT) and KO siblings, but the urine calcium/creatinine ratio was significantly lower (60% of WT; p<0.05). Dietary NaCl-loading stimulated kaliuresis and reduced serum $K^+$ concentration to a similar extent in both groups, but urinary calcium excretion increased only in WT mice. Systolic blood pressures did not differ between WT and KO mice on control diet; dietary NaCl restriction reduced blood pressure in KO (by 10mmHg) but not WT mice. Total NCC protein abundance was 60% lower in KO than in WT animals (p<0.001); the level of phosphorylated NCC (T53 and S71) was 80% lower in KO than WT mice, but cellular distribution of NCC did not differ. The fractional volume of the DCT was reduced by 46% in KO mice. The abundance of total NKCC2 was not different in KO versus WT mice, but phosphorylated NKCC2 was markedly increased. These results show that SPAK deletion abrogates calciuresis induced by extracellular fluid volume expansion, despite preserved flow-dependent $K^+$ excretion. In summary, SPAK has a non-redundant role in arterial pressure homeostasis by activating NCC in the DCT, but surprisingly they do not confirm such a role with respect to NKCC2.

**SPAK Knockout Mice Manifest Gitelman's Syndrome and Impaired Vasoconstriction** Sung-Sen Yang,[1] Pauling Chu,[1] Shinichi Uchida,[2] Sei Sasaki,[2] Shih-Hua P. Lin.[1] *[1]Division of Nephrology, Department of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [2]Department of Nephrology, Graduate School of Medicine, Tokyo Medical and Dental University, Tokyo, Japan.*

Polymorphisms in the STK39 gene encoding SPAK [STE20 (sterile 20)/SPS1-related proline/alanine-rich kinase] have been identified as hypertension susceptibility genes in humans. SPAK interacts with WNK 1 and 4 to regulate ionic transporters, $Na^+$-($K^+$)-(2)$Cl^-$ cotransproter [N(K)CC]. Mutations in WNK1/4 and N(K)CC can cause changes in blood pressure and dyskalemia in humans. To elucidate the physiologic role of SPAK *in vivo*, we generated and analyzed SPAK-null mice by targeting disruption of exons 9 and 10 of SPAK. Blood pressure, aortic contractility, blood and urine electrolytes and biochemistries,

and relevant protein expression in the kidneys and aortic tissues were examined. Compared with $SPAK^{+/+}$ mice littermates, $SPAK^{+/-}$ mice exhibited hypotension without significant electrolyte abnormalities while the $SPAK^{-/-}$ mice not only exhibited hypotension but also recapitulated Gitelman's syndrome (GS) with hypokalemia, hypomagnesemia, and hypocalciuria. In the kidney tissues of $SPAK^{-/-}$ mice, the expression of total and phosphor (p-)NCC was markedly decreased but that of p-OSR1, total NKCC2 and p-NKCC2 was significantly increased. Blunted response to thiazide but normal response to furosemide was also observed in $SPAK^{-/-}$ mice. In aortic tissues, both $SPAK^{+/-}$ and $SPAK^{-/-}$ mice had impaired response to phenylephrine (a selective $\alpha_1$-adrenergic agonist) and bumentanide (a NKCC1 inhibitor). While total NKCC1 expression was increased, p-NKCC1 was decreased. Thus, SPAK-null mice have defects of NCC in the kidneys and NKCC1 in the blood vessels, leading to hypotension through renal salt wasting and vasodilatation.SPAK may be a promising target for anti-hypertensive therapy.

**Impaired $Na^+$ and $K^+$ Excretion in Inducible Renal Tubule-Specific Nedd4-2 Knockout Mice** Caroline Ronzaud,[1] Dominique Loffing,[2] Baoli Yang,[3] John B. Stokes,[4] Robert Koesters,[5] Johannes Loffing,[2] Olivier Staub.[1] *[1]Department of Pharmacology & Toxicology, Lausanne University, Switzerland; [2]Institute of Anatomy, Zurich University, Switzerland; [3]Obstetrics and Gynecology, Iowa University; [4]Department of Internal Medicine, Iowa University; [5]INSERM UMRS 702, UPMC, Tenon Hospital, Paris, France.*

Generation of Nedd4-2 total knockout (KO) mice revealed that Nedd4-2 inactivation leads to $Na^+$ retention and hypertension. To determine the role of renal Nedd4-2 in mediating salt-sensitive hypertension *in vivo*, inducible renal tubule-specific Nedd4-2 KO mice were generated by combining the TetOn and CreLoxP systems. Pax8-rtTA transgenic mice expressing the reverse tetracycline (Tet)-dependent transactivator (rtTA) along all renal tubules were bred with TRE-LC1 transgenic mice expressing the Cre recombinase under the control of a rtTA-response element (TRE). Double transgenic Pax8-rtTA/TRE-LC1 mice (Pax8/LC1) allowing Tet-inducible renal tubule-specific Cre-mediated recombination were bred with mice homozygous for the Nedd4-2 floxed allele to obtain the mutants ($Nedd4\text{-}2^{fl/fl}$/Pax8/LC1). Controls ($Nedd4\text{-}2^{fl/fl}$/Pax8 or $Nedd4\text{-}2^{fl/fl}$/LC1) and mutants were treated with doxycyclin (Dox, 2mg/ml) for 11d and fed with high-$Na^+$ diet for 8d. Western-blot on total kidney lysates revealed complete loss of Nedd4-2 in Dox-treated mutants. Daily urine volume was increased in mutants, whereas plasma aldosterone, urine $Na^+$ and absolute urinary $Na^+$ excretion were decreased. Interestingly, mutants showed impaired urinary $K^+$ excretion, paralleled with hyperkalemia. Western blot on kidneys showed increased α-, β-, γ-ENaC, and NCC protein abundance in mutants. In addition, immunofluorescence revealed increased ROMK protein expression in distal convoluted tubules and connecting tubules in mutants, which might be secondary to the hyperkalemia. Taken together, these data suggest that inducible Nedd4-2 ablation in renal tubules of adult mice leads to $Na^+$ retention, likewise via ENaC and NCC over-activation. The impaired $K^+$ excretion in mutants suggests that Nedd4-2 is important for maintaining $K^+$ balance. The mechanisms behind this regulation remain to be elucidated.

**F-FC283**

**Differential Regulation of NCC and ENaC by the Sgk1/Nedd4-2 Pathway** Juan Pablo Arroyo,[1] Dagmara Lagnaz,[2] Caroline Ronzaud,[2] Norma Hilda Vázquez,[1] Gerardo Gamba,[1] Olivier Staub.[2] *[1]INNSZ-INCICH-IIB, UNAM, Mexico; [2]Laussane University, Switzerland.*

Appropriate regulation of renal $Na^+$ transport is essential for control of blood pressure and $Na^+$ homeostasis. Aldosterone stimulates $Na^+$ reabsorption in the aldosterone-sensitive distal nephron (ASDN). It is known that aldosterone increases NCC expression at the protein level by an unknown mechanism, without increasing the NCC gene transcription rate or mRNA levels. In this regard, in the ASDN the ubiquitin-protein ligase Nedd4-2 regulates the sodium channel ENaC: under aldosterone induction, Sgk1 phosphorylates Nedd4-2, thus preventing the interaction of Nedd4-2 with ENaC and avoiding the ubiquitylation and degradation of the channel. In the present study we investigated if NCC is also regulated to this pathway. We obtained evidences that Nedd4-2 is indeed a regulator of NCC. In transfected Hek293 cells, Nedd4-2 co-immunoprecipitated with NCC, stimulated NCC ubiquitylation at the cell surface, and increased its turnover. In *Xenopus laevis* oocytes co-injection of cRNA of NCC with wild-type Nedd4-2, but not the catalytically inactive Nedd4-2, dramatically decreased NCC-induced thiazide-sensitive $^{22}Na^+$ uptake. This inhibition was prevented by Sgk1 in a kinase-dependent manner. In contrast to the regulation of ENaC by Sgk1/Nedd4-2, the modulation of NCC by Nedd4-2 is PY independent and mutation of Nedd4-2 Ser328 either to alanine or to aspartate did not interfere with Sgk1 action on Nedd4-2-NCC, implying a differential regulation of NCC and ENaC by Sgk1-Nedd4-2 pathway. Additionally, NCC expression is up-regulated in an inducible nephron-specific Nedd4-2 knockout mouse model, whereas NCC expression is reduced in Sgk1 knockout mice. These results strongly suggest that NCC activity is controlled by a regulatory pathway involving Nedd4-2 and Sgk1, provides an explanation for the well known aldosterone-induced increase in NCC protein expression and suggest a differential regulation of NCC-ENaC by Sgk1-Nedd4-2 pathway that has implications to understand the modulation of ion transport pathways during high aldosterone states like hyperkalemia.

**F-FC284**

**Insulin and IGF1 Enhance Endocytosis of ROMK Via a PI3 Kinase-Akt1/SGK1-WNK1 Dependent Pathway** Chih-Jen Cheng,[1,2] Chou-Long Huang.[1] *[1]Medicine, UT Southwestern Medical Center, Dallas, TX; [2]Medicine, Tri-Service General Hospital, NDMC, Taipei, Taiwan.*

WNK1 (with-no-lysine-1) kinase inhibits ROMK channel by stimulating its endocytosis, which contributes to hyperkalemia in patients with pseudohypoaldosteronism type 2 (PHA2) caused by overexpression of WNK1. Members of ACG protein kinase family, Akt1 and SGK1, phosphorylate WNK1 *in vitro*. In this study, we investigate the importance of this phosphorylation in the regulation of ROMK expressed in HEK cells using patch-clamp recording and biochemical studies. We find that serum deprivation increases ("dis-inhibits") whole-cell ROMK current. Application of insulin or insulin-like growth factor IGF1 (at physiological concentrations) after serum deprivation (re)inhibits ROMK within 30 minutes. The inhibition of ROMK by insulin/IGF1 is diminished by pre-treatment with phosphatidylinositol 3 (PI3)-kinase inhibitor wortmannin or by siRNA knockdown of endogenous WNK1, SGK1 or Akt1. The effect of knocking down both Akt1 and SGK1 is greater than that of knocking down Akt1 or SGK1 individually. Western blot analysis using respective residue-specific phospho-antibodies reveals that serum deprivation diminishes phosphorylation of Akt1 at the T-loop and the hydrophobic motif and of WNK1 at a threonine equivalent to T58 of rat WNK1. Addition of insulin thereafter increases respective phosphorylation of Akt1 and WNK1 in a wortmannin-sensitive manner. Overexpression of Akt1, SGK1 or WNK1 inhibits ROMK in serum-containing media. Co-expression with T58A mutant of WNK1 prevents the inhibition of ROMK caused by Akt1 or SGK1. The inhibition of ROMK by SGK1 is prevented by coexpression of a dominant-negative dynamin2 mutant, but not by mutation of S44 of ROMK1, a previously reported phosphorylation site for SGK1. We conclude that phosphorylation of WNK1 at T58 by Akt1/SGK1 enhances its ability to stimulate endocytosis of ROMK. This mechanism allows for regulation of ROMK and renal potassium secretion by PI3 kinase-activating hormones. One such condition is chronic dietary potassium restriction, in which IGF1 is upregulated and renal potassium secretion is inhibited to conserve potassium.

**Hypertension Resistance Polymorphisms in ROMK (Kir1.1) Alter Channel Function by Different Mechanisms** Liang Fang, Dimin Li, Paul A. Welling. *Physiology, University of Maryland School of Medicine, Baltimore, MD.*

The ROMK potassium channel plays a critical role in renal sodium handling. Recent genome sequencing efforts in the Framingham Heart Study offspring cohort (Ji et al, Nature Genet, '08) recently revealed an association between suspected loss-of-function polymorphisms in the ROMK channel and resistance to hypertension, suggesting that ROMK activity may also be a determinant of blood pressure control in the general population. Here, we examine whether these sequence variants do, in fact, alter ROMK channel function and explore the mechanisms. As assessed by two-microelectrode voltage clamp in Xenopus oocytes, 3/5 of the variants (R193P, H251Y and T313FS) displayed an almost complete attenuation of whole-cell ROMK channel activity. Surface antibody binding measurements of external epitope tagged channels and analysis of glycosylation-state maturation revealed that these variants prevent channel expression at the plasmalemma, likely as a consequence of retention in the endoplasmic reticulum. The other variants (P166S, R169H) had no obvious effects on the basal channel activity or surface expression but, instead, conferred a gain in regulated-inhibitory gating. As assessed in giant excised patch-clamp studies, apparent PIP2 binding affinity of the variants was reduced, causing channels to be more susceptible to inhibition upon PIP2 depletion. Unlike the protein product of the major ROMK allele, these two variants are sensitive to the inhibitory affects of G-protein coupled receptor stimulation of phospholipase C (PLC) and PIP2 hydrolysis. In summary, we have found that hypertension resistance sequence variants inhibit ROMK channel function by different mechanisms, providing new insights into the role of the channel in blood pressure control.

**F-FC286**

**Regulation of BK Channel-Mediated Net K Secretion (JK) by NKCC in the Cortical Collecting Duct (CCD)** Wen Liu,[1] Carlos Schreck,[1] Beth Zavilowitz,[1] Thomas R. Kleyman,[2] Lisa M. Satlin.[1] *[1]Mount Sinai School of Medicine, NY, NY; [2]University of Pittsburgh, Pittsburgh, PA.*

Apical SK/ROMK and Ca2+-activated BK channels mediate baseline and flow-induced JK (FIKS; pmol/min.mm), respectively, in the CCD. BK channels are detected in both principal (PCs) and intercalated (ICs) cells. Although the density of BK channels is greater in ICs than PCs, Na/K-ATPase activity in ICs is considered inadequate to sustain high rates of urinary K secretion. Immunodetectable basolateral 'secretory' Na-K-2Cl cotransporter (NKCC1) is present in ICs in rat medullary CD (Ginns et al, JASN 7:2533, 1996). Furthermore, microdissected rabbit CCDs express mRNA encoding NKCC1 (Liu et al, ASN Renal Week 2009: F-PO1167). To test whether basolateral NKCC in the CCD contributes to BK channel-mediated FIKS, we measured JK and net Na absorption (JNa) in NZW rabbit CCDs (n=3) microperfused in vitro at fast (~5 nl/min.mm) flow rates in the absence and presence of bumetanide (10 μM) added to the bath. Bumetanide did not affect JNa (73.7±4.6 to 70.1±8.5; p=NS), but inhibited FIKS (-15.8±2.1 to -8.4± 3.8; p<0.05); addition of luminal iberiotoxin (50 nM) to these same tubules did not further reduce JK (-6.3 ±2.1, p=NS). To confirm that FIKS requires basolateral Cl, we measured the effect of basolateral Cl removal (replaced with gluconate) on FIKS. Basolateral Cl removal reversibly inhibited FIKS (-22.7±5.6 to -8.2± 0.8; n=5, p<0.05) but, in CCDs perfused at a slow flow rate (~1 nl/min.mm), had no effect on JK (-10.4± 2.2 to -11.8± 1.9; p=NS) or JNa (p=NS). These results suggest that BK channel-mediated FIKS is dependent on a basolateral bumetanide-sensitive Cl-dependent transport pathway, proposed to be NKCC, in the CCD. Studies are underway to more precisely define the cell type to which this cotransporter is localized.

**F-FC287**

**Basolateral Kir2.3 and Kir 4.1 Form Heteromeric Potassium Channels That Are Disrupted by EAST/SeSAME Syndrome Mutations** Bernardo Ortega, Dimin Li, Boyoung Kim, James B. Wade, Paul A. Welling. *Physiology, University of Maryland School of Medicine, Baltimore, MD.*

Basolateral inwardly rectifying potassium channels (Kir) in the distal nephron are responsible for maintaining a negative membrane potential, essential for salt and mineral reabsorption. Although different Kir channel subunits are expressed in distal segments, the recent discovery that loss-of-function mutations in Kir 4.1 cause profound renal salt wasting (EAST/ SeSAME syndrome, Bockenhauer, NEngl J Med, 2009 and Scholl, Proc Natl Acad Sci, 2009) suggests Kir 4.1 may play an especially dominant role, possibly through assembly with the other Kir subunits. Kir 4.1 interacts with Kir 5.1, but the extent to which it may operate with the other basolateral Kir remains unknown. Here, we explore this issue. We found Kir2.3 co-localizes with Kir4.1 in the mouse distal nephron, and co-immunoprecipitation studies in a heterologous expression system revealed that Kir 2.3 is capable of interacting with Kir 4.1. As studied in Xenopus oocytes, co-expression of Kir 2.3 with Kir4.1 potentiated potassium current density and increased cell surface expression. Indicative of heteromultimeric assembly, a dominant negative mutation in the Kir4.1 potassium-selectivity filter blocked Kir2.3 activity, and a comparable mutation in Kir2.3 inhibited Kir4.1. At the single channel level, Kir2.3/4.1 channels exhibit properties different than Kir2.3 or Kir4.1 alone, more similar to the native 20pS channel in the CCD basolateral membrane. Interestingly, of the 6 described EAST/SeSAME syndrome mutations (R65P, C140R, T164I, A167V, R199X, R297C), 4 of them exerted a partial reduction on Kir4.1/5.1 function (R65P, C140R, T164I, R297C), and 3 of them (R65P, C140R, T164I) exerted a similar or even greater (C140R) dominant negative effect on Kir2.3. In conclusion: 1) basolateral K channels of the distal nephron can be formed through heterotetrameric assembly of Kir4.1/5.1 or Kir4.1/2.3 subunits; 2) Consequently, the inhibitory effects of EAST/SeSAME syndrome mutations can be broadly transmitted throughout the basolateral membrane conductance.

**The Novel Plasminogen Receptor, Plg-$R_{KT}$, Colocalizes with ENaC and Regulates Plasmin-Dependent ENaC Processing** Kevin W. Chen,[1,2] Hongdong Bai,[1,2] Stan Krajewski,[3] Volker Vallon,[1,2] William B. Kiosses,[4] Lindsey A. Miles,[4] Robert J. Parmer.[1,2] *[1]University of California, San Diego; [2]VA San Diego Healthcare System; [3]Sanford-Burnham Medical Research Institute; [4]The Scripps Research Institute, La Jolla, CA.*

Plasminogen (Plg) binding to cells markedly enhances its activation, and concentrates and localizes the proteolytic activity of plasmin on cell surfaces. Recent results suggest a key role for plasmin in the processing and activation of ENaC in nephrotic syndrome, in which increased Plg concentrations are present in urine. We recently identified a novel transmembrane Plg receptor, Plg-$R_{KT}$, from macrophages. Here, we tested the hypothesis that Plg-$R_{KT}$ regulates plasmin-mediated ENaC processing in renal epithelial cells. Immunohistochemistry with specific anti-Plg-$R_{KT}$ mAb demonstrated prominent expression of Plg-$R_{KT}$ in human kidney sections, particularly in distal tubular epithelium. Western blotting of MDCK and M1 mouse collecting duct cells revealed that Plg-$R_{KT}$ was highly expressed and localized to the cell membrane. In confocal microscopy Plg-$R_{KT}$ was immunodetected at the apical surface, an orientation allowing for interaction with urinary Plg. Moreover, merged images demonstrated prominent colocalization of Plg-$R_{KT}$ with ENaC and the urokinase receptor (uPAR); the extent of colocalization of Plg-$R_{KT}$ with ENaC was 79±3% and 75±3%, and with uPAR was 82±1% and 73±3% in MDCK and M1 cells, respectively. Thus, Plg-$R_{KT}$, uPAR and ENaC are present in very close proximity on the cell surface in an orientation to promote Plg activation and ENaC processing. When Plg activation was initiated by addition of Plg and urokinase to M1 cell membranes, plasmin-dependent γENaC processing was markedly inhibited by pre-incubation with anti-Plg-$R_{KT}$ mAb and by epsilon aminocaproic acid (a lysine analog that blocks the interaction of Plg with Plg-$R_{KT}$). These results demonstrate that Plg-$R_{KT}$ is prominently expressed in the kidney, and is colocalized with ENaC and with uPAR on the apical surface of distal nephron cells. The results also suggest that Plg-$R_{KT}$ is an important regulator of Plg activation and plasmin-dependent ENaC processing in renal epithelial cells.

**Pretransplant Risk Factors for Posttransplant Polyoma BK-Virus Nephropathy** Anke Schwarz,[1] Verena Broecker,[2] Hermann G. Haller,[1] Silvia Linnenweber-Held.[1] *[1]Nephrology, Hannover Medical School, Hannover, Germany; [2]Pathology, Hannover Medical School, Hannover, Germany.*

BK virus (BKV) replication threatens renal transplant function. - Methods: We tried to find out the source of BKV infection by testing blood and urine of 67 donor/recipient pairs before living transplantation by quantitative PCR (qPCR) (CE labeled in vitro diagnostic kit, Cepheid-Affigene); the recipient then was followed by regular posttransplant qPCR and protocol biopsies at 6, 12, and 26 weeks. Results: Ten of 67 recipients (15%) developed posttransplant BKV nephropathy (BKVN). In 6 of these BKVN patients, urine qPCR of either the donor (3) or the recipient (2) or both (1) as well as blood qPCR of the donor (1) or the recipient (1) had been positive before transplantation. However, in 4 of the 10 BKVN patients, pretransplant urine and blood PCRs had been negative. On the other hand, 4 donors and 1 recipient had a positive pretransplant urine (4) or blood (1) qPCR but the recipient did neither develop BKVN nor elevated BKV loads. In 1 other donor and recipient each, urine and blood PCR were positive before transplantation, but the recipients developed just a transient increase of blood and urine BKV loads without BKVN. Moreover, 7 other recipients with a negative pretransplant urine and blood qPCR developed transient urine and/or blood BKV loads. - Thus, in 13 of 67 donor/recipient pairs (19%), one of them or both showed pretransplant viral replication in urine and/or blood. Six of these developed BKVN and 2 nonsignificant BKV loads suggesting a BKV infection risk (8 of 13, 62%) and a BKVN risk (6 of 13, 46%); in comparison, only 12 of 54 recipients (22%) with negative pretransplant donor/recipient viral replication developed BKV infection (62% vs 22%, p=0.01) and only 4 of 54 recipients BKVN (46% vs 7%, p=0.001). We conclude that pretransplant viral replication of donor or recipient means a risk for later recipient BKVN. Only a minority of patients may develop BKVN by pretransplant low level BKV persistence of donor or recipient beyond the sensitivity threshold of qPCR. We are now going to sequence BKV DNA from pretransplant urine and blood samples and compare these with posttransplant viremia.

**The Association of HLA Epitopes with BK Virus Reactivation in Renal Transplant Recipients** Janna L. Huskey,[1] Michael T. Aubrey,[2] Ronald P. Schuyler,[3] Brian M. Freed,[2] Alexander C. Wiseman.[1] *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]ClinImmune Labs, University of Colorado Denver, Aurora, CO; [3]Computational Bioscience, University of Colorado, Aurora, CO.*

Background:BK virus (BKV) is a significant cause of renal allograft dysfunction and graft loss. However, only a fraction of patients develop BK reactivation despite similar degrees of immunosuppression, suggesting that additional individual factors such as HLA variations may contribute to the development of BK infection post-transplant (tx). We tested the hypothesis that there are HLA epitopes that may confer a protective or permissive state to BK reactivation.

Methods:We performed a molecular HLA analysis for Class I (HLA-A,B,C) and Class II (HLA-DRB1, DQB1) alleles to compare epitope frequencies in 52 kidney tx patients with BK viremia to a race-matched healthy control group of 891 umbilical cord blood donors. A validated R-based bioinformatics program capable of analyzing HLA data sets and identifying shared epitopes was used.

Results:HLA-A,B,C and DRB1 did not contain any epitopes that were associated with BK reactivation. However, the HLA-DQB1 analysis identified an epitope (EV--RGI$^{84\text{-}90}$) that was associated with BK resistance (p=0.028;corrected for multiple comparisons). EV--RGI$^{84\text{-}90}$ is found in DQ5 and DQ6 alleles, and amino acids in positions 86-87 appear to have no effect. Patients with BKV were more likely to be homozygous for the absence of EV--RGI$^{84\text{-}90}$ vs. controls (59.6% vs. 36.9%, p=0.001). The presence of a single DQB1 allele with the EV--RGI$^{84\text{-}90}$ epitope was more common in controls vs. those with BK infection (45.8% vs. 23.1%, p = 0.008) suggesting that being heterozygous for EV--RGI$^{84\text{-}90}$also confers BK resistance.

Conclusions:Individuals lacking the EV--RGI$^{84\text{-}90}$ epitope may be more susceptible to BK viremia after kidney tx, potentially due to less robust BK viral antigen presentation. This may help identify individuals who are at increased risk for BK reactivation and require more aggressive screening for BKV.

**A Multicenter Experience of Re-Transplantation for BK Virus Nephropathy**
Duvuru Geetha,[1] Stephen M. Sozio,[1] Mythili Ghanta,[2] Michelle A. Josephson,[3] Darshana Dadhania,[4] Ron Shapiro,[5] Sundaram Hariharan.[6] *[1]Johns Hopkins University; [2]Columbia; [3]University of Chicago; [4]Cornell; [5]Univ of Pittsburgh; [6]Medical College of Wisconsin.*

BK virus nephropathy (BKVAN) is a significant cause of renal graft loss. The aim of this multi center study is to describe the characteristics and outcomes of patients who have undergone re-transplantation after loss of their prior allograft to BKVAN. 25 patients from 5 centers underwent re-transplantation at a mean of 17 months after failure of the first allograft with 8/25 undergoing pre-emptive transplantation. 20/25 had clearance of viremia documented and 9 had transplant (Tx) nephrectomy performed prior to the re-transplant. 20/25 received induction therapy. 2 of 5 centers had changed immunosuppression protocols in the re-transplants. Post transplant, 22 had BKV screening with 9 patients having BKV replication in urine and/or plasma while none developed BKVAN. Only 4/9 had documented viremia clearance at the time of re-transplant. 7 of the 25 patients experienced 10 rejection episodes. In univariate analysis, documented viremia clearance was significantly associated with lack of BKV replication post transplant, while there was a trend toward more acute rejections in those that experienced BKV replication post transplant and a statistically significant higher creatinine at 1 year in those patients.

TABLE 1

| | BKV replication | No BKV replication | p-value* |
|---|---|---|---|
| Documented viremia clearance | 4 (44%) | 16 (100%) | 0.002 |
| Transplant nephrectomy | 2 (22%) | 7 (44%) | 0.4 |
| Induction Use | 7 (78%) | 13 (81%) | 0.9 |
| Acute Rejection | 6 (67%) | 4 (25%) | 0.09 |
| Creatinine at 1 year (mg/dl), median (IQR) n=13 | 1.6 (1.6, 2.2) | 1.45 (1.3, 1.5) | 0.03 |

*p-value by Fisher's exact or Wilcoxon rank-sum test

One graft loss occurred due to rejection. In this largest study to date examining risk of recurrent BKVAN, we conclude re- transplantation is safe and effective for patients with prior graft loss to BKVAN provided pretransplant BK viremia clearance is achieved. Screening and preemptive reduction in immunosuppression may be effective in preventing BKVAN after re-transplantation.

Disclosure of Financial Relationships: nothing to disclose

**Peripheral Reduction of γδ T Cell Numbers Is a Possible Risk Factor for Cytomegalovirus Activation in Kidney Transplant Recipients**
Maria Teresa Gandolfo,[1] Loredana Alberti,[1,2] Antonio Leoni,[1] Andrea Artoni,[3] Deborah Mattinzoli,[1,2] Maria Pia Rastaldi,[1,2] Piergiorgio Messa.[1] *[1]Nephrology, Fondazione IRCCS Cà Granda- Ospedale Maggiore Policlinico; [2]Nephrology Research Laboratory – Fondazione D'Amico; [3]Medicine and Medical Specialities, Fondazione IRCCS Cà Granda- Ospedale Maggiore Policlinico, Milan, MI, Italy.*

Recent data suggest that gamma-delta (γδ) T cells can play a role in renal transplantation (RT). The aim of the present study was to evaluate the behaviour of peripheral blood γδ T cells in the first 12 months after RT and the relationships between γδ T cell numbers and percentages and the main clinical events.

T cell phenotype was serially analyzed in the peripheral blood of 31 kidney transplant recipients; clinical and biochemical parameters, included CMV DNA assessment, were also collected. Total numbers of γδ T cells increased from day 90 onward, as compared with baseline ($p<0.01$-$0.05$). The expression of CD8α, one of the hallmarks of intraepithelial T cell activated state, increased transiently on γδ T cells as well, with higher percentages on day 60 and 90 ($p<0.05$ versus day 0). T cell numbers inversely correlated with serum creatinine values in renal transplant recipients during the first 12 months after RT ($p<0.001$).

Sixteen recipients developed CMV activation. These patients showed reduced γδ T cell numbers and percentages in the early period after RT, preceding CMV activation, compared to patients that never experienced it (γδ T cell numbers: day 15 $p<0.01$, day 30 $p<0.05$; percentages: day 0, 15, 30 and 45 $p<0.05$). After CMV activation had occurred, γδ T cells expanded, achieving the levels of patients without CMV activation; a transient increase in CD8α expression was also present in these recipients on day 90 compared to baseline ($p<0.05$) and on day 60 and 90 compared to patients that did not developed CMV activation ($p<0.05$). Three recipients suffered from an acute rejection episode; no unique behaviour of γδ T cells was detected.

In conclusion, these data suggest that reduced γδ T cell numbers and percentages in kidney transplant recipients may represent an important risk factor for developing CMV activation in the early period after RT.

**F-FC293**

**Everolimus Significantly Reduces Cytomegalovirus Infection Incidence Versus Mycophenolate in *De Novo* Renal Transplant Patients: Pooled Analysis of Three Prospective Studies**
Daniel C. Brennan,[1] Dharmesh Patel.[2] *[1]Washington University School of Medicine, Barnes-Jewish Hospital; [2]Novartis Pharmaceuticals Corporation.*

Cytomegalovirus (CMV) infections are associated with acute and chronic graft rejections. Everolimus (EVR) in heart and renal transplant (RTx) patients is known to decrease the incidence of CMV.

CMV data from 2004 *de novo* RTx from 3 EVR studies A2309 (N=833), B201(N=588) and B251(N=583) were analyzed to identify differences between two EVR dosing groups and mycophenolate (MPA) control groups. In all studies, EVR groups received 1.5 mg/day, or 3 mg/day with either standard (SD-CsA) or reduced dose cyclosporine (RD-CsA). All control groups received (mycophenolic acid) MPA with ST-CsA. Steroids and CMV prophylaxis were given as per center practice. CMV events (infection, syndrome, disease, viremia) were reported as per local center evaluations.

Donor and recipient (D/R) CMV status at baseline were comparable between the treatment groups. Incidences of any CMV event by 12 months were 2.10 and 1.95% for EVR 1.5 and 3.0mg vs MPA of 4.34% ($p<0.0001$).

**Incidence of CMV events by treatment group - n (%)**

| | EVR 1.5 mg/day, N=664 | **EVR 3.0 mg/day, N=671** | **MPA,N=669** |
|---|---|---|---|
| CMV prophylaxis at baseline | 201 (30.3) | 199 (29.7) | 205 (30.6) |
| CMV infection/syndrome - no prophylaxis | 25 (5.4)* | 22 (4.7)** | 66 (14.2) |
| CMV infection/syndrome with prophylaxis | 12 (6.0) | 13 (6.5) | 15 (7.3) |
| CMV viremia - no prophylaxis | 18 (3.9)# | 13 (2.8)* | 40 (8.6) |
| CMV viremia with prophylaxis | 10 (5.0) | 6 (3.0) | 12 (5.9) |
| CMV disease - no prophylaxis | 9 (1.9) | 5 (1.1) | 10 (2.2) |
| CMV disease with prophylaxis | 2 (1.0) | 5 (2.5) | 6 (2.9) |
| CMV infection/syndrome by serology status | | | |
| D+R-subgroup | 17 (6.2) | 19 (18.1) | 27 (25.2) |
| D+R+subgroup | 14 (4.9)^ | 10 (3.4)* | 33 (12.0) |
| D-R-subgroup | 1 (0.7) | 2 (1.7) | 6 (4.3) |
| D-R+subgroup | 3 (3.0) | 1 (0,8)*** | 8 (6.7) |

*p<0.001 vs MPA; **p<0.0001 vs MPA; #p=0.004 vs MPA; ***p=0.036 vs MPA; ^p=0.0034

This pooled analysis documents significant reductions in incidence of CMV infection/syndrome and viremia in EVR-treated *de novo* RTx recipients, primarily those who did not receive CMV prophylaxis compared with the MPA control group.

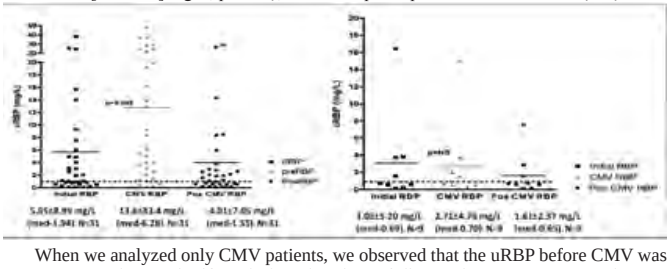
**Early Tubular Injury and Late Graft Dysfunction Associated with Cytomegalovirus Viremia in Kidney Transplants**
Lucio R. Requião-Moura, Erika A. Ferraz, Rogerio Chinen, Ana C. Matos, Thiago Corsi Filiponi, Eduardo J. Tonato, Mauricio Fregonesi, Marcelino Souza Durao, Alvaro Pacheco-Silva. *Transplant, Israeli Hospital Albert Einstein, São Paulo, São Paulo, Brazil.*

**Background:** Cytomegalovirus (CMV) is a risk factor for acute rejection and it could be associated with IF/AT as early as 3 month post kidney transplantation. A**im** of this study is assess the impact of CMV viremia in early predictor of tubular damage (urinary Retinol Binding Protein), and in 2 years graft function. **Methods:** We evaluated 195 renal transplants from deceased donor (Jan/02 to Jun/09). Patients received Thymoglobulin and preemptive therapy to CMV. A subgroup of 74 patients with uRBP serial measurement were analyze in separate and compared patients with or without CMV. **Results:** CMV viremia occurred in 63.5%. Patients with CMV used Sirolimus more frequently (7.2 vs 0.8%, p=0.04) than without. Time to CMV diagnose was 54.9±39.6 days. There no differences in acute rejection, loss and death among patients with or not CMV. Variables related with CMV risk were receptor age (OR=1.62, CI95% 1.11-2.38, p=0.01, when age > 45 yrs.) and Tacrolimo use (OR=2.03, CI95% 1.26-3.30, p=0.004). 2-years graft functions was 62.9±28.2 in no-CMV patients and 52.2±16.4 ml/min in CMV patients (p=0.028). CMV viremia was related with risk to chronic graft dysfunction (OR=1.42, CI95% 1.06-2.33, p=0.004). In similar time that occurred CMV diagnose, uRBP was higher in CMV patients (1.A) (17.4±50.5 [med=3.9] vs. 3.0±4.3 [med-1.1] mg/L, p=0.01), when compared patients without CMV (1.B).



When we analyzed only CMV patients, we observed that the uRBP before CMV was 5.65±8.99 [med-1.9], significantly less that time of diagnostic – 28.5±66.2 [med-6.28], p=0.005. **Conclusion:** CMV viremia was related with worse graft function and a profile of early tubular injury, measured by urinary RBP.

**Antiviral Therapy in Kidney Transplant Recipients with BK Virus Nephropathy** Billy Gilbert,[1] Abdul A. Abdellatif,[1] Luan D. Truong,[2] Aashish M. Pandya,[3] Venkataraman Ramanathan.[1] *[1]Nephrology, Baylor College of Medicine, Houston, TX; [2]Pathology, The Methodist Hospital and Baylor College of Medicine, Houston, TX; [3]Nephrology, Renal Specialists of Houston, PA, St. Lukes Episcopal Hospital Transplant Center, Houston, TX.*

**Background** The mainstay of therapy of BK virus nephropathy (BKVN) has been reduction in immunosuppressive medications. We report our experience with the use of adjunctive leflunomide or cidofovir in patients with BKVN and their influence on allograft function and outcome.

**Methods** - We identified kidney transplant recipients with BK virus in urine and / or blood between 2004 and 2009. BKVN was defined as (a) biopsy proven BKVN, i.e., at least one biopsy showing typical features of polyoma infection, or (b) elevated BK virus levels in blood (> 10,000 copies/ml).

**Results** We identified 52 patients with BKVN, translating to an incidence of 4.9%. Almost all patients had reduction in immunosuppressive medications. Thirty one (60%) and ten patients (19%) were started on i.v. cidofovir and oral leflunomide, respectively. Twelve patients (23%) had allograft failure, within a mean of 9.3 months after the diagnosis of BKVN. One-year allograft failure rate in leflunomide and cidofovir groups was 30% and 16%, respectively (p-value=ns) and serum creatinine for both groups at baseline and follow-up was similar.

When the groups of patients who did and did not have allograft failure after BKVN were compared, elevated serum creatinine at baseline (1.90.7 mg/dL vs. 1.40.5 mg/dL, p=0.003) and at the time of diagnosis of BKVN (2.80.9 vs. 1.70.6 mg/dL, p<0.0001) negatively influenced allograft outcome. Also, patients with allograft failure had significantly higher blood BK virus loads at the time of diagnosis (6.21.6 vs. 4.81.1 copies/mL, p<0.003). The presence of concomitant rejection, type of donor, induction or maintenance immunosuppressive drugs did not influence graft survival.

**Conclusion** Graft outcome and renal function after BKVN was similar between cidofovir and leflunomide. Higher serum creatinine values at baseline and at the time of BKVN diagnosis and higher blood BK viral load portend poor allograft outcome.

**F-FC296**

**The Determinants of the Evolution of Coronary and Aortic Calcification in Renal Transplant Recipients** Céline Maréchal,[1] Georg Schlieper,[2] Olivier Devuyst,[1] Michel Y. Jadoul.[1] *[1]Nephrology, UCL Medical School, Brussels, Belgium; [2]Nephrology, University Hospital Aachen, Aachen, Germany.*

**Background:** Vascular calcifications (VC) independently predict cardiovascular disease, the major cause of death in renal transplant recipients (RTR). We assessed the evolution of coronary artery and aortic calcification and its determinants in a published cohort of prevalent RTR. **Methods:** 281 RTR underwent a 16-slice spiral computerized tomography in order to measure the Agatston score at the time of inclusion. A second CT could be analyzed in 197 RTR 4.4 (0.2) years later. Indeed, the other 84 patients either had died (n = 40), refused to undergo a second CT (n = 37) or had a second CT that was not interpretable (n = 7). Demographic, clinical, biochemical and calcification parameters were recorded and DNA sampled at inclusion. The progression of coronary score was defined as an increase of the score by 90% or more or the development of coronary calcification in patients with a 0 score at baseline. **Results:** The coronary score increased significantly after 4.4 years follow up (616 mg (83) versus 957 mg (138); p = 0.001) whereas the aorta score did not change significantly (2384 mg (405) versus 2582 mg (411); p = 0.096). By univariate analysis, older age at inclusion, the absence of use of azathioprine, higher levels of homocysteine, of total cholesterol and lower levels of 25(OH)vit D3 were associated (p<0.05) with progression of coronary calcification. Higher phosphate (p = 0.07) and osteoprotegerin levels (p = 0.16) tended to be associated with progression. By multivariate logistic regression, a higher total cholesterol (HR = 1.01, 95% CI 1.01 - 1.02, p = 0.002), a lower 25 (OH)vitD3 (HR = 0.95, 95% CI 0.91 - 0.99, p = 0.013), and a higher phosphate level (HR = 1.74, CI 95% 1.12 - 2.72, p = 0.014) as well as the absence of use of azathioprine (HR = 0.36, 0.15 - 0.86, p = 0.021) are independent predictors of coronary calcification progression. **Conclusions:** In contrast to previous small sized short term studies, we demonstrate that coronary calcification progression is common within 4 years FU in prevalent RTR and associated with several potentially modifiable factors.

**F-FC297**

**Change in Mortality Risk over Follow-Up in Young Kidney Transplant Recipients** Bethany J. Foster,[1,2] Mourad Dahhou,[1] Xun Zhang,[1] Robert Platt,[1,2] James A. Hanley.[2] *[1]Pediatrics, McGill University, Montreal, QC, Canada; [2]Epidemiology and Biostatistics, McGill University, Montreal, QC, Canada.*

Mortality risk for young kidney transplant recipients (KTR) may change over follow-up and with change in renal replacement therapy (RRT) modality. We sought to characterize changes in mortality rates over follow-up in young KTR, and to identify time and RRT modality related risk factors for higher mortality. 18,911 patients who received a 1st transplant at <21 years of age (1983-2006), whose data were recorded in the USRDS were studied. There were 2713 deaths over a median follow-up of 10.8 y. Mortality was highest in the 1st post-transplant year, at 22/1000 py, then fell to 6.8/1000 py among those in whom the 1st graft was functioning, and varied little over time. Time-dependent Cox models with time-varying covariates (timescale age) were used to estimate the additional risk associated with each of the following RRT modality categories compared with the first transplant: dialysis, first year of re-transplant, and subsequent years of re-transplant. The following potential confounders were considered: sex, race, SES, donor source, primary disease, era (year) of transplant, and duration of dialysis before first transplant. Compared to KTR of the same age beyond the 1st year of the 1st transplant, mortality rates were higher by 4.4 times [95% CI 4.0, 4.9] for those who had returned to dialysis (p<0.001), 2.4 times [1.9, 3.1] for those in the 1st year of their 2nd transplant (p<0.001), and 1.2 times [1.0, 1.5] for those beyond the 1st year of their 2nd transplant (p=0.02). For every 5 y increment after the end of the 1st year of the 1st transplant, age-adjusted mortality rates fell by 10% [5%, 15%] (p=0.04). Mortality rates were lower in more recent eras: for every 5 y increment after 1983, mortality rates fell by 10% [5%, 15%] (p<0.001). Cause of death was cardiovascular disease for 37%, infection for 19%, malignancy for 4%, other for 22%, and unknown for 18%. The pattern of change in mortality risk over follow-up and by RRT modality was similar regardless of the cause of death. The most important risk factors for mortality were return to dialysis and temporal proximity to a transplant event.

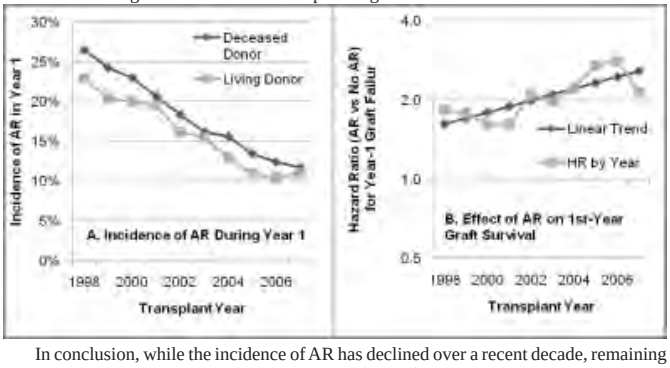
**Association between Early Acute Rejection and All-Cause Kidney Allograft Failure Has Increased While the Incidence of AR Has Decreased over a Recent Decade in the US** Jon J. Snyder, Melissa Skeans, Bertram L. Kasiske. *United States Renal Data System, Minneapolis, MN.*

Acute rejection (AR) is a well known risk factor for allograft failure. We explored changes in the incidence of AR during the first post-transplant year over a ten-year period and concurrent changes in the hazard for all-cause graft failure associated with having an AR. We used USRDS data to construct a population of first-time kidney-alone transplants in patients age 18+, 1998-2007, who were discharged from the transplant hospitalization with a functioning allograft (N=121,055). AR, defined as at least one reported episode or indication of AR treatment in the first post-transplant year, were identified from Organ Procurement and Transplantation Network (OPTN) recipient follow-up data during year 1 post-transplant. For transplants in 1998, 26% of deceased donor transplants and 23% of living donor transplants reported AR in the first post-transplant year. These incidence rates declined steadily from 1998 to 2007, a decline of 52% in deceased donor transplants and 46% in living donor transplants (Figure, Panel A). The adjusted hazard ratio for all-cause graft failure during year one for those with AR vs. no AR increased from 1998 through 2007 (Panel C, test for linear trend p<0.0001), indicating that while the incidence of AR has declined, the risk associated with having an AR has increased, thereby offsetting the effect of declining incidence of AR on improved graft survival.



In conclusion, while the incidence of AR has declined over a recent decade, remaining AR episodes are associated with greater hazard for graft loss.

**Alemtuzumab Versus Thymoglobulin and Interleukin 2 Inhibitor Induction in Deceased Donor Kidney Transplant, an Analysis of OPTN/UNOS Database** Hung-Tien Kuo,[1,2] Edmund Huang,[1] Marcelo Santos Sampaio,[1] Suphamai Bunnapradist.[1] *[1]UCLA Medical Center, Los Angeles, CA; [2]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan.*

**INTRODUCTION.** Induction with alemtuzumab (ALE) has been increasing in kidney transplantation. We aimed to compare post-transplant outcomes between ALE and the other induction agents in deceased donor kidney transplant recipients in the United States.

**METHODS.** Using OPTN/UNOS database (as of Nov 2009), we identified deceased donor kidney recipients [≥18 years] who received primary kidney transplant alone between 2001-2005. Those who received induction therapy with thymoglobulin (THY, n=10264), interleukin-2 antagonist (IL2A, n=10900), or ALE (n=1386) were included into the study population. The impacts of induction agent on acute rejection (AR) at 1 year post-transplant, death-censored graft failure (DCGF), and mortality were analyzed using multivariate analysis (logistic regression for AR at 1year; Cox regression for DCGF and mortality).

**RESULTS**. There were 3987 DCGF (17.7%) and 4030 mortality (17.9%) events in median follow up of 1508 days (interquartile range 1097-2138 days). The incidence of AR at 1 year in those with THY, IL2A, and ALE was 11.9%, 14.8%, and 18.2%, respectively (p<0.001). Unadjusted death-censored graft survival at 5 year in those with THY, IL2A, and ALE was 81.3%, 82.7%, and 76.0%, respectively (p<0.001). Compared to ALE, both THY and IL2A were associated with lower risks of AR at 1 year and DCGF after adjusting

for other confounding factors. There was no significant difference in the risk of mortality among recipients with different induction agent.

Adjusted Relative Risks for Outcomes

| | AR at 1 year | | DCGF | | Mortality | |
|---|---|---|---|---|---|---|
| THY | 0.54(0.44-0.65) | p<0.001 | 0.81 (0.68-0.96) | p=0.02 | 0.89 (0.75-1.07) | p=0.22 |
| IL2A | 0.73 (0.60-0.89) | p=0.001 | 0.83 (0.70-0.99) | p=0.03 | 0.93 (0.77-1.11) | p=0.40 |
| ALE | 1 | - | 1 | - | 1 | - |

**CONCLUSION.** Compared to ALE, induction with THY and IL2A were associated with lower risks for AR at 1 year post-transplant and DCGF in median follow up of 4 year post-transplant.

**Mycophenolate Mofetil (MMF) vs. Azathioprine (AZA) as Adjunctive Therapy to Cyclosporine (CSA)-Based Immunosuppression in the Long-Term Rates of Renal Allograft Loss Due to Primary Renal Disease Recurrence** Phuong-Thu T. Pham,[2] Phuong-Chi T. Pham.[1] *[1]Nephrology Division, UCLA-Olive View Medical Center, Sylmar, CA; [2]Kidney and Pancreas Transplantation, David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Internal Medicine, Greater Los Angeles VA Medical Center, Sepulveda, CA.*

In the current study, we update the long-term follow-up of the impact of MMF on the rate of renal allograft loss due to glomerular disease recurrence compared to AZA as adjunctive therapy with CSA-based immunosuppression in both deceased and living primary kidney transplantation.

Kidney transplants performed during 1988-2003 (OPTN/UNOS database as of 2/05/2010) with the primary diagnoses of diabetes mellitus, IgA nephropathy, membranous glomerulonephropathy (MGN), membranoproliferative glomerulonephropathy (MPGN), lupus nephritis (LN), focal segmental glomerulonephropathy (FSGS), hypertensive nephrosclerosis, polycystic kidney diseases, and tubulointerstitial diseases (TIN) were included.

At 10-year follow-up, there was no statistically significant difference in Kaplan-Meier graft survival rates between AZA and MMF adjunctive therapy to cyclosporine-based immunosuppression in the rates of graft loss due to any of the glomerulonephropathies in either deceased or living renal transplants. There was however, a significantly worse outcome in the CSA+MMF group (n=1210) for recipients with the primary diagnosis of tubulointerstitial diseases compared to those on CSA+AZA (n= 1468), 2.45% vs 0.85%, log-rank p-value 0.048.

The rates of graft loss due to recurrence of the primary renal disease were highest for MPGN (types 1 & 2 not specified) at 6.5% vs 7.8% (CSA+AZA vs CSA+MMF respectively), FSGS (6.8%, same for either AZA or MMF), and MGN (6.8%, same for either AZA or MMF). The rates of graft loss due to recurrence of LN were only 3.2 vs. 4.2% (CSA+AZA vs CSA+MMF respectively).

The efficacy of MMF adjunctive therapy to CSA-based immunosuppression in reducing the recurrence of common glomerulonephropathies was comparable to that of AZA at 10-year follow-up. The rates of graft loss due to recurrence of primary renal disease were highest in those with MPGN, FSGS, and MGN.

### F-FC301

**Estimating Glomerular Filtration Rate in Renal Transplant Recipients with Cystatin C-Based Equations: A Systematic Review** Gavin Harman,[1] Greg A. Knoll,[1,3] Christine A. White.[2] *[1]Department of Medicine, University of Ottawa, Ottawa, ON, Canada; [2]Department of Medicine, Queen's University, Kingston, ON, Canada; [3]Kidney Research Centre, Ottawa Health Research Institute, Ottawa, ON, Canada.*

We performed a systematic review of diagnostic assessment studies evaluating the performance of Cystatin C (CysC)-based glomerular filtration rate (GFR) prediction equations in adult renal transplant recipients (RTRs).

We searched MEDLINE and EMBASE from 1966 and 1980 respectively to August 2009 for all entries related to renal disease or GFR and CysC, yielding 1,012 unique articles. Inclusion criteria were: subjects above 18 years of age, use of a GFR estimating equation and the direct measurement of GFR as a reference standard. Seven studies (475 GFR measures in 484 patients) were included in this review. Techniques used to measure GFR included 99mTc-DTPA (n=3), 125I-iothalamate (n=2) and inulin clearance (n=2). CysC was measured by particle enhanced nephelometric immuno-assay (n=4), turbidimetric immuno-assay (n=2) or ELISA (n=1). Prediction equations most commonly evaluated were those of Larsson (n=5), Hoek (n=4), Filler (n=4), LeBricon (n=3) and Rule (n=2). The analysis of each study reported bias (mean difference between measured GFR and GFR estimated by the prediction equation) and accuracy (percent of GFR estimates within 10%, 20%, or 30% of measured GFR) of each equation.

The range of bias among studies and the pooled weighted mean 30% accuracy (proportion of GFR estimates falling within 30% of the measured GFR) for each equation are reported in Table 1.

Disagreement between studies is likely due to differences in patient population, reference standard GFR measurement techniques and the immuno-assays used for serum CysC. The wide range of bias and poor accuracy of measured GFR suggests that CysC -based equations are not superior to those based on creatinine for estimating GFR in RTRs.

Table 1. Range of mean bias and weighted mean 30% accuracy from pooled data of included studies

| Equation | Bias (ml/min/1.73m2) | 30% accuracy |
|---|---|---|
| Hoek | -10.6 – -5.8 | 75 |
| LeBricon | -3.8 – +2.8 | 74 |
| Filler | -1.7 – +6.72 | 71 |
| Rule | -0.86 – -5 | 69 |
| Larson | -16.1 – -3.2 | 64 |

Disclosure of Financial Relationships: nothing to disclose

### F-FC302

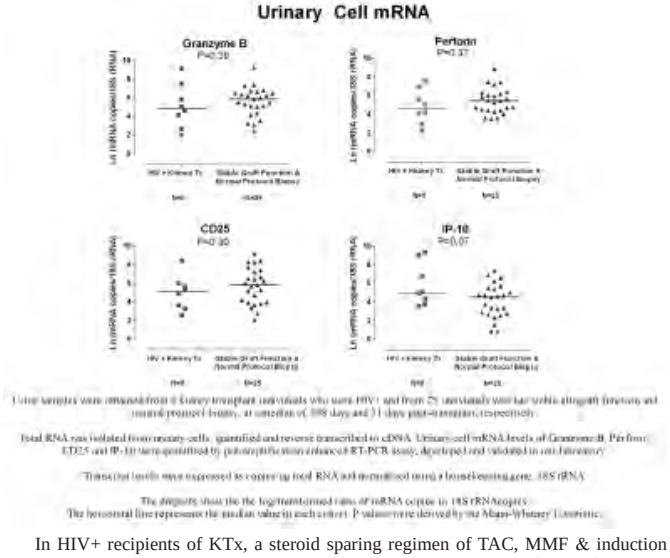
**HIV+ Individuals with Kidney Transplantation (KTx) on an Early Steroid Withdrawal Protocol Are Clinically Stable and Molecularly Quiescent** Thangamani Muthukumar, C. Afaneh, Choli Hartono, David Serur, Jun Lee, Darshana M. Dadhania, Roxana M. Bologa, D. Leeser, S. Kapur, Manikkam Suthanthiran. *Cornell University, New York.*

KTx is emerging as a viable option for individuals infected with HIV. Most receive IL-2 receptor antibody (IL-2R Ab)as induction agent & are on 3-drug immunosuppression. Increased incidence of acute rejection (AR) however has been observed in this cohort.

We studied 10 HIV+ individuals who received KTx on an early steroid withdrawal protocol (steroids stopped <7 d of KTx) & maintenance immunosuppression of tacrolimus (TAC) & mycophenolate mofetil (MMF). Induction was either Thymoglobulin® (N=8) or IL-2R Ab (N=2).

| | |
|---|---|
| N | 10 |
| Age, mean (SD) | 50 (9) |
| Gender (M:F) / Race (Black:Hispanic) | 9:1 / 7:3 |
| Dialysis duration, months, median (range) | 80 (6-227) |
| HBV/HCV pre KTx | 1/1 |
| HIV load, not detected, pre KTx | 9 |
| CD4 count in cu.mm, median (range) | 571 (134-938) |
| History of opportunistic infections | 0 |
| Donor type (deceased: living) | 7:3 |
| Cold ischemia time, hours, median (range) | 22 (12-40) |
| Delayed graft function | 5 |
| Acute rejection, N (months from transplant) | 2 (0,16) |
| Follow up, months, median (range) | 12 (7-34) |
| Graft loss, N (months from transplant) | 2 (0,25) |
| HIV load at last follow up, copies/ml | <48 in 8, 70 in 1 and not done in 1 |
| CD4 count in cu.mm at last follow up, median (range) | 183 (24-565) |
| Infections post KTx | UTI-3, Pneumonia 2, Bacterial diarrhea 1, Osteomyelitis 1 |
| Cancer post KTx | 0 |

We performed urinary cell mRNA profiling on them. Levels of granzyme B, perforin, CD25 & IP-10 were similar (P>0.05) to a cohort of stable transplants.



In HIV+ recipients of KTx, a steroid sparing regimen of TAC, MMF & induction with Thymoglobulin® or IL-2R Ab is associated with a low incidence of AR, safe & well-tolerated. These individuals remain clinically stable & are molecularly quiescent.

Disclosure of Financial Relationships: nothing to disclose

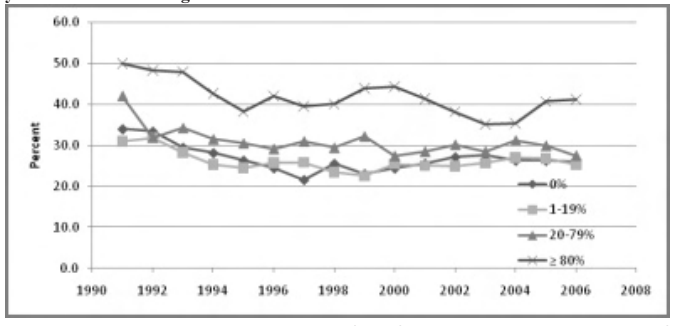
### F-FC303

**Continued Use of Transfusion in the Transplant Waitlist Population, Even among Non-Sensitized Candidates** Jon J. Snyder,[1] Hassan N. Ibrahim,[2] Bertram L. Kasiske,[2] Melissa Skeans,[1] Allan J. Collins.[1,2] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]Department of Medicine, University of Minnesota, Minneapolis, MN.*

Sensitized patients spend more time on the kidney transplant waiting list than do non-sensitized patients. Exposure to blood products via transfusion may result in sensitization, thereby increasing the likelihood of a prolonged waiting time. We explored the 3-year

cumulative incidence of transfusion, stratified by PRA at the time of listing, to see if transfusions were used more sparingly in non-sensitized patients. We used USRDS data including adult wait-listed patients from 1991-2006 whose primary payer was Medicare (N=110,669). We examined Medicare inpatient and outpatient claims for evidence of transfusion in the first three years post-listing. We estimated 3-year cumulative incidence of transfusion, stratified by PRA at the time of listing, censoring at de-listing, death, and transplant. From 1991 to 1994, transfusion rates declined in patients at all levels of listing PRA. Patients with listing PRA > 80% had the highest incidence of post-listing transfusions. Patients with a PRA of 0% at listing had a similar incidence of transfusion on the waitlist as those with PRA of 1-19%, which ranged from 23% to 27% over the past decade. Overall, there was no difference in transfusion incidence in patients with PRA of 0% vs. patients with PRA of 1-19% (log-rank p-value=0.8066). Those with PRA of 20-79% had only slightly higher incidence of transfusion, which ranged from 27% to 32% over the last decade (Fig 1).

**Fig 1: Three-year cumulative incidence of transfusion in waitlisted patients, by year and PRA at listing**



Although one might expect the avoidance of transfusions in patients with listing PRA of 0%, use of the procedure remains common and is similar to the frequency seen in patients with low to mid levels of sensitization.

### F-FC304

**Likelihood of Preemptive Transplant (Txpl) and Candidate Survival as Predicted by Renal Function at the Time of Listing for Renal Transplantation** Rachel B. Fissell,[1] Joseph V. Nally,[1] Sankar D. Navaneethan,[1] Emilio D. Poggio,[1] Titte Srinivas,[1] David A. Goldfarb,[2] Jesse D. Schold.[3] *[1]Department of Nephrology/Hypertension, Cleveland Clinic, Cleveland, OH; [2]Glickman Urological/Kidney Institute, Cleveland Clinic, Cleveland, OH; [3]Department of Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH.*

Purpose: This analysis evaluates whether renal function (eGFR or Creatinine Clearance (CrCl)) at listing is associated with likelihood of receiving a preemptive Txpl, and candidate survival prior to transplantation.

Methods: We included 61,020 solitary renal Txpl candidates from the national SRTR database listed preemptively from 2000-2009 with available renal function estimate. Multivariable linear regression was used to characterize associations between patient characteristics and renal function at listing. Multivariable logistic regression and survival models were used to assess likelihood of preemptive Txpl and candidate survival.

Results: Mean eGFR was 14.8 mL/min/1.73 kg/m$^2$(std=3.8) and CrCl was 14.7 mL/min/1.73 kg/m$^2$ (std=4.4) at listing. Factors associated with higher renal function at listing were male gender, Caucasian race/ethnicity, prior Txpl, presence of diabetes, and higher education level. A Txpl was received by 54% of the population over the study period (49% from a living donor and 51% from a deceased donor). Among those that received a Txpl, 51% had a preemptive Txpl prior to dialysis initiation. Higher renal function was significantly associated with likelihood of receiving a preemptive Txpl (AOR=1.34 per 5 ml/min, 1.29-1.40), for both deceased and living donor Txpls. Patients with higher renal function at listing had significantly better candidate survival prior to Txpl: 5-yr survival 82% with eGFR>15 vs. 79% with eGFR<15 (p<0.001).

Conclusions: Higher renal function at the time of preemptive listing was significantly associated with both higher likelihood of preemptive transplant and lower candidate mortality. Renal function at listing is a potentially modifiable factor. These results suggest that candidates for a preemptive Txpl should be listed at as high a level of renal function as possible.

Disclosure of Financial Relationships: nothing to disclose

### F-FC305

**Chronic Kidney Disease (CKD) Stage Progression in Liver Transplant Recipients** John C. Lamattina, David P. Foley, Alexandru Musat, Luis A. Fernandez, Joshua Mezrich, Anthony M. D'Alessandro, John D. Pirsch, Arjang Djamali. *Medicine and Surgery, UW Madison School of Medicine and Public Health, Madison, WI.*

There is little information on CKD stage progression rates and outcomes in liver transplant recipients. We performed a retrospective review of 1151 adult, deceased-donor, single-organ primary liver transplants between July 84 and December 07 and analyzed renal outcomes and risk factors for CKD stage progression. We included 729 patients in the study since they had available MDRD GFR levels at one year posttransplant, thus defining their baseline stage of CKD. Stage progression was calculated using all measured outpatient creatinine values during the follow-up interval. Mean recipient age at the time of transplant was 52.0±10.1 years. Recipients were more commonly male (61%) and Caucasian (96%). Mean recipient body-mass index (BMI) was 28.2±6.6 kg/m$^2$. The majority of liver transplants were from donation after brain death donors (95%). Mean donor age was 37.1±16.4. Donors were more often male (64%) and Caucasian (93%). Donor BMI was 26.2±6.0 kg/m$^2$. Mean cold ischemia time was 8.3±2.4 hours. At one year, 7%, 34%, 56%, 3% and 1% of patients were in stages 1, 2, 3, 4, and 5 CKD. The incidence of stage progression was 28%, 40%, and 53%, at 3, 5, and 10 years. The incidence of ESRD was 2.6%, 7.5%, and 18% at 5, 10, and 20 years. Pretransplant diabetes, hypercholesterolemia, and infectious complications during the first year were predictive of stage progression. Caucasian race and higher physiologic MELD at the time of transplant proved protective.

| | Univariate | | | Multivariable | | |
|---|---|---|---|---|---|---|
| Pretransplant diabetes | 1.4 | 1.06-1.81 | 0.01 | 1.90 | 1.38-2.63 | <0.0001 |
| Hypercholesterolemia | 1.44 | 1.05-1.98 | 0.02 | 1.46 | 1.04-2.05 | 0.02 |
| Infectious complications | 1.31 | 1.03-1.66 | 0.02 | | | |
| UTI | 1.38 | 1.06-1.81 | 0.01 | 1.39 | 1-1.93 | 0.04 |
| Caucasian | 0.6 | 0.41-0.88 | 0.008 | | | |
| MELD | 0.98 | 0.96-0.99 | 0.04 | | | |

In conclusion close monitoring and management of modifiable risk factors may prove critical to delay CKD progression in liver transplant recipients.

### F-FC306

**Characterization of Epithelial Oxalate Absorption** Felix Knauf,[1] Zhirong Jiang,[1] James M. Anderson,[2] Peter S. Aronson.[1] *[1]Nephrology, Yale University, New Haven, CT; [2]Physiology, UNC, Chapel Hill, NC.*

Calcium oxalate (CaOx) is the predominant constituent of kidney stones. Mice deficient for oxalate transporter SLC26A6 develop hyperoxaluria and CaOx stones on the basis of a defect in intestinal back secretion of oxalate. The goal of the current study was to characterize the mechanism(s) of epithelial oxalate absorption. We used native mouse intestine and measured unidirectional absorption of [14C]-oxalate simultaneously with flux of [3H]-mannitol as a marker of the paracellular pathway. Although absorptive fluxes of both oxalate and mannitol varied in parallel in different segments of small and large intestine, absorptive flux of oxalate was always the same as that of mannitol, indicating that it is predominantly passive and paracellular. In contrast, the secretory flux of oxalate exceeded that of mannitol in duodenum of wild type mice, indicating active transcellular secretion of oxalate. This excess of oxalate secretion compared to mannitol was abolished in duodenum of Slc26a6-null mice. Similarly, luminal addition of the anion transport inhibitor DIDS to wild-type duodenum reduced the secretory flux of oxalate to that of mannitol, but did not affect oxalate absorption. We then used cultured epithelial cells with gene silencing of tight junction proteins to alter paracellular permeability. Unidirectional transport of oxalate and mannitol increased in parallel when paracellular permeability to larger molecules was increased by knockdown of ZO-1. In contrast, induction of claudin-10a increased the anion permeability of the tight junction as shown by the change in dilution potential but had no effect on oxalate flux. Taken together, our studies in mouse intestine and cultured epithelial cells indicate that oxalate absorption is passive and paracellular, and that oxalate traverses the low capacity paracellular pathway for larger solutes but not the higher capacity claudin-based pores. We hypothesize that in the intestine the role of SLC26A6 in mediating active oxalate secretion is to counteract the passive absorption of ingested oxalate that takes place through the paracellular pathway.

### F-FC307

**Leptin Signaling Regulates Oxalate Transport by Intestinal Cells** Hatim A. Hassan, Zhen-Guo Wang, Ming Cheng. *Medicine, The University of Chicago, Chicago, IL.*

The vast majority of kidney stones are composed of calcium oxalate, and minor changes in urinary oxalate affect stone risk. Intestinal oxalate secretion mediated by anion exchanger Slc26a6 plays a major constitutive role in limiting net intestinal absorption of ingested oxalate. Leptin is emerging to play an important role in the regulation of intestinal transport through signaling pathways including PKC activation, which also regulates intestinal oxalate transport. We therefore examined whether leptin affects intestinal oxalate transport using the human intestinal Caco2 BBE cells, which express leptin receptors and in which ~50% of oxalate transport is mediated by SLC26A6. We measured apical [14C]oxalate uptake in the presence of an outward Cl gradient as an assay of Cl-oxalate exchange activity. Interestingly, we found that apical or basolateral lepin (0.2 or 100 nM x 6 hours) significantly inhibited [14C]oxalate uptake by ~ 20-30%, without affecting the transepithelial resistance. Importantly, Leptin also inhibits mouse duodenal oxalate secrtion. Following a 30-minute control period, the effects of mucosal or serosal leptin (100 nM) on transepithelial unidirectional 14C-oxalate fluxes (mucosa to serosa, JMS, and serosa to mucosa, JSM) was assessed over another 30-minute period. Mucosal leptin significantly inhibited oxalate secretion (by >29%), a process largely mediated by Slc26a6, without affecting absorption (Control: JMS = 32.11 ± 3.70, JSM = 41.95 ± 5.71, Jnet = -10.56 ± 6.59 pmol/cm2/h; Leptin: JMS = 35.22 ± 2.99, JSM = 29.73 ± 4.19, Jnet = 5.49 ± 5.13 pmol/cm2/h), resulting in conversion of oxalate transport from net secretion in control tissues to net absorption in leptin-treated tissues. Using RT-PCR, the observed leptin-induced inhibition of oxalate uptake by CaCo2 cells is not due to reduced SLC26A6 mRNA expression. However, we observed in preliminary experiments that leptin treatment led to

redistribution of some of the SLC26A6 protein to an intracellular space, suggesting that leptin inhibits oxalate uptake by CaCo2 cells by reducing SLC26A6 surface expression. We conclude that leptin negatively regulates intestinal oxalate transport.

Disclosure of Financial Relationships: nothing to disclose

**F-FC308**

***AGXT* Mutation Type Correlates with Phenotype in Primary Hyperoxaluria Type 1** Carla G. Monico,[1] Regina M. Herges,[2] Barbara M. Seide,[1] Julie B. Olson,[1] Andrea G. Cogal,[1] Eric J. Bergstralh,[2] Dawn S. Milliner.[1] *[1]Mayo Clinic Hyperoxaluria Center, Division of Nephrology, Mayo Clinic, Rochester, MN; [2]Division of Biostatistics & Epidemiology, Mayo Clinic, Rochester, MN; [3]International Primary Hyperoxaluria Registry Investigators, .*

Primary hyperoxaluria type 1 (PH1) is caused by deficiency or peroxisome-to-mitochondria mistargeting of hepatic alanine:glyoxylate aminotransferase (AGT) and characterized by markedly elevated urine oxalate excretion, recurrent calcium oxalate urolithiasis, nephrocalcinosis and renal failure. Previously, we showed an association between the most common mutation (G170R) and response to pyridoxine (VB6) treatment.

To further explore associations between genotype and phenotype, we classified PH1 patients in the International Primary Hyperoxaluria Registry by mutation type: mistargeting (M), missense (S) or truncating (T), where M=G170R or F152I, S=other single amino acid change, and T=splice site, nonsense or frameshift mutations. Associations between mutation type and clinical factors [age @ symptoms (Sx) and diagnosis (Dx), and urinary oxalate (Uox) @ Dx] were evaluated using non-parametric ANOVA and chi-square tests.

Clinical Characteristics According to Mutation Type in 129 PH1 Patients

| Genotype by Mutation Type | n | Age @ Sx* (yrs) | Age @ Dx* (yrs) | U ox/BSA @ Dx* |
|---|---|---|---|---|
| M/M | 25 | 12.7 (10) | 28.3 (18) | 1.3 (0.8) |
| S/S | 21 | 16.9 (13) | 25.8 (14) | 1.4 (0.7) |
| T/T | 10 | 10.2 (14) | 14.9 (17) | 2.4 (0.9) |
| M/S | 23 | 8.5 (12) | 17.3 (18) | 1.9 (1.4) |
| T/M or T/S | 50 | 7.8 (10) | 11.6 (13) | 2.8 (1.2) |
| p-value | | 0.01 | 0.0001 | 0.0004 |

*Mean (SD). Uox/BSA = mmol/1.73m2/24 hrs

Mutation type appears to correlate with PH1 phenotype. The presence of one truncating allele (T/M or T/S) was associated with younger age @ symptoms and diagnosis, and higher Uox @ Dx whereas M/M seemed to predict a lower Uox and older age @ diagnosis, suggesting a milder phenotype. Mistargeting and missense genotypes may portend greater mutant AGT dimer stability, perhaps due to more functional AGT protein. *AGXT* genotyping may hence be of value in optimizing treatment strategies in individual PH1 patients.

Disclosure of Financial Relationships: nothing to disclose

**F-FC309**

**Changes in Mitochondrial Proteome of Distal Renal Tubular Cells upon Calcium Oxalate Monohydrate Crystal Adhesion and Internalization** Visith Thongboonkerd,[1] Sakdithep Chaiyarit,[1] Supachok Sinchaikul,[2] Shui-Tein Chen.[2] *[1]Medical Proteomics Unit, Office for Research and Development, Siriraj Hospital, Mahidol University, Bangkok, Thailand; [2]Institute of Biological Chemistry, Academia Sinica, Taipei, Taiwan.*

Calcium oxalate monohydrate (COM), the major crystalline compound found in kidney stones, has been thought to trigger oxidative stress, which subsequently leads to renal tubular cell damage. Several reports have shown that COM crystals can induce overproduction of reactive oxygen species (ROS) followed by cellular injury. Our present study aimed to identify a set of altered mitochondrial proteins in distal renal tubular cells upon COM crystal adhesion and internalization. Madin-Darby Canine Kidney (MDCK) cells were maintained in the presence or absence of COM crystals. Crystal adhesion and internalization were investigated by immunofluorescence staining and laser-scanning confocal microscopy. Thereafter, mitochondria were isolated by differential centrifugation technique and the purity of mitochondrial isolation was confirmed by Janus Green B staining, Western blotting, and transmission electron microscopy. Subsequently, mitochondrial proteins were resolved by 2-DE (n=5 gels derived from 5 independent samples in each group; COM-treated vs. controlled) and visualized by Deep Purple dye. A total of 15 differentially expressed mitochondrial proteins (12 increased and 3 decreased) were successfully identified by Q-TOF MS and MS/MS analyses. The altered mitochondrial proteins included those involved in several biological processes; i.e., cellular metabolism, stress response, and cellular structure. Global protein network analysis of the altered mitochondrial proteins demonstrated that energy production and cellular development were affected by adhesion and internalization of COM crystals. Our data indicated that mitochondrial proteome of renal tubular cells was altered in response to COM crystal adhesion and internalization. The altered proteins were involved in important cellular processes, which might subsequently lead to cellular injury.

Disclosure of Financial Relationships: nothing to disclose

**F-FC310**

**Temporal Changes in the Expression of mRNA of Various NADPH Oxidase Subunits in Renal Epithelial Cells Exposed to Oxalate and Calcium Oxalate Crystals** Saeed R. Khan, Karen J. Byer. *Pathology, Immunology and Laboratory Medicine, University of Florida, Gainesville, FL.*

Recent experimental and clinical studies suggest that kidneys may endure oxidative stress (OS), injury and inflammation during stone formation. It is our hypothesis that OS is caused by oxalate (Ox) and/or calcium oxalate (CaOx) crystals induced activation of NADPH oxidase and production of reactive oxygen species (ROS).

To investigate the activation of NADPH oxidase, we exposed HK2 human kidney epithelial cell line to 100 µmol Ox or 66.7 µgm/cm$^2$ CaOx monohydrate crystal for 6, 12, 24 or 48 hours. After the exposure media was collected to determine LDH, 8-isoprostane (IP) and extracellular SOD. cells were processed to determine NADPH oxidase activity. Expression of subunits, gp91, p22, p40, p47, p67 and RAC-GTPase was determined by real time PCR.

Exposure to both Ox and CaOx crystals resulted in significant LDH release and production of significant amounts of 8IP. SOD production also increased after both Ox and CaOx exposures. However NADPH oxidase activity increased significantly only after CaOx crystal exposure. Both Ox and CaOx crystals produced changes in the expressions of subunits in comparison to control as well as to each other.

Results indicate that exposure to both oxalate and CaOx crystals lead to changes in the expression of various NADPH oxidase subunits, lipid peroxidation and membrane injury. Oxalate and CaOx crystals appear to affect differently. Expression of a number of macromolecules such as monocyte chemoattaractant protein and osteopontin is increased when renal epithelial cells are exposed to high oxalate and CaOx crystals. While generation of large amount of ROS may play a major role in tissue injury or death, but regulated generation of low concentration of ROS, possibly by NADPH oxidase, may represent a second messenger system for generation of many of the upregulated macromolecules involved in biomineralization and inflammation.

Disclosure of Financial Relationships: nothing to disclose

**F-FC311**

**Effects of Calcium Oxalate Monohydrate Crystals on Expression and Function of Tight Junction of Renal Tubular Epithelial Cells** Visith Thongboonkerd, Paleerath Peerapen. *Medical Proteomics Unit, Office for Research and Development, Siriraj Hospital, Mahidol University, Bangkok, Thailand.*

Tight junction plays crucial role in regulating paracellular transports (as a barrier), and in separating apical from basolateral compartments to maintain cell polarity (as a fence). Tight junction can be disrupted by various stimuli, including oxidative stress, pathogens and proinflammatory cytokines. However, association of defective tight junction with kidney stone pathogenesis remains unknown. We therefore examined whether calcium oxalate monohydrate (COM) crystals, which are the major crystalline composition in kidney stones, have any effects on expression and function of tight junction of polarized renal tubular epithelial cells. Western blot analysis revealed marked decrease in levels of occludin and zonula occludens-1 (ZO-1) in COM-treated polarized MDCK cells. Immunofluorescence staining revealed not only the decline of these tight junction proteins but also their redistribution and dissociation in COM-treated cells. Additionally, transepithelial resistance (TER) was significantly decreased indicating impaired tight junction barrier and increased paracellular permeability in COM-treated cells. Subcellular fractionation followed by Western blot analysis of $Na^+/K^+$-ATPase-$\alpha$1 revealed that this basolateral membrane marker was also detectable in apical membrane fraction of COM-treated cells, but not in apical membrane fraction of controlled cells. These data provide the first evidence to demonstrate decreased expression and defective barrier and fence functions of tight junction of renal tubular epithelial cells exposed to COM crystals that may be fundamental for subsequent renal tubulointerstitial injury, which in turn enhances the stone pathogenesis.

**Oxalate Stimulates the Production of TNF-alpha Via NF-kappaB Activation in Renal Epithelial Cells** Vijayalakshmi Thamilselvan, Mani Menon, Sivagnanam Thamilselvan. *Vattikuti Urology Institute, Henry Ford Health System, Detroit, MI.*

INTRODUCTION: Hyperoxaluria is one of the major risk factors for calcium oxalate urolithiasis, and its intrinsic toxicity results in tubular dysfunction and interstitial inflammation. We have previously shown that oxalate induces free radical injury through activation of NADPH oxidase. NF-kB is an oxidative stress-responsive transcription factor that plays an important role in the regulation of pro-inflammatory mediators. Therefore, we explored the contribution of specific reactive oxygen species (ROS) to oxalate-induced NF-kB activation and subsequent TNF-$\alpha$ gene regulation in renal epithelial cells.

METHODS: LLCPK1 cells were exposed to 0.5-1.0 mM oxalate for different time periods with or without antioxidants (SOD, catalase, sodium formate, vitamin E and vitamin C) and NF-kB inhibitor peptide. Superoxide and H2O2 production were determined by colorimetry. NF-kB activation was determined by DNA binding activity using electrophoretic mobility shift assay combined ELISA and nuclear translocation by Western blot. TNF -$\alpha$ mRNA expression and secretion were determined by RT-PCR and ELISA respectively.

RESULTS: Oxalate treatment induced a time and dose dependent increase in ROS production. Oxalate significantly increased NF-kB activation as well as TNF-α mRNA expression and secretion in a time-dependent manner. Addition of SOD augmented oxalate-induced superoxide generation, NF-kB activation whereas catalase lowered H2O2 generation and NF-kB activation. Sodium formate significantly inhibited NF-kB activation. Sodium formate or NF-kB inhibitor peptide significantly blocked TNF-α mRNA expression and secretion. Treatment of vitamin E and C together significantly inhibited oxalate-induced NF kB activation and TNF-α gene upregulation.

CONCLUSION: We conclude that ROS dependent NF-kB activation is an important signaling pathway of oxalate toxicity and could be crucial for induction of inflammatory signals in renal epithelial cells. Free radical scavengers prevented oxalate-induced NF-kB mediated TNF-α secretion. Therefore these pathways may represent a novel therapeutic target for patients with kidney stones.

**Nephrolithiasis in Brown Norway Wpk/+ Rats** Vincent H. Gattone,[1] James Williams,[1] Kenneth E. White,[1] Sharon M. Moe,[1] Elaine M. Worcester.[2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Chicago, Chicago, IL.*

Nephrolithiasis is a relatively common clinical condition. Kidney stones come in many different forms and compositions. Kidney stones can start as outgrowths from the renal papilla and remain attached. Old (ages 12-18 months) Brown Norway(BN)- Wpk/+ rats develop spontaneous nephrolithiasis. They are heterozygote carriers of a mutation for Meckel Syndrome, a lethal autosomal recessive condition with renal cystic pathology. We evaluated renal function and morphology in old BN-Wpk/+ retired breeders versus retired BN breeder control rats. Metabolic cage studies were performed and at termination, rats were anesthetized and kidneys evaluated using X-ray, microCT, histology and stones were further evaluated using microCT and/or scanning electron microscopy followed by spectroscopic analysis. Calcifications were typically associated with the medullae and a hypertrophic papillary epithelium and were more prominent in males compared with female Wpk/+ rats. Kidney stones were also found in the pelvis and pelvic recess in many rats, some of which were adherent while others were free floating. MicroCT analysis identified a distinct attachment site while the remainder of the stone exhibited a laminated appearance. Urine had an increased concentration of phosphate while calcium, citrate and oxalate were all decreased. The urinary P/Cr ratio was increased suggesting an increased phosphate excretion in male Wpk/+ rats. There was misexpression of NPT2a mRNA in Wpk/+ renal cortex. The stones were composed of amorphous calcium phosphate. This laminated appearance is reminiscent of kidney stones found in humans and suggests a prolonged period of deposition. This is the first rodent model with spontaneous nephrolithiasis linked to a specific mutant gene and could be a clinical condition associated with carriers of Meckel Syndrome.

**Chlorthalidone Improves Bone Quality in Genetic Hypercalciuric Stone-Forming Rats** David A. Bushinsky,[1] Thomas Willett,[2] John R. Asplin,[3] Marc D. Grynpas.[2] *[1]U. Rochester, Rochester, NY; [2]Mt. Sinai Hospital, Toronto, ON, Canada; [3]U. Chicago, Chicago, IL.*

We have bred a strain of rats to maximize urine (U) calcium (Ca) excretion to model hypercalciuric nephrolithiasis. These GHS rats now excrete far more UCa than control Sprague-Dawley rats, uniformly form kidney stones and, similar to patients, demonstrate lower bone mineral density (BMD). Clinically thiazide diuretics are used to reduce UCa and prevent stone formation. Whether they have a beneficial effect on bone is not clear. We used GHS rats to test the hypothesis that the thiazide diuretic chlorthalidone (CTD) would favorably affect bone density and quality. Twenty GHS rats received a fixed amount of a standard 1.2% Ca diet and half were also fed CTD (4-5 mg/kg/day). U was collected weekly during the 18 wk study and then femurs and vertebrae were analyzed. Compared to vehicle, rats fed CTD had a marked reduction in UCa. Bone quality assessment techniques were used to study the effect of CTD treatment on the axial and appendicular skeleton. Compared to vehicle, CTD caused a significant increase in the bone mineral content and BMD of the lumbar vertebrae, measured by DEXA. An increase in the trabecular mineralization and architecture was observed with CTD. As indicated by the structural parameters obtained from micro CT, trabecular bone volume (BV/TV), trabecular thickness and trabecular number all increased significantly with CTD. Additionally, from static histomorphometry, there was a significant increase in trabecular thickness with CTD. Unsurprisingly therefore, CTD also improved the connectivity of trabecular bone. However, CTD did not alter formation parameters. CTD led to a significant improvement in vertebral strength and stiffness measured by vertebral compression. CTD treatment had a greater effect on trabecular bone than on cortical bone. These results obtained in hypercalciuric rats suggest that CTD can favorably influence vertebral fracture risk. CTD did not alter formation parameters suggesting that the improved bone strength was due to decreased bone resorption and retention of bone structure. Whether CTD will favorably affect human bone should be tested.

**Hydroclorthiazide & Spironolactone Decrease Urinary Calcium Oxalate Saturation in Premature Infants** Gregory Lee Braden,[1] Thomas Campfield,[2] Gary F. Rockwell.[2] *[1]Dept of Medicine, Baystate Medical Center/Tufts University School of Medicine, Springfield & Boston, MA; [2]Dept of Pediatrics, Baystate Medical Center/Tufts University School of Medicine, Springfield & Boston, MA.*

We have shown that hypercalciuria, hyperoxaluria & increased urinary calcium oxalate saturation ratios(CaOxRSR) may occur in premature infants(PI) at risk for nephrocalcinosis(NC). Furosemide may induce hypercalciuria & increased CaOxRSR in PIs with lung disease but there are no data on the effects of hydrochlorthiazide(HC) & spironolactone(SP) on CaOxRSR in PIs. We studied 39 PIs, 19 on HCTZ & SPIR for lung disease and 20 PI controls(C).Timed urine samples were obtained for Ca, Ox, uric acid, Na,K,Cl, phosphorus, creatinine & ph. Urine CaOxRSR was calculated with the EQUIL program. 19 PIs on HC&SP weighed less & were younger at birth(1185vs1414gms; gest age 26 vs 29 weeks), had 3 fold >Na intake(12.7 vs 4.3 mmol/d) but equal weight gain, serum Na, total calorie & Ca intake and daily urine output. Urinary ph and excretion of Ox, phosphorus,& uric acid were similar in both PIs. Na excretion was greater in PIs on HC&SP vs C (134mmol/L vs 47mmol/L,p<.01) & urine Ca less ( 1.2mmol/L vs 1.4mmol/L,p<.05). The mean CaOxRSR in PIs on HC&SP was less than C ( 7.8 vs 15.0,p<.01). There were no differences in CaPhos saturation (.62 vs .45)between PIs. CaOxRSR increased as urinary Ca increased while an inverse association occurred in CaOxRSR with Ox excretion in both groups. At any level of urinary Ca or Ox excretion, PIs on HC & SP had lower urine CaOxRSR p<.01. We conclude: In PIs, HC & SP lower urine CaOxRSR & may decrease the risk for NC. Lower urine Ca excretion despite a 3 fold > Na intake & 3 fold > Na excretion along with equal weight gain, serum Na & urine output in PIs on HC&SP vs C makes us speculate that Ca reabsorption may occur in the distal nephron via TRPV5 channels.

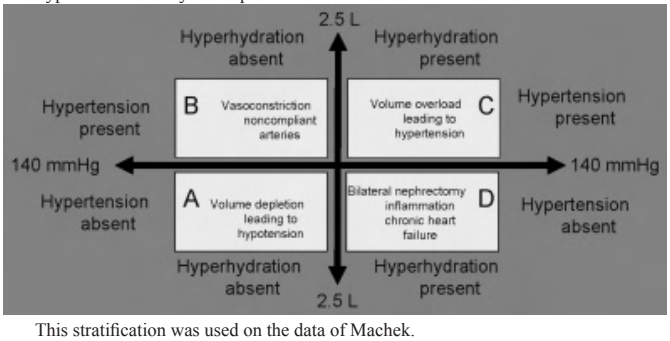
**Hypertension & Fluid Status Management – Stratification of CKD Patients** Peter Wabel,[1] Petr Machek,[2] Paul William Chamney,[3] Tomas Jirka.[1] *[1]Fresenius Medical Care D GmbH; [2]NephroCare Czech; [3]Fresenius Medical Care UK.*

Introduction

Control of hypertension and management of fluid overload are closely linked. In the DRIP study, Agarwal (Hypertension 2009) demonstrated that management of hypertension by lowering fluid status can be successful. But not all hypertensive patients tolerated the reduction of post weight. Machek (NDT 2009) managed the fluid overload in a one year prospective trial. He showed a significant reduction in the fluid overload accompanied by an improvement of the hypertension status and the intradialytic adverse events. Agarwal (Sem Dial 2009) and Wabel (NDT 2008) proposed a separation of hypertensive patients into hyper- and normohydrated patients.



This stratification was used on the data of Machek.

Methods

The hypertensive patients were divided into a “hyperhydration present” and a “hyperhydration absent” group. We used a cut-off of 140mmHg for BPsys and 2.5 L for the hydration status (measured with the BCM-Body Composition Monitor).

Results

31 of 52 patients presented BPsys>140 mmHg. 39% of these patients could be assigned to group C (hypertension and hyperhydration). After the intervention (one year) period it was possible to reduce the BPsys by 25 mmHg (p=0.006) by reducing the fluid overload by 2 L (p<0.001). The antihypertensive medication was reduced significantly. Intradialytic adverse events reduced slightly.

Conclusion

For the successful management of hypertension it is essential to stratify the patients according to a measurement of their fluid status. In group C patients (hypertension and hyperhydration) control of hypertension can be achieved by sufficient removal of fluid overload. Not all hypertensive patients will benefit from a reduction in the fluid status. In some patients (group B) aggressive reduction of the hydration status can result in a higher incidence of intradialytic adverse events.

**Nocturnal Dysregulation of Heart Rate Is Associated with Cardiovascular and All-Cause Mortality in End-Stage Renal Disease Patient on Hemodialysis** Nobumasa Nakamura,[1] Hirotake Kasuga,[1] Keiko Kimura,[1] Ryo Takahashi,[1] Seiichi Matsuo.[2] *[1]Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; [2]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

**Background:** It has been established that elevated resting heart rate (HR) is associated with cardiovascular (CV) morbidity and mortality, besides, some reports have described that blunted nocturnal dipping of HR independently predicts the poor survival in general population. On the other hand, CV disease is a leading cause of death in patients on hemodialysis (HD), however, the association between CV mortality and the nocturnal HR regulation is little known in this population. We investigated whether the amplitudes of nocturnal HR dipping could predict CV and all-cause mortality in HD patients.

**Methods:** A total of 309 HD patients (male 55%, age 63±11years, diabetes 46%) underwent 24hr ambulatory Holter ECG monitoring during inter-dialysis day. From obtained mean diurnal HR and mean nocturnal HR during each periods based on ambulatory recording, diurnal-nocturnal HR dipping ratios were calculated as following; (mean diurnal HR – mean nocturnal HR) / mean diurnal HR x 100. They were divided into tertiles according to the percentage reduction of HR levels; <5.4% (T1, n=103), 5.4-11.7% (T2, n=103) and >11.7% (T3, n=103). They were followed up for 8years.

**Results:** During follow-up period (75±25months), 88 patients (28.6%) died including 36 CV death (11.7%). Eight-year event-free survival rates were 76.9%, 89.6% and 93.2% for CV mortality (p=0.0013), and were 60.4%, 68.1% and 81.0% for all-cause mortality in the groups of T1, T2 and T3 (p=0.0018), respectively. After adjustment for gender, age, diabetes, hypertension, hyperlipidemia, smoking, history of CV disease, hemoglobin, albumin and C-reactive protein, the reduction of HR dipping was an independent predictor for CV mortality (HR 3.31 for T1 vs. T3, p=0.011) and for all-cause mortality (HR 2.13 for T1 vs. T3, p=0.035), respectively. Neither diurnal HR nor nocturnal HR was associated with the mortality.

**Conclusion:** Nocturnal dysregulation of HR expressed as the reduction of HR dipping was strongly associated both CV and all-cause mortality in HD patients.

**Higher Ultrafiltration Rate (UFR) Is Associated with Increased Cardiovascular (CV) Morbidity and Mortality on Hemodialysis (HD)** Jennifer E. Flythe, Steven M. Brunelli. *Brigham and Women's Hospital, Boston, MA.*

HD patients have very high rates of CV morbidity and mortality that may be related to the hemodynamic effects of rapid ultrafiltration.

**Aim:** This study was designed to test the hypothesis that higher UFRs are associated with greater all-cause and CV mortality, hospitalization for CV disease, and intra-dialytic hypotension.

**Methods:** Data were taken from the Hemodialysis Study, a randomized trial conducted between March 1995 and December 2001 that included 1,846 thrice-weekly chronic HD patients. UFR was considered as both a cubic spline and a categorical exposure: ≤10 ("low"; n=644), 10-13 ("intermediate"; n=517), and >13 ml/hr/kg ("high"; n=685).

**Results:** Cubic spline analysis revealed a steep rise in the risk for all-cause and CV mortality at UFR >10 ml/hr/kg. On categorical analysis, high UFRs were associated with increased all-cause and CV mortality: adjusted HRs (95% CIs) 1.36 (1.14- 1.61, p=0.001) and 1.53 (1.16- 2.03, p= 0.003), respectively, when compared to low UFRs.

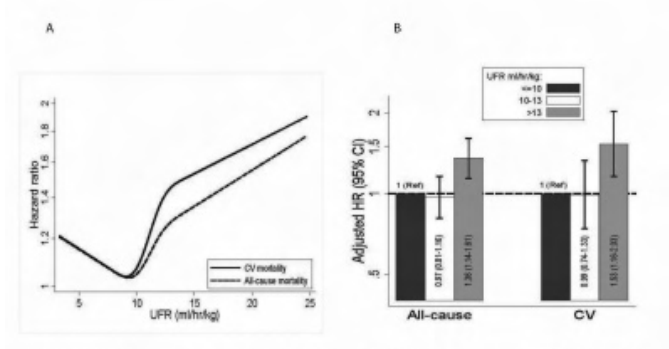

Figure. Association between UFR, considered as a cubic spline (A) and categorical (B) exposure, and all-cause and cardiovascular mortality.

Intermediate UFRs were not associated with mortality overall, but were among subjects with congestive heart failure: HR (95% CI) 0.73 (0.56-0.96) and 1.30 (1.02-1.66) among CHF- and CHF+, respectively (p-interaction=0.002). Secondary analyses considered time to: CV hospitalization or all-cause mortality (1081 events), CV hospitalization or CV mortality (843 events), and CV hospitalization alone (742 events); results followed a similar pattern to those of the primary analyses. Intermediate and high UFRs were significantly associated with intradialytic hypotension: adjusted ORs (95% CIs) 1.28 (1.18- 1.39) and 1.48 (1.35- 1.63), respectively.

**Conclusion:** UFRs >13 ml/hr/kg are associated with a higher risk of all-cause and CV death in chronic HD patients. The mechanism by which higher UFRs influence CV outcomes may relate to associated increases in intradialytic hypotension.

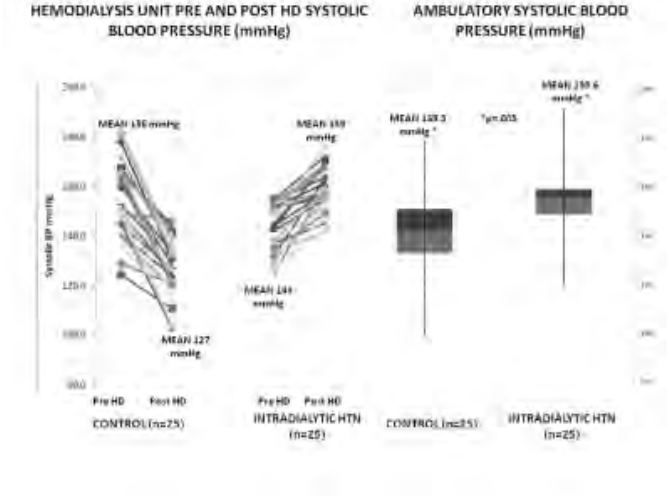
**Interdialytic Ambulatory Blood Pressure in Patients with Intradialytic Hypertension** Peter N. Van Buren, Robert D. Toto, Jula K. Inrig. *Internal Medicine-Division of Nephrology, University of Texas Southwestern Medical Center-Dallas, Dallas, TX.*

Purpose: Hemodialysis (HD) patients with intradialytic hypertension (IH) have higher risk for hospitalization and mortality compared to those in whom BP decreases during a routine HD session. The mechanism involved in IH is incompletelely understood. We hypothesized that those with IH have a higher time-integrated interdialytic BP burden as compared to those without IH.

Methods: We performed a case-control study including 25 subjects with IH (defined as systolic blood pressure [SBP] increase ≥ 10 mmHg in 4/6 consecutive HD treatments) and 25 HD control subjects (SBP decreased ≥ 10 mmHg during 4/6 consective HD treatments). Interdialytic ambulatory SBP (ASBP) was measured by 44-hour recording using a Spacelabs 90207 machine. SBP was recorded every 30 minutes during the daytime and hourly at night. ASBP were compared between groups using Wilcoxon Rank Sum test. Spearman Rank Correlation was used to compare ASBP with pre and post-HD SBP.

Results: The mean age of all subjects was 54 years; 80% were male, 38% were African American, and 82% were diabetic. Two-week time averaged pre and post HD unit SBP was 156 and 127 mmHg in controls and 140 and 159 mmHg in IH subjects (Figure). Mean 44 hour ASBP for the control and IH subjects was 140 and 156 mmHg, respectively (p=.005, Figure). There was a significant correlation with ASBP and post HD SBP (r=.61, p< 0.0001), but not pre HD SBP (r=.28, p=.05).



Conclusions: Patients with IH experience a greater inter-dialytic SBP burden compared to HD controls. The inter-dialytic ASBP correlates with post HD, but not pre HD SBP. Adverse outcomes associated with IH may partially be the result of increased interdialytic SBP burden.

Disclosure of Financial Relationships: nothing to disclose

**F-FC320**

**A Randomized Controlled Trial of Low Dialysate and Dietary Sodium on Blood Pressure in Hemodialysis** Albert J. Power, Seema Singh, Claire Edwards, Damir Tandaric, David Taube, Neill D. Duncan. *Imperial College Kidney & Transplant Institute, West London Renal & Transplant Centre, Hammersmith Hospital, London, United Kingdom.*

Up to 85% hemodialysis [HD] patients need antihypertensives as well as ultrafiltration for blood pressure [BP] control. Dietary sodium [Na] restriction with aggressive ultrafiltration and lowered dialysate Na can reduce interdialytic weight gain [IDWG] & antihypertensive use. We studied the combined effect of these measures which has not been prospectively examined to date.

Fifty stable maintenance HD patients entered an open-label prospective trial Aug 2008-Dec 2009 with a 12wk run-in [dialysate Na 140mM, unrestricted diet] and a 36wk intervention phase. Sodium gradient [NaG] is defined by the difference dialysate - serum Na. Groups consisted of controls, low dialysate Na alone [target 3mM below patient's mean serum level by graded reduction: 1mM / 2 wks], low dietary Na alone [2.3g/d with dietetic input], low dialysate & dietary Na. BP was recorded on HD and 24hr ambulatory records taken 6 weekly [midpoint of dialysis week]. Antihypertensive dose was recorded as defined daily dose [WHO]. A 22-point version of the Dialysis Symptom Index was completed 6 weekly.

Patients reaching the treatment phase were analysed [n=31, mean age 65.1±12.4yrs, 84% male, 40% diabetic]. Na restriction did not significantly alter predialysis Na. Low dialysate Na alone led to significant changes in NaG [+1.3 → -1.0mM, p<0.05]. Combined restriction led to reductions in NaG [+0.3 → -2.6mM, p<0.05] as well as IDWG [1.9 → 1.5kg, p<0.001] & improved intradialytic BP stability [p<0.05].

Any form of Na restriction caused more frequent but not severe cramps [+21%, p=0.04] vs controls. Isolated low dialysate Na reduced symptomatic intradialytic hypotension [27% → 4%, p=0.002].

Significant reductions in IDWG and antihypertensives require combined Na restriction which improves intradialytic hemodynamic stability. Na restriction (dialytic +/- dietary) leads to more muscle cramps but not of a degree to force treatment change. Findings from this small but prospective study need larger numbers and longer follow up to determine any long term impact on cardiovascular outcomes.

Disclosure of Financial Relationships: nothing to disclose

## F-FC321

**Heart Failure with Normal Ejection Fraction (HFNEF) – Why Defining This Entity in End-Stage Renal Disease Patients?** Angela Yee Moon Wang,[1,2(previous)] Mei Wang,[1,2(previous)] Christopher W. K. Lam,[3] Siu Fai Lui,[2] John E. Sanderson.[2] *[1]Medicine, Queen Mary Hospital, University of Hong Kong, Hong Kong, Hong Kong; [2]Medicine & Therapeutics, Prince of Wales Hospital, Chinese University of Hong Kong, Hong Kong, Hong Kong; [3]Chemical Pathology, Prince of Wales Hospital, Chinese University of Hong Kong, Hong Kong, Hong Kong.*

Heart failure (HF) is a frequent complication & powerfully predicts mortality in ESRD. This study aimed to determine the prevalence, severity, risk factors & prognostic importance of HF with normal ejection fraction (EF) (HFNEF) or diastolic dysfunction. We conducted a prospective study in 218 ESRD patients with 2D-echo & tissue Doppler imaging (TDI) done at baseline, then followed prospectively for 4 yrs. 100 had no HF, normal EF (EF ≥ 50%); 32 had no HF but EF < 50%; 47 (21.6%) had HFNEF; 39 had HF+ & EF < 50%. A significant increase in coronary artery disease (P<0.001), diabetes (P<0.001), & heart valve calcification (P=0.018) was observed across 4 groups. Hemoglobin (P=0.002) & serum albumin (P=0.002) showed significant decrease while systolic blood pressure (P=0.021), pulse pressure (P<0.001), C-reactive protein (P=0.037), troponin T (P<0.001) & NT-pro-BNP (P<0.001) showed significant increase across 4 groups. LV mass index & early mitral inflow velocity to peak mitral annulus velocity (E/Em ratio) was highest in HF+, EF < 50% group, followed by HFNEF group, then no HF group (P<0.001). The 4-yr cumulative cardiovascular (CV) & heart failure event-free survival probability were lowest in HF+, EF< 50% group, followed by HFNEF group, then no HF group (P<0.001). In multivariable Cox regression analysis, adjusted hazard ratios in relation to CV events were 2.9 in HF+, EF <50% group (P<0.001) & 2.2 in HFNEF group (P=0.002) using no HF & EF ≥ 50% as reference. These data clearly suggest the importance to define 'HFNEF' in ESRD patients & differentiate heart failure ESRD patients with normal & depressed EF as their clinical & cardiovascular profiles & outcomes are not the same. HFNEF patients had an increased risk of adverse CV outcomes though lower than HF+, EF <50% group. These results raise the need to differentiate treatment strategies in these two groups of patients.

## F-FC322

**A Prospective Randomized Controlled Open-Label Study on the Effect of Biocompatible Peritoneal Dialysis Fluids on Daily Urine Volume and Residual Renal Function** Sing-Leung Lui,[1] Wai Kei Lo,[1] Daniel Tak Mao Chan.[2] *[1]Medicine, Tung Wah Hospital, Hong Kong, China; [2]Medicine, Queen Mary Hospital, Hong Kong, China.*

The aim of this study was to examine the effect of biocompatible peritoneal dialysis fluids (PDF) on daily urine volume and residual renal function (RRF) in patients newly started on continuous ambulatory peritoneal dialysis (CAPD). One hundred and fifty patients were randomized to use either biocompatible PDF, consisting of neutral-pH low glucose degradation product fluid (Physioneal®), amino acid-based fluid (Nutrineal®) and icodextrin (Extraneal®) or conventional dextrose-based PDF (Dianeal®) for 48 weeks. The daily urine volume and RRF (mean of urea and creatinine clearance) were determined by 24-hour urine samples at baseline, 24 and 48 weeks. Seventy-seven and 73 patients were randomized to use biocompatible PDF and conventional PDF respectively. The demographics of both study groups were similar. There were no statistically significant differences in their daily urine volume (1087 ± 656 ml vs. 1067 ± 553 ml respectively, p=0.845) and RRF (4.02 ± 2.10 ml/min/1.73m² vs. 3.68 ± 2.09 ml/min/1.73m² respectively, p=0.377) at baseline. The biocompatible PDF group had significantly higher daily urine output at week 48 (959 ± 515 ml vs. 798 ± 615 ml, p=0.046), but the biocompatible and the conventional PDF groups showed similar RRF at week 24 (3.67 ± 2.17 ml/min/1.73m² vs. 3.43 ± 2.49 ml/min/1.73m² respectively, p=0.579) and at week 48 (3.24 ± 1.98 ml/min/1.73m² vs. 2.88 ± 2.43 ml/min/1.73m², p=0.379), and similar rates of RRF decline over 48 weeks (-0.76 ± 1.77 ml/min/1.73m² vs. -0.91 ± 1.92 ml/min/1.73m², p=0.568). KT/V values of the two groups at baseline, 24 and 48 weeks were similar. The two groups did not differ in diuretic and ACEI usage, peritonitis free survival, hospitalization rate, and patient or technique survival. We conclude that the use of a combination of Physioneal®, Extraneal® and Nurtrineal® for 48 weeks was associated with greater urine volume in CAPD patients, but did not affect RRF compared with conventional PDF after 48 weeks of treatment.

Disclosure of Financial Relationships: nothing to disclose

**Alkaline Phosphatase Improves Sepsis-Induced Acute Kidney Injury: A Double Blind Prospective Randomized Placebo-Controlled Phase II Trial** Peter Pickkers,[1] Suzanne Heemskerk,[1,2] Johannes G. van der Hoeven.[1] *[1]Intensive Care Medicine, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands; [2]Pharmacology and Toxicology, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands.*

Rationale: Alkaline phosphatase (AP) is an endogenous detoxifying enzyme that is depleted in the kidney during an ischemic or inflammatory insult. Administration of AP improves outcomes in animal models and decreases urinary excretion of markers of tubular damage in a previous sepsis trial.

Objective: To evaluate whether AP treatment improves renal function in sepsis patients with acute kidney injury (AKI).

Methods: Thirty-six sepsis patients (27m/9f, mean age 66±14 yrs) with evidence for kidney injury (minimal AKIN stage 1) were included in a double-blind, randomized, placebo-controlled study on the safety and efficacy of AP. Patients on dialysis were excluded and during the study renal replacement therapy (RRT) was started according to the ADQI criteria. AP was administered intravenously as a bolus injection of 67.5U/kg followed by continuous infusion of 132.5U/kg for 48h and followed up for 28 days.

Measurements and Main Results: Progress in renal parameters was the primary endpoint (combined creatinine clearance, requirement and duration of RRT). Secondary endpoints were clinical improvement (duration of ventilator support and ICU LOS) and changes in the urinary excretion of biomarkers of renal injury.

AP treatment was well-tolerated by patients with sepsis and AKI. Creatinine clearance is restored to normal in the AP group within 7 days and remains impaired in the placebo group (p=0.02) and this improvement was sustained during the follow-up period (p<0.05). Fewer patients in the AP group tended to require RRT (19 vs. 36%, p=0.29) and the relative duration of RRT was shorter (12 vs. 34% of total time in study, p=0.04), supported by significant changes in biomarkers such as renal KIM-1. Furthermore, AP treatment reduced mean ICU LOS (10.9 vs 24.5 days, p=0.02) and duration of mechanical ventilation (8.0 vs 13.9 days, p=0.094).

Conclusions: Alkaline phosphatase treatment attenuates renal damage and improves renal function in sepsis patients with AKI.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC324

**Statin Use Is Associated with Less Acute Kidney Injury after Major Elective Surgery** Amber Molnar,[1] Steven G. Coca,[2] Arsh Jain,[1,3] Jin Luo,[4] Chirag R. Parikh,[2] John Michael Paterson,[4] Ron Wald,[5] Michael W. Walsh,[6] Amit X. Garg.[1,3,4,6] *[1]Division of Nephrology, University of Western Ontario, London, ON, Canada; [2]Section of Nephrology, Yale University, New Haven, CT; [3]Department of Epidemiology and Biostatistics, University of Western Ontario, London, ON, Canada; [4]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; [5]Division of Nephrology, University of Toronto, Toronto, ON, Canada; [6]Department of Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, ON, Canada.*

Animal studies suggest statins protect the kidneys when administered prior to an ischemic insult. Whether a similar benefit occurs in humans is uncertain. We conducted a population-based retrospective cohort study of all older patients who underwent major elective surgery in the province of Ontario, Canada from 1995 to 2008 (cardiac, thoracic, vascular, intra-abdominal and retroperitoneal surgeries). The primary outcome was acute kidney injury within 14 days of surgery determined using administrative database codes. Secondary outcomes were acute dialysis within 14 days of surgery and mortality within 30 days of surgery. A total of 219,524 patients had major elective surgery. The incidence of postoperative acute kidney injury was 2.6% (5786 patients), acute dialysis 1.3% (2954 patients) and mortality 2.8% (6201 patients). Prior to surgery, 32% (70,485) of patients were taking a statin. After statistical adjustment for patient and surgical characteristics, statin use was associated with less acute kidney injury (odds ratio [OR] 0.88; 95% confidence interval [CI] 0.82 to 0.93), less acute dialysis (OR 0.91; 95% CI 0.84 to 0.99) and less mortality (OR 0.79; 95% CI 0.74 to 0.85). Similar results were seen with propensity score matching. Our data suggest statins prevent important renal complications after major elective surgery and reduce perioperative mortality. The hypothesis warrants testing in large multi-centre randomized controlled trials. However, conducting trials which establish a benefit on the most important renal outcomes will be logistically challenging.

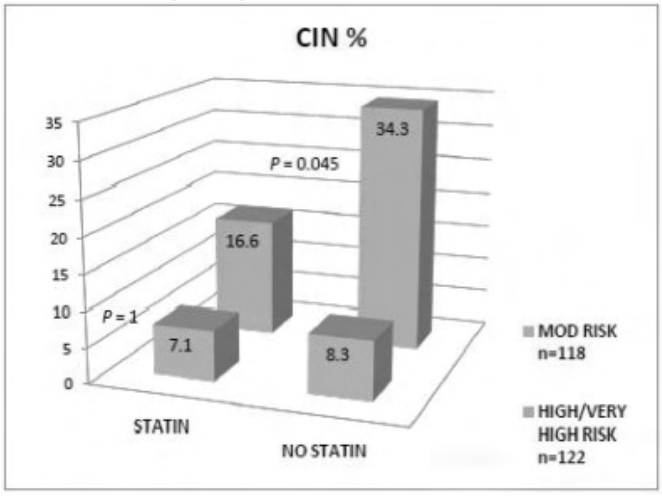
## SA-FC325

**Role of Statins in the Prevention of Contrast-Induced Nephropathy (CIN) in High Risk Patients** Hector Castro,[1] Ivonne Hernandez Schulman.[1,2] *[1]Nephrology Division, University of Miami, Miami, FL; [2]Nephrology and Hypertension Division, Miami VAMC, Miami, FL.*

*PURPOSE*: We investigated whether statin pretreatment may prevent CIN in high risk patients.

*METHODS*: 240 patients that underwent vascular procedures requiring the use of contrast media between 2007 and 2009, and that were at moderate, high or very high risk for CIN were studied. 160 patients received preprocedure statin, and 80 did not. CIN was defined as an increase in serum creatinine of ≥ 0.5 mg/dl or ≥ 25% from baseline 24 to 48 hs after contrast exposure. Multivariable regression analysis was used to determine the statistical significance of the findings.

*RESULTS*: The average risk score was similar in both groups (11.3 ± 3.2 and 10.5 ± 3.5, $p = 0.098$). There was a lower incidence of CIN in the statin group compared to the no-statin group (12.5% vs 18.75%, respectively), but it was not significant ($p = 0.24$). Sub-group analysis showed a significant reduction of CIN in high/very high risk patients in the statin group compared to the no-statin group ($p = 0.045$), whereas no difference was seen for moderate risk patients ($p = 1$).



In high/very high risk patients, multivariate analysis revealed that statin use was independently associated to the absence of CIN when adjusted for age, DM, CHF, eGFR and contrast volume (OR 0.3, 95% CI 0.10 – 0.91, $p = 0.03$). This association was not seen in the moderate risk group.

Multivariate association with CIN

| Variable | | High/very high risk patients | |
|---|---|---|---|
| | *p* | OR | 95% CI |
| Statin | 0.03 | 0.3 | 0.10 - 0.91 |
| Age | 0.13 | 0.96 | 0.91 - 1.01 |
| DM | 0.23 | 2.13 | 0.63 - 7.26 |
| CHF | 0.15 | 2.41 | 0.73 - 8.01 |
| eGFR | 0.004 | 0.96 | 0.94 - 0.99 |
| Contrast volume | 0.99 | 1 | 0.99 - 1.00 |

*CONCLUSIONS*: Statin pretreatment may be a useful strategy for CIN prevention in high risk populations.

**Association of Pre-Operative ACEIs or ARBs with a Reduction in Post-Operative AKI after Elective CABG** Tao-Min Huang, Vincent Wu, Guang-Huar Young, Fan-Chi Chang, Pi-Ru Tsai, Wen-Je Ko, Kwan-Dun Wu. *Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan.*

Objectives: To examine the association of pre-operative ACEi/ARBs and renal outcome post CABG.

Background: The effect of ACEi/ARBs on renal outcomes in CABG is controversial. We evaluated the effect of pre-operative ACEi/ARBs on renal outcomes in this patient group.

Methods: We included non-dialysis patients undergoing CABG from 2002 to 2007. The primary endpoint was post-operative AKI, defined with RIFLE and the secondary endpoints were postoperative renal replacement therapy (RRT) and 30-day all-cause mortality.

Results: Total 1,172 patients were enrolled and 451 took ACEi/ARBs before surgery. AKI developed in 6.1% patients. Stepwise logistic regression revealed that pre-operative ACEi/ARB usage was associated with a lower incidence of AKI [OR 0.48, p =0.01]. After propensity score matching, pre-operative ACEi/ARBs were significantly associated with a lower incidence of post-operative AKI (3.7% vs. 9.1%, p=0.01). There was no significant difference of post-operative RRT or 30-day mortality.

Table 1. Demographic characteristics and outcomes of the propensity score matched cohort

| Variables | ACEi/ARBs (n = 298) | No ACEi/ARBs (n = 298) | P |
|---|---|---|---|
| | | | |
| Age | 65.6±10.2 | 65.6±10.9 | 0.988 |
| Gender (Male) | 78.2% | 75.5% | 0.497 |
| | | | |
| Recent MI | 18.8% | 18.8% | 1.000 |
| CHF | 12.8% | 11.4% | 0.706 |
| | | | |
| DM | 50.7% | 47.3% | 0.461 |
| HTN | 71.8% | 67.8% | 0.326 |
| | | | |
| Low LVEF | 47.7% | 46.3% | 0.806 |
| CPB | 13.1% | 11.1% | 0.053 |
| | | | |
| Cr (mg/dL) | 1.36±0.83 | 1.34±0.81 | 0.764 |
| | | | |
| Beta-blockers | 47.3% | 49.3% | 0.682 |
| CCB | 22.8% | 24.5% | 0.700 |
| Statins | 29.5% | 31.9% | 0.594 |
| Propensity scores | 0.434±0.209 | 0.430±0.207 | 0.802 |
| Outcome | | | |
| AKI | 3.7% | 9.1% | 0.011 |
| Need for RRT | 1.4% | 1.4% | 1.000 |
| 30-day mortality | 1.7% | 2.4% | 0.772 |
| Composite endpoint | 4.7% | 9.4% | 0.038 |

Composite endpoint: composite endpoint of acute kidney injury, renal replacement therapy, and 30-day mortality

Conclusions: We demonstrated an association between pre-operative ACEi/ARBs and reduced post-operative renal dysfunction in this patient group.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC327

**Risk of Acute Kidney Injury (AKI) in Hospitalized Medical Patients on ACE Inhibitors (ACE I) and Angiotensin Receptor Blockers (ARBs) Versus Other Antihypertensives** Etti Deborah Zeldis, David Schwarzbaum, Ladan Golestaneh, Michal L. Melamed. *Albert Einstein College of Medicine/ Montefiore Medical Center.*

AKI is a common hospital acquired event with substantial morbidity and mortality. ACE I and ARBs are inhibitors of the renin-angiotensin system and are associated with long term improved renal outcomes, but their effects in acutely ill hospitalized patients has not been established.

We studied all patients >18 years with no known end-stage renal disease on the medical services at two urban hospitals admitted in 2009 (n=12504). Use of ACE I/ ARBs and other antihypertensives (calcium channel blockers, beta blockers, diuretics) during admissions, baseline demographics, comorbidities, laboratory data, vital signs, and exposure to IV contrast and NSAIDs were obtained from electronic records. The primary outcome was the diagnosis of AKI risk using the RIFLE criteria, a rise in creatinine 50% from baseline (n=1602). Baseline creatinine was defined as the last creatinine value recorded within 1 year prior to admission.

Among the included patients, 4878 (39%) were on ACE I/ARBs (and potentially other anti-hypertensives) and 7626 (61%) were on other antihypertensives but not ACE I/ARBs. The mean age was 67 years, 58% were female, 36% were African-American, 36% were Hispanic, and 40% had diabetes mellitus. Mean baseline creatinine was 1.22 mg/dL for patients on ACE I/ARBs and 1.66 mg/dl for patients on other antihypertensives. Overall, 14.8% of the patients developed AKI risk. The presence of systolic blood pressures <90 mmHg (odds ratio (OR) 2.9, 95% CI: 2.4, 3.3), concomitant NSAID use (OR 1.4, (1.1,1.7)), and elevated baseline creatinine (OR 1.28, (1.24,1.32)) were associated with an increased AKI risk. Overall, 10.9% of those on ACE I/ARBs developed AKI risk compared to 17.2% on other anti-hypertensives. After multivariable adjustment, patients who were on ACE I/ ARBS during their hospitalization had an OR of 0.84 (0.74, 0.95) for the development of AKI compared to patients on other antihypertensives.

In summary, ACE I/ARB use was associated with a lower incidence of AKI risk in hospitalized medical patients. Future studies are needed to confirm these associations.

**Acute Renal Events Associated with Fibrate Use: A Population-Based Study** Ying Y. Zhao,[1] Matthew A. Weir,[1] Michael Manno,[2] Peter E. Cordy,[1] Tara Gomes,[2] Daniel G. Hackam,[3] David N. Juurlink,[4] Muhammad Mamdani,[2,4] Louise M. Moist,[1] Chirag R. Parikh,[5] John Michael Paterson,[2] Ron Wald,[4] Amit X. Garg.[1,2] *[1]Division of Nephrology, Department of Medicine, University of Western Ontario, London, ON, Canada; [2]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; [3]Division of Clinical Pharmacology, University of Western Ontario, London, ON, Canada; [4]Department of Medicine, University of Toronto, Toronto, ON, Canada; [5]Section of Nephrology, Yale University School of Medicine, New Haven, CT.*

***Background***: Modest increases in serum creatinine associated with the use of fibric acid derivatives (fibrates) have been observed in randomized trials.

***Method***: We conducted a population-based cohort study of all patients 66 years or older with a new prescription for a fibrate or ezetimibe (comparator drug) in Ontario, Canada. Patients were accrued from January 2004 to December 2008. The main outcomes were

hospitalization for acute kidney injury (AKI) and consultation with a nephrologist within 90 days of a new prescription. We also compared characteristics of fibrate users in our cohort to those enrolled in three randomized trials.

***Results:*** Compared to ezetimibe users (n=61,831), fibrate users (n=19,072) had a higher risk of AKI requiring hospitalization (adjusted odds ratio [OR] 2.4, 95% CI 1.7 to 3.3) and were more likely to see a nephrologist in consultation (adjusted OR 1.3, 95% CI 1.1 to 1.6). Among those with serum creatinine measurements, 9.1% of fibrate users and 0.3% of ezetimibe users experienced a 50% or more increase in serum creatinine concentration (OR 29.6, 95% CI 8.7 to 100.5). The risk of AKI requiring hospitalization was greatest in patients with chronic kidney disease (CKD) (adjusted OR 3.4, 95% CI 2.2 to 5.1; test for interaction, p=0.043). Compared to patients in randomized trials, fibrate users in our cohort had a higher prevalence of CKD, were more likely to be on a higher dose of fibrate given their renal function, and had less routine renal monitoring in follow-up.

***Conclusion***: Fibrates are associated with adverse acute renal events. Their use warrants careful patient selection and close monitoring of renal function.

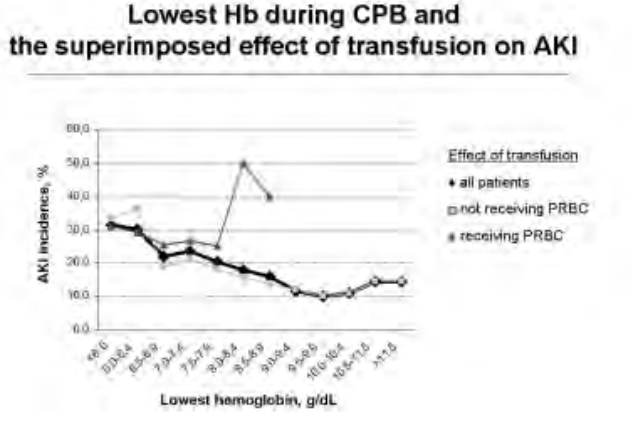
**Mean Arterial Pressure, Hemoglobin, and Blood Transfusion during Cardiopulmonary Bypass and Postoperative Acute Kidney Injury** Michael Haase. *Nephrology and Intensive Care, Charité, Berlin, Germany.*

*Purpose:* To investigate whether intraoperative hypotension, anemia, transfusion or their combination are independent risk factors for acute kidney injury (AKI).

*Methods:* We linked cardiac surgery and pathology databases with electronically stored systemic mean arterial pressure (MAP) data (three measurements/min) and blood gas analyses during cardiopulmonary bypass (CPB). We calculated indices of MAP (variability, time and area under the curve of MAP <50, <60 and <70 mmHg) and obtained hemoglobin, arterial oxygen saturation and pressure values. We tested the relationship of such variables and the need for red blood cell transfusion and vasopressor use in a mixed linear multivariable model with the development of AKI using RIFLE criteria.

*Results:* We analyzed 381,468 MAP measurements from 920 on-pump cardiac surgery patients of whom 19.5% developed AKI associated with 8.2-fold increased in-hospital mortality. Hemoglobin (Hb) concentration (OR 1.19 per g/dL decrease in concentration [95% CI 1.05-1.34]; *P*=0.006) was an independent risk factor for AKI with systemic arterial oxygen saturation and pressure values not adding further value. MAP alone or vasopressor administration was not independently associated with AKI but volume of red blood cell transfusion was with its impact being apparent at Hb levels >8.0 g/dL.



In patients with severe hypotension, the effect of anemia was more pronounced than in patients with minimal hypotension (OR 3.31 [95% CI 1.36-8.07]; *P*=0.007).

*Conclusions:* Intra-operative avoidance of the extremes of anemia, especially during severe hypotension and avoidance of transfusion in patients with Hb levels >8.0g/dL may help decrease AKI in patients undergoing cardiac surgery.

**EArly RenaL Involvement in Hospital Acquired Acute Kidney Injury (EARLI)** Tarek M. Elachkar,[1] Geetha Balasubramanian,[1] Abdul Moiz,[1] Michael I. Rauchman,[1] Zhiwei Zhang,[1] Ziyad Al-Aly.[2] *[1]Department of Medicine-Nephrology, Saint Louis University and St. Louis VA Medical Center, St. Louis, MO; [2]Department of Medicine-Nephrology, St. Louis Veterans Affairs Medical Center, St. Louis, MO.*

**Background:** The optimal timing of nephrology consultation in hospital-acquired acute kidney injury (AKI) is unknown.

**Methods:** We examined the effect of Early Renal Involvement (EARLI) defined as a one-time Nephrology consultation at the onset of AKI on the risk of subsequent severe renal failure (≥250% increase in serum Creatinine (Cr)). We screened daily Cr of 4,296 patients admitted to the St Louis Veterans Affairs Medical Center between September 2008 and May 2009. 354 subjects (8.2%) met the definition of in-hospital AKI (Cr increase by 0.3mg/dl over 48 hours), of whom 176 patients met all inclusion criteria; 85 and 91 patients were enrolled in the control (standard care) and EARLI groups respectively.

**Results:** The two groups had similar baseline characteristics and at the time of AKI. Nephrology recommendations in the EARLI group included specific diagnostic, therapeutic and preventative components. Severe renal failure occurred in 12.9% of patients in the control group compared to 3.3% of patients in the EARLI group (p= 0.024). Patients in the EARLI group had a lower peak Cr of 1.8± 0.1 vs. 2.1± 0.2 mg/dl in control (p= 0.014). In a multivariate model adjusting for demographics and risk factors, both EARLI (OR= 0.08, CI= 0.13-0.47; p= 0.012) and statin use (OR= 0.04, CI= 0.01-0.25; p< 0.01) were associated with reduced risk of severe renal failure.

**Conclusion:** Early Nephrology involvement in AKI reduces the risk of severe subsequent renal failure. Our data also suggests that statin use may protect from worsening AKI.

## SA-FC331

**Ang II-Induced TRPC6 Expression Is Cooperatively Regulated by NFAT, NF-κB, CREB, and Elk-1 in Cultured Mouse Podocytes** Gentzon Hall, Jason J. Eckel, Peter J. Lavin, Rasheed A. Gbadegesin, Guanghong Wu, Alison Byrd, Alison Homstad, Michelle P. Winn. *Department of Nephrology, Duke University Medical Center.*

TRPC6 is a non-selective $Ca^{2+}$ channel that has been found to be a cause of hereditary FSGS. Ang II is a potent inducer of TRPC6 activity and expression that has been associated with glomerulosclerosis and podocyte apoptosis. Nuclear Factor of Activated T-cells (NFAT), Nuclear Factor-κB (NF-κB), Cyclic AMP Response Element Binding Protein (CREB), and Elk-1 are transcriptional regulators involved in proinflammatory and proapoptotic signaling whose activity is induced by Ang II. We hypothesize that NFAT, NF-κB, CREB and Elk-1 cooperatively regulate the Ang II-induced expression of TRPC6 and that the activity of these transcription factors is modulated by the Mitogen and Stress Activated Protein Kinase (MAPK) and Phosphatidylinositol-3 Kinase (PI-3K) pathways, Inhibitor-κB Kinase (I-κK), $Ca^{2+}$/Calmodulin Kinase II (CamKII), and Calcineurin (Cn) in podocytes. Using a model system of immortalized mouse podocytes and a combination of immunoblot analyses, immunoflourescence staining, and chromatin immunoprecipitation (ChIP) we provide evidence that NFAT, NF-κB, CREB, and Elk-1 are activated in response to Ang II stimulation and that the activation of these transcription factors can be attenuated with inhibitors of the MAPK and PI-3K pathways, I-κK, CamKII, and Cn. Specifically, we demonstrate that Ang II induces phosphorylation of the p65 subunit of NF-κB, CREB, and Elk-1 at key serine residues associated with the activation of these transcription factors. This effect is attenuated with inhibitors of the MAPK and PI-3K pathways, I-κK, CamKII, and Cn. Additionally, we demonstrate that Ang II induces an upregulation of TRPC6 expression in podocytes and that this effect is also attenuated with inhibitors of the MAPK and PI-3K pathways, I-κK, CamKII, and Cn. Finally, using ChIP, we demonstrate the Ang II-induced recruitment of NFAT, NF-κB, CREB, and Elk-1 to sites within the upstream 450bp of the mouse *TRPC6* gene. Based on these findings, we propose a model of Ang II-induced TRPC6 expression governed by the cooperative activities of NFAT, NF-κB, CREB, and Elk-1.

## SA-FC332

**miR-30 Protects Podocytes Against TGF-β Induced Apoptosis** Shaolin Shi, Taoran Zhang, Liping Yu, Haiying Qi, Erwin P. Bottinger. *Nephrology/Medicine, Mount Sinai School of Medicine, New York, NY.*

microRNAs control many biological processes by post-transcriptional regulation of gene expression. We have previously shown that podocyte-specific deletion of Dicer, the enzyme required for microRNA production, caused proteinuria, progressive glomerulosclerosis, and death, suggesting essential requirements for microRNAs in podocytes. We showed that miR-30 family was abundantly expressed in podocytes and miR-30 target genes were significantly enriched for apoptosis-associated genes [Shi et al, ASN abstract, 2008]. Based on these findings, we hypothesized that miR-30 members regulate apoptosis in podocytes. We have previously shown that TGF-β induces podocyte apoptosis *in vitro* and *in vivo* [Schiffer et al., JCI, 2001].

RESULTS: miR-30 family members (miR-30a, b, c, d, e) were strongly downregulated by TGF-β in conditionally-immortalized mouse podocytes within 24 hrs, and in glomeruli isolated from double transgenic (NPHS2-rTA/tet-O-TbRI(AAD)) mice with ligand-independent, doxycycline-inducible expression of constitutively active TGF-β receptor type I in podocytes, compared with controls. Lentivirus-mediated overexpression of miR-30d in podocytes significantly inhibited TGF-β-induced activation of caspase-3 and apoptosis (TUNEL-assay), compared to control scramble miRNA. We conclude that miR-30s protect against apoptosis and downregulation of miR-30 is required for TGF-β induced apoptosis of podocytes.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC333

**PAR-3 Activation by Activated Protein C: A Novel Podocyte Protective Signalling Pathway** Madhusudhan Thati, Hongjie Wang, Muhammed Kashif, Sandra Muller-Krebs, Vedat Schwenger, Martin G. Zeier, Peter Nawroth, Berend H. Isermann. *Internal Medicine-1 and Clinical Chemistry, University of Heidelberg, Heidelberg, Baden-Wuttenberg, Germany.*

Activated protein C (APC) has anti-coagulant and cytoprotective effects. The cytoprotecive role of APC has been well studied in endothelial cells but remains less well defined in non-endothelial cells. Here we used a rat model of puromycin aminonucleoside

(PAN) induced nephropathy and show that APC protects against PAN induced podocyte apoptosis and glomerular disease. *In vitro* experiments were performed using immortalized differentiated human podocytes to delineate the receptor mechanism.

PAN administration (150 mg/kg, i.p.) induced podocyte apoptosis and albuminuria by day-4, peaking at day 6. Administration of APC (5 mg/kg, i.v.day 1-6) protected against podocyte apoptosis and albuminuria. APC treatment after disease onset (day 4-6) significantly reduced podocyte apoptosis and albuminuria. Pre-incubation of APC with HAAPC antibody which blocks the anticoagulant, but not the cytoprotective, property of APC, did not abolish the cytoprotective effect, establishing that the protective effect of APC is independent of its anticoagulant property. To demonstrate the direct cytoprotective effect of APC on podocytes, FITC labelled APC was administered i.v. Within 3 min FITC-APC accumulated in the pericapillary space of rat glomeruli. In addition significantly elevated levels of PC were detected in urine samples of PAN treated rats as well as of diabetic patients or mice. These results suggest that APC can directly act on podocytes *in vivo*. *In vitro* APC (2 nM) prevented PAN induced apoptosis in podocytes. This anti-apoptotic effect is independent of endothelial protein C receptor (EPCR) but mediated by limited proteolysis of PAR-3 and cross-activation of either PAR-1 (mouse, rat) or PAR-2 (human).

In conclusion, we demonstrate a novel cyto-protective mechamism of APC in an acute model of nephropathy, which depends on APC mediated limited proteolysis of PAR-3. This novel podocyte protective signalling pathway may lay ground to the delineation of new pathophysiological concepts and therapeutic approaches.

## SA-FC334

**Autophagy Induced by TGF-β1 Suppresses Apoptosis and Promotes Mesangial Cell Survival under Serum Deprivation Via Activation of the Akt Pathway** Yan Ding, Jin Kuk Kim, Sung I. L. Kim, Hee-Jun Na, Mary E. Choi. *Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Autophagy is a fundamental cellular homeostatic process that cells use to degrade and recycle proteins and remove damaged organelles. It can lead to cell death in response to stress, but it can also act as a protective mechanism for cell survival. We show that TGF-β1 induces autophagy and protects glomerular mesangial cells from undergoing apoptosis during serum deprivation. Serum withdrawal rapidly induced autophagy within 1 h in mouse mesangial cells (MMC) as determined by increased microtubule-associated protein 1 light chain 3 (LC3) levels and punctate distribution of the autophagic vesicle-associated-form LC3-II. We demonstrate that after 1 h there was a time-dependent decrease in LC3 levels, which was accompanied by induction of apoptosis evidenced by increases in cleaved caspase 3 and in the number of sub-G1 apoptotic cells. However, treatment with TGF-β1 resulted in an increase of mRNA and protein levels of the autophagy protein LC3 and increased autophagic flux, while suppressing caspase 3 activation and reduction in the number of sub-G1 apoptotic cells. TGF-β1 failed to rescue MMC from serum deprivation-induced apoptosis upon knockdown of LC3 by siRNA, and in MMC from LC3 null ($LC3^{-/-}$) mice. We show that TGF-β1 induced autophagy through Akt activation, and inhibition of PI3K-Akt-mTOR-S6K pathway by LY294002 or dominant-negative Akt suppressed LC3 levels and enhanced caspase 3 activation. TGF-β1 also up-regulated cyclin D1 and E protein levels, while down-regulating p27, thus stimulating cell cycle progression. Bafilomycin A1, but not MG132, blocked TGF-β1 down-regulation of p27, suggesting that p27 levels were regulated through autophagy. Taken together, our data indicate that TGF-β1 rescues MMC from serum deprivation-induced apoptosis via induction of autophagy through activation of the Akt pathway. Conversely, inhibition of autophagy led to mesangial cell apoptosis. The autophagic process may constitute a protective mechanism against glomerular injury by inhibiting apoptosis and promote mesangial cell survival.

**Epithelial Notch Signaling Regulates Tubulointerstitial Fibrosis Development in the Kidney** Yasemin Sirin,[1] Bernhard O. Bielesz,[1] Volker H. Haase,[2] Katalin Susztak.[1] *[1]Medicine, Albert Einstein College of Medicine, Bronx, NY; [2]Medicine, Vanderbilt University, Nashville, TN.*

Tubulointerstitial fibrosis (TIF) is considered the final common pathway leading to end stage renal failure. Previously, we and others showed that the Notch pathway is activated in tubules of patients with TIF and in animal models thereof. Notch1, Jagged1 and HeyL were increased in Unilateral Ureteral Obstruction (UUO) and Folic Acid (FA) induced TIF models. Pharmacological inhibition of Notch activation with a γ-secretase inhibitor reduced the expression of profibrotic genes, such as collagen1, smooth muscle actin (SMA), vimentin, and fibronectin as well as TIF development in both models.

To better understand the mechanism of Notch induced TIF, we generated mice with a tubular defect for RBPj, the downstream transcriptional binding partner of Notch, by using the tubule specific PEPCK promoter (PEPCKCre-Rbpj flox/flox). These mice were significantly protected against fibrosis which was also reflected in a reduced expression of profibrotic genes after FA injection.

To further elucidate the role of Notch in TIF, we generated a doxycyclin inducible Notch1 over expressing mouse line using the tubule specific Pax8 promoter (Pax8rtTA-tetO-ICN1). Notch1 expression was induced at 4 weeks of age. We found that double transgenic animals develop severe TIF and die 5-6 weeks after induction with doxycyclin. We observed increased expression of markers of TIF including collagen1, 3, fibronectin, and SMA.

To get more insight into the involved pathways, we performed gene expression analysis using Affymetrix microarrays. We found 1784 differentially expressed transcripts (2-fold change, $p < 0.01$, Benjamini-Hochberg correction). Markers of proliferation were significantly increased. In accordance, we observed Notch induced proliferation both in tubular and interstitial cells on Ki67 immunostaining. Thus, we propose that epithelial Notch signaling induced interstitial cell proliferation and signaling might play a role in TIF development.

In summary, here we demonstrate in a proof of concept experiment that Notch activation in epithelial cells alone is sufficient to induce TIF.

## SA-FC336

**AMP-Activated Protein Kinase Potentiates Hypertonicity-Induced Apoptosis by Blocking the NFκB/COX-2 Survival Pathway in Renal Medullary Interstitial Cells** Youfei Guan,[1,2] Hang Yang.[1] *[1]Department of Physiology and Pathophysiology, Peking University Health Science Center, Beijing, China; [2]Division of Nephrology, Vanderbilt University Medical Center, Nashville, TN.*

Renal medulla is characterized by extreme hypertonicity and severe hypoxia. Cells residing in this harsh environment depend on dynamic mechanisms that repeatedly reassess the status of amassed energy in order to adapt energy supply to demand. The AMP-activated protein kinase (AMPK) is a Ser/Thr protein kinase acting as a sensor of cellular energy status. The present study was designed to examine the role of AMPK in the survival of renal medullary interstitial cells (RMICs) under hyperosmotic condition both in vitro and in vivo. AMPK phosphorylation was decreased under hypertonic condition within 12 hours and then gradually returned to the baseline. Activation of AMPK by either an AMPK activator AICAR or a constitutively active AMPK construct markedly increased hypertonicity-induced RMIC apoptosis. This effect was associated with the suppression of hypertonicity-induced NFκB nuclear translocation and COX-2 expression and was abolished by overexpression of COX-2. AMPK activation also resulted in a marked reduction in the generation of reactive oxygen species (ROS) and expression of tonicity-responsive enhancer binding protein (TonEBP), which prevented up-regulation of osmoprotective genes in hypertonicity-treated RMICs. In vivo study further demonstrated that treatment of mice with AICAR caused a massive apoptosis of RMICs after a 12-hour water restriction. Taken together, these results identify AMPK as a critical factor involved in the maintenance of RMIC viability and suggest that AMPK is an important regulator of the NFkB-COX-2 survival pathway in renal medulla. Since tremendous efforts have been made in developing novel AMPK activator as potential anti-diabetic medicine, the present study raises safety concerns for such treatment in patients with dehydration.

**HIF2α Is Sufficient for Rapid Generation of Renal Cysts in a Mouse Model of RCC** Nasir A. Shah,[1,2] Susan E. Quaggin.[1,3,4] *[1]Samuel Lunenfeld Research Institute, Toronto, ON, Canada; [2]Department of Physiology, University of Toronto, Toronto, ON, Canada; [3]Institute of Medical Science, University of Toronto, Toronto, ON, Canada; [4]Department of Nephrology, St. Michael's Hospital, Toronto, ON, Canada.*

Renal cell carcinoma is the most common urogenital tumor, accounting for 3% of all adult malignancies, 34,000 new cases, and a mortality of 13,000 each year in the United States. It has been shown that hypoxia inducible factors (HIFs) are upregulated in renal cell carcinoma (RCC). During normoxia the HIFα subunits are hydroxylated at specific proline residues, which allows for recognition by the VHL E3 ubiquitin ligase (composed of pVHL, Cullin2, elongin B, elongin C and Rbx1), and subsequent proteasomal degradation. In RCC, inherited or sporadic mutations in the VHL gene allow the HIFα subunits to escape degradation and translocate to the nucleus. Here they dimerize with HIF1β (ARNT), recruit transcriptional co-factors, and bind to consensus sequences in the promoter region of their downstream target genes. Although HIF-1α and HIF-2α are both upregulated in RCC, it has been suggested that HIF2α plays the more critical role. To further elucidate the role of HIF2α in RCC, we have generated an inducible transgenic mouse model that permits temporal stabilization of a transcriptionally active form of HIF2α in mature renal tubular epithelial cells under control of a Pax8rtTA driver. Induction of HIF2α results in the rapid development of renal cysts with concomitant loss of markers of tubular epithelial differentiation, which are both features of early RCC. Additionally, tubular-specific loss-of-function mutations in VHL and/or the tumor suppressor PTEN are predicted to result in full blown RCC and mice carrying these additional mutations have been generated and phenotyping is underway. Taken together, these results suggest that HIF2α is a key player in development of RCC and an excellent candidate target for therapy of this disorder.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC338

**Long Chain Acyl-CoA (LCA) Inhibition of NHE1 Plays a Role in Proximal Tubular Epithelial Cell (PTC) Deletion and Progressive Renal Disease** Bassam G. Abu Jawdeh, Shenaz Khan, Monu Goel, Satya P. Yadav, Raymond C. Harris, William P. Schilling, Eckhard K. Ficker, Jeffrey R. Schelling. *Case School of Medicine.*

Tubular atrophy caused by PTC apoptosis predicts CKD progression. Although free fatty acid (FFA) uptake by PTCs has been associated with accentuated apoptosis and tubulointerstitial disease, a pathophysiologic mechanism has not been delineated. We previously reported that NHE1 is regulated by a $PI(4,5)P_2/PIP_3$ dependent "on-off" switch, and defends against PTC apoptosis by $Na^+/H^+$ exchange-dependent increases in cell volume and pH. LCAs, the direct metabolites of FFAs, are structurally similar to phosphoinositides and regulate other exchangers. We hypothesize that LCAs accumulate in CKD and facilitate

lipotoxicity by inhibiting NHE1 activity. In ENOS$^{-/-}$db/db mice with diabetic nephropathy, triacylglycerol lipid droplets were observed in PTCs by Oil red O staining, reflecting FFA reabsorption. Kidney LCA content, determined by GC-MS, was significantly increased in ENOS$^{-/-}$db/db and ROP$^{Os/+}$(FSGS model) mice. The NHE1-LCA interaction was characterized by surface plasmon resonance, using purified, His-tagged wild-type (cNHE1) and point-mutant (KR/A) NHE1 peptides immobilized as ligands on a sensor chip, while flowing LCAs as analytes. LCAs bound cNHE1 with low affinity ($K_d$ ~10μM), which is similar to PI(4,5)$P_2$ affinity for cNHE1. LCA binding was attenuated by poly-L-lysine and $Mg^{2+}$ and to the KR/A mutant, suggesting an electrostatic interaction. To address the LCA effect on NHE1 function, LLC-PK1 cells were loaded with albumin-bound fatty acids, and inhibitors of FFA (triacsin C) and LCA (etomoxir) metabolism. Etomoxir inhibited NHE1-regulated $Na^+/H^+$ exchange (determined by BCECF fluorescence microscopy) and enhanced apoptosis (assessed by TUNEL). FFA-induced NHE1 inhibition and apoptosis were abrogated with triacsin C. Our data suggest that in proteinuric disease states PTCs reabsorb FFA-laden albumin, which leads to increased intracellular concentration of LCA. We conclude that accumulated LCA then inhibits NHE1, perhaps by competing with PI(4,5)$P_2$/$PIP_3$ binding, which enhances PTC apoptosis leading to tubular atrophy.

## SA-FC339

**Defective Proteolysis of Albumin in the Proximal Convoluted Tubule of Limp2 Knockout Mice** Darren H. K. Lee,[1,2] Michael James Desmond,[1,2] Scott Andrew Fraser,[1] Marina Katerelos,[1] Kurt Gleich,[1] David A. Power.[1,2] *[1]Department of Nephrology, Austin Health, Heidelberg, Victoria, Australia; [2]Department of Medicine, University of Melbourne, Parkville, Victoria, Australia.*

Inactivating mutations of the lysosomal protein Limp2 cause Action Myoclonus Renal Failure Syndrome (AMRFS) in humans, which is associated with collapsing FSGS. Limp2 KO mice, by contrast, have a milder renal phenotype but develop tubular proteinuria and albuminuria. To identify the defect in tubular protein handling, Limp2 KO mice were injected with HRP and fluorescein-conjugated albumin. Uptake of HRP by the proximal tubule (PCT) at 7 mins showed no difference between KO and WT mice, indicating normal fluid phase endocytosis. Uptake of fluorescein-conjugated albumin at 7 mins was also similar in both groups. At 30 mins, however, there was persistence of albumin in the PCT of the KO mice with a change in distribution compared to the original uptake, indicating a failure of proteolysis. The presence of a normal tubular uptake system in the KO mice was confirmed by similar expression of the proteins taken up by the receptors megalin and cubilin along the brush border of the PCT. EM of perfusion fixed kidneys demonstrated an accumulation of large vacuoles in the PCT of KO mice, some apparently in contact with the luminal or basolateral surface of the cells. The appearance was similar to that seen in EBV-transformed lymphoblastoid B cells from 2 patients with AMRFS. This data suggests that the absence of Limp2 in the PCT leads to a lack of fusion of lysosomes with endosomes, persistence of the proteins reabsorbed by the PCT, and their eventual release from the surface of the cell into the urine. This data does not support the proposed ability of the PCT to reabsorb significant quantities of albumin without lysosomal degradation.

## SA-FC340

**A Novel Protease-Activated Receptor-2 Antagonist Targeting Inflammation and Proliferation in Human Renal Tubular Epithelial Cells** David A. Vesey,[1] Jacky Yung Suen,[2] David W. Johnson,[1] David Fairlie.[2] *[1]Centre for Kidney Disease Research, The University of Queensland, Brisbane, QLD, Australia; [2]Institute for Molecular Bioscience, The University of Queensland, Brisbane, QLD, Australia.*

Protease-activated receptor-2 (**PAR2**) is a G-protein-coupled receptor (GPCR) activated by trypsin-like proteases and experimentally by hexapeptides corresponding to the receptors tethered ligand. Its ubiquitous expression has been linked to pro-inflammatory and proliferative conditions in a wide variety of tissues, including the kidney, and as such it is a highly desirable target for drug development. To date, little progress has been made in development of drug compounds targeting this receptor. Here we describe the actions of a non-peptidic specific **PAR-2** antagonist (GB88), which effectively inhibits these two responses in primary cultures of human kidney tubular epithelial cells (HTEC). In addition we reveal a potent non-peptidic **PAR2** agonist (GB110) which matches the peptidic **PAR2** agaonist, 2f-LIGRLO-$NH_2$, in its potency. Compared to the colon carcinoma cell line HT29, HTEC cells expressed 3-fold more **PAR2** mRNA (qRTPCR). In a calcium mobilisation assay, 2f-LIGRLO-$NH_2$ and GB110 were equally potent ($EC_{50}$ 1.5μM). GB88 reduced calcium release in response to these ligands and its natural ligand trypsin, with an $IC_{50}$ around 10μM. Exposure of these cells to either 2f-LIGRLO-$NH_2$ (0.5-2μM), or GB110 (0.5-5μM) induced a robust **DNA** synthetic response which was completely inhibited by 8μM GB88. In a human inflammation antibody array, more than 10 inflammatory cytokines were up-regulated by 2f-LIGRLO-$NH_2$ (2μM), or GB110 (2μM), including GM-CSF, MCP-1, IL-6, IL-8, RANTES, ICAM-1, MIP-1β, TIMP-2, IL-1α and TNFα. The 10-fold increase in IL-6 & IL-8 secretion induced by GB110 or 2f-LIGRLO-$NH_2$ was inhibited by GB88 ($IC_{50}$ <10μM). GB88 represents a novel druggable antagonist of **PAR2**, which will be invaluable in refining our understanding of the role of **PAR2** in disease processes. It also paves the way for the development of a new class of anti-inflammatory and anti-proliferative drugs with potential to treat inflammatory kidney diseases.

**The Transmembrane Tyrosine Phosphatase CD148 (DEP-1) Functions as a Receptor for Thrombospondin-1** Keiko Takahashi,[1] Ray Mernaugh,[2] David Friedman,[2] Rebecca S. Weller,[1] Rosie T. Jiang,[1] Nobuo Tsuboi,[1] Takamune Takahashi.[1] *[1]Nephrology, Vanderbilt University Medical Center, Nashville, TN; [2]Biochemistry, Vanderbilt University School of Medicine, Nashville, TN.*

Anti-angiogenesis therapy is a promising strategy for a variety of human diseases, including diabetic vascular complications. Definition of the molecular determinants regulating angiogenic vessel growth promises a better anti-angiogenesis therapy. CD148 is a receptor-type tyrosine phosphatase which is abundantly expressed in vascular endothelial cells of many organs, including renal vasculature. Growing evidence demonstrates a prominent role for CD148 in negative regulation of endothelial cell growth. However, the regulatory mechanisms of CD148, including extracellular ligands, remain unknown.

To identify the extracellular proteins which bind to CD148, we introduced HA-tagged CD148 protein into cultured endothelial cells and isolated the CD148 interacting surface proteins by biotin-surface labeling, followed by affinity purifications using anti-HA affinity column and avidin beads. The binding proteins were identified by mass spectrometry. Here, we show that soluble thrombospondin-1 (TSP1) binds to the extracellular part of CD148 with high affinity and specificity (in vitro and in situ binding assays, Kd=13.03nM), increases its catalytic activity (PTP assay), and induces dephosphorylation of CD148 substrate proteins including VEGFR, EGFR, and ERK1/2. Furthermore, we show that introduction of wild-type, but not catalytically inactive, CD148 confers TSP1 cell growth inhibition to the CD148-deficient cells, whereas TSP1 increases cell proliferation when the cells lack CD148 expression. These TSP1 effects were antagonized by soluble CD148 ectodomain protein as well as by CD148 gene silencing. Lastly, we demonstrate that CD148 gene silencing reduces the anti-angiogenesis activity of TSP1 in endothelial cells. Taken together, these findings demonstrate that CD148 tyrosine phosphatase functions as a receptor for TSP1 and plays an important role in TSP1-mediated endothelial cell growth inhibition. Further investigation of this pathway would explore a novel strategy for anti-angiogenesis therapy.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC342

**Macrophage Angiotensin II Type 1a Receptor (AT1aR) Underlies Renal Injury-Induced Atherosclerosis by Modulating the Macrophage Phenotype** Suguru Yamamoto,[1] Yiqin Zuo,[1, 2] Patricia G. Yancey,[3] Zhi-Qi Xu,[1] Iekuni Ichikawa,[1] Valentina Kon.[1] *[1]Pedeiatrics, Vanderbilt University, Nashville, TN; [2]Pathology, Vanderbilt University, Nashville, TN; [3]Medicine, Vanderbilt University, Nashville, TN.*

**Background** We and others have shown that infusion of angiotensin II (AII) potentiates atherosclerosis. We also showed that reduction in renal parenchyma potentiates atherosclerosis and increases macrophage infiltration which are lessened by systemic antagonism of AII receptor. Although the macrophage is central to atherosclerosis and expresses AT1R, its role in atherogenesis remains uncertain because macrophage AT1aR (MacAT1aR) has a variable impact on atherosclerosis that depends on the level of circulating angiotensin II achieved by exogenous AII. Since renal injury is an AII-activated state, we examined the contribution of AT1aR on macrophages versus resident vascular cells in uninephrectomized (UNx)-induced amplification of atherosclerosis.

**Methods and results** Apolipoprotein E deficient mice (apoE-/-) were transplanted with bone marrow from apoE-/-:AT1aR-/- or apoE-/-:AT1aR+/+ mice and then underwent UNx or sham operation. Four groups were examined: Sham-MacAT1aR+/+ (n=10), UNx-MacAT1aR+/+ (n=15), Sham-MacAT1aR-/- (n=10), UNx-MacAT1aR-/- (n=15). There were no differences in body weight, blood pressure, lipid profile and creatinine clearance among the groups. In mice reconstituted with intact MacAT1aR, UNx significantly increased atherosclerosis (UNx-MacAT1aR+/+: 169071±21473 vs Sham-MacAT1aR+/+: 116071±8180μm$^2$, $p<0.05$) while reconstitution with MacAT1aR-/- prevented UNx-induced amplification in atherosclerosis (77174±9947 vs 75714±11333μm$^2$, *NS*). Further characterization of plaque lesions in UNx reconstituted with MacAT1aR-/- revealed greater number of macrophages with alternatively activated phenotype with anti-inflammatory/anti-atherogenic functions [Ym-1 positive macrophages (65.4±2.0 vs 38.7±3.5%, $p<0.05$)].

**Conclusions** AT1aR on bone marrow-derived macrophages modulates renal injury–induced acceleration of atherosclerosis by modifying the macrophage phenotype which in turn determines the extent and severity of disease.

## SA-FC343

**Glyoxalase I Prevent Age-Related Aortic Medial Thickening by Reducing TGF-β and CTGF Signals Independent of Blood Pressure** Yoichiro Ikeda,[1] Reiko Inagi,[1] Airi Jo,[1] Takamoto Ohse,[1] Toshio Miyata,[2] Ichiro Manabe,[3] Ryozo Nagai,[3] Toshiro Fujita,[1] Masaomi Nangaku.[1] *[1]Nephrology and Endocrinology, University of Tokyo, School of Medicine, Tokyo, Japan; [2]Tohoku University, Japan; [3]Cardiology, University of Tokyo, School of Medicine, Japan.*

Background

Glyoxalase I (GLO1) decomposes precursors of AGEs, and we previously demonstrated that GLO1 retards age-related morphological and functional phenotypes of kidney. Atherosclerosis is the most important change related to senescence as well as chronic kidney disease. Aortic medial thickening is the hallmark of atherosclerotic changes, and TGF-β contributes to the histological changes. Here we investigated whether GLO1 prevents age-related atherosclerosis or not.

Methods

Aorta from young and aged rats of GLO1 transgenic and wild type was harvested, and morphological and functional changes were studied. Senescence status was evaluated by senescence-associated β-galactosidase (SABG) staining. The cDNA was isolated from smooth muscle cells of aortic medial wall. The expression levels of TGF-β1 and CTGF were measured to evaluate the profibrotic status *in vivo*.

Results

There were no significant differences among blood pressure and chow intake of young (10-week-old) and aged (14-month-old) rats of GLO1 transgenic and wild type (sBP; young WT 106±3, young GLO1-TG 105±6, aged WT 104±11, aged GLO1-TG 102±8 mmHg). Aortic media were thickened when aged, whereas in aged GLO1-TG rats, aortic thickening was attenuated (100±10, 97±15, 132±16, 111±11μm). Aortic structures showed age-dependent changes including extracellular matrix accumulation, which was reduced in aged GLO1-TG than aged WT. Positive staining of aorta from aged WT was observed in SABG staining, whereas no staining was observed in aorta of aged GLO1-TG. Expression levels in TGF-β and CTGF of aged WT were significantly increased 5.5 and 3.3 folds respectively compared to young WT, whereas those of young GLO1-TG were lower than those of WT (0.044 and 0.058 fold, respectively). We did not observe age-dependent increases of TGF-β and CTGF in GLO1-TG.

Conclusion

GLO1 prevents age-related aortic medial thickening by reducing TGF-β and CTGF singals independent of blood pressure.

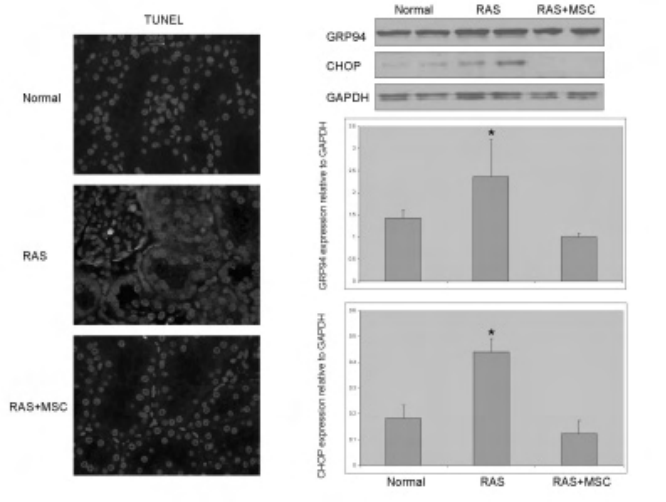
**Adipose-Derived Mesenchymal Stem Cells Blunt Endoplasmic Reticulum Stress and Apoptosis in Experimental Swine Renal Artery Stenosis** Xiang-Yang Zhu,[1] Victor Urbieta Caceres,[1] James Krier,[1] Stephen C. Textor,[1] Amir Lerman,[2] Lilach O. Lerman.[1] *[1]Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [2]Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

**Objective**: Endoplasmic reticulum (ER) stress has been recently recognized to play an important role in apoptosis and tissue damage. Adipose-derived mesenchymal stem cells (ad-MSC) can participate in tissue repair, but their effect on ER stress is unknown. This study tested the hypothesis that ad-MSC would reduce ER stress-induced apoptosis and protect the post-stenotic kidney. **Methods:** Allogenic Ad-MSCs were isolated from porcine omentum, expanded, and characterized by cell surface markers (e.g. CD44 and CD90). Single kidney hemodynamics and function were assessed using multi-detector CT in pigs after 10 weeks of renal artery stenosis (RAS) treated 4 weeks earlier with an intra-renal infusion of vehicle (n=7) or ad-MSC (10x10^6, RAS+MSC, n=6), and normal controls (n=6). Kidneys ER stress was evaluated by expression of the mediators GRP94 (in isolated ER) and CHOP, and apoptosis by TUNEL. **Results**: The degree of stenosis and hypertension were similar in RAS and RAS+MSC. Renal blood flow and glomerular filtration rate in RAS were lower than normal controls, but improved in RAS+MSC. Apoptotic tubular and interstitial cells were increased in RAS compared to normal (1.8±0.9 vs. 0.8±0.2 cells/field, p<0.05) and improved in RAS+MSC (1.1±0.9 cells/field, p=NS vs. normal). RAS produced increased expression of GRP94 and CHOP and fibrosis that all decreased with ad-MSC treatment.



**Conclusion**: Experimental chronic RAS was associated with increased ER stress and apoptosis in the injured kidney. Intra-renal delivery of ad-MSC improved renal function and attenuated ER stress, cell death, and fibrosis, demonstrating an anti-fibrotic therapeutic potential of ad-MSC in the ischemic kidney.

## SA-FC345

**Liver-Specific and Kidney-Specific Angiotensinogen Gene Knockout Revealed That Renal Renin Activity, and JGA and Renal Vascular Morphology Are Dependent on Blood Pressure, Not Renal Angiotensin** Iekuni Ichikawa,[1] Fumio Niimura,[2] Akira Nishiyama,[3] Akihiro Shimizu,[4] Taiji Matsusaka.[4] *[1]Department of Pediatrics, Vanderbilt University Medical Center, TN; [2]Department of Pediatrics, Tokai University School of Medicine, Kanagawa, Japan; [3]Department of Pharmacology, Kagawa University School of Medicine, Kagawa, Japan; [4]Department of Internal Medicine, Tokai University School of Medicine, Kanagawa, Japan.*

Whole-body angiotensinogen gene (Agt) knockout (KO) mice are characterized by hypotension, polyuria, renal vascular hypertrophy and hypoplastic papilla. To gain insight into the mechanism of these abnormal phenotypes, we have generated kidney-specific and liver-specific Agt KO mouse strains. In the kidney Agt KO mice (n=15), renal Agt mRNA was decreased, on average, to 14.4% of that in control mice (n=9)(p<0.05), but renal Agt protein was unchanged. Renal renin activity (222±62 vs. 209±27 ng AngI/ml/h/g protein), JGA morphology, Ang II content in the kidney (175±62 vs. 177±48 fmol/g tissue) and systolic blood pressure (120.7±8.1 vs. 121.7±9.3) were also comparable to those of control mice. In the liver Agt KO mice (n=8), the levels of hepatic Agt mRNA, hepatic Agt protein and plasma Agt protein were all too low to detect. In the kidney of liver KO, although Agt mRNA was increased by 45% (p<0.05), Agt protein was undetectable by Western and immunostaining. However, renal renin activity was markedly increased (1821±557, p<0.05) with JGA hypertrophy, and renal Ang II content was maintained at levels similar to controls (147±39). The liver KO showed low systolic blood pressure (74.9±1.7, p<0.05), polyuria, renal arterial hypertrophy without hypoplastic papilla. These results indicate that Agt of liver origin is essential for maintaining normal blood pressure and urine concentration and that blood pressure, not renal Ang II, is the primary regulator for renal renin activity, and JGA and renal vascular morphology.

## SA-FC346

**Role of Farnesoid X Receptor (FXR) in Regulation of Vascular Calcification in Chronic Kidney Disease** Makoto Miyazaki,[1] Moshe Levi,[1, 2] Shinobu Miyazaki-Anzai.[1] *[1]Division of Renal Diseases and Hypertension, University of Colorado-Denver; [2]Denver Veterans Affairs Medical Center.*

**Rationale:** Vascular calcification is highly associated with cardiovascular morbidity and mortality, especially in patients with chronic kidney disease. The nuclear receptor farnesoid X receptor (FXR) has been implicated in the control of lipid, carbohydrate and bile acid metabolism in several cell types. Although recent studies have shown that FXR is also expressed in vascular smooth muscle cells, its physiological role in vasculature tissue remains obscure.

**Objective:** Here, we have examined the role of FXR in vascular calcification.

**Methods and Results:** The FXR gene, a bile acid nuclear receptor, was highly induced during osteogenic differentiation of bovine calcifying vascular cells (CVC) and in the aorta of apolipoprotein E ($ApoE)^{-/-}$ mice with chronic kidney disease which are common tissue culture and mouse model, respectively, for aortic calcification. FXR activation by a synthetic FXR agonist, 6a-ethyl chenodeoxycholic acid (INT-747) inhibited phosphate induced-mineralization and triglyceride accumulation in CVC. FXR dominant negative expression augmented mineralization of CVC and blocked the anti-calcific effect of INT-747 whereas VP16FXR that is a constitutively active form reduced mineralization of CVC. In addition, INT-747 ameliorates chronic kidney disease (CKD) induced-vascular calcification in 5/6 nephrectomized $ApoE^{-/-}$ mice. FXR deficiency on the other hand accelerates atherosclerosis and vascular calcification in both $ApoE^{-/-}$ and $LDLR^{-/-}$ mice with CKD.

**Conclusions:** These observations provide direct evidence for that FXR is a key signaling component in regulation of vascular calcification.

## SA-FC347

**Ebselen Prevents Stress-Induced Premature Senescence (SIPS) of Endothelial and Endothelial Progenitor Cells (EPC) by Restoring Sirtuin-1 (SIRT1)** Jun Chen, Leonid Buryanovskyy, Eliza Moskowitz-Kassai, Connie Y. Lu, Robert Chen, Frank Fan Zhang, Alberto Nasjletti, Michael S. Goligorsky. *New York Medical College, Valhalla, NY.*

SIPS of endothelial cells has emerged as a notable contributor to endothelial cell dysfunction (ECD) in diseases. Endothelial progenitor cells (EPC) also undergo SIPS. Sirtuins have recently been recognized as potent regulators of longevity of cells and organisms. Chronic treatment with an antioxidant and peroxynitrite scavenger ebselen (Ebs) reversed SIPS in vivo and in vitro. In the renal vasculature of db/db mice, the expression of Sirt1 was depleted compared to age-matched db/m control mice. We inquired whether a combined antioxidant and peroxynitrite scavenging therapy with Ebs, to protect endothelial cells and EPC from SIPS, exerts its effect via SIRT 1 and what is the possible mechanism. Exposure of EPC and EC to cardiovascular stressors (ADMA, non-enzymatically glycated collagen, H2O2) resulted in depletion of SIRT1. The impact of SIRT1 on EPC viability (apoptosis, senescence) was studied by overexpressing or downregulating Sirt1 levels. The data showed that overexpression of exogenous Sirt1 in EPC prevented apoptosis and senescence induced by these stressors. In contrast, downregulation of endogenous Sirt1 by shRNA or using its inhibitor, Sitrinol, exaggerated apoptosis and senescence in EPC exposed to stressors. Pretreatment of EPC with Ebselen prevented apoptosis and senescence induced

by stressors and this effect was accompanied by the prevention of downregulation of Sirt1. This effect of Ebselen was mediated via modulation of autophagy in EPC. Exposure of EPC to the stressors increases the accumulation of intracellular p62, a marker of impaired autophagic process. Pretreatment with Ebselen prevented p62 accumulation under stress conditions in EPC. Disruption of autophagy process using chloroqine or 3-methyladenine increased p62 level and decreased Sirt1 expression in EPC. In conclusion, 1) ebselen is a potent inducer of SIRT 1 expression in EPC, 2) ebselen normalizes impaired autophagy and by doing so 3) prevents SIPS and apoptotic cell death induced by several cardiovascular stressors.

### SA-FC348

**The Bone Marrow: A Novel Source of Smooth Muscle Cells Able To Undergo Osteoblastic Transformation** Rajesh Mohandas, Mark S. Segal. *Department of Medicine, University of Florida, Gainesville, FL.*

Though bone marrow derived progenitor cells, which are cells derived from the bone marrow that circulate in the blood stream, have definitively been shown to differentiate into endothelial cells, their ability to differentiate into a smooth muscle phenotype (smooth muscle progenitor cells or SMPCs) is less well documented. We hypothesized that SMPCs are derived from the bone marrow and because of their stem cell like characteristics these cells have an increased propensity to undergo osteoblastic transformation.

**Methods:** Monocyte rich plasma was isolated using Ficoll and plated in smooth muscle cell media supplemented with PDGF. Double immuno-fluorescent staining for actin and myosin was used to definitively demonstrate a smooth muscle phenotype. Wild-type mice transplanted with GFP bone marrow were used to confirm the bone marrow origin of the smooth muscle progenitor cells. Calcification was induced by supplementing media with inorganic phosphate and tendency to calcify quantified by measuring intracellular calcium normalized to protein content.

**Results:** Smooth muscle cell colonies isolated from mice appeared after one week of culture and those isolated from healthy adults appeared after two weeks. These cells demonstrate the characteristic spindle shaped cells arranged in a hill and valley pattern and stained positive for actin as well as myosin heavy chain. Smooth muscle progenitor cells isolated from the GFP chimeric mouse also expressed GFP confirming the bone marrow origin of these cells. In the presence of phosphate, these cells expressed the transcription factor cbfa1 suggesting transition to an osteoblastic phenotype and demonstrated evidence of intracellular calcium deposition.

**Conclusions:** Demonstration of cells that express two different smooth muscle markers, actin and myosin, definitively identify these cells as circulating smooth muscle progenitor cells. At least in mice, these cells are derived from the bone marrow on the basis of their GFP expression. In presence of phosphate these cells will undergo osteoblastic transformation. Studies are ongoing to examine the role of these cells in vascular calcification seen in chronic kidney disease.

### SA-FC349

**Accelerated Vascular Lesion Formation in Mice Lacking All Nitric Oxide Synthases: Contribution of Bone Marrow Cells** Yumi Furuno,[1] Masato Tsutsui,[2] Tsuyoshi Morishita,[1] Kiyoko Shibata,[1] Yoko Fujimoto,[1] Tetsu Miyamoto,[1] Tatsuya Shibata,[3] Ryota Serino,[1] Narutoshi Kabashima,[3] Nobuyuki Yanagihara,[4] Yutaka Otsuji,[1] Masahito Tamura.[3] *[1]Second Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan; [2]Department of Pharmacology, University of the Ryukyus, Okinawa, Japan; [3]Kidney Center, University of Occupational and Environmental Health, Kitakyushu, Japan; [4]Department of Pharmacology, University of Occupational and Environmental Health, Kitakyushu, Japan.*

***Background*:** The precise role of nitric oxide synthases (NOSs) in vascular remodeling still remains to be fully elucidated. We addressed this issue in mice lacking all NOS genes. ***Methods and Results***: Permanent ligation of a unilateral carotid artery was performed in wild-type, singly nNOS$^{-/-}$, iNOS$^{-/-}$, and eNOS$^{-/-}$, and triply n/i/eNOS$^{-/-}$ mice. At 2 weeks after the carotid artery ligation, significant neointimal formation (NF), constrictive vascular remodeling (VR), and inflammatory leukocyte infiltration (LI) were noted in the ligated arteries of all genotypes. However, these vascular pathological alterations were most aggravated in n/i/eNOS$^{-/-}$ genotype. Although blood pressure was significantly elevated in eNOS$^{-/-}$ and n/i/eNOS$^{-/-}$ genotypes, those changes were not significantly correlated with the extents of the vascular lesion formation, indicating a minor role of hypertension. Finally, we studied the cell origin of vascular lesions. Bone marrow of WT, singly or triply NOS$^{-/-}$ genotype was transplanted into WT genotype, and 4 weeks later, the carotid artery ligation was performed. NI, VR, and LI were all similarly most exacerbated in the case of n/i/eNOS$^{-/-}$ transplantation, suggesting the contribution of bone marrow cells in the vascular lesion formation. ***Conclusions***: These results indicate that complete disruption of all NOS genes, especially in bone marrow cells, causes accelerated inflammatory vascular lesion formation caused by blood flow disruption in mice in vivo, demonstrating the critical role of the whole endogenous NOS system in preventing vascular remodeling.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC350

**Comparison of the Effects of Manumycin A and FTI-277 on Vascular Calcification** Arvind Ponnusamy,[1,2] Smeeta Sinha,[1] Colette A. Inkson,[1] Gareth D. Hyde,[1] Philip A. Kalra,[2] Ann E. Canfield.[1] *[1]University of Manchester, Manchester, United Kingdom; [2]Renal Department, Salford Royal NHS Trust Foundation, Salford, United Kingdom.*

Patients with chronic kidney disease have poor cardiovascular outcomes due to increased vascular calcification and atherosclerosis. Previous work from our laboratory has shown that nitrogen-containing bisphosphonates attenuate vascular calcification by inhibiting farnesylpyrophosphate synthase thereby depleting cells of farnesylpyrophosphate and geranylgeranylpyrophosphate which are essential for the prenylation and activation of small GTPases such as Ras and Rho.

This study compares the effects of 2 different farnesyl transferase inhibitors (FTI-277 and manumycin A) on vascular calcification using well validated in vitro and ex vivo model systems. Mineralisation was assessed by histological staining using alizarin red and quantified using a calcium assay. FTI-277 (10 μM) significantly inhibited β-glycerophosphate-induced calcification of vascular smooth muscle cells (VSMC) in vitro ($p<0.001$), whereas manumycin A (10 μM, 20 μM) either increased calcification or had no effect on this process. FTI-277 (10 μM) also inhibited phosphate-induced mineralisation of rat aortic rings ex vivo. Interestingly, manumycin A (10 μM) increased mineralisation ex vivo, although this was localised in the intima of the aortic ring, compared to the vessel media of phosphate-treated controls. Pull-down assays and westerns blots confirmed that both FTI-277 and manumycin A decreased Ras GTPase activation in VSMC.

To determine the effects of these farnesyl transferase inhibitors on signalling downstream of Ras, VSMCs were pre-incubated with FTI 277 (10 μM) or manumycin A (10 μM), and stimulated with serum-containing medium for 5 min. Cell lysates were collected and analysed for Akt phosphorylation by western blotting. Results showed that FTI-277, but not manumycin A, increased Akt phosphorylation in VSMC.

These studies demonstrate that farnesyl transferase inhibitors can inhibit vascular calcification. Intriguingly, however, manumycin A and FTI-277 exerted different effects on calcification and we suggest that this may be due to their differential effects on Akt phosphorylation.

### SA-FC351

**Association of eGFR and Albuminuria with Kidney Outcomes. A Collaborative Meta-Analysis of General and High-Risk Population Cohorts on Behalf of the CKD Prognosis Consortium** Ron T. Gansevoort,[1] Kunihiro Matsushita,[2] Marije Van de Velde,[1] Brad C. Astor,[2] Mark Woodward,[4] Andrew S. Levey,[3] Paul E. de Jong,[1] Josef Coresh.[2] *[1]Dept. Nephrology, University Medical Center, Groningen, Netherlands; [2]Dept. Epidemiology, John Hopkins Institute, Baltimore; [3]Div. Nephrology, Tufts Medical Center, Boston; [4]George Inst. Int. Health, University of Sydney, Sydney, Australia.*

While both low eGFR and albuminuria are known risk factors for ESRD, data on their joint contribution to this and other kidney outcomes are limited.

We performed a collaborative meta-analysis of 9 general population cohorts with 845,125 participants and 8 cohorts with 173,892 participants selected because of high risk for CKD. Both eGFR (MDRD) and albuminuria (ACR or dipstick) were tested as risk factors for ESRD, acute kidney injury (AKI) and progressive CKD (pCKD).

In general population cohorts, the risk for ESRD was unrelated to eGFR at values 75-105 ml/min/1.73m$^2$ and increased exponentially at lower eGFR. Hazard ratios (HRs) (95% CI) at eGFR 60, 45, and 15 (versus 95) ml/min/1.73m$^2$ were 3.69 (2.36-5.76), 29.3 (19.5-44.1) and 454.9 (112.4-1840.2), respectively, after adjustment for ACR and CV risk factors. Albuminuria was associated with ESRD risk linearly without thresholds. Adjusted HRs at ACRs 30, 300 and 1000 (versus 5) mg/g were 4.87 (2.30-10.3), 13.4 (5.49-32.7) and 28.4 (14.9-54.2), respectively. eGFR and albuminuria were multiplicatively associated with ESRD, without evidence for interaction. Similar, but numerically less pronounced associations were observed for AKI and progressive CKD. The findings in high risk cohorts were generally comparable to those in general population cohorts. These pattern of increased HRs were seen for subjects above and below age 65 years, although HRs increased more steeply in younger subjects.

In conclusion, lower eGFR and higher albuminuria are risk factors for ESRD, AKI and pCKD independent of each other and of cardiovascular risk factors, both in the general population and high risk cohorts. These findings provide a quantitative basis for including these two kidney measures in CKD definition, staging and risk stratification.

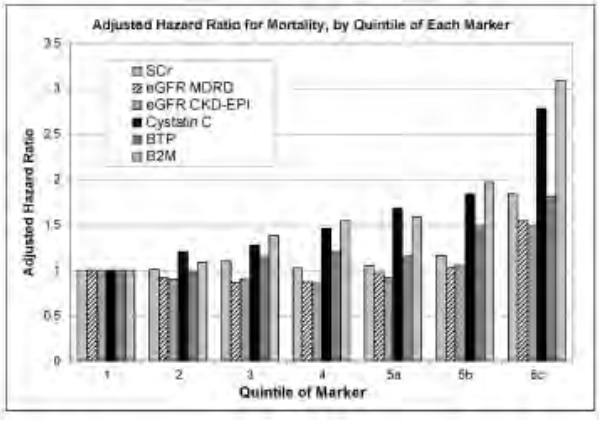
Disclosure of Financial Relationships: nothing to disclose

### SA-FC352

**Novel Markers of Kidney Function as Predictors of Mortality in the Atherosclerosis Risk in Communities (ARIC) Study** Brad C. Astor,[1] Tariq Shafi,[1] Ron C. Hoogeveen,[2] Yaping Wang,[1] Kunihiro Matsushita,[1] Christie M. Ballantyne,[2] Josef Coresh.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Baylor College of Medicine, Houston, TX.*

Serum Cystatin C predicts mortality more strongly than does serum creatinine (Shlipak et al., NEJM 2005), but it is unknown whether this is true for other novel filtration markers. We tested ß-trace protein (BTP), and $ß_2$-microglobulin (B2M) as risk factors for mortality and whether their association was independent of serum creatinine-based estimated GFR. We assessed the association between quintiles of each marker and incidence of death in 10,189

participants in the ARIC Study, a population-based study in 4 US communities (43% male; 22% African-American, ages 54-74 years at baseline). Quintile 5 was further divided into three tertiles (5a, 5b, 5c). Percentile cut-offs for $eGFR_{MDRD}$ were: Quintile 1>95.0, 83.4, 78.3, 68.2, 64.4, and subquintile 5c<59.6 mL/min/1.73m$^2$. A total of 1477 deaths occurred over a median of 9.8 years. Cox regression models were used to adjust for age, race, sex, diabetes, history of cardiovascular disease, smoking, systolic blood pressure, total cholesterol and urinary albumin:creatinine ratio. Other models further adjusted for eight categories of eGFR. Higher categories of BTP and B2M were strongly associated with greater mortality risk (Figure), even after adjustment for $eGFR_{MDRD}$ or $eGFR_{CKD\text{-}EPI}$ (all p-trend<0.001). Results were similar after further adjustment for high-sensitivity CRP.



These results suggest that additional filtration markers (B2M, and to a lesser extent BTP) share Cystatin C's advantage over serum creatinine as risk factors for mortality in a population based cohort. Translation into clinical practice will require balancing costs, benefits and implications for clinical decision making.

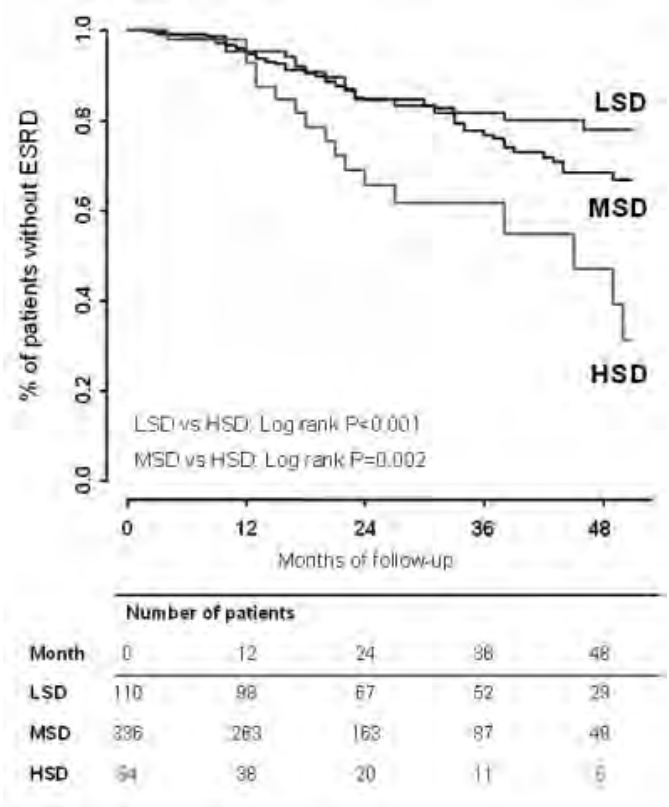
**Sodium Intake, ACE Inhibition and Progression to ESRD: An Outcome Analysis of Five-Hundred REIN and REIN-2 Patients with Proteinuric Chronic Nephropathy** Stefan Vegter,[1, 2] Annalisa Perna,[3] Maarten J. Postma,[1] Gerjan Navis,[2] Giuseppe Remuzzi,[3, 4] Piero Ruggenenti.[3, 4] *[1]Unit of PharmacoEpidemiol & PharmacoEconomics, University of Groningen, Netherlands; [2]Division of Nephrology, University of Groningen, Netherlands; [3]Mario Negri Institute, Bergamo, Italy; [4]Ospedali Riuniti di Bergamo, Italy.*

Background: High sodium intake limits the antihypertensive and antiproteinuric effect of ACE inhibitors in chronic kidney disease (CKD) patients. Whether this translates into less renoprotection is not known

Methods: To assess the interactions between sodium intake, ACE inhibition and CKD progression, we compared by time-dependent Cox models progression to end stage renal disease (ESRD) over 4.25-year ramipril therapy in 500 subjects with proteinuric CKD retrieved from the Ramipril Efficacy In Nephropathy (REIN) and REIN 2 trials who were categorized to have low (LSD), medium (MSD) or high (HSD) sodium diet according to average follow-up 24-h urinary sodium/creatinine excretion <100, ≥100 and <200, or ≥200 mEq/g, respectively.

Results: 92 subjects (18.4%) developed ESRD. Among 110, 336 and 54 patients on LSD, MSD or HSD, ESRD incidence (95% CI) was 6.2 (3.9-9.9); 8.0 (6.2-10.4); and 18.1 (11.2-29.1) per 100 patients-years, respectively (P<0.001). Follow-up ESRD incidence and proteinuria were higher in HSD than LSD or MSD patients.



Number of patients

| Month | 0 | 12 | 24 | 36 | 48 |
|---|---|---|---|---|---|
| LSD | 110 | 98 | 67 | 52 | 29 |
| MSD | 336 | 283 | 163 | 87 | 40 |
| HSD | 54 | 38 | 20 | 11 | 5 |

Blood pressure (BP) was similar among groups. ESRD incidence increased by 1.53 (1.17-2.00) folds every 100 mEq/g increase in urinary sodium/creatinine excretion. This association was independent of BP, but was lost after adjustment for follow-up proteinuria.

Conclusions: In CKD patients, high sodium intake (>12 g/d of salt) blunts the antiproteinuric effect of ACE inhibition which, independent of BP control, translates into less protection against ESRD. Salt restriction is crucial to optimize renoprotection in this high-risk population.

**MYH9 Variations Are Associated with Chronic Kidney Disease (CKD) Progression in the African American Study of Hypertension and Kidney Diseases (AASK)** Brad C. Astor,[1] Michael S. Lipkowitz,[2] Wen Hong Linda Kao,[1] Rulan S. Parekh,[3] Michael J. Choi,[4] Jeffrey B. Kopp,[5] Lawrence J. Appel,[6] Cheryl Winkler,[7] George W. Nelson.[7] *[1]Epidemiology, Johns Hopkins University, Baltimore, MD; [2]Nephrology, Mount Sinai School of Medicine, New York, NY; [3]Nephrology, University of Toronto, Toronto, ON, Canada; [4]Nephrology, Johns Hopkins University, Baltimore, MD; [5]NIDDK, Bethesda, MD; [6]Medicine, Johns Hopkins University, Baltimore, MD; [7]SAIC Frederick Inc., Frederick, MD.*

Common variations in the gene MYH9 have been shown to be cross-sectionally associated with FSGS and non-diabetic ESRD. It is unknown whether these variations are also associated with chronic kidney disease (CKD) progression. We genotyped 706 participants with CKD from the African American Study of Kidney Disease and Hypertension (AASK) for six selected single nucleotide polymorphisms (SNPs) in MYH9. Time-to-event analysis was performed for both the AASK composite outcome of significant decline in GFR, ESRD, or death and the more specific outcome of only decline in GFR and ESRD. Several SNPs were associated with both outcomes as there was high correlations between the six SNPs. The strongest signal was observed for rs4821480. Individuals with the common genotype (55% with GG) at rs4821480 were about 1.5 times more likely to have the composite endpoint (p=0.004) and CKD progression (p=0.004) than their counterparts with the other genotypes irrespective of treatment groups, age, and sex. Common variations in MYH9 are associated with increased risk of CKD progression among African Americans with hypertensive nephropathy.

**A Prospective Study of Albuminuria and Cognitive Decline in Women** Julie Lin, Fran Grodstein, Gary C. Curhan, Jae Hee Kang. *Renal Division and Channing Laboratory, Brigham and Women's Hospital, Havard Medical School, Boston, MA.*

Background: End-stage renal disease is associated with substantial cognitive deficits but how early kidney damage such as presence of albuminuria may be related to subsequent cognitive decline is not well defined. In particular, increased levels of urinary albumin are consistently noted in older adults, who are at highest risk for cognitive decline.

Materials and Methods: Over 19,000 women aged ≥70 years in the Nurses' Health Study participated in a prospective study with repeated measures of cognitive function administered by phone every two years, including tests of general cognition (TICS), verbal memory, verbal fluency, and working memory. Of these, 1764 women had urinary albumin-to-creatinine ratios (ACR) measured in the year 2000, prior to their cognitive testing. Mixed effects regression analysis was applied to calculate mean differences in rate of cognitive decline between women with ACR≥5 vs. lower levels. Multivariable models were adjusted for numerous key potential confounding factors (including age, HTN, BMI, diabetes, smoking, physical activity, education level, and others).

Results: Median age was 74 years, 99% were Caucasian, 55% had HTN, 12.4% had diabetes, median BMI was 25 kg/m^2, median plasma creatinine was 0.84 mg/dL, and 25% had ACR≥5 mcg/mg. Main findings are in **Figure 1.** The apparent effect of ACR ≥ 5 mcg/mg was cognitively equivalent to that seen with 2 to 7 years of aging; that is the presence of higher ACR accelerated cognitive decline by 2 to 7 times faster than seen with aging alone (all p-values <0.05).

Conclusions: Presence of urinary ACR as low as 5 mcg/mg is independently associated with faster decline in cognitive function. As a non-invasive reflection of small vessel disease, screening for ACR ≥ 5 mcg/mg may be important as a prognostic marker for subsequent cognitive decline.

**Complete Recovery of Renal Function after Acute Kidney Injury Increases the Risk of Incident Chronic Kidney Disease in a Large Managed Care Organization** Jennifer A. DeGraauw,[1] John R. Holmen,[2] Jason Jones,[2] Sidney N. Thornton,[2] Michel B. Chonchol.[1] *[1]University of Colorado Denver Health Sciences Center, Aurora, CO; [2]Intermountain Health Care, Salt Lake City, UT.*

Purpose: Risk of incident chronic kidney disease (CKD) among patients with complete recovery of renal function after an episode of acute kidney injury (AKI) has not been studied. This study aimed to determine the risk of development of incident CKD in hospitalized patients who have an episode of AKI with complete recovery of renal function.

Methods: We conducted a population-based cohort study of adult patients with no history of CKD and who developed AKI requiring hospitalization and had complete renal function recovery between January 1 1999 and December 31 2009. AKI was defined by the RIFLE classification, which requires at least a 50% increase in serum creatinine. Complete recovery of renal function was defined if the serum creatinine returned to a level less than 50% above baseline serum creatinine within 7 days after discharge. The primary outcome of interest, incident CKD, was defined as an estimated glomerular filtration rate < 60 mL/min/1.73 m2 persisting for at least 3 months. Patients were tracked for outcomes beginning at discharge until March 31 2010. All subjects were required to have a minimum of 12 months follow-up data. These patients were matched for demographics and risk factors associated with kidney disease progression with individuals without AKI or CKD.

Results: We identified 1411 individuals with complete recovery of renal function after AKI and 1411 matched controls with no AKI during the index hospitalization. The median age of the enrolled participants was 65 years, 45% were women, and 56% had diabetes. After a median follow-up of 2.8 years, new cases of CKD were 14% and 2% among those with and without AKI, respectively, corresponding to an unadjusted HR of 7.65 (95% CI, 5.30-11.04). After adjusting for other potential confounders, the HR was 7.12 (95% CI, 4.89-10.37).

Conclusion: Subjects with an episode of AKI during hospitalization that have complete renal function recovery have an increased risk of kidney disease progression to incident CKD.

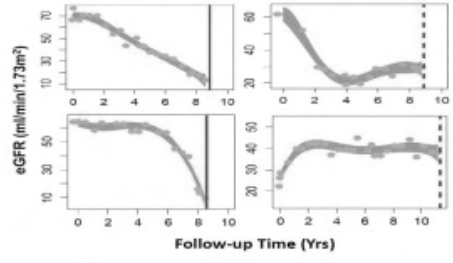
**Long-Term Trajectories of Estimated GFR (eGFR) in CKD Patients Are Often Nonlinear** Liang Li,[1] Bo Hu,[1] Lawrence J. Appel,[2] Brad C. Astor,[2] Julia Lewis,[3] Michael S. Lipkowitz,[4] Robert D. Toto,[5] Xuelei Wang,[6] Jackson T. Wright,[6] Tom H. Greene.[7] *[1]Clev Clinic; [2]Johns Hopkins; [3]Vanderbilt; [4]MSSM; [5]UTSW; [6]CWRU; [7]Utah.*

**Introduction** Decline in GFR in CKD is often assumed to be linear with constant slope over time. We investigated long-term trajectories of eGFR in 1094 African American Study of Kidney Disease (AASK) pts over a planned follow-up of 9-12 yrs to determine if long-term progression is approximately linear in most.

**Methods** Penalized cubic splines were used to estimate smooth but possibly nonlinear eGFR trajectories while accounting for random variation in individual eGFR measures. For each pt, deviation from linearity was expressed as difference in slope between the 5/8ths of the follow-up period with the fastest decline vs. the 5/8ths with the slowest decline. Statistical simulation was used to determine if the maximum deviation of a given pt's trajectory from linearity exceeded 95% of such deviations generated under the assumption of linear decline.

**Results** 768 pts had ≥ 10 eGFRs measurements with no measurement gaps ≥ 2 yrs. The mean (SD) eGFR overall slope was -2.11 (2.30) ml/min/1.73m$^2$/yr. 180 pts (23%) exhibited extreme changes in slope ≥ 4 ml/min/1.73m$^2$ /yr between the slowest and fastest portions of their progression trajectory; 299 (39%) exhibited slope changes ≥ 3 ml/min/1.73m$^2$/yr. Deviations from linearity were too large to be explained by chance fluctuations for 232 (30%) pts. Trajectories of the 4 patients below exemplify common patterns. Solid and dashed lines indicate ESRD and censoring.



**Conclusion** With extended follow-up, trajectories of eGFR in CKD often exhibit major deviations from a linear decline. Investigation of sources of these deviations, which represent acceleration or deceleration in the rate of CKD progression, may yield useful insight into pathophysiology of CKD progression.

**Prenatal Risk Factors for Childhood Chronic Kidney Disease** Christine W. Hsu,[1, 2] Kalani T. Yamamoto,[3] Rohan K. Henry,[1, 4] Jordan M. Symons.[1, 2] *[1]Pediatrics, University of Washington, Seattle, WA; [2]Nephrology, Seattle Children's Hospital, Seattle, WA; [3]Nephrology, University of Washington, Seattle, WA; [4]Endocrinology, Seattle Children's Hospital, Seattle, WA.*

**BACKGROUND:** Development of childhood chronic kidney disease (CKD) may be programmed prenatally. To our knowledge, this is the first study to evaluate maternal diabetes mellitus (DM) and obesity/overweight as primary risk factors for CKD.

**PURPOSE:** To determine the association of childhood CKD with maternal DM and obesity/overweight in Washington State (WA).

**METHODS:** Population-based case control study of 4,063 childhood CKD cases (diagnosed ≤21 years of age) and 20,032 controls. Maternal and infant data were obtained by linking WA birth records to hospital discharge data for 1987-2008. We used ICD-9 codes to identify cases, defined by the most common childhood CKD diagnoses (NAPRTCS) and CKD stage (KDOQI). We estimated the associations of maternal DM and obesity/overweight with the risk of childhood CKD by stratified analysis using Mantel-Haenszel odds ratios (ORs) and 95% confidence intervals (CIs).

**RESULTS:** CKD prevalence was 258.1 per 100,000 births. After adjusting for gestational length, maternal pre-gestational DM (PDM) was associated with increased risk of CKD in offspring, with an OR of 1.69 (95% CI=1.09, 2.62). Maternal gestational DM (GDM) was associated with increased risk of CKD in offspring, with an OR of 1.28 (95% CI=1.07, 1.54). Both maternal obesity and overweight were associated with increased risk of CKD in offspring, with respective ORs of 1.22 (95% CI=1.08, 1.38) and 1.08 (95% CI=0.96, 1.22). In our subgroup analysis, maternal PDM was associated with increased risk of renal aplasia/dysplasia, with an OR of 6.81 (95% CI=3.54, 13.10). Maternal GDM, obesity and overweight were associated with obstructive uropathy, with respective ORs of 1.34 (95% CI=1.02, 1.75), 1.23 (95% CI=1.03, 1.47) and 1.21 (95% CI=1.03, 1.43).

**CONCLUSIONS:** Maternal PDM, GDM, obesity and overweight were associated

with development of CKD in offspring. Maternal PDM was associated with renal aplasia/dysplasia. Maternal GDM, obesity and overweight were associated with obstructive uropathy.

### SA-FC359

**Albuminuria, Kidney Function and the Incidence of Cognitive Impairment in US Adults** Manjula Kurella Tamura,[1] Virginia G. Wadley,[2] Mary Cushman,[2] Frederick W. Unverzagt,[2] Neil A. Zakai,[2] Brett Kissela,[2] David G. Warnock,[2] William M. McClellan.[2] *[1]Medicine, Stanford, Palo Alto, CA; [2]For the REGARDS Study Group, UAB, Birmingham, AL.*

Objective: Albuminuria and low estimated glomerular filtration rate (eGFR) are each associated with an increased risk for cognitive impairment, however the joint associations of these kidney disease markers with cognitive impairment have not been studied.

Methods: We used data from 19,442 individuals participating in the Renal Reasons for Geographic and Racial Differences in Stroke (REGARDS) study. GFR was estimated using serum creatinine and albumin to creatinine ratio (ACR) was measured on a single-voided urine sample, both obtained at baseline. Cognitive function was assessed annually. Incident cognitive impairment was defined as a score ≤ 4 on the Six-item Screener at the last study follow-up visit among individuals without cognitive impairment at baseline.

Results: There were 6999 participants (36%) with albuminuria at baseline (ACR ≥10 mg/g) and 1884 (10%) with Stage 3-4 CKD (eGFR <60 ml/min/1.73m$^2$). There were 1575 participants (8.1%) who developed cognitive impairment over a mean follow-up time of 3.5 ± 1.3 years. In separate models that were adjusted for demographics, diabetes, hypertension, cardiovascular disease, and tobacco and alcohol use, albuminuria (odds ratio (OR) 1.23, 95% CI 1.11-1.37) and eGFR <45 ml/min/1.73m$^2$ (OR 1.36, 95% CI 1.08-1.71) were separately associated with incident cognitive impairment. Incident cognitive impairment occurred in 6.7% of individuals with neither condition; 10.1% with albuminuria; 18.8% with eGFR <45 ml/min/1.73m$^2$; and 13.4% with both. Compared to neither condition, the fully adjusted OR for cognitive impairment among participants with albuminuria was 1.25 (1.12-1.40); among those with an eGFR <45 ml/min/1.73m$^2$, 1.78 (1.23-2.57); and 1.41 (1.05-1.88) among those with both conditions. Similar relationships were noted when eGFR <60 ml/min/1.73m$^2$ was substituted.

Conclusions: Albuminuria predicts incident cognitive impairment independent of low eGFR.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC360

**Urinary Connective Tissue Growth Factor Levels Predict Incident Chronic Kidney Disease in the General Population** Conall M. O'Seaghdha,[1,2] Nrupen Anjan Bhavsar,[3] Anna Kottgen,[4] Josef Coresh,[3] Brad C. Astor,[3] Caroline S. Fox.[1,2] *[1]NHLBI's Framingham Heart Study; [2]Harvard Medical School; [3]Welch Center, Johns Hopkins University; [4]University Hospital Freiburg, Germany.*

Introduction: Connective tissue growth factor (CTGF) is an important cytokine involved in renal fibrosis, repair and diabetic nephropathy. It is unknown whether urinary CTGF levels are associated with risk for incident CKD in the general population.

Methods: We conducted an age-sex matched nested case-control study (n = 200) of incident CKD (eGFR < 60 ml/min per 1.73m2) within the Framingham Heart Study (FHS). Findings were externally replicated in participants from the Atherosclerosis Risk in Communities (ARIC) Study (n=276). Urinary CTGF concentrations were measured using the Human Kidney Tox 1 assay (Rules Based Medicine, TX). A paired t-test was used to assess for differences in baseline log CTGF concentrations between pairs of cases and controls. The odds ratio of CKD by quartile of baseline CTGF levels was modeled using conditional logistic regression.

Results: Baseline urinary CTGF concentrations were inversely related to case-control status 9.9 yr later in FHS. The median urinary CTGF concentration at baseline was lower among cases (1.42 ng/mL) than controls (2.32 ng/mL; paired t-test P<0.0001). We observed a significant trend of lower risk of incident CKD for each higher quartile of CTGF concentration in an unadjusted model and in models adjusted for CKD risk factors. Results in ARIC showed a similar trend (p=0.13) and were robust in meta-analysis: quartile 2 vs. quartile 1: OR for CKD 0.83; 95% confidence interval 0.49-1.40; quartile 3 vs. quartile 1: OR 0.30; 95% C.I. 0.16-0.57; quartile 4 vs. quartile 1: OR 0.34 (95% C.I. 0.18-0.64. P-value for trend across quartiles <0.001). Results were similar among those participants without diabetes.

Conclusions: Lower urinary CTGF concentrations precede the onset of CKD in the general population. These findings suggest that CTGF provides useful information on the balance of repair and fibrosis early in the development of CKD.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC361

**Activating and Inhibitory Roles of Ret-Docking Tyrosine Sites in Wolffian Duct Development and Maturation** Masato Hoshi, Sanjay Jain. *Internal Medicine (Renal), Washington University, St. Louis, MO.*

Several genes important in kidney development have been indentified from gene deletion studies, however, little is known about their specific attributes that are relevant to normal kidney development and malformations. Activation of receptor tyrosine kinase Ret signaling by Gdnf-Gfrα1 is essential for kidney formation. Mice harboring individual docking tyrosine mutations of Ret-Plcγ or Ret-Pi3k/Mapk pathways exhibit multiple kidney and ureter abnormalities (supernumerary ureters, hydroureters, hypoplasia and dysplasia) or agenesis, respectively. To elucidate early developmental mechanisms gone awry in these disparate phenotypic spectrums of CAKUT we generated Ret-EGFP reporter mice and bred them to Ret-Plcγ or Ret-Pi3k/Mapk mutant mice, and performed ontogenic characterization of their urinary systems. We discovered distinct abnormalities in Wolffiian duct (WD) maturation and development in both mutants. Analysis in vivo and exvivo by time-lapse microscopy demonstrates that supernumerary ureters in Ret-Plcγ mutants are not due to failure of mesonephros to degenerate but due to new outgrowths from the anterior mesonephric WD emerging as early as E9.5 and clearly evident by E10.5. Compared to UB budding site at a single somite level in controls, the budding site is markedly expanded over 3 somite levels in these mice leading to multiple UBs invading metanephric mesenchyme producing multiplexed kidneys. Gdnf haploinsufficiency in these mice normalizes these defects in a subset of Ret-Plcγ mutant mice suggesting overactive Ret signaling. Gdnf was abnormally expressed in the mesonephric mesenchyme indicating that it is normally repressed by Ret-Plcγ signals in the anterior WD. The common nephric duct in Ret-Plcγ mutants showed abnormal Ret expression and was deficient in normal degeneration. In contrast, Ret-Pi3k/Mapk mutants have normal anterior WD, show normal position of UB, but were deficient in UB induction. Further, Ret-Pi3k/Mapk distal WDs show a delay/arrest in growth towards the cloaca. These results delineate how specific pathways have activating and inactivating roles in sculpting a competent WD to make a normal kidney and ureter.

**Cell Fate Determination in Zebrafish Pronephric Kidney by Wtip/Notch Signaling** Tomoko Obara. *Cell Biology, University of Oklahoma Health Science Center, Oklahoma City, OK.*

WT1 plays an important role for urogenital development. To further understand the function of WT1, yeast two-hybrid assay was performed with mice WT1 and WTIP was discovered. WTIP contains three LIM and one PDZ binding domain at the C-terminus. However, the precise in vivo function of the WTIP is still unknown.

Zebrafish wtip gene is a maternal gene, and ubiquitous expression is detected in the early embryonic stage. At 48 hpf, wtip expression is restricted to anterior brain, eye, inner ear, heart, and pronephros. Wtip protein express in the pronephros are in the glomerular, multiple ciliated cells (MCCs) in the early late segment and posterior segment. Next, we examined the effects of Wtip by loss- and gain-of-function experiments in zebrafish. Knock down of zebrafish wtip led to an increased number of MCCs in the early distal and also ectopic MCCs in the proximal region of the pronephros. Conversely, wtip mRNA injected embryos reduced the number of MCCs. Since Notch signaling has been shown to be a major regulator in MCC development, we next examined whether Wtip functions downstream of Notch signaling, by asking whether wtip mRNA could rescue the increased number of MCCs in the mind bomb (mib) (Notch signaling is impaired) and in the knocked down jagged2 morphants. Indeed, injection of wtip mRNA suppressed the mib and jagged2 morphant phenotype, suggesting that Notch signaling is epistatic to Wtip mediated cell signaling.

In addition to the MCCs effect, wtip morphants showed other pronephric defects. Gene expression in late distal pronephros was altered and cloaca was fused in the wtip morphants. Moreover, we also found glomerular defects similar to FSGS. These were probably due to the decrease in the heart rate caused by abnormal wt1a expression in the proepicardial organ (PEO). In wtip morphants and mibta52b, both podocytes and endothelial cells differentiate normally but remain unmerged and fail to terminally differentiate. In addition, the podocyte gene marker expression level were decreased by injection of wtip mRNA. Taken together, our data suggest that Wtip is an important regulator in the establishment of MCC fate, posterior pronephro and glomerulus development.

### SA-FC363

**Disruption of Smad Signaling in the Lower Urinary Tract Causes UPJ Obstruction** Piyush Tripathi, Yinqiu Wang, Feng Chen. *Internal Medicine, Renal Division, Washington University School of Medicine, St Louis, MO.*

Ureteropelvic Junction (UPJ) Obstruction is a common congenital anomaly in pediatric population and is presumably caused by developmental defects in the ureter, a Wolffian ducts (WD) derivative. By E10.5, the ureteric bud (UB) emerges from the WD and invades the metanephric blastema for nephrogenesis. The proximal part of the UB undergoes branching and elongation to make the collecting duct system of kidney, the distal part of the UB develops into ureter for transporting urine to the bladder. Although collecting duct epithelia and ureteric epithelia share common embryonic origin, the ureter recruits smooth muscle progenitors and other cells from the tail-bud-derived mesenchyme instead of the metanephric mesenchyme that gives rise to the nephrons within the kidney proper. In this study, we have combined a *Tbx18-Cre* transgene with specific expression in lower urinary tract mesenchyme and a *floxed-Smad4* allele to disrupt Smad signaling in the ureteric and bladder mesenchyme during embryogenesis. *Tbx18-Cre/+, Smad4$^{flox/flox}$* mice have severe bilateral hydronephrosis at as early as E17.5. Indian ink injection experiment has confirmed UPJ obstruction as main cause of hydronephrosis, which is further evident by the absence of urine in the mutant bladders. We further determine that constriction within the ureteric lumen may be the main cause for UPJ obstruction. Although differentiation of the urothelium and ureteric smooth muscle occurred, disorganization of the urothelium was observed. Microarray study on E16.5 mutant and control ureters revealed transcriptional alterations in known Bmp targets, smooth muscle specific genes, and genes involved in extracellular matrix remodeling/maintenance. In particular, Id2 expression was significantly reduced in the mutants, consistent with previous finding that Id2 heterozygous mutants develop

UPJ obstruction. These data indicate an important functional role of Smad signaling in organizing the development of the lower urinary tract and provides a model to further study the pathogenesis of UPJ obstruction.

**The Developmental Corepressor Groucho4, GRG 4, Associates with a Nuclear Phosphatase and Methyltransferase To Repress Transcription** Sanjeevkumar R. Patel,[1] Samina Bhumbra,[1] Lekshmi Nair,[1] Gregory R. Dressler.[2] *[1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Pathology, University of Michigan, Ann Arbor, MI.*

In mammals, the Gro/TLE family consists of four proteins of similar molecular weight and structure, termed groucho gene-related protein 1-4 (Grg1-4) in mice. The Grg proteins modulate the process of transcription by physical interaction with DNA-binding transcription factors. These proteins can down regulate the expression of target genes of transcriptional activators, enhance the transcriptional repression effect of transcriptional repressors, or convert transcriptional activators into repressors. Grg/TLE co-repressors interact with multiple transcription factors including HES, RUNX and Pax proteins.

Expression of Grg1, 3 and 4 is widespread during development and overlaps partially with the Pax2/5/8 family in the neural tube and the kidney. Interaction of the Grg members and Pax proteins may repress Pax-regulated genes. To understand how Grg4 mediates repression, we identified Grg4 containing complexes from mammalian nuclear lysates by fractionation, immunoaffinity purification, and mass spectrometry. We show that Grg4 associates with a nuclear serine-threonine phosphatase and a histone methyltransferase. The associated methyltransferase activity was confirmed by immunoprecipiation of Grg4 and the methylation of various histone substrates. Using antibodies against specific histone H4 arginine residues, we have mapped the amino acid residues methylated by theGrg4 complex. Moreover, the phosphatase dephosphorylates Pax2 *in vitro*. At an integrated Pax2 responsive gene, co-expression of Pax2 and Grg4 results in gene silencing by a combination of mechanisms: displacement of a PTIP dependent activation complex by the Grg4 complex, possibly via dephosphorylation of DNA-bound Pax2, as well as deposition of repressive arginine methylation marks at the promoter. Our data suggest that Pax2 marks specific regions of chromatin by modification of histones. These epigenetic marks can delineate both active and inactive regions of the genomes in a stable and heritable manner through potential interactions with chromatin effectors.

### SA-FC365

**Genetic Basis for the Iron Delivery in the Developing Kidney** Andong Qiu, Melanie Viltard, Neal A. Paragas, Kristen Mcnierney, Jonathan M. Barasch. *Columbia.*

Iron is a growth factor required for kidney development. Transferrin receptor 1 (TFRC) was thought to be the single, ubiquitous high affinity mechanism of iron delivery to mammalian cells for growth and development. Surprisingly, our recent study in chimeras of TFRC ko and wt kidneys suggested that TFRC was not required for the development of most organs or cell types of the embryo, except possibly for the development of ureteric and lung bud tips at late stages of morphogenesis. In contrast, TFRC was dispensable in both ureteric bud and lung stalks and in mesenchymal cells (Developmental Cell, 2009). To precisely dissect the functional role of TFRC in kidney development, we generated a conditional murine knockout model for the tissue-specific ablation of the TFRC gene. When the TFRC gene was deleted specifically in the ureteric bud using a Hoxb7-Cre mouse, we observed limited renal hypoplasia at E12.5, but after birth we found the TFRC-deleted kidneys demonstrated either severe hydronephrosis or severe hypoplasia, and histological analysis showed deranged cells particularly in the distal nephron and papilla, indicating that loss of TFRC in the UB led to kidney hypoplasia and damage in an accumulative process. Hence TFRC is required during late stages of the maturation of the ureteric bud, but additional iron delivery pathways may compensate for TFRC early in embryogenesis. In fact, iron starvation produced severe renal hypoplasia early in development, indicating that TFRC alone can not fully explain iron trafficking. Hence, using a functional screening approach, we have now identified a novel iron transporter, SPNS1 which increased ferrous iron uptake with an apparent Km of 1.6μM when expressed in Xenopus oocytes. SPNS1 was present both on the cell surface and in transferrin filled endosomes (recycling compartment). Over expression of SPNS1 stimulated transferrin-mediated iron uptake in Hek293 cells and SPNS1 showed a high pH optimum consistent with activity at the cell surface or in transferrin endosomes. In sum, TFRC is required for the normal function of the ureteric bud, but SPNS1 is an alternative pathway which conducts iron in the ureteric bud.

**Notch Can Drive MET in the Developing Kidney Independently of Wnt** Scott C. Boyle, Raphael Kopan. *Developmental Biology, Washington University, St Louis, MO.*

Nephrons are formed from the metanephric mesenchyme (MM) by mesenchymal to epithelial transition (MET) through a stereotypical process, the early hallmarks of which are induction of the renal vesicle (RV) and progression to the S-shaped body (SSB). These structures are made up of undifferentiated epithelia but are polarized into proximal and distal domains that predict nephron segmentation in the adult. The Wnt and Notch signaling pathways are critical for this process. When Wnt4 is deleted, the RV does not form and epithelialization fails causing a complete loss of nephrons. Without Notch signaling, the RV forms but fails to segment into the SSB, resulting in non-functional nephrons that lack all proximal components, including glomeruli and tubules. Studies in the developing zebrafish kidney indicate that Notch is required for Wnt activity. We asked whether Notch and Wnt cooperate to drive MET in the mouse. Constitutive Notch activation in the MM drives MET, converting all progenitors to proximal fates at the expense of distal cell types. Contrary to observations in the zebrafish, Notch is not required for Wnt4 expression, and exogenous Wnt4 or LiCl do not rescue segmentation defects in Notch mutants. We then asked if developing nephrons must be exposed to Wnt4 to gain competence for Notch induced MET. To test this, we implemented a novel Tat-Cre based system to activate Notch in cultured metanephroi. Remarkably, when we activate Notch in Wnt4 null kidneys, MM cells still undergo MET. The epithelial cells that form express multiple markers of mature proximal tubule epithelia. A minority of cells make immature podocytes. These structures, however, do not develop apical basal polarity or form a lumen, instead adopting a tumor-like morphology. Furthermore, not all the cells in the metanephros are competent to form proximal epithelia in response to Notch: duct cells and mesenchyme lateral to the ureter are resistant. These data demonstrate that Notch can control a master program of proximal tubule differentiation, and show for the first time that MET of renal stem cells can be induced by pathways other than Wnt. Notch dependence on Wnt9b, the initial inductive factor in this process, is under investigation.

**Growth-Arrest Specific 1 (Gas1) Is a Novel Target of the Wilms' Tumor Suppressor Gene Wt1 and Is Implicated in Nephron Progenitor Cell Maintenance** Martin Kann,[1] Eunnyung Bae,[1] Sunny Hartwig,[2] Mary E. Taglienti,[1] Jordan A. Kreidberg.[1] *[1]Department of Nephrology, Children's Hospital Boston, Boston, MA; [2]Department of Biomedical Sciences, Atlantic Veterinary College, University of Prince Edward Island, Charlottetown, PEI, Canada.*

The transcription factor WT1 has long been known to be a key molecule in renal development as its homozygous deletion results in renal agenesis due to apoptosis of nephron progenitor cells (NPC). However, mechanisms by which WT1 maintains NPCs are largely unknown. Gas1 has been implicated in several signalling pathways relevant to apoptosis. We recently identified Gas1 as a putative WT1 target gene in a genome-wide siRNA approach in vitro.

Coexpression of Gas1 and Wt1 in NPC in vivo was shown by in situ hybridization (ISH). We confirmed binding of WT1 to the Gas1 gene DNA in vivo by chromatin immunoprecipitation followed by qPCR. Biological relevance of this interaction was established in vitro, ex vivo and in vivo: Knock-down of Wt1 by siRNA in a cell line expressing Gas1 and Wt1 resulted in downregulation of Gas1 mRNA. ISH signals for Gas1 were reduced in embryonic kidney organ cultures cultivated in the presence of a morpholino oligonucleotide (MO) that blocks Wt1 translation. Furthermore, we established a novel transgenic mouse line to generate hypomorphic Wt1 phenotypes by conditionally expressing an shRNA directed against Wt1 in NPC. By ISH, Gas1 was downregulated in NPC in mouse embryos hypomorphic for Wt1.

Functional relevance of Gas1 in NPC was investigated in embryonic kidney organ cultures treated with MO directed against Gas1. Efficient knockdown was confirmed by ISH. After 24 hours, branching morphogenesis arrested in Gas1 morphants, and NPC expression domains of Six2, Pax2, and Wt1 were abolished or significantly reduced as shown by ISH and immunofluorescence staining, respectively. TUNEL staining revealed increased apoptosis in the NPC pool. In summary we present a novel mechanism by which WT1 may protect NPCs from apoptosis.

**DLG1 and CASK Cooperate To Influence Nephron Progenitor Proliferation and Migration** Sun-Young Ahn,[1] Sung Tae Kim,[1] Gloriosa K. Go,[1] Wojciech Swat,[2] Jeffrey H. Miner.[1] *[1]Renal Division, Washington University, St. Louis, MO; [2]Dept. of Pathology and Immunology, Washington University, St. Louis, MO.*

DLG1 (discs-large homolog 1), the mouse ortholog of the *Drosophila* discs-large tumor suppressor protein, functions to maintain epithelial cell polarity and synaptic function in neurons. We previously reported that DLG1-null mice demonstrate severe urogenital abnormalities, including hydronephrosis due to ureteric smooth muscle orientation defects and occasional renal dysplasia or renal agenesis. Due to its interaction with CASK (calcium/calmodulin-dependent serine protein kinase) at the membrane-cytoskeleton interface, we sought to further define the role of DLG1 in murine urogenital development by generating mice deficient in both DLG1 and CASK using the Cre-lox system. Whereas CASK null mice had normal-sized kidneys, kidneys deficient in both DLG1 and CASK were very small and dysplastic. DLG1+/-;CASK null kidneys were also small, though not as small as the double-null kidneys. We discovered several cellular and molecular defects in the double mutants. These include: reduced proliferation and increased apoptosis of cells in the nephrogenic zone; a decrease in the number of cells expressing Six2, a transcription factor essential in maintaining the nephron progenitor population; impaired aggregation of Six2-positive cells around the ureteric bud tips, indicating possible cell migration defects; and reduced nephrogenic zone expression of both Pax2, an upstream regulator of Six2, and Raldh2, an essential enzyme in retinoic acid synthesis and an important regulator of kidney development. To determine whether the impaired nephrogenesis was due to defects in the nephron progenitor pool or in the ureter, we deleted DLG1 and CASK in the urothelium and collecting ducts with HoxB7-Cre. These mice did not show a significant difference in kidney size compared to controls. Taken together, these results show that a DLG1 mutation

can synergize with a mutation in another gene to affect urogenital development and that scaffolding proteins play an important role in generating or maintaining the nephron progenitor population.

**Isolation of Adult Renal Progenitors Capable of Nephron Formation in Zebrafish** Alan J. Davidson,[1] Cuong Diep,[1] Dongdong Ma,[2] Frank Bollig,[3] Christoph Englert,[3] Neil A. Hukriede,[4] Robert I. Handin.[2] *[1]Center for Regenerative Medicine, Massachusetts General Hospital, Boston, MA; [2]Hematology Division, Brigham and Women's Hospital, Boston, MA; [3]Leibniz Institute for Age Research, Fritz Lipmann Institute, Jena, Germany.*

Zebrafish have the ability to regenerate damaged tissues including organs such as the kidney. Using transgenic zebrafish where specific renal cell populations are fluorescently tagged, combined with gentamicin-induced nephron injury and transplantation experiments, we have identified a population of renal progenitors that when injected into the kidney can regenerate new functional nephrons. Time-lapse imaging in larval fish revealed that single renal progenitors coalesce together to form clusters that then differentiate into renal vesicle-like structures. These cells express a number of renal transcription factors including wilms' tumor suppressor-1 and pax2. Similar to nephrogenesis in the developing mammalian kidney, the renal vesicles grow into primitive nephrons that fuse with existing renal tubules and acquire blood filtration capabilities. These observations support the notion that adult renal regeneration recapitulates a developmental kidney program. Taken together, our results demonstrate that the zebrafish kidney contains a transplantable population of renal progenitors capable of de novo nephron formation. Our work provides new insights into the cellular mechanisms of renal regeneration and may lead to the development of novel therapies to treat kidney disease.

### SA-FC370

**Oct4 Overexpression but Not Chromatin Modifying Agents Reprograms Adult Human Kidney Cells into a Renal Progenitor State** Dorit Omer,[1,2] Orit Harari-Steinberg,[1,2] Ella Buzhor,[1,2] Sally Metsuyanim,[1,2] Naomi Pode Shakked,[1,2] Benjamin Dekel.[1,2] *[1]Pediatric Stem Cell Research Institute, Sheba Medical Center, Tel Hashome, Sackler Faculty, Tel Aviv University, Tel Aviv, Israel; [2]Sheba Center of Regenerative Medicine, Sheba Medical Center, Tel Hashome, Sackler Faculty, Tel Aviv University, Tel Aviv, Israel.*

The nephrogenic cortex in which renal stem/progenitor cells are induced to form nephrons through mesenchymal to epithelial transition ceases to operate in the 34th week of human gestation, severely limiting the adult kidney's regenerative capacity. This cessation correlates with shutdown of *Six2* and *Osr1* which maintain responsible the nephron progenitor population. Here we show that human adult kidney (HAK) cells can be induced to highly re-express *Six2*/*Osr1* along with pluripotency markers (*Oct4*, *nanog*) following epigenetic modulation with chromatin-modifying agents, e.g. valproic acid (VPA) which induces epigenetic changes of the histones at multiple sites of the *Six2* promoter leading to gene activation. Nevertheless, VPA treated cells failed to undergo epithelial to mesenchymal transition (EMT), possibly due to activation of the Wnt pathway supporting epithelialization and cellular senescence appeared in early passages, all limiting cells developmental potency. Surprisingly, this could be overcome by lentiviral overexpression (OE) of *Oct4* and isolation by puromycin selection, generating HAK cells that re-express *Six2*/*Osr1*, appear uniform as round cells in culture and undergo EMT (high *vimentin*, low *E-cadherin*). *Oct4* OE HAK cells could be readily expanded and propagated into late passages while maintaining their traits. Finally, *in vitro* differentiation and colony-forming-unit assays of *Oct4* OE HAK cells showing epithelial re-differentiation, multipotentiality and clonogenic capabilities indicated enhanced developmental plasticity. Altogether, our results indicate that *Oct4* alone as opposed to chromatin-modifying agents is likely to be sufficient to induce HAK cells into a renal progenitor state.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC371

**Genotype Polymorphisms of Matrix Metalloproteinases Are Associated with Arteriovenous Fistula Patency in Hemodialysis Patients** Chih-Ching Lin.[1,2] *[1]Divison of Nephrology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan; [2]School of Medicine, National Yang-Ming University, Taipei, Taiwan.*

Matrix metalloproteinases (MMPs) are risk factors for cardiovascular diseases. This study evaluated the association of genotype polymorphisms of MMPs and tissue inhibitors of MMP (TIMPs) in hemodialysis patients (HD) with arteriovenous fistula (AVF) failure. Genotype polymorphism of MMP-1, -2, -3, -9 and TIMP-1, -2 as well as clinical and laboratory parameters were compared between Chinese HD patients with (n=170) and without AVF failure (n=426).

Cox regression model of factors associated with AVF failure in HD patients

| | Significance | Hazard ratio |
|---|---|---|
| HD duration (months) | <0.001 | 1.007 |
| Cardiovascular disease | 0.039 | 1.656 |
| Maximal venous pressure (mmHg) | <0.001 | 1.016 |
| MMP-1 -1607 genotypes (1G/1G vs. 1G/2G+1G/2G) | 0.007 | 2.315 |
| MMP-3 -1612 genotypes (6A/6A vs. 5A/6A+5A/5A) | 0.049 | 1.712 |
| MMP-9 -1562 genotypes (C/C vs. C/T+T/T) | 0.048 | 1.650 |

Significant associations were found between AVF failure and 1G/1G genotype of MMP-1 -1607 1G>2G SNP (2.315 vs. 1G/2G+2G/2G ), 6A/6A genotype of MMP-3 -1612 5A>6A SNP (1.712 vs. 5A/6A+5A/5A ), and C/C genotype of MMP-9 -1562 C>T SNP (1.650 vs. C/T+T/T ). The positive predictive rates for AVF failure were 63.0% and 6.7% for patients with the highest-risk (1G1G/6A6A/CC) and lowest-risk (2G2G or 2G1G/5A5A or 6A6A/TT or TC) composite MMP-1/-3/-9 genotype, respectively. The unassisted patency of AVF at 5 years decreased significantly from 72.2% to 55.2% for different MMP-1 genotypes (2G/2G + 1G/2G vs. 1G/1G, P=0.0038), from 77.3% to 67.9% for MMP-3 genotypes (5A/5A+5A/6A vs. 6A/6A, P=0.0094), from 79.0% to 67.3% for MMP-9 genotypes (C/T + T/T vs. C/C, P=0.0205), and from 93.3% to 38.4% for the composite MMP-1/-3/-9 genotypes (lowest vs. highest risk, P<0.001). In conclusion, specific genotypes of MMP-1, MMP-3 and MMP-9 with lower transcriptional activity are associated with higher frequencies of AVF failure, which may result from more extensive accumulation of intravascular extracellular matrix, thus leading to a higher risk of AVF stenosis.

### SA-FC372

**Chymase Is Increased in Hyperplasic Veins Used for AVF Creation in Stage 4-5 CKD Patients** Monnie Wasse,[1] Rong Huang,[1] Angel Rivera,[2] Nawazish Naqvi,[2] Ahsan Husain.[2] *[1]Renal Division, Emory University, Atlanta, GA; [2]Cardiology Division, Emory University, Atlanta, GA.*

Angiotensin II and matrix metalloproteinases (MMPs) have been implicated in the development of venous neointimal hyperplasia (VNH) within arteriovenous fistulae (AVF). Angiotensin II causes vascular smooth muscle cells to proliferate and differentiate into a synthetic phenotype with upregulated α-smooth muscle actin (α-SMA) expression. MMPs, which degrade matrix, promote adverse vascular remodeling. Mast cell chymase converts angiotensin I to II and it activates several pro-MMPs. We studied chymase protein expression in veins used for AVF creation prior to AVF surgery in pre-dialysis Stage 4–5 CKD patients presenting for their first vascular access creation.

All 5 vein specimens exhibited VNH; average luminal stenosis and ratio of intima-to-media thickness and intima-to-media area were 84±7.3%, 0.39±0.23 and 0.3±0.16, respectively. The control vein had a normal thin intima and media (Figure.1A).Chymase and α-SMA protein (localized by immunofluorescence) were weakly expressed in these veins (Figure1.B). By contrast, the CKD veins demonstrated aggressive VNH, reflected by an intensely thickened intima (Figure.1C). Chymase expression was abundant in these veins (Fig.1D) and co-localized with α-SMA in the media and adventitia. These findings not only suggest a role for chymase in VNH, but also point to a therapeutic target for the treatment of VNH in the setting of dialysis vascular access.

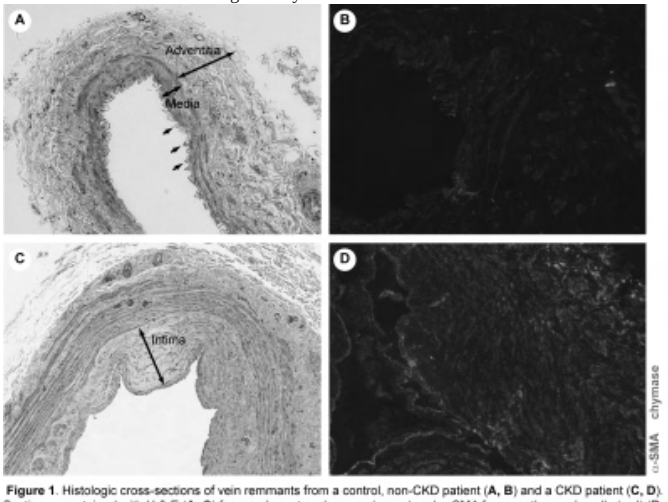

**Figure 1**. Histologic cross-sections of vein remnants from a control, non-CKD patient (**A, B**) and a CKD patient (**C, D**). Sections are stained with H & E (**A, C**) for morphometry, chymase (green) and α-SMA for smooth muscle cells (red) (**B, D**). **A**) Control vein with normal histology, a normal, thin intima (small arrows), and normal media and adventitial layers; **C**) CKD vein has a thickened intima and media; **B**) Control vein with little evidence of chymase and α-SMA, reflecting limited media layer; **D**) CKD patients has abundant chymase and colocalization with α-SMA, reflecting smooth muscle cells in the media layer.

**The Impact of Arterial Micro-Calcification on Aortic Stiffness and Endothelial Dysfunction in Patients with End-Stage Renal Disease** Hyun Gyung Kim,[#1] Young Soo Kim,[#1] Young Ok Kim,[#1] Hye Eun Yoon.[#2] *[1]Division of Nephrology, Department of Internal Medicine, The Catholic University of Korea Uijeongbu St. Mary's Hospital, Uijeonbu, Korea; [2]Division of Nephrology, Department of Internal Medicine, The Catholic University of Korea Incheon St. Mary's Hospital, Incheon, Korea.*

**Purpose**: We previously reported that arterial micro-calcification (AMC) at vascular access is associated with early failure of vascular access in patients with end-stage renal disease (ESRD) [ASN 2008]. Although vascular gross calcification is known as an independent risk factor for cardiovascular outcome, the role of AMC is not reported yet. **Methods**: Sixty-five ESRD patients awaiting vascular access operation were included in this study. Aortic stiffness and endothelial dysfunction were evaluated with brachial-ankle pulse wave velocity(baPWV) and flow mediated dilatation (FMD) of the brachial artery, respectively. Diagnosis of AMC was made by microscopic analysis with von Kossa staining. **Results**: Mean age of the patients was 60±12 years. The gross calcification by plain X-ray was detected in 29 out of the 65 aortic arches (44.6%) and 5 out of the 27 radial arteries (18.5%). The AMC was detected in 36 patients (55.4%). The AoAC score was higher in the positive AMC group compared to the negative AMC group (17.8±17.1% vs 5.1±12.3%, p=0.001). The baPWV was also higher in the positive AMC group (26.5±9.4 m/s vs 19.8±6.6 m/s, p=0.006). But there was no difference in FMD between the two groups (5.4±2.6% vs 5.7±3.5%, p=0.764). The positive AMC group had higher incidence of DM (91.6% vs 44.8%, p=0.001), systolic blood pressure (156±23 mmHg vs. 143±25 mmHg, p=0.036) and pulse pressure (67±9 mmHg vs 55±17 mmHg, p=0.014) than the negative AMC group. **Conclusion** : This data showed that AMC at vascular access site was related to baPWV but not to FMD in ESRD patients. Therefore we suggest that AMC is associated with cardiovascular morbidity and mortality via aortic stiffness in ESRD patients.

Disclosure of Financial Relationships: nothing to disclose

**SA-FC374**

**Effect of Initial Blood Flow Rate (BFR) on Progression of Stenosis and Loss of Patency in New Arteriovenous (AV) Grafts** Bradley S. Dixon,[1] Bo Hu,[2] T. Alp Ikizler,[3] Gerald J. Beck,[2] Milena Radeva,[2] John W. Kusek,[4] Harold I. Feldman.[5] *[1]VA Med Cntr & U of IA, Iowa City, IA; [2]Biostatistics, Cleveland Clinic, Cleveland, OH; [3]Vanderbilt U, Nashville, TN; [4]NIDDK, NIH, Bethesda, MD; [5]U Penn, Philadelphia, PA; [6]for the DAC Study Group, .*

BFR contributes to blood vessel wall shear stress and may mediate the development of neointimal hyperplasia contributing to graft stenosis and failure. We examined whether baseline BFR (BBFR) in newly created AV grafts predicted the subsequent rate of development of stenosis or primary unassisted graft patency (PUGP). Development of stenosis was ascertained by the rate of decline in BFR after the baseline measurement. BFR was measured by the ultrasound dilution technique in a randomized clinical trial examining the effect of extended release dipyridamole plus aspirin (ERDP/ASA) compared to placebo on PUGP of newly created AV grafts for hemodialysis. BFR was measured twice within 4 weeks of first using the graft for dialysis and monthly thereafter until 1 month after loss of PUGP. Of 649 randomized patients, 308 had at least one BFR measured after baseline and were included in this analysis; the remaining 341 grafts failed before the required minimum 3 BFR measurements. Median BBFR was 1189 (IQR: 929, 1415) ml/min at a median of 9 (IQR: 6.86, 12.14) weeks after graft placement and was not statistically significantly different between patients taking ERDP/ASA (1214; 935-1476 ml/min) and placebo (1160; 919-1335 ml/min; p=0.09). High BBFR was significantly associated with younger age, male gender, upper arm graft, higher diastolic BP, less cardiovascular disease and diabetes, higher hemoglobin, less aspirin use, and more tobacco use. Log transformed data were used to normalize the skewed BFR distribution. Higher BBFR (>1189 ml/min) was associated with longer PUGP (adjusted HR= 0.52. 95% CI=0.35-0.77, p<0.001). The mean weekly decline in BFR (ΔBFR) at the median BBFR was 0.7% (0.6, 0.8; p<0.001), but ΔBFR was not significantly related to BBFR (p=0.44). The results suggest that overall patency is longer in grafts with higher BBFR but variation in BBFR over the observed range did not influence the rate of development of stenosis.

**SA-FC375**

**Evolution and Clinical Course of First (EVER) Fistulas and Grafts** Eduardo K. Lacson, Weiling Wang, J. Michael Lazarus, Raymond M. Hakim. *Fresenius Medical Care, North America, Waltham, MA.*

**Introduction:** The evolution and clinical course of arteriovenous (AV) access placement in patients new to hemodialysis (HD) are reported mainly as single center experiences. We describe results from a nationally distributed cohort for the first (ever) constructed AV accesses in the 1st year of HD.

**Methods:** We tracked 8,280 (55.8%) patients with newly constructed fistulas or grafts from 14,836 incident HD patients admitted solely with an HD catheter at Fresenius Medical Care North America facilities within 15 days of first-ever dialysis between January 1 and December 31, 2007. Three periods were carefully tracked: 1) Time to fistula or graft placement within one year of admission; 2) Time to maturation (i.e. catheter removal), for up to one year from placement; and 3) Time to AV access failure requiring a new access (predominantly catheter), for up to one year after maturation.

**Results**: The mean age was 62.0 ± 15.2 years, 55.4% male, 62.3% white and 33.3% black, with 57.5% having diabetes. Fistulas predominated at a ratio of 3:1 (see Table 1).

Table 1: Distribution of time to key access-related events (in days) for 8,280 patients.

| Fistula | N (%) | Median | Mean | SD |
|---|---|---|---|---|
| Time to placement | 6,364 (76.9) | 77 | 98 | 77 |
| Time to maturation | 3,736 (58.7)* | 111 | 122 | 78 |
| Time to failure | 666 (17.8)** | 87 | 120 | 102 |
| Graft | | | | |
| Time to placement | 1,916 (23.1) | 82 | 102 | 77 |
| Time to maturation | 1,364 (71.2)* | 49 | 57 | 46 |
| Time to failure | 357 (26.2)** | 119 | 146 | 106 |

* denominator consists of all placed fistulas or grafts;
** denominator consists of all matured fistulas or grafts.

Grafts had a better maturation rate (71.2% vs. 58.7%, p<0.0001) but worse failure rate (26.2% vs. 17.8%, p<0.0001) compared to fistulas. Though fewer, failure with abandonment occurred earlier in fistulas than in grafts.

**Conclusions:** Current surgical outcomes for AV access construction present major opportunities for improvement. Maintaining optimal AV access function may be another. More studies are needed to address low maturation and high failure rates as well as to determine cost-effectiveness of available interventions.

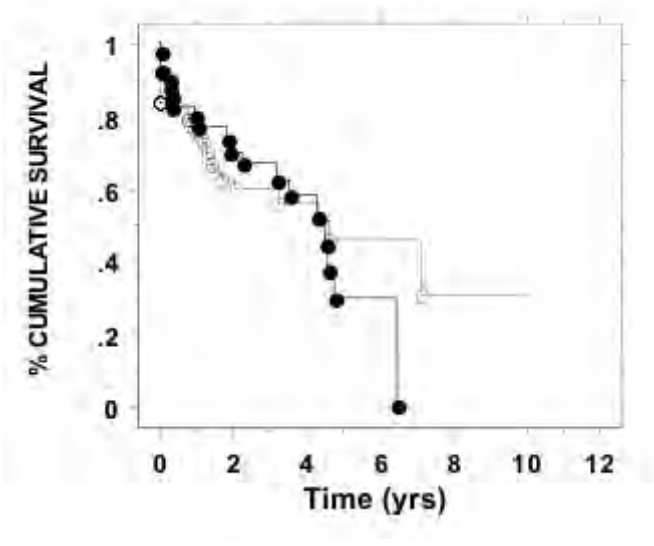
**SA-FC376**

**Comparison of Primary and Secondary Arteriovenous Fistulas: A Nested Case-Control Study** Sunanda J. Ram, Bharat Sachdeva, Kenneth D. Abreo. *Medicine/Nephrology, LSU Health Sciences Center, Shreveport, LA.*

Background: We showed recently that secondary fistulas survive longer than prior ipsilateral forearm grafts. Upperarm fistulas are increasingly placed in patients with inadequate forearm vessels. Survival of these 'primary' brachiocephalic fistulas has not been compared to secondary fistulas, which may benefit from prior graft function. Methods: In this retrospective review of a prospective clinical database we determined whether secondary fistulas were superior to primary fistulas. Forty patients underwent secondary (type I) fistula creation following the loss of forearm synthetic grafts between 5/1/95 through 5/1/08. During this time, 267 upperarm fistulas were placed in patients without ipsilateral forearm grafts. As the sizes of the 2 groups were highly divergent, a sample of 80 patients was randomly selected from the 267 patients with primary fistulas, and matched for 2 characteristics known to influence fistula maturation and survival, namely, gender and diabetes. Results: Most patients were black, 50% were female and 40% had diabetes. Mean patient age was 52 yrs in both groups (NS). Primary fistulas did not have higher maturation failure rate than secondary fistulas (16% vs. 15%). Rates of infection, thrombosis, and failure were also similar. Cumulative survival at 1, 2, 3, and 5 yrs was 80, 70, 62 and 30% for secondary fistulas and 76, 61, 56 and 46%, respectively for primary fistulas. The figure confirms that the survival of primary and secondary fistulas was not significantly different.

Cumulative survival of primary (open circles) and secondary (closed circles) fistulas.



Conclusion: This study shows that both primary and secondary fistulas provide similar survival and confirms that fistulas are the access of choice. Differences in time to maturation and number of interventional procedures in the 2 groups needs further study.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC377

**Hospitalization and CKD: Are We Protecting Our Patients' Futures?** Rita L. McGill, Piyush S. Lohiya, Ankur A. Patel, Maria D. Vornicu, Mari Mori, Tomoki Tsukahara, Jeannie P. Co, Imran Dosani, Uzoamaka T. Nwaogwugwu, Rahul Bhardwaj, Richard J. Marcus. *Nephrology/Medicine, West Penn Allegheny Health System, Pittsburgh, PA.*

Fistula First recommendations for patients with CKD suggest that IV lines should not be placed in the non-dominant arm, and that PICC lines be avoided entirely, to avoid exhaustion of native veins in patients who may someday need a fistula (AVF). We prospectively examined the vein protection and access practices on a typical day in a referral hospital associated with an active fistula promotion program.

MDRD estimated GFR (eGFR) could not be determined for 8 of 391 patients. CKD, defined as eGFR<60, was present in 80 patients (21%), of whom 15 were dialyzing (CKD Stage 6), 15 were in CKD Stage 4, and 50 were in CKD Stage 3. Limb protection bracelets were found on 13/80 patients, of whom 7 had existing AVF (3 dialysis patients, and 4 transplant patients in stage 3 and 4 CKD), and 2 had CKD 3 and mastectomy. 4 patients dialyzing via permcath had bracelets, and 8 did not. No bracelets were found on transplant patients without fistulae.

Among patients with bracelets, no IV's or PICC lines were found in protected arms.

Access in Unprotected CKD patients (n=67)

| | PICC | IV's |
|---|---|---|
| non-dominant arm | 8 (12%) | 27 (40%) |
| dominant arm | 12 (18%) | 19 (28%) |

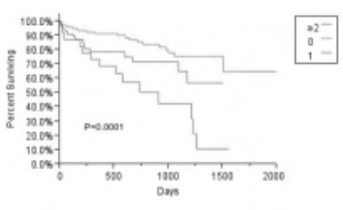
Limb protection bracelets effectively prevent undesirable exhaustion of future fistula veins during hospitalization, but are deployed infrequently among populations at risk, even in an institution with a proven commitment to fistula promotion. Unprotected inpatients with CKD have a 30% rate of PICC placement, and a 52% rate of having an intravenous device placed in the non-dominant arm; punctures for phlebotomy could not be assessed. Strategies that increase the use of simple limb protection devices during hospitalization, and protect future fistula vessel prospects by discouraging routine PICC and IV placement, may improve the outcomes of patients with CKD.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC378

**Decreased Cumulative Access Survival in Arteriovenous Fistulas Requiring Interventions To Promote Maturation** Timmy C. Lee,[1] Michael Allon,[2] Prabir Roy-Chaudhury.[1] [1]*Internal Medicine, University of Cincinnati, Cincinnati, OH;* [2]*Medicine, University of Alabama at Birmingham, Birmingham, AL.*

New arteriovenous fistulas (AVF) are frequently unsuitable for hemodialysis due to failure to mature. Aggressive endovascular (angioplasty) or surgical interventions are often undertaken to salvage non-maturing AVFs. The impact of early interventions to promote AVF maturation on subsequent long-term AVF outcomes is unknown. We evaluated 173 hemodialysis patients from two large academic centers, who received a new AVF. Of these, 96 (56%) required no further intervention, 54 (31%) required 1 intervention, and 23 (13%) required ≥2 interventions to achieve suitability for dialysis. We calculated AVF survival and frequency of post-maturation interventions in each group. Cumulative AVF survival (first cannulation to permanent failure) in patients with ≥2 vs 1 vs 0 interventions before maturation was 68 vs 78 vs 92% at 1 year, 57 vs 71 vs 85% at 2 years, and 42 vs 57 vs 75% at 3 years.



Using Cox regression analysis with interventions before maturation, age, sex, race, diabetes, peripheral vascular disease, access site, and obesity in the model, interventions before maturation (≥2) was the only factor associated with cumulative AVF survival (HR 1.67, 95% CI, 1.01 to 2.70). The number of interventions required to maintain patency after maturation was 3.51±2.20 vs 1.37±0.31 vs 0.76±0.10 per year in patients with ≥2 vs 1 vs 0 interventions before maturation (p=0.004 comparing ≥2 interventions with 0 interventions). Compared with AVF that mature without further interventions, AVF that require interventions have decreased cumulative survival and require more interventions to maintain their patency for hemodialysis.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC379

**Stent Grafts Decrease Risk for Restenosis Compared to Venous Angioplasty Alone in Non-Maturing Primary Arteriovenous Fistulas Secondary to Juxta-Anastomosis Stenosis** Saravanan Balamuthusamy,[1] Benjamin Estes,[1] Sasha Monty,[1] Mark Taylor,[1] William Mckee,[1] John Lucas.[2] [1]*Nephrology, Hypertension and Vascular Access, Northwest Mississippi Regional Medical Center, Clarksdale, MS;* [2]*Lucas Surgical Group, Greenwood Leflore Hospital, Greenwood, MS.*

Background: Over 40% of primary Arteriovenous fistulas do not mature in patients with end stage renal disease. The role of covered stents (stent grafts) in non-maturing AV fistulas secondary to juxta-anastamotic stenosis has not been well studied so far.

Methods:We performed a retrospective analysis of primary Arteriovenous fistulas over 1 year that wear considered non-maturing fistulas. Fistulas were considered non-maturing if they were less than 5mm in size after 8 weeks and if the blood pump could not be ran at 350ml/min despite using optimal sized needles. Stenosis at the juxta-anastomosis site was defined as greater than 60% narrowing of the luminal diameter on angiogram.

Results: We analyzed 46 new arteriovenous fistulas that were not suitable for cannulation after 8 weeks of its creation. Fistula angiograms revealed significant Juxta anastomosis stenosis as the reason for poor maturation in 37 fistulas. Fourteen patients had received a stent graft in the juxta-anastamosis site due to severe stenosis and the remaining 23 patients received angioplasty. Primary patency at 6 months was 100% for the patients with stent grafts vs 82% in patients receiving angioplasty alone (p=0.NS). The need for re-intervention in less than 3 months was 7% in the angioplasty group vs 39% in the stent group (p=NS). All 37 patients had follow-up angiograms in 3 months after the initial procedure. All the fourteen patients in the stent group met "single pool" Kt/V of >1.20 as opposed to 61% in the balloon angioplasty group (p=0.02). Restenosis occurred in 7% in the stent group as opposed to 43% in the angioplasty group (p=0.04).

Conclusion: Stent grafts are a safe and effective option for salvaging poorly maturing AV fistulas secondary to severe juxta-anastomosis stenosis. Stent graft placement decreased the risk for re-stenosis and enabled patients to achieve single pool Kt/V goals.

**Long Term Vascular Access Survival and Complications with Daily Dialysis** Steven Achinger,[1] T. Alp Ikizler,[2] Aihua Bian,[2] Juan Carlos Ayus.[3] [1]*Nephrology, Watson Clinic, LLP, Lakeland, FL;* [2]*Nephrology, Vanderbilt University, Nashville, TN;* [3]*Renal Consultants of Houston, Houston, TX.*

**Background:** A potential complication of daily hemodialysis is repeated access cannulation (six times per week). There are no studies that examined long term effects of FHD on vascular access patency.

**Methods:** We conducted a non-randomized, controlled trial of the effect of daily (six sessions/week of three hours each) or conventional (three sessions/week of four hours each) hemodialysis on hemodialysis access outcomes. We enrolled 26 short daily hemodialysis and 51 matched conventional hemodialysis patients and collected vascular access procedures and treatment attendance. Baseline characteristics were similar between groups in terms of age, diabetes status and baseline vascular access.

**Results:** At 48-month follow-up, there were no significant differences between the two groups in the numbers of access procedure (thrombectomy or revision); 320.7/1000 person/year in the daily dialysis group versus 433.3/person/year in the conventional dialysis group ($P$ = 0.4). At 4 year follow-up, there were 7 access revisions in the daily dialysis group and one access revision in the conventional dialysis group. The numbers of treatments per month was significantly higher in the daily dialysis group compared with the conventional dialysis group (25 [24, 25] versus 14 [13, 22] $P$ = 0.008).

**Conclusion:** At four years of follow-up, 3 hour daily (six times a week) hemodialysis does not lead to increased vascular access complications and is associated with good long term fistula and graft survival.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC381

**Novel Insertion-Deletion Mutation in *Uromodulin* in a Large Kindred with Familial CKD and Nephrotic Range Proteinuria** Rasheed A. Gbadegesin,[1] Peter J. Lavin,[2] Alison Homstad,[1] Guanghong Wu,[2] Alison Byrd,[2] Jason J. Eckel,[2] Michelle P. Winn.[2] [1]*Pediatrics, Duke University, Durham, NC;* [2]*Medicine, Duke University, Durham, NC.*

***Background:*** Focal and segmental glomerulosclerosis (FSGS) remains an important cause of nephrotic syndrome (NS) and chronic kidney disease (CKD). The pathogenesis is not clearly defined; however current evidence from studies of large families with familial disease suggests that the podocyte plays a central role in this disorder.

***Objective:*** To positionally clone the gene mutated in a large kindred with familial CKD and proteinuria.

***Methods:*** We identified a large family with eight affected individuals spanning three generations. We performed genome-wide linkage analysis (GWLA) using the Illumina Infinum II HumanLinkage-12 beadchip genotyping assay and fine mapping with informative microsatellites.

***Results:*** Two of the affected individuals had 3g and 5g of proteinuria. Renal biopsy in four affected individuals showed foci of interstitial infiltrates and focal global glomerulosclerosis. GWLA and fine mapping yielded a multipoint parametric LOD score of 2.9 on chromosome 16p. Positional cloning of the genes within the locus yielded a novel

in-frame insertion deletion mutation 278_289delins T**CTGCCCCGAAG>CCGCCTCCT** in exon 3 of *uromodulin*. The in-frame change leads to loss of a highly conserved cysteine residue in position 94. The mutation segregates in affected individuals in the family.

***Conclusions:*** Phenotype previously associated with uromodulin defects include chronic interstitial nephritis, juvenile familial hyperurecimic syndrome and glomerulocystic disease. This finding in combination with the recent GWAS[1] reveal that uromodulin is a common disease locus in subjects with CKD and suggests that defective uromodulin may have wider deleterious effects on different compartments of the kidney and the podocyte. In conclusion, a novel insertion-deletion mutation in uromodulin in a large family with CKD and proteinuria expands the clinical spectrum of disease associated with defective uromodulin.

**ENU Mutagenesis Identifies a Mutation in Mouse Stk39 Causing a Gitelman's Syndrome-Like Phenotype with Albuminuria** Susan Marie Sheehan, Christina R. Caputo, Karen L. Svenson, Ron Korstanje. *The Jackson Laboratory, Bar Harbor, ME.*

In an ENU mutagenesis screen for albuminuria, 16 male C57BL/6J mice were identified with albuminuria at 20 weeks of age. A line was established from each mouse and a mapping cross was started to localize the underlying mutation. For our first mutant line (Rnl5), the mutation was mapped to a 6 Mb region on Chromosome 2. Next Generation Sequencing of the region identified 5 polymorphisms in the mutant line compared to the normal C57BL/6J sequence. Further validation showed a mutation in intron 10 of Stk39 as the most likely cause of the phenotype. This gene has recently been associated in human hypertension. It regulates NCC, in which mutations cause Gitelman's Syndrome, and Nkcc2, in which mutations cause proteinuria in mice. We phenotypically characterized animals with the mutation and determined that, in addition to albuminuria, mice carrying the mutation have polyuria, hypokalemia, reduced vascular resistance, and premature death in utero or perinatally. These phenotypes are consistent with Gitelman's Syndrome. Currently, we are using molecular genetic techniques to establish the effect of the intronic mutation on gene function. Additionally, mapping and gene identification of the other lines is in progress.

**A Genome-Wide Screen for Novel Genomic Disorders of the Kidney and Urinary Tract Development** Simone Sanna-Cherchi,[1] Katelyn E. Burgess,[1] Monica Bodria,[2] Krzysztof Kiryluk,[1] Vladimir J. Lozanovski,[3] Anna Materna-Kiryluk,[4] Valentina Corbani,[5] Roel Sterken,[1] Nadica Ristoska-Bojkovska,[3] Patricia L. Weng,[1] Nilgun Kacak,[1] Gianluca Caridi,[2] Richard P. Lifton,[6] Landino Allegri,[5] Anna Latos-Bielenska,[4] Zoran Gucev,[3] Francesco Scolari,[7] Velibor Tasic,[3] Gian Marco Ghiggeri,[2] Ali G. Gharavi.[1] *[1]Columbia Univ, NY; [2]Gaslini Inst, Genoa, Italy; [3]Children Hospital of Skopje, Macedonia; [4]PRCM, Poznan, Poland; [5]Univ of Parma, Italy; [6]Yale Univ, CT; [7]Hospital of Montichiari, Italy.*

A novel approach to gene identification for congenital anomalies of the kidney and urinary tract (CAKUT) consists in assessing the whole genome for rare structural variants (copy number variants, CNVs). No adequately powered CNV studies for CAKUT have been conducted so far.

We performed a genome-wide search for CNVs using ILMN 610-Quad arrays in 163 CAKUT patients and 5,086 controls. We developed an analytic pipeline to identify rare pathogenic CNVs, which includes: annotation in public databases; testing for frequency in a large panel of controls; identification of recurrent CNVs or CNVs disrupting genes; prioritization based on linkage loci and gene expression.

Analysis of 163 patients yielded 2,532 unique CNVs. Comparison with 5,086 controls and cross-annotation with public databases led to 105 rare CNVs disrupting exons. Eleven patients (7%) carried CNVs diagnostic of known genomic disorders, indicating that our approach is robust for identification of pathogenic CNVs. Thirty patients (18%) carried unique CNVs with a high likelihood of pathogenicity: absence in > 5,000 controls; *de novo* occurrence in patients with unaffected parents; enrichment for genes expressed in embryonic kidney development; co-localization with linkage loci from our studies of familial CAKUT. We validated 92% of these CNVs and 13% were *de novo*.

In conclusion, we diagnosed known genomic disorders and identified unique CNVs highly suggestive of novel genomic disorders responsible for CAKUT. Our data indicate that rare genic CNVs play a major role in the pathogenesis of CAKUT, motivating larger CNV screens to confirm and discover novel genes underlying this common cause of kidney failure.

## SA-FC384

**Targeted and Whole Exome Sequencing Reveals Multiple Deleterious Variants in CAKUT Patients** Rajshekhar Chatterjee, Enrique Ramos, Stanley P. Hmiel, Anne Beck, Keith A. Hruska, Douglas Coplen, Helen Liapis, Rob D. Mitra, Paul Austin, Todd E. Druley, Sanjay Jain. *Departments of Internal Medicine (Renal Division), Pediatrics, Genetics and Surgery (Urology), Washington University at St Louis, St Louis, MO.*

CAKUT are the most common cause of renal failure in children. Here we examined the association of mutations in developmentally important genes such as Gdnf, Ret, Spry1 and others in a subset of CAKUT using traditional and novel Whole Exome Next-generation sequencing.

Sanger sequencing of coding regions, splice sites and conserved promoter regions revealed non-synonymous polymorphisms/mutations in RET/GDNF in 21 of 84 patients. Of these 18 harbor RET-G691S polymorphism, previously associated with increased risk of CAKUT and predicted to alter MAPK signaling. In addition to RET-G691S, one of the patients harbored a mutation in GDNF between the predicted proteolytic processing site and canonical TGFβ cysteine residues (R93W), while Another had mutation in the RET tyrosine kinase domain (R982C, patient 2). The R982C is a rare variant with a potential to alter RET-SRC and RET-PLCγ signaling. Mutations in both these pathways in mice reveal a spectrum of CAKUT similar to this patient. We further established a pipeline to analyze capture based whole exome sequencing to investigate the possibility of other genetic changes in Patient 2 with features of renal dysplasia, dilated ureters and cryptorchidism. We found additional mutations in the GDNF-GFRα1-RET pathway and other developmentally important genes. Notably a novel ns mutation G438D in GFRα1 was discovered that is predicted to modulate anchoring of GFRα1 to the cell membrane. In this patient, the RET mutations were found to be inherited from father while the GFRα1 mutation from the mother. Interestingly, unaffected brother of patient 2 harbors the GFRα1 mutation but neither of the RET mutations.

Our studies for the first time provide evidence for presence of multiple deleterious rare variants in kidney development genes using a combination of traditional and Next-gen sequencing methods, and support the idea that increased deleterious rare variant burden plays a role in pathogenesis of CAKUT.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC385

**Identification of Two Novel Genetic Factors for CAKUT Origin: Results from the AGORA Project** Kirsten Y. Renkema,[1] Ernie M. H. F. Bongers,[1] Iris Van Rooij,[2] Loes F. M. Van der Zanden,[2] Albertien M. Van Eerde,[3] Jacques Giltay,[3] Wout F. Feitz,[4] Antoine Reginensi,[5] Andreas Schedl,[5] Franz S. Schaefer,[6] Barbara Franke,[1] Nine V. Knoers.[1] *[1]Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Epidemiology, Biostatistics, and HTA, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [3]Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands; [4]Pediatric Urology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [5]Inserm U636, University of Nice, Nice, France; [6]Pediatric Nephrology, University of Heidelberg, Heidelberg, Germany.*

Congenital Anomalies of the Kidneys and Urinary Tract (CAKUT) occur frequently and comprise the most common cause of end-stage renal disease in children. Structural disorders belonging to the spectrum of these anomalies include renal agenesis, multicystic kidney dysplasia, ureteropelvic junction obstruction, and duplex collecting system. Not much is known about the origin of CAKUT. Alterations in genes expressed during nephrogenesis are considered to be important, with the final phenotypic outcome depending on additional modifying genetic and environmental factors. The aim of this study is to identify new genetic factors involved in CAKUT aetiology. From the AGORA biobank of the Radboud University Nijmegen Medical Centre over 700 well-documented CAKUT case-parent triads and 10 families with multiple affected members were recruited, comprising the largest CAKUT cohort world-wide. Mutation analysis of two novel CAKUT candidate genes was performed and revealed interesting genetic variants that were functionally tested *in vitro*. Genome-wide exome sequencing in CAKUT families identified variants possibly involved in CAKUT aetiology. In addition, linkage analysis of a large CAKUT family demonstrated suggestive linkage for loci on chromosomes 1, 2, 4, 7, and 11. The present identification of new genetic factors for CAKUT contributes to the understanding of the pathogenesis and the design of genetic diagnostic screening tests, facilitating early detection and recurrence risk estimations for CAKUT.

## SA-FC386

**Rapid Genetic Diagnosis of Consanguineous Families with Histological Findings of FSGS by Homozygosity Mapping Coupled with Whole Exome Capture and Massively Parallel Sequencing** Khaldoun Al-Romaih,[1,2] Giulio Genovese,[1] Richard P. Lifton,[3] Martin R. Pollak.[1] *[1]Nephrology, Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [2]Research Centre, King Faisal Specialist Hospital, Riyadh, Saudi Arabia; [3]Yale University School of Medicine, Yale University, CT.*

Focal segmental glomerulosclerosis is a histological glomerular phenotype that can be familial, primary, or secondary to a multitude of pathological processes including such tubulointerstitial diseases as nephronophthisis. Mutations in a number of distinct

nephronophthisis genes (NPHPs) have been described to date. We describe consanguineous unrelated Saudi Arabian families with NPHP1 deletion. Affected individuals in the two families presented with renal failure and clinical and histological features consistent with focal segmental glomerulosclerosis. Since FSGS patients may present atypical radiological findings, making the clinical diagnosis of the genetic syndrome difficult, we applied whole-genome single-nucleotide polymorphism analysis followed by state of the art sequence capture and exome sequencing on genomic DNA samples from these families. This analysis facilitated accurate diagnosis after isolation of homozygosity run of ~ 2 Mb. This homozygous run falls between rs6754115 (NCBI 36 genomic position 109,328,776) and rs17464100 (NCBI 36 genomic position 111,284,252), and is identical in affected subjects from the unrelated families. This provides evidence that this deletion is widely spread in the families' geographical regions, and implies its significant involvement in the development of chronic kidney disease in Saudi Arabia.

## SA-FC387

**Genome-Wide Association Study (GWAS) for Albuminuria in Individuals of African and European Descent with and without Diabetes** Carsten A. Böger,[1] Ming-Huei Chen,[2] Adrienne Tin,[3] Matthias Olden,[1] Anna Kottgen,[3] Ian H. de Boer,[4] Conall M. O'Seaghdha,[5] Ching-Ti Liu,[2] L. Adrienne Cupples,[6] Jacques S. Beckmann,[7] Iris M. Heid,[1] Rainer Rettig,[8] Albert W. Dreisbach,[9] Murielle Bochud,[7] Caroline S. Fox,[6] Wen Hong Linda Kao.[3,10,11] *[1]Regensburg University Medical Center, Germany; [2]Boston University; [3]Johns Hopkins University; [4]University of Washington; [5]Brigham and Women's Hospital; [6]NHLBI's Framingham Heart Study; [7]Centre Hospitalier Vaudois, Switzerland; [8]Greifswald University, Germany; [9]Mississippi University; [10]For the CKDGen Consortium; [11]For the CARe Consortium.*

Background: Albuminuria is an independent predictor of chronic kidney disease progression and cardiovascular morbidity and mortality in the general population, but little is known about the influence of common genetic variants on albuminuria.

Methods: We performed a meta-analysis of data from 63,153 individuals of European ancestry with genotype data from GWAS (CKDGen consortium) and from a large candidate gene study (CARe consortium) to identify susceptibility loci for the quantitative trait urinary albumin-to-creatinine ratio (UACR) and the dichotomous trait microalbuminuria (MA). Findings were verified in 6,981 African Americans (CARe Consortium).

Results: A SNP in the CUBN gene (minor allele frequency=0.1) was associated with UACR (p=1.1*10-11) and MA (odds ratio=1.06, p=0.001). CUBN encodes cubilin, which is an integral protein of the complex responsible for receptor-mediated endocytotic albumin reabsorption in the kidney's proximal tubule. Similar associations were observed in CARe African Americans between the SNP's minor allele (frequency=0.03) and UACR (p=0.005) as well as MA (odds ratio=1.4, p=0.008). The associations were independent of diabetes or hypertension.

Conclusion: We identified a SNP in CUBN that is associated with albuminuria across different populations and irrespective of diabetes or hypertension status, thus highlighting the potential role of shared genetic susceptibility for albuminuria in diverse clinical settings.

## SA-FC388

**Association of T2D Genetic Variants with Kidney Function: The Strong Heart Family Study** Nora Franceschini,[1] V. Saroja Voruganti,[2] Sandra L. Laston,[2] Karin Haack,[2] Jean W. Maccluer,[2] Barbara V. Howard,[3] Shelley A. Cole,[2] Kari North,[1] Jason G. Umans.[3] *[1]University of North Carolina, Chapel Hill, NC; [2]Southwest Foundation for Biomedical Research, San Antonio, TX; [3]MedStar Health Research Institute, Hyattsville, MD.*

Type 2 diabetes (T2D) is highly prevalent and is the major cause of progressive chronic kidney disease (CKD) in American Indians. Recent genome wide association (GWA) studies have identified several loci associated with T2D but their impact on susceptibility to T2D complications is largely unknown. We studied the association of 18 recently GWA-T2D identified single nucleotide polymorphisms (SNPs) in 16 loci with kidney function (estimated glomerular filtration rate: eGFR, MDRD) and urine albumin to creatinine ratio (ACR) in 3807 American Indian participants of the Strong Heart Family Study. Center-specific residuals of eGFR and of log ACR were obtained from linear regression models adjusted for age and sex. The residuals were regressed onto SNP dosage using variance component models to account for family relatedness and population history. Summary estimates across centers were combined using a weighted average of point estimates meta-analyses (alpha=0.002 for Bonferroni correction). T2D prevalence varied from 14 to 33% among centers. A SNP in the *WFS1* gene (rs10010131, minor allele frequency 7 to 20%), previously shown to associate with T2D in American Indians (p=0.01), was associated with eGFR (p=0.0005) and ACR (p=0.009). Each copy of the G allele (which confers increased risk of T2D in Caucasians) was associated with both increased eGFR (beta=0.13, se=0.04) and ACR (beta=0.09, se=0.04) residuals. Interestingly, the G allele was also associated with increased insulin levels among non-T2D American Indians (p<0.0001). These findings suggest that *WFS1* may be related to increased eGFR (hyperfiltration) and albuminuria in populations with high susceptibility to T2D.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC389

**Evaluation of SORCS1 as a Candidate Gene for Kidney Failure** Jozef Lazar,[1,2] Haiyan Xu,[2] Caitlin C. O'Meara,[3] Zelmira Lazarova,[1] Carol Patricia Moreno Quinn,[2,3] Howard J. Jacob.[2,3] *[1]Dermatology, Medical College of Wisconsin; [2]Human and Molecular Genetics Center, Medical College of Wisconsin; [3]Physiology, Medical College of Wisconsin, Milwaukee, WI.*

In 2010, Paterson et al. published that SORCS1 is a potential candidate gene for renal disease in humans. This linkage has confirmed our rat work. We have been investigating a quantitative trait locus, renal failure 1 (*Rf-1*) in a hypertension-associated renal disease model. Over the years, we have generated a series of congenics and sub-congenic animals in attempt to clone the gene by position. SORCS1 is one of the genes in our minimal congenic region. These data combined with Paterson's work warranted a more detailed analysis of this gene.

SORCS1 is large gene (26 exons spanning over 500Kb) and member of the type-I transmembrane receptors family containing a Vps10p-domain. To investigate its potential role, we used a cellular assay, sequence analysis and gene knock-out. The porcine proximal tubular cell line LLC-PK1 combined with shRNA against SORCS1 demonstrated that the reuptake of gold-labeled albumin was significantly reduced, demonstrating a potential role for this gene. We next sequenced the entire genomic region of SORCS1 utilizing 454 pyrosequencing technology. The results showed the presence of sequence variants in coding regions with potential functional impact. To further validate the role of this gene, we generated a SORCS1 knocked out rats. The gene was KO'ed using the zinc finger nuclease strategy previously published by our group. In conclusions, our results strongly indicate that SORCS1 plays a role in protein trafficking in kidney.

## SA-FC390

**Non-Diabetic End-Stage Renal Disease (ESRD) in African Americans: Candidate Genes from Analysis of a Pooled DNA-Based Genome Wide Association Study (GWAS)** Meredith A. Bostrom,[1,4] Lingyi Lu,[2] Jeff W. Chou,[2] Pamela J. Hicks,[1] Jianzhao Xu,[4] Carl D. Langefeld,[2] Donald W. Bowden,[1,4] Barry I. Freedman.[3] *[1]Biochemistry, Wake Forest University School of Medicine; [2]Biostatistical Sciences, Wake Forest University School of Medicine; [3]Internal Medicine, Wake Forest University School of Medicine; [4]Centers for Human Genomics and Diabetes Research, Wake Forest University School of Medicine, Winston-Salem, NC.*

African Americans have increased susceptibility to non-diabetic (hypertension-attributed) ESRD compared to Caucasians and extensive evidence supports a genetic contribution. We performed a GWAS on 1000 African Americans, 500 cases with non-diabetic ESRD and 500 non-nephropathy controls, to identify genes associated with non-diabetic ESRD in African Americans. DNA was quantified using gel electrophoresis and spectrophotometric analysis. Samples were pooled to create 10 case pools and 10 control pools (50 samples/pool). Pools were genotyped in duplicate on the Illumina HumanHap550-Duo BeadChip. 1420 top scoring SNPs from the GWAS were genotyped individually on 962 African American non-DM ESRD cases and 947 non-nephropathy controls on the Illumina 1536 GoldenGate custom chip at the Center for Inherited Disease Research. SNPs were tested for association with non-DM ESRD with covariate adjustment for age, gender, logBMI, and percentage of African ancestry as determined by 70 admixture informative markers. The 5 most associated SNPs were located in the *MYH9* gene region on chromosome 22, previously associated with non-DM ESRD (p=5.91E-24 to 7.98E-5, odds ratio (OR) 0.33-0.65, various models). Other top SNPs included rs379489 in the *CFH* gene (p=2.05E-4, OR=0.73, confidence interval (CI) 0.62-0.86; additive) and rs12487085 located in an intergenic region on chromosome 3 (p=5.48E-4, OR=1.29, CI 1.12-1.50; additive). A case-only interaction analysis for *MYH9* risk status revealed association at rs9687184 on chromosome 5 in an intergenic region, (p=9.14E-4, OR=0.59, CI 0.43-0.80, additive). The first GWAS for non-DM ESRD in African Americans replicated association in the *MYH9* gene region and identified additional candidate loci for follow-up studies.

## SA-FC391

**Identification of Soluble Urokinase Receptor as Circulating FSGS Factor** Changli Wei,[1] Shafic El Hindi,[1] Jing Li,[1] George William Burke,[1] Alessia Fornoni,[1] S. Ananth Karumanchi,[2] Hui Kim Yap,[3] Moin Saleem,[4] Pirouz M. Daftarian,[1] Phillip Ruiz,[1] Jochen Reiser.[1] *[1]University of Miami; [2]Beth Israel Deaconess Medical Center; [3]National University of Singapore, Singapore; [4]University of Bristol, United Kingdom.*

The identification of circulating FSGS factor(s) has haunted nephrologists for decades with limited success. Here we report the identification of a FSGS circulating factor as soluble urokinase receptor (suPAR), which is increased in the blood of FSGS patients and particularly high in transplant recurrent FSGS patients. Comparatively, suPAR is not elevated in the blood of healthy subjects or in patients with minimal change disease or preeclampsia. Biochemically, suPAR binds integrin β3 via a moiety on domain 2. This binding is sufficient to activate integrin β3, which then drives podocyte disease. We found increased integrin β3 activity in podocytes from failing kidney allograft due to recurrent FSGS. While suPAR-rich FSGS serum activates integrin β3 in human podocytes, co-incubation with uPAR antibody or cycloRGDfV reduces integrin activity. To define whether suPAR is cause or effect in FSGS, we set up three murine models. First,

we injected recombinant suPAR into uPAR knockout mice which led to dose-dependent suPAR deposits, β3 integrin activation and proteinuria. Second, we released large amounts of suPAR in wt mice that received one uPAR null kidney as a transplant (hybrid mouse). Interestingly, suPAR was deposited into uPAR null kidneys and caused foot process (FP) effacement showing that endogenous suPAR can cause podocyte injury. Third, we achieved overexpression of suPAR in the blood of mice by gene delivery. These mice had sustained elevation of serum and urine suPAR levels. Elevated wt suPAR but not the β3 integrin-binding mutant caused FP effacement and proteinuria. Moreover, the morphological changes after 4- 6 weeks are consistent with a progressive glomerulopathy reminiscent of FSGS. Both, proteinuria and histological glomerular changes could be ameliorated by co-administration of antibodies blocking suPAR. In conclusion, our studies identify suPAR as circulating proteinuria/FSGS factor.

## SA-FC392

**Podocyte-Specific Deletion of NDST1, a Key Enzyme in the Sulfation of Heparan Sulfate Glycosaminoglycans, Leads to Abnormalities in Podocyte Organization, Adhesion, and Migration** Terrel D. Sugar,[2] Deborah J. McCarthy,[1] Jeffrey D. Esko,[3] Lawrence B. Holzman,[4] Kevin J. McCarthy.[1] *[1]Pathology, LSU Health Sciences Center, Shreveport, LA; [2]Cell Biology and Anatomy, LSU Health Sciences Center, Shreveport, LA; [3]Cellular and Molecular Medicine, University of California, San Diego, La Jolla, CA; [4]Medicine, University of Pennsylvania School of Medicine, Philadelphia, PA.*

Previous work in our laboratory investigated alterations in the ability of heparan sulfate (HS) deficient podocytes to interact with pericellular matrices *in vivo* and *in vitro*. HS- podocytes develop foot process effacement *in vivo* and show compromised adhesion and migration *in vitro*. The present study reports the development of a novel mutant mouse (2.5P-Cre/NDST1$^{fl/fl}$) and immortalized cell lines (Immortomouse™/NDST1$^{fl/fl}$) in which HS glycosaminoglycan (GAG) assembly is preserved but sulfation of the HS glycosaminoglycan chains is greatly diminished via podocyte-specific deletion of NDST1 (N-deacetylase-N-sulfotransferase), a critical enzyme responsible for HS GAG sulfation . Both PCR for NDST1 and immunohistochemistry of tissue sections with a monoclonal antibody (10E4), which recognizes N-sulfated epitopes present on HS GAG chains, was used to confirm deletion of the *NDST1* gene. Comparison of H&E stained tissue sections from wild type and mutant animals showed no major glomerular changes but in older 2.5P-Cre/NDST1$^{fl/fl}$ cystic changes were observed in some of the renal tubules. Electron microscopy studies of thin section from mutant animals showed podocyte foot process effacement and the presence of autophagic vacuoles in podocytes. Deletion of the *NDST1* gene in immortalized podocytes having the NDST1$^{fl/fl}$ genotype was done using adenoviral delivery of Cre recombinase. The ability of the NDST1-null podocytes to attach, spread and migrate on fibronectin was significantly less ($p<0.01$) than NDST1+ podocytes. The data from both models are indicative that sulfation of the HS GAG chains is a key element in mediating normal podocyte behavior both *in vivo* and *in vitro*, further highlighting the importance of cell surface HS in mediating podocyte cell behavior.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC393

**Novel Therapeutics in Nephrotic Syndrome: Sialic Acid Precursor ManNAC Improves Sialylation of Angiopoietin-Like 4 (Angptl4) in Podocytes and Reduces Selective Proteinuria in Minimal Change Disease (MCD)** Lionel C. Clement,[1] Maria Carmen Avila-Casado,[2] Camille E. Mace,[1] Elizabeth Soria-Castro,[2] Sumant S. Chugh.[1] *[1]Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Pathology, Instituto Nacional de Cardiologia, Mexico City, Mexico.*

Studies from our lab show that upregulation of Angptl4, a secreted glycoprotein, in podocytes is a key event in the pathogenesis of experimental and human MCD (Clement *et al*, Nature Medicine, in revision). Angptl4 is upregulated up to 70 fold in vivo in podocytes in experimental MCD (PAN) and in biopsies from patients with glucocorticoid sensitive MCD. To study the consequences of this upregulation, podocyte specific NPHS2-Angptl4 transgenic rats were developed. These rats mimic all aspects of human MCD i.e. develop diffuse foot process effacement, selective proteinuria with over 500 fold increase in albuminuria, loss of Glomerular Basement Membrane (GBM) charge (assessed by alcian blue and PEI staining), and demonstrate clustering of podocyte secreted Angptl4 in the GBM. Proteomic analysis of glomerular Angptl4 in wild type rats using 2D gel electrophoresis revealed 2 distinct clusters of Angptl4 oligomers migrating either at neutral (major) or high isoelectric point (minor). By contrast, NPHS2-Angptl4 TG rats and rats with PAN show a reversal in this pattern. Using sialic acid binding lectins (MAA and SNAI), we showed that high isoelectric point Angptl4 lack normal sialylation present in neutral isoelectric point Angptl4 oligomers. Treatment of a stable cell line that secretes recombinant Angptl4 with a sialic acid precursor ManNAc (N-acetyl mannosamine) results in normalization of Angptl4 sialylation. Feeding NPHS2-Angptl4 TG rats ManNAc in tap water over a 12 day period resulted in 41% reduction in albuminuria from baseline, and increased sialylation of glomerular Angptl4. ManNAc, therefore, represents a novel non-immunomodulatory therapeutic option for MCD and other forms of nephrotic syndrome.

**Divergent Functions of Rho GTPases in the Podocyte: Deletion of Cdc42 Results in Podocyte Failure, but Loss of Rac1 Protects Against Podocyte Injury** Jeffrey B. Hodgin,[1] Simone M. Blattner,[2] Courtenay M. Vining,[2] Abdul A. Soofi,[1] Matthias Kretzler.[2] *[1]Pathology, University of Michigan; [2]Nephrology, University of Michigan, Ann Arbor, MI.*

Injury to the podocyte results in characteristic morphological cellular changes, known as foot process effacement, and is closely correlated with the development of proteinuria. The changes in podocyte shape are dependent on rearrangement of the actin cytoskeleton and the Rho GTPases Cdc42 and Rac1 are best known for their roles in cytoskeleton assembly and organization. We hypothesize that Cdc42 and Rac1 are important for podocyte architecture and maintenance of the glomerular filtration barrier. Using NPHS2-Cre expression, floxed Cdc42 and Rac1 were conditionally deleted in mouse podocytes. Both podocyte-specific Cdc42 and Rac1 knockout mice (pod-Cdc42-/- and pod-Rac1-/- respectively) were born healthy and at expected Mendelian ratios. Pod-Cdc42-/- mice died within the first 5 weeks of life due to massive proteinuria and renal failure. By 4 weeks of age, pod-Cdc42-/- mice demonstrated extensive focal and global glomerulosclerosis accompanied by severe tubulointerstitial lesions and proteinaceous casts. Transmission and scanning electron microscopy revealed near total effacement of podocyte foot processes. Pod-Cdc42+/- mice (heterozygotes) showed no phenotype up to 16 months of age. In contrast to pod-Cdc42-/- mice, pod-Rac1-/- mice demonstrated no proteinuria or morphologic alterations. However, when challenged with protamine sulfate perfusion, pod-Rac1-/- kidneys were protected from foot process effacement, whereas control mice showed a 20% reduction of filtration slit frequency and broadening of podocyte foot processes. Our findings reveal podocyte-specific Cdc42 to be indispensible to podocyte architecture and maintenance of the glomerular filtration barrier. In contrast, Rac1 does not play a critical role in the establishment and homeostasis of podocyte shape and function, but appears to be required for podocyte response to injury, thus highlighting inhibition of Rac1 as a potential therapeutic target.

**Central Role for TRPC6 in a Calcineurin/NFAT Feed-Forward Signaling Pathway Involved in Podocyte Injury and Proteinuria** Tom Nijenhuis,[1,2] Alexis J. Sloan,[3] Joost G. Hoenderop,[2] Harry Van Goor,[4] Jan Flesche,[3] Marinka Bakker,[1] Rene J. Bindels,[2] Rudolf Allert De Boer,[5] Gerjan Navis,[6] Jack F. Wetzels,[1] Jo H. M. Berden,[1] Jochen Reiser,[3] Christian Faul,[3] Johan Van der Vlag.[1] *[1]Nephrology, Radboud University Nijmegen Medical Centre (RUNMC), Netherlands; [2]Physiology, RUNMC, Netherlands; [3]Nephrology and Hypertension, Miami, FL; [4]Pathology, UMCG; [5]Cardiology, UMCG; [6]Nephrology, UMCG, Netherlands.*

TRPC6 is a slit diaphragm-associated ion channel expressed by podocytes. TRPC6 gain-of-function mutations and overexpression result in proteinuria. Angiotensin II (AngII) enhances TRPC6 expression in vitro as well as in vivo in glomerular injury models. We hypothesize that activation of the $Ca^{2+}$-dependent calcineurin/NFAT pathway is the intracellular route involved in TRPC6-mediated glomerular pathology.

AngII significantly enhanced NFAT activation and TRPC6 expression in cultured podocytes. PAN and adriamycin-induced TRPC6 expression was also AngII-dependent. Co-incubation with the calcineurin inhibitor ciclosporin A (CsA) prevented AngII and adriamycin-induced TRPC6 transcription. Calcineurin inhibition also blocked PAN-induced NFAT activation. $Ca^{2+}$ influx blockade by $LaCl_3$ or the TRP-channel blocker 2-APB inhibited AngII-induced TRPC6 transcription. Importantly, knockdown of TRPC6 expression by TRPC6 siRNA significantly reduced AngII-induced NFAT activation. This suggested that $Ca^{2+}$ influx through TRPC6 itself activates NFAT, which could result in a feed-forward signal constitutively activating the pathway promoting TRPC6 transcription and podocyte injury. We constructed a novel transgenic mouse model with podocyte-specific inducible expression of a constitutively active NFAT mutant, which indeed induced TRPC6 expression and proteinuria, showing that NFAT activation is sufficient to provoke these effects. Accordingly, in vivo interruption of this pathway by CsA treatment reduced adriamycin-induced and AngII-mediated glomerular TRPC6 expression and proteinuria.

In conclusion, our data show that AngII activates a TRPC6-dependent calcineurin/NFAT feed-forward signaling pathway that enhances TRPC6 expression and results in podocyte injury and proteinuria.

**Podocyte-Specific Deletion of MYH9 Predisposes Mice to Nephropathy** Duncan B. Johnstone, Jidong Zhang, Britta George, Lawrence B. Holzman. *Dept of Medicine; Renal, Electrolyte and Hypertension Division, U of Pennsylvania, Philadelphia, PA.*

MYH9 mutations result in rare but severe CKD due to Epstein's/Fetchner's syndromes, and MYH9 non-coding polymorphisms or "risk alleles" correlate with common causes of CKD among African Americans and Hispanics, including non-diabetic CKD, FSGS and HIVAN. However, it remains unclear how these common MYH9 "risk alleles" result in altered MYH9 expression or regulation as, despite extensive sequencing, causative mutations remain elusive. Moreover, the mechanism by which both common MYH9 "risk alleles" and rare MYH9 mutations result in CKD remains unclear.

We hypothesize that rare MYH9 mutations and common MYH9 "risk alleles" result in CKD, including FSGS and HIVAN, by disrupting cytoskeletal dynamics in podocytes. To investigate the role of MYH9 in kidney disease we selectively deleted MYH9 in podocytes in C57BL/6 mice (Podocin::Cre/+; MYH9f/f). Surprisingly, we found that PodΔMYH9 mice survive in expected Mendelian ratios and do not develop overt CKD or proteinuria when compared to f/f control littermates, even in mice aged to 9 months (uP/C 0.13+/-0.1 PodΔMYH9; 0.24+/-0.2 control). Deletion of MYH9 was confirmed by PCR, and by loss of MYH9 staining only in podocytes in kidney sections of PodΔMYH9 mice using antibodies that we generated and purified. The absence of CKD was not due to MYH10 redundancy, which we find is not expressed in podocytes of either wild type or PodΔMYH9 mice. Thus, on the C57BL/6 background, PodΔMYH9 is not sufficient to cause kidney disease, but we hypothesized it might predispose mice to an additional provocation, which we tested using the Adriamycin nephropathy model. We found significantly more proteinuria in PodΔMYH9 mice from weeks 2 through 6 (wk6 uP/C: 26.5+/-27 in PodΔMYH9; 2.5+/-1.4 in controls; 0.2+/-.1 in PodΔMYH9 saline-injected). On histologic evaluation we found, only in Adriamycin-injected PodΔMYH9 mice, severe glomerulosclerosis by H+E and PAS, and severe FP effacement by SEM and TEM. Thus, MYH9 mutations may not be sufficient to cause CKD but may predispose mice, and possibly humans, to kidney disease by sensitizing podocytes to additional genetic or environmental provocation.

**Targeting Activated Gα12 to Podocytes Leads to Proteinuria, Glomerulosclerosis (GS) and Changes in the Extracellular Matrix (ECM)** Ilene Boucher,[1,2] Sarah Beaudry,[1,2] Wanfeng Yu,[1,2] Bradley M. Denker.[1,2] *[1]Medicine, Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Podocytes are specialized epithelial cells important in maintaining the glomerular filtration barrier. Due to their location, podocytes are uniquely susceptible to injury in numerous kidney diseases. Many pathways regulating podocyte function are mediated by G protein-coupled-receptors (GPCR). Gα12 couples to GPCRs important for vascular regulation (angiotensin II), inflammatory mediators (LPA, thrombin), and the actin cytoskeleton. Gα12 is upregulated in minimal change disease and is localized to the major podocyte processes and at the branch points proximal to the foot processes. We hypothesized that Gα12 regulates podocyte barrier function and the actin cytoskeleton and when activated could lead to increased permeability and podocyte injury. Transgenic mice were established with EE-tagged, constitutively active human Gα12 (QLα12) inserted after a floxed LacZstop. After crossing with podocin-Cre mice, podocyte expression of QLα12 was confirmed by confocal microscopy with EE immunofluorescence. QLα12$^{LacZ+/Cre+}$ mice developed proteinuria at 6m which increased with age. By 12-14m, GS was noted in some glomeruli and electron microscopy revealed focal thickened basement membranes and foot process fusion. Podocyte number was not altered in the QLα12$^{LacZ+/Cre+}$ mice compared to controls and increased apoptosis was not detected. Changes in podocyte and ECM gene expression were monitored by real-time PCR. No significant changes in nephrin, podocin, or CD2AP gene expression were found in 12-18m mice (n=7). However, nephrin was downregulated by 60% in QLα12$^{LacZ+/Cre+}$ mice at 6m (n=6). Analysis of ECM genes at 12-18m (n=6) revealed increased laminin α5 (3 fold), increased collagen IVα1 and α2 (2-4 fold), with no change in α3 and α4 chains, and decreased α5. Taken together, these findings indicate that activation of Gα12 in podocytes leads to proteinuria and changes characteristic of GS by affecting expression of slit diaphragm proteins and ECM composition. Gα12 may be a novel therapeutic target to delay or prevent progressive GS.

## SA-FC398

**Podocyte-Specific Knockout of mTOR Results in Nephrotic-Range Proteinuria and Severe Glomerular Damage** Davide Pietro Cina,[1] Tuncer Onay,[1] Susan E. Quaggin.[1,2] *[1]Samuel Lunenfeld Res. Inst., University of Toronto, Toronto, Canada; [2]St. Michael's Hospital, Toronto, Canada.*

mTOR inhibitors (rapamycin and sirolimus) have been approved by the FDA for the treatment of renal transplants, renal cell carcinoma and are currently under investigation for the treatment of polycystic kidney disease. mTor is a serine-threonine kinase that controls cell growth, proliferation, and immune function. Despite the great promise for these drugs, glomerular toxicity including proteinuria have limited their use, especially in the transplant setting. We hypothesize that inhibition of mTor signaling in the podocyte is responsible for the observed renal toxicities. In vitro studies have suggested that mTOR may regulate slit diaphragm proteins and factors such as VEGF, but in vivo models have been lacking. To elucidate the mechanism underlying proteinuria and structural glomerular changes associated with mTOR inhibition in humans, we generated a mouse model with a podocyte-specific deletion of the mTor gene. mTor floxed mice were generated using a BAC recombineering approach to insert loxP sites around the first 3 exons of the mTor gene. The floxed mTOR allele was validated by global deletion using a pCaggs Cre deletor mouse strain. This resulted in embryonic death, identical to the standard KO mice. To generate a podocyte specific mTOR knock out, the floxed mTOR mouse was bred to podocin-Cre or pod-rtTA/TetOCre recombinase mice. Mice of all genotypes were born at the expected Mendelian frequency and appeared normal with no proteinuria up until 3 weeks of age. At 4 weeks, the mutant mice had growth restriction, and had developed nephrotic range proteinuria. Light microscopy of kidneys from 5 week-old mutants showed extensive glomerular lesions with Bowman capsular dilation, mesangial proliferation and tubular protein casts consistent with end stage renal failure. Deletion of mTor from mature podocytes also resulted in proteinuria and glomerular injury. Taken together, we have shown that disruption of mTOR signaling within the podocyte results in proteinuria and glomerular damage during development and in adulthood providing a model to dissect the glomerular toxicity observed in patients.

**Robo2 Regulates Podocyte Actin Polymerization and Glomerular Permeability** Xueping Fan,[1] Qing-Gang Li,[1] Anna Pisarek-Horowitz,[1] Xiangling Wang,[1] Ramon G. Bonegio,[1] Hang Wang,[1] Margaret M. Mclaughlin,[2] Dennis Brown,[2] David J. Salant,[1] Weining Lu.[1] *[1]Renal Section, Department of Medicine, Boston University Medical Center, Boston, MA; [2]Nephrology Division, Massachusetts General Hospital, Boston, MA.*

Robo2 is the cell surface receptor for the repulsive guidance cue Slit and is involved in axon guidance and neuronal migration. It is also required for normal kidney induction and restricts outgrowth of the ureteric bud from the Wolffian duct to a single site. Disruptions of *ROBO2* are associated with congenital anomalies of the kidney and urinary tract (CAKUT) and vesicoureteral reflux (VUR) in humans and mice. Mouse mutants without either *Slit2* or *Robo2* develop supernumerary ureteric buds, abnormal ureterovesical junctions, and die after birth from severe hydronephrosis and kidney dysplasia. In addition to its role in the developing urinary tract, we have found that Robo2 is also expressed on the basal side of podocytes adjacent to the slit-diaphragm and co-localizes with nephrin and podocin. Yeast two-hybrid and protein co-precipitation assays revealed that Robo2 interacts directly with Nck SH3 domains and forms a complex with nephrin *in vivo* and *in vitro*. By analyzing the formation of F-actin tails in cells, we found that Slit-Robo2 signaling down-regulates actin polymerization induced by nephrin. Furthermore, podocyte-specific *Robo2* knockout mice develop significant albuminuria that is associated with podocyte foot-process effacement. These results suggest that Robo2 forms part of a signaling complex that regulates podocyte F-actin cytoskeleton and influences it structure and function. Our study thus identifies a novel level of regulation of Slit-Robo signaling to counterbalance nephrin-induced actin polymerization and maintain normal kidney glomerular permeability.

## SA-FC400

**Rhophilin-1 Is a Podocyte-Specific Protein Required for Glomerular Filtration** Mark Lal, Karl Tryggvason. *Medical Biochemistry and Biophysics, Karolinska Insitutet, Sweden.*

We recently identified *Rhpn1* as a novel, highly expressed gene of the mouse glomerulus of the kidney. Here, we describe the generation of *Rhophilin-1* knockout mice and their resultant phenotype. Immunohistochemical analysis indicates that Rhophilin-1 is uniquely expressed in the podocytes of both mouse and human glomeruli. Kidney sections as well as protein extracts derived from isolated *Rhpn1*$^{-/-}$ glomeruli reveal that protein expression of the targeted gene was completely ablated in knockout mice. *Rhpn1* knockout mice were phenotypically normal at birth but developed progressive albuminuria from about two weeks of age into adulthood. Histological examination of kidneys from severely albuminuric mice revealed tubular protein casts and FSGS-like lesions as well as glomerular hypertrophy. Widespread podocyte foot process effacement as well as thickening of the glomerular basement membrane were readily detected upon electron microscopy. Immunochemical analysis of a host of podocyte-marker proteins indicated that glomerular dysfunction in *Rhpn1*$^{-/-}$ was not likely a result of any overt alterations in the pattern of their expression. In addition to yeast-2-hybrid identification of Rhophilin-1 interacting proteins, we have implemented a next-generation sequencing platform known as shotgun sequencing by hybridization to analyze the transcriptome profile of single glomeruli isolated from wild-type and knockout mouse kidneys. The development of this novel methodology has allowed us, for the first time, to describe glomerular gene expression at an individual glomerulus level. In summary *Rhpn1* is a glomerular gene necessary for maintaining proper kidney function in the mouse.

## SA-FC401

**Abnormal O-Glycosylation of Serum IgA1 Early in the Disease Is Associated with Risk of Progression in IgA Nephropathy** Alice C. Smith,[1,2] Javeria Peracha,[1] Karen Molyneux,[1,2] Joanna Boyd,[2] John Feehally,[1,2] Jonathan Barratt.[1,2] *[1]Infection, Immunity & Inflammation, University of Leicester, Leicester, United Kingdom; [2]John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom.*

IgA nephropathy (IgAN) is progressive in some but not all patients; as yet, there are no prognostic indicators specific to IgAN. Known abnormalities of serum IgA include raised IgA1 levels, altered IgA1 O-glycosylation, and increased usage of lambda light chain. However, it is not known whether occurrence of any of these abnormalities at an early stage of IgAN can predict long term outcome.

We studied sera from 76 patients with biopsy-proven IgAN obtained early in the course of their disease while renal function was normal, and 74 matched controls. The patients were classified as Progressors (serum creatinine increased by >100% during follow up), or Non-Progressors (serum creatinine remained normal after a minimum ten years follow up). We measured serum IgA1 and IgA1 kappa:lambda ratio by ELISA, and used Helix aspersa (HA) lectin binding assays to quantify IgA1 O-glycosylation. Raised HA binding to IgA1 indicates altered glycosylation.

Serum IgA1 and IgA1-HA binding were significantly higher in IgAN than controls, but we found no difference in kappa:lambda ratio. Of the 76 patients studied, 36 (47%) were Progressors and 40 were Non-Progressors. Neither serum IgA1 level nor kappa:lambda ratio correlated with outcome in IgAN. However, while the IgA1-HA binding of the Non-Progressors did not differ from controls (Non-Progressors 251.51AU, control 211.04AU, p=NS), the Progressors had significantly higher IgA1-HA binding than both Non-Progressors and controls (Progressors 312.09AU, p<0.005 vs Non-Progressors, p<0.0005 vs controls).

These results demonstrate a clear association between the presence of aberrantly O-glycosylated IgA1 in the serum at an early stage of IgAN and subsequent development of progressive renal disease. The findings lend further support to the importance of altered IgA1 O-glycosylation in the pathogenesis of IgAN, and suggest that it may be considered as a diagnostic marker and a possible therapeutic target.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC402

### Predictors of Progression in Idiopathic Membranous Nephropathy: A Comparison of Urinary $\beta_2$-Microglobulin and the Proteinuria Risk Score

Jan A. J. G. van den Brand, Jack F. Wetzels. *Nephrology, Radboud University Nijmegen Medical Center, Nijmegen, Gld, Netherlands.*

Outcome is variable in idiopathic membranous nephropathy (iMN). Accurate prediction of outcome allows optimized treatment for individual patients. We showed that urinary $\beta_2$-microglobulin ($U\beta_2m$) predicts progression in iMN. An alternative risk score based on the 6 month period of maximal proteinuria and creatinine clearance ($eC_{creatinine}$) is often used. We compared both predictors.

We included 102 patients with biopsy proven iMN, serum creatinine levels < 1.5mg/dl and nephrotic syndrome. We calculated risk scores using the first six months of follow up and the period of maximum proteinuria during the first two years of follow up. $U\beta_2m$ excretion was obtained by standardized measurement within three years of biopsy.

42% showed progression, defined as 50% rise in serum creatinine or a 25% rise and absolute level over 1.5 mg/dl. 25% and 15% went into spontaneous complete or partial remission respectively. When predicting progression, risk scores calculated in the first six months were comparable to scores during follow up, ROC-$AUC_{6\ months}$=0.788 (95% CI: 0.700-0.877) versus ROC-$AUC_{follow\ up}$=0.742 (0.642-0.841). $U\beta_2m$ yielded similar accuracy, ROC-AUC=0.798 (0.704-0.892). $\beta_2m$ was slightly more accurate in the prediction of spontaneous remission, ROC-$AUC_{U\beta2m}$=0.770 (0.632 – 0.908) versus ROC-$AUC_{6\ months}$=0.730 (0.589 – 0.871) for partial and ROC-AUC=0.704 (0.588 – 0.820) versus 0.611 (0.485 – 0.737) for complete remission. Adding $\beta_2m$ to the risk score did not lead to better prediction of progression, ROC-AUC=0.853 (0.776-0.930). A parsimonious model with change in $eC_{creatinine}$ during the first six months of follow up and $Ub_2m$ gave comparable results, ROC-AUC=0.833 (0.753 – 0.915).

Risk score calculated the first six months of follow up appears to be a sufficient predictor of prognosis. Evaluation during longer follow-up is no longer needed. Intensified ACEi/ARB use during follow up may explain these results. Risk scores and $U\beta_2m$ give similar accuracy when predicting progression. $Ub_2m$ seems slightly more accurate for spontaneous remission of proteinuria. A compound score including $U\beta_2m$ does not lead to better prediction of progression.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC403

### Influence of a Functional Polymorphism of Aldosterone Synthase Gene on Focal Segmental Glomerulosclerosis: A Clinicopathologic Study

Christos Bantis,[1,2] Peter J. Heering,[1] Maria Stangou,[2] Magdalena Siekierka-Harreis,[1] Christina Schwandt,[1] Dimitrios Memmos,[2] Lars C. Rump,[1] Katrin Ivens.[1] *[1]Department of Nephrology, Heinrich-Heine University, Düsseldorf, Germany; [2]Department of Nephrology, Aristotle University, Thessaloniki, Greece.*

The C-344T polymorphism of the aldosterone synthase gene was associated with serum aldosterone levels and the development of arterial hypertension. In the present study we evaluated its influence on focal segmental glomerulosclerosis (FSGS).

Eighty-one patients with biopsy-proven primary FSGS were followed up for 8.0±12 years. Patients were classified according to the slope of reciprocal serum creatinine (≥or < -0.1 $dl*mg^{-1}*year^{-1}$) into groups A (slow progressors, n=57) and B (fast progressors, n=24). One hundred volunteers were analysed as controls. C-344T polymorphism was determined by PCR. The biopsies of 40 patients were reviewed by the same pathologist. Serum aldosterone levels were determined by ELISA in 57 patients with chronic glomerulonephritis.

C-344T polymorphism influenced the serum aldosterone levels (CC/CT: 106.8±70.4, TT: 243.2±323 pg/ml, p<0.05). The allele frequencies differed significantly between patients (C-allele: 0.55, T-allele: 0.45) and controls (C-allele: 0.45, T-allele: 0.55, p<0.05). The percentage of sclerosed glomeruli tended to be lower in patients with the TT genotype (segmental 19.8±14 and global 9.7±19 vs. 25.4±22 and 17.2±21% in CC/CT, ns). The degree of tubulointerstitial fibrosis tended also to be lower in the TT genotype (14.8±15 vs 19.4±17%, ns). C-344T polymorphism was associated with the progression of FSGS: 36.4% of the CC/CT genotype carriers and 0% of the patients with the TT genotype belonged to group B (fast progressors, p<0.01). There was also a significant difference in the rate of progression between the CC/CT and TT genotypes: -0.216±0.449 vs. -0.030±0.041$dl*mg^{-1}*year^{-1}$ (p<0.05). C-allele carriers had a worse kidney survival in the Kaplan Meier analysis compared to the TT genotype (p<0.05).

The functional aldosterone synthase gene C-344T polymorphism not only acts as a risk factor for the development of FSGS, but may influence its pathologic appearance and could serve as a progression marker.

### Long-Term Outcomes for Patients Receiving Multiple Treatments of Rituximab for Anti-Neutrophil Cytoplasmic Antibody Associated Vasculitis

Mark R. Openshaw, Jennifer A. Tamblyn, Stuart W. Smith, Matthew David Morgan, Lorraine Harper. *Renal Immunobiology, University of Birmingham, United Kingdom.*

Introduction: Anti-neutrophil cytoplasm antibody associated vasculitis (AAV) is a life threatening autoimmune inflammatory disease. Current treatment with cyclophosphamide and prednisolone is associated with significant morbidity and mortality. Rituximab (anti-CD20) is a promising alternative treatment for patients with relapsing AAV and cyclophosphamide related organ damage. Given the relapsing nature of AAV long-term efficacy and safety data for rituximab is required following multiple treatment courses. This study retrospectively evaluated all rituximab used to treat AAV at University Hospital Birmingham between November 2002 and February 2009.

Methods: Standardised case-note based data collection.

Results: 34 patients received 66 treatment courses. All patients became B cell deplete following treatment. 31/34 patients achieved remission following primary rituximab therapy. 8/31 did not relapse (median follow up 35 (4-71) months); 23/31 had one or more relapse (median time to relapse 13 (5-45) months. 31/32 rituximab re-treatment courses achieved further disease remission. 7/31 had sustained remission (median follow up 14 (9-43) months); 19/31 had further relapses (median time to relapse 12 (4-30**)** months); 5/31 had elective treatment before relapse. In patients receiving >1 treatment course there was no difference between the length of the first (13 (5-45) months) and subsequent (11 (4-30) months) periods of remission. 13/26 patients received concomitant immunosuppressive therapy with mycophenolate mofetil, azathioprine or methotrexate during remission. Concomitant immunosuppression did not affect the time to relapse (13 (3-45) vs 14 (4-30) months).

6 patients had infections that required hospitalization and 5 patients died during follow-up, in line with published adverse event rates for similar groups of patients. No significant adverse effects were directly attributable to Rituximab.

Conclusion: Rituximab is a safe and effective alternative treatment in patients with relapsing AAV. Treatment efficacy was not lost with multiple treatment courses.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC405

### Two Year Follow-Up Results from a Randomised Trial of Rituximab Versus Cyclophosphamide for ANCA-Associated Renal Vasculitis: RITUXVAS

Rachel B. Jones,[1] Michael W. Walsh,[2] David R. W. Jayne.[1] *[1]Vasculitis and Lupus Clinic, Addenbrooke's Hospital, Cambridge, United Kingdom; [2]Department of Epidemiology and Biostatistics, McMaster University, Hamilton, Canada.*

Purpose: Cyclophosphamide (CYC) based induction regimens are standard therapy for ANCA-associated renal vasculitis (AAVr); however, associated mortality and adverse event rates are high and safer regimens are required. Rituximab (RTX) based regimens are a potential alternative to CYC induction.

Methods: We report the two year results of a randomised trial comparing a RTX based induction regimen with a standard intravenous CYC regimen for new AAVr. All patients had newly diagnosed AAVr and ANCA positivity. 44 patients were randomised; 33 to RTX 4x375$mg/m^2$ & 2x15mg/kg intravenous (IV) CYC; and 11 to IV CYC 6-10x15mg/kg. Both groups received the same IV and oral prednisolone regimen.

Results: At entry: median age was 68 years, Wegener's granulomatosis 50%, microscopic polyangiitis 50%; CRP 28; BVAS 18; PR3-ANCA 57%, MPO-ANCA 43%, GFR 18ml/min, 20% required dialysis. At two years, the primary composite outcome of relapse, death or end stage renal failure (ESRF) occurred in 14/33 (42%) RTX versus 4/11 (36%) CYC (p=1.00). Relapse occurred in 7/33 (21%) RTX versus 2/11 (18%) CYC (p=1.00), death in 6/33 (18%) RTX versus 3/11 (27%) CYC (p=0.67) and ESRF in 2/33 (6%) RTX versus 0/11 CYC (p=0.57). Median estimated glomerular filtration rate was 20 & 44$ml/min/m^2$ in RTX patients at 0 and 24 months respectively compared to 12 & 31$ml/min/m^2$ in CYC patients. Serious adverse events (SAEs) occurred in 61% RTX (50 events, 20/33 patients) versus 36% CYC (15 events, 4/11 patients) (incidence rate ratio 1.16; 95% confidence interval 0.64-2.22) (p=0.64).

Conclusions: RTX based induction therapy is efficacious but is not superior to IV CYC at two years in terms of combined relapse, mortality and ESRF outcome. Further strategies to reduce mortality and SAEs and prevent relapse should be considered.

Disclosure of Financial Relationships: Honoraria: Lecture fees from Roche.

Sheerin,[4] David J. Cohen,[5] A. Osama Gaber,[6] Frank Eitner,[7] Yahsou Delmas,[8] Chantal Loirat,[9] Laurence A. Greenbaum,[10] Lothar Bernd Zimmerhackl.[11] *[1]Hôpital Necker, France; [2]Fort Wayne Med, IN; [3]Weill Cornell Med College, NY; [4]Newcastle upon Tyne, United Kingdom; [5]Columbia Univ Med Ctr, NY; [6]Methodist Hospital, TX; [7]Univ Aachen, DE; [8]CHU Bordeaux - Pellegrin, France; [9]Hopital Robert Debré, France; [10]Emory Univ, GA; [11]Univ Innsbruck, AT.*

Atypical hemolytic uremic syndrome (aHUS) is a rare, chronic, life-threatening disease characterized by thrombotic microangiopathy (TMA) due to complement inhibitor (CI) deficiencies, constitutive complement activation and chronic inflammation. TMA results in platelet (plt) consumption, renal failure, hemolytic anemia, and 60% 1 year ESRD/death despite plasma therapy (PT). The safety/efficacy of terminal CI eculizumab (Ecu) to reduce TMA in 17 adult/adolescent aHUS patients (pts) with TMA exacerbation despite PT is evaluated in a 26-week (wk) single-arm trial. Ecu dosing: 900mg/wk x4;1200mg Q2 wk starting wk 5. Neisseria vaccine and prophylatic antibiotic x 14 days. Median age 28 yrs, 29% male, 71% CI mutation, 41% post transplant. Primary endpoint: Change in plt count, a measure of TMA. Interim 26 wk analysis was positive:Plts increased 80±64x10∧9/L vs baseline(P<0.0001), positive by Day 7 (P<0.05). Secondary endpoints: with Ecu, 80%[95%CI 52-96] TMA-Event Free (stable plt,no PT,no new dialysis), no observed TMA Intervention (TMAI;PT or dialysis), time to first TMAI (K-M analysis) not reached. CKD improved ≥1 stage in 59%[33-82]. Exploratory analyses: Complete Heme Response(CHR;normal LDH+plts) 76%[50-93], 90% (9/10) [56-100] with abnormal baseline plt/LDH. Complete TMA Response (CHR+sCr ↓≥25%) 65%[38-86]. eGFR improved ≥15mL/min/1.73*m∧2 in 53%[28-77];5/7 dialysis pts became dialysis-free(P<0.01). Hb improved ≥20g/L in 65% [38-86]. Similar response in pts with/without mutations. Ecu was well tolerated. Most common AEs: anemia (1 severe), diarrhea, headache;2 pts discontinued. All pts remain alive. These interim results indicate early and sustained Ecu therapy rapidly stops TMA and restores renal function without need for PT.

**SA-FC407**

**Hypoalbuminemia Is a Risk Factor of Venous Thromboembolism in Membranous Nephropathy (MN)** Sophia Lionaki,[1,2] Vimal K. Derebail,[1] Susan L. Hogan,[1] Michelle A. Hladunewich,[3] Sean Barbour,[3] Yichun Hu,[1] Caroline E. Jennette,[1] J. Charles Jennette,[1] Ronald J. Falk,[1] Daniel C. Cattran,[3] Patrick H. Nachman,[1,4] Heather N. Reich.[3,4] *[1]UNC Kidney Center, Chapel Hill, NC; [2]Laiko Hopsital, Athens, Greece; [3]Univeristy of Toronto, Toronto, Canada; [4]Contributed Equally.*

**Objectives** To assess the frequency and risk factors of venous thromboembolic events (VTE) in patients with MN.

**Methods** Patients with biopsy-proven idiopathic MN from the Glomerular Disease Collaborative Network (n=412) & the Toronto Glomerulonephritis Registry (n=395) inception cohorts were reviewed. The cohorts were similar with respect to demographics, eGFR, proteinuria and serum albumin at biopsy, and were pooled. Cases with at least one VTE (pulmonary embolus, deep vein or renal vein thrombosis, or other) were identified. Groups were compared by Fisher's exact and Wilcoxon rank tests. Logistic regression models were used to estimate odds ratios (OR) for VTE.

**Results** Of 807 patients, 62(7.7%) had at least one VTE, and this rate did not differ between registries (7.04% vs. 8.35%, p>0.05). Mean time to VTE was 11±53 months from the first clinical assessment. Hypoalbuminemia was associated with a 2.5 fold increased risk of VTE with each g/dl decrease in serum concentration (OR= 2.5, 95% CI:1.5-4.1, p=.0003). At serum albumin levels of 2.0 to <2.5 mg/dl the adjusted OR of VTE was 2.50 (95% CI: 1.1-5, p=0.02) and at <2.0 mg/dl the adjusted OR of VTE was 3.8 (95% CI: 1.7-8.6, p=0.002), compared to albumin >2.5 g/dl after controlling for age, gender, proteinuria, and immunosuppressive therapy. Smoking status did not influence these results.

| | With VTE, N=62 | Without VTE, N=745 | p-value |
|---|---|---|---|
| Age at MN diagnosis (yrs) | 46±14 | 50±16 | 0.11 |
| Gender, males, N(%) | 45(73%) | 454(61%) | 0.08 |
| Race, Caucasian, N(%) | 44 (71%) | 496 (67%) | 0.22 |
| Serum albumin (g/dl) | 2.2±0.6 | 2.7±2.3 | <0.0001 |
| eGFR (ml/min) | 71±29 | 73±34 | 0.731 |
| 24hour proteinuria (g/day) | 8.6±5.1 | 7.7±5.5 | 0.07 |

**Conclusions** In a large cohort of patients with MN, the frequency of VTE was 7.7%. Hypoalbuminemia, particularly at levels below 2.5 mg/dL, was the strongest independent predictor of VTE risk.

Disclosure of Financial Relationships: nothing to disclose

**SA-FC408**

**Disease-Specific Risk of Venous Thromboembolic Events in Idiopathic Glomerulonephritis** Sean Barbour,[1] Allen Greenwald,[3] Ognjenka Djurdjev,[1] Adeera Levin,[1] Michelle A. Hladunewich,[2] Daniel C. Cattran,[2] Heather N. Reich.[2] *[1]University of British Columbia; [2]University of Toronto; [3]Queen's University.*

The nephrotic syndrome is a known risk factor for the development of venous thromboembolic events (VTEs). While membranous glomerulonephritis (MGN) is thought to be associated with an increased risk of VTE compared to other forms of idiopathic glomerulonephritis (GN), this has not been confirmed in a large population of patients with only primary glomerular disease. Accordingly we sought to identify the disease-specific risk of VTE in patients with idiopathic GN.

We reviewed a large inception cohort of patients with biopsy proven idiopathic MGN (n=395), focal segmental glomerulosclerosis (FSGS n=370), and IgA nephropathy (IgAN n=548) followed prospectively for a minimum of 12 months in the Toronto GN Registry. All episodes of VTE recorded in the Registry were tabulated. Cox proportional hazards modelling was used to evaluate the association between VTE risk and type of idiopathic GN, adjusting for the degree of proteinuria, serum albumin, age and sex.

At baseline the cohort had a mean age of 42 years, was 63% male, had a creatinine clearance of 73ml/min/1.73m$^2$ with proteinuria of 3.1g/day, and 46% had proteinuria >3.5g/day. A total of 44 patients (3.35% of subjects) with idiopathic GN had a VTE during a median follow-up of 63 months. The risk of VTE was highest in patients with FSGS (11 events, HR 7.8, 95% CI 1.7-35.2, p<0.01) and MGN (31 events, HR 22.0, 95% CI 5.3-92.1, p<0.01) compared to patients with IgAN (2 events, reference group). Proteinuria at the time of first clinical assessment and during follow-up were also predictive of the risk of VTE (p<0.01 for trend test). After adjustment for the degree of proteinuria in the multivariate analysis, the underlying pathologic diagnosis remained an independent predictor of the risk of VTE.

In summary, in this large cohort of patients with idiopathic GN, the underlying pathologic diagnosis is an important predictor of the risk of VTE. Even after adjustment for the degree of proteinuria, MGN is associated with the highest risk of VTE, followed by FSGS and IgAN.

**The Treatment of Resistant Nephrotic Syndrome with Acthar Gel (ACTH)** Andrew S. Bomback,[1] James A. Tumlin,[2] Joel J. Baranski,[3] James E. Bourdeau,[4] Anatole Besarab,[5] Jai Radhakrishnan,[1] Gerald B. Appel.[1] *[1]Columbia University; [2]Southeast Renal Research Institute; [3]Balboa Nephrology; [4]Nephrology Specialists of Oklahoma; [5]Henry Ford Hospital.*

**Objective:** Synthetic ACTH has shown efficacy in European studies as primary and secondary therapy for nephrotic syndrome (NS). To date, there is no modern published experience on using the natural, highly-purified Acthar Gel (repository corticotropin, ACTH), available in America, for NS. We here summarize the initial use of Acthar for NS in non-research settings.

**Methods:** Participating centers evaluated all cases of NS treated with Acthar outside of research settings (i.e. by prescription) with therapy initiatied by 11/30/09, allowing at least 6 months of follow-up. Treating nephrologists collected data on pts' clinical response to therapy and adverse events. Complete remission was defined as stable or improved renal function with proteinuria <500 mg/day. Partial remission was defined as stable or improved renal function with ≥50% reduction in proteinuria and proteinuria 500-3500 mg/day.

**Results:** 21 pts with NS were treated with Acthar: 10 with MN, 2 with MPGN, 2 with FSGS, 1 with MCD, 1 with IgA nephropathy, 1 with class V SLE GN, 3 with DM nephropathy, and 1 with NS without biopsy. The most common treatment regimen was 80 units SC twice weekly for 6 months. Follow-up data was available for 19 pts. Acthar was used as primary therapy for 6 pts with diagnoses of diabetic nephropathy, IgA nephropathy, and non-biopsied NS. The remaining pts had failed a mean 2.7 therapies prior to Acthar therapy. Overall, 9 pts (47%) achieved a complete or partial remission, with 5 (26%) in complete remission. Of these 9 responders, 7 had MN, 1 had class V SLE GN, and 1 had IgA nephropathy. Of the 10 pts with MN, 3 achieved complete remission and 4 achieved partial remission despite having previously failed a mean 2.3 therapies. 5 pts reported steroid-like adverse effects with therapy; there were no infectious complications.

**Conclusion:** Acthar is a viable treatment option for resistant nephrotic syndrome (NS) due to MN. Short-term data suggests that for this disease, complete and partial remission rates may approach 70%.

**Outcome in Children with Steroid Sensitive Nephrotic Syndrome (SSNS)** Aditi Sinha,[1] Piyush Kumar Sharma,[1] Rahul Chanchlani,[1] Asha Moudgil,[2] Pankaj Hari,[1] Arvind Bagga.[1] *[1]Pediatrics, All India Institute of Medical Sciences, New Delhi, India; [2]Nephrology, Children National Medical Center, Washington, DC.*

**Objectives:** To review the course of SSNS & analyze the factors associated with its outcome

**Methods:** Records of all patients with SSNS, between 1990 & 2005, were reviewed. Outcome, evaluated only in those with ≥1 yr follow up at this center, was defined as infrequent relapses (IFR), frequent relapses or steroid dependence (FR) & late resistance (LR). Stata 9.0 was used for statistical calculations.

**Results:** Of 3070 patients with NS, 2603 (84.8%) had SSNS. The mean age at onset of NS was 4.1±2.8 yr; 75% were boys. Hematuria was seen in 242 (9%), 67 (3%) had allergies & 46 (1.8%) had family history of NS. The duration of initial steroid therapy was 10±8 weeks, with initial remission lasting 20±28 wk. Of 1071 patients followed for more than 1yr, 37.4% had IFR, 56.7% FR & 5.9% LR. Renal biopsy in patients with LR showed focal segmental glomerulosclerosis (67%) & minimal change disease (33%). During follow up of 21±30 months, the illness was complicated by peritonitis (9.7% patients), pneumonia (6.6%), urinary infections (5.7%), tuberculosis (2.4%), meningitis (0.4%) & thrombosis (0.5%). Six patients died due to infections. Cushingoid features, hypertension & cataract were seen in 32.5%, 8.2% & 3.8% patients respectively.

Patients with FR, compared to IFR, had an early age at onset (44±32 *vs.* 54±36 months) [diff of means (95% CI) 10.4 (6,15)] (P=0.00) & short initial remission (13±21 *vs.* 35±39 months) [diff of means 22 (17,27)] (P=0.00). The duration of initial steroid therapy in FR & IFR was 9.9±5.8 & 10±5.9 wk respectively [diff of mean (95% CI) 0.15 (-0.6,1)] (P=0.7). On univariate analysis, early age of onset (P=0.00), hematuria (P=0.057) and short duration of initial remission (P=0.000) were associated with FR, while hematuria (P=0.005) was associated with LR.

**Conclusions:** Over half of all patients with SSNS followed at this referral center show frequent relapses. Young age at onset & shorter duration of initial remission are associated with frequent relapses. Infectious and therapy associated complications constitute significant morbidity in these patients.

**Caveolae on Glomerular Endothelial Cells Play a Pivotal Role for Urinary Albumin Excretion in Chronic Kidney Disease** Takahito Moriyama, Keiko Uchida, Kosaku Nitta. *Medicine, Kidney Center, Tokyo Women's Medical University, Shinjyuku-ku, Tokyo, Japan.*

Glomerular endothelial cells (GEC), together with the glomerular basement membrane and glomerular epithelial cells, play a pivotal role in glomerular permeability and selectivity. Caveolae are cell membrane invaginations on GEC. The role of caveolae on GEC remains unknown, though caveolae on vascular endothelial cells have been reported to play an important role in endocytosis, cell signaling, and the transport of macromolecules. We examined the expression of caveolin-1 (Cav-1), a main component of caveolae, on GEC and determined the relationship between Cav-1 expression and renal pathological findings and clinical findings in 104 patients with chronic kidney diseases (CKD) and 50 healthy controls. The control specimens were obtained from 0-hour biopsy tissues of donor kidneys intended for renal transplantation. Cav-1 was expressed very weakly in the control tissues, and the area of Cav-1 expression on the capillary loops relative to the total glomerular area was 0.57 ± 0.65%. However, the area of Cav-1 expression was significantly larger in biopsy tissues from patients with membranous nephritis (MN; 4.89 ± 3.11, P<0.001), membranoproliferative glomerulonephritis (MPGN; 2.95 ± 3.06, P<0.001), crescentic glomerulonephritis (Cre GN; 1.79 ± 1.05, P<0.01), focal segmental glomerulosclerosis (FSGS; 1.75 ± 1.12, P<0.01) and diabetic nephropathy (DMN; 2.86 ± 1.38, P<0.001), compared with the level in the control group. Cav-1 expression was positively correlated with the urinary albumin level (r=0.40, p=0.0009) and negatively correlated with the total protein (r=-0.30, p=0.001) and serum albumin (r=-0.27, p=0.009) level in the clinical findings but not in the histological findings. Electron microscopy revealed numerous caveolae in the GEC of the specimens from patients with MN. These results indicated that caveolae are rarely located on stable GEC but increase in number on the GEC of specimens from patients with MN, MPGN, Cre GN, and DMN; thus, caveolae might play an important role in the transportation of albumin in GEC, increasing urinary albumin excretion.

**BOLD Kidney MRI in Patients with Chronic Kidney Disease and Healthy Volunteers before and during Anti-Hypertensive Treatment** Laima Siddiqi,[1] Hans Hoogduin,[2] William P. Th. M. Mali,[2] Peter J. Blankestijn.[1] *[1]Nephrology and Hypertension, University Medical Center Utrecht, Utrecht, Netherlands; [2]Radiology, Radiotherpay and Nuclear Medicine, University Medical Center Utrecht, Utrecht, Netherlands.*

Imaging of the kidney using blood oxygen level dependent MR presents a major opportunity to examine differences in tissue oxygenation within the cortex and medulla applicable to human disease. The aim of this study was to evaluate intra-renal oxygenation assessed by BOLD MRI (3.0 Tesla) before and after treatment with RAS-blockers in hypertensive CKD patients. Methods: 10 patients with stable CKD and 5 healthy volunteers are included. 5 CKD patients were subjected to kidney BOLD MRI scan before and after treatment with 300mg/day aliskiren for 6 weeks. 5 other CKD patients received BOLD before and 1 hour after acute treatment with 50mg captopril (oral). A group of controls (n =5) was scanned before and 1 hour after acute treatment with 50mg captopril (oral). Results: The ten patients (7 men) had a mean age of 61 ± 17 years and eGFR of 30 ± 11 ml/min per 1.73 $m^2$. Office systolic and diastolic blood pressures when on a RAS-blocker, were 130/86 ± 10/5 mmHg respectively. Controls had normal kidney function and were not on any medication. In untreated condition, systolic and diastolic blood pressure elevated, 145/95 ± 6/4 mmHg, respectively. After chronic treatment with aliskiren, arterial blood pressure decreased in all patients in this group, 122 ± 3 mmHg and 75 ± 3 mmHg. After acute treatment with captopril arterial blood pressure reduced to 125 ± 4 and 71 ± 8 mmHg. Tissue intensity signal (T2*) i.e. tissue oxygenation was increased in medulla after chronic treatment from 29 ± 6.5 to 34 ± 6.0 and after acute treatment from 34 ± 8.7 to 37 ± 11 in CKD patients. In addition, T2* ratio between cortex and medulla decreased in CKD patients after chronic treatment and acute treatment. This ratio remained stable in healthy volunteers before and after treatment with captopril 1.62 ± 0.1 and 1.65 ± 0.1, respectively. Conclusion: This study shows for the first time that RAS blockers improve intra-renal oxygenation in patients with stable CKD. Further investigation is required.

## SA-FC413

**Vitamin D Receptor Activation Ameliorates Cachexia in Chronic Kidney Disease** Robert H. Mak,[1] Jianying Zhan,[2] Wai W. Cheung.[1] *[1]Pediatrics, University of California, San Diego, La Jolla, CA; [2]Pediatrics, ZheJiang University, HangZhou, ZheJiang, China.*

Cachexia, characterized by anorexia, increased basal metabolic rate and the pathologic loss of lean and fat mass, is prevalent in chronic kidney disease (CKD). We have previously shown that uremic cachexia is associated with maladaptive responses in energy homeostasis and body composition and that the pathogenesis may be mediated by inflammation(Cheung W et al JCI 2005). Vitamin D deficiency is prevalent in inflammatory conditions such as CKD and may influence cachexia. Using a mouse model of CKD-associated cachexia, 8-wk old c57BL/6J mice were subjected to 5/6 nephrectomy (N) or sham operation (S). Serum 25-hydroxyviamin D3 and 1,25-hydroxyvitamin D3 were significantly lower in N mice compared to S mice (p<0.01). We studied the effect of paracalcitol (PC), a vitamin D receptor activator, in this model. N mice received either PC(N-PC) (1.5 mg/kg, i.p., thrice/week) or vehicle. S mice received vehicle. Serum creatinine was higher in N (0.7 mg/d) and N-PC(0.6 mg/dl) compared with S mice(0.2 mg/dl, p<0.01). All 3 groups of mice were pair-fed and observed for 2 weeks. S and N-PC mice gained more weight than N mice (p<0.01) despite equal food consumption. Basal metabolic rate was elevated in N compared with S and N-PC mice (p<0.01). Efficiency of food consumption was decreased in N mice compared with S and N-PC mice. N mice lost lean and fat mass whereas S and N-PC mice gained lean and fat mass. mRNAs of uncoupling proteins(UCP)- 1 and 2, which control energy expenditure, were upregulated in skeletal muscle and adipose tissue in N compared with S and normalized in N-PC mice. mRNAs of myogenic pathway genes, IGF-I, MyoD and PAX3, were all downregulated in the skeletal muscles in N compared with S and normalized in N-PC mice. IL-6 mRNA in skeletal muscle and adipose tissue was upregulated in N compared with S and normalized in N-PC mice. In summary, vitamin D receptor activation ameliorated energy homeostasis and body composition abnormalities as well as reversed cytokine over-expression in CKD-associated cachexia. Vitamin D deficiency may be an important factor in the pathogenesis of cachexia and inflammation in CKD.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC414

**Rigorous Control of Blood Pressure Is Justified in Older People with Chronic Kidney Disease** Stephen G. John,[1] Paul J. Owen,[1] Jane H. Youde,[1] Chris W. McIntyre.[1,2] *[1]Royal Derby Hospital, Derby, United Kingdom; [2]University of Nottingham, Derby, United Kingdom.*

Chronic kidney disease (CKD) is highly prevalent in older people. Aggressive blood pressure (BP) control is the cornerstone of CKD management. Doubt exists concerning the optimal BP targets in this group, primarily due to a perceived risk of inducing additional CV instability and increasing falls risk. We performed a prospective, controlled study of the effects of antihypertensive therapy (AHT) on CV function, body composition, functional capacity and falls in older (>70 yrs) non-diabetic patients with CKD 3/4.

We recruited 61 subjects (including non-CKD controls). AHT was fully withdrawn for 2 weeks before initial assessment of body composition (bioimpedance analysis) and function (Timed get Up and Go test (TUG)), as well as CV function (pulse wave velocity (PWV) and baroreflex sensitivity (BRS)). AHT was restarted to target BP 130/80mmHg. We repeated assessment 4 weeks after full AHT titration (AHTr), and after a further 12 months follow-up (FU). Falls diaries were maintained.

Mean age was 76±4yrs, mean eGFR (CKD group) was 42±14ml/min/1.73$m^2$. AHT was in line with current guidelines, predominantly RAAS inhibition (mean achieved BP 128/69 mmHg). Improvements in PWV (13 to 12 m/s, p<0.001) and BRS (4.2 to 5.7 ms/mmHg, p=0.002) with AHTr were sustained over 12 months. Intra- and extra-cellular water fell slightly by around 0.3L. Muscle mass fell with AHTr and at FU (0.7, p=0.031; 1.0kg; p=0.020). A trend to bone mass reduction after AHTr (0.03kg; p=0.085) was confirmed at FU (0.6kg; p=0.021). TUG fell over the year by 8 to 9 s (p=0.001). Falls rates were low, with only 27 episodes (range 0-6 per individual). No associations were noted with AHT, BRS or BP. Increased arterial stiffness was associated with increased falls risk. Overall response to AHT was similar between patients with CKD or preserved renal function.

AHT use in older patients rapidly results in sustained improvement in CV function. Body composition and function decline, this does appear to be clinically significant. Concern that older patients with CKD may have a different risk/benefit profile for aggressive AHT than younger patients appears unfounded.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC415

**Trefoil Factor 3 Predicts Incident Chronic Kidney Disease in the General Population: The Atherosclerosis Risk in Communities (ARIC) Study and Framingham Heart Study** Brad C. Astor,[1] Anna Kottgen,[2] Shih-Jen Hwang,[3] Nrupen Anjan Bhavsar,[1] Caroline S. Fox,[3] Josef Coresh.[1] *[1]Department of Epidemiology, Johns Hopkins University, Baltimore; [2]Renal Division, University Hospital Freiburg, Germany; [3]Framingham Heart Study, National Heart, Lung and Blood Institute, Framingham.*

Chronic kidney disease (CKD) is associated with elevated risk for cardiovascular disease, end stage renal disease and death, but few factors that predict incident CKD have been identified. Urinary levels of trefoil factor 3 (TFF3) are associated with acute kidney injury in animal models, but the potential association of TFF3 levels with incident CKD in humans is unknown.

We conducted a case-control study nested within the Atherosclerosis Risk in Communities (ARIC) Study and ARIC Carotid MRI Study. Individuals with an estimated glomerular filtration rate (eGFR) ≥60 mL/min/1.73m$^2$ and with urinary albumin:creatinine ratio (ACR) <30 mg/g were eligible for selection. Incident CKD was defined as an eGFR decreasing by 25% to below 60 mL/min/1.73$^2$ after a median of 8.6 years of follow-up. The 143 cases that occurred were matched on age, sex and race to 143 non-cases. The median TFF3 level was 0.55 pg/mL (interquartile range: 0.27, 1.10). Higher TFF3 levels were seen in blacks, females, individuals with diabetes and those using anti-hypertensive medications. A doubling of TFF3 levels was significantly associated with higher incidence of CKD after adjustment for these factors, as well as for other CKD risk factors, including urinary ACR (adjusted odds ratio [OR] = 1.35; 95% confidence interval [CI]: 1.11, 1.64). Similar analyses were conducted in a case-control sample (n=200) nested within the Framingham Heart Study. The association between TFF3 level and incident CKD was positive, but substantially weaker and not statistically significant (adjusted OR=1.12, 95% CI: 0.80, 1.58). Combined analyses found that a doubling of TFF3 was associated with a 29% higher odds of incident CKD (p=0.004).

We hypothesize that higher urinary TFF3 levels indicate ongoing repair of damage in the kidney and may be useful as a marker of increased risk for CKD.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC416

**FG-4592, a Novel Oral HIF Prolyl Hydroxylase Inhibitor, Elevates Hemoglobin in Anemic Stage 3/4 CKD Patients** Anatole Besarab,[1] Henry N. Hulter,[2] Stephen Klaus,[2] Tyson T. Lee,[2] David E. Lilienfeld,[2] Thomas B. Neff,[2] Beth Anne Piper,[2] Robert Provenzano,[3] Kin-Hung Peony Yu.[2] *[1]Henry Ford Hospital; [2]FibroGen, Inc.; [3]St. Clair Specialty Physicians.*

Given heightened concerns about clinical outcomes arising from use of ESAs that cause supraphysiologic circulating EPO levels, use of agents producing transient, more physiologic increases in endogenous EPO (eEPO) may have significant benefit in CKD anemia. In this randomized, single-blind, placebo-controlled phase 2 study, 117 subjects were randomized with 116 (108 unique) treated: 88 to FG-4592 and 28 to placebo, in 4 dose cohorts (0.7, 1.0, 1.5, and 2.0 mg/kg FG-4592) administered 2 [BIW] or 3 [TIW] times weekly for 4 wks. 97 subjects who were anemic at baseline (BL Hb<11 g/dL) and treated for at least 2.5 wks were eligible for efficacy evaluation. BL Hb was 10.0 ± 0.7 g/dL (mean ± SD). Maximal Hb change from BL by wk 6 and Hb responder rate (% subjects with Hb increase ≥1 g/dL from BL at any time from wk 3-6) are shown in table.

Mean±SD Maximal ΔHb g/dL (%Hb Responders)

| Cohort | BIW [N] | TIW [N] |
|---|---|---|
| 0.7 mg/kg | 0.9±0.8 (33) [9] | 1.0±0.9(62) [13] |
| 1.0 mg/kg | 0.9±0.8 (60) [5] | 1.0±0.9 (60) [5] |
| 1.5 mg/kg | 1.7±1.0 (80) [10] | 2.0±0.9 (91) [11] |
| 2.0 mg/kg | 1.9±0.6 (100) [9] | 2.2±0.8(100) [11] |
| placebo | 0.4±0.5 (8) [24] | |

For responders, median time to Hb response was 22-43 and 15-22 days for BIW and TIW groups, respectively, generally faster than observed with ESA. FG-4592 administered for 4 wks was well-tolerated and led to dose-dependent Hb correction with observed peak eEPO levels 1-2 orders of magnitude lower than values reported for ESA. During treatment, one AE of increased BP was reported in the 0.7 mg/kg group; no significant BP change was observed across cohorts despite rapid rate of Hb rise with higher doses. There were no reports of thrombosis, sustained liver enzyme abnormality, or study drug related SAE. These results support a potentially unique mechanism of action permitting safer Hb increase and maintenance while avoiding thrombotic or hypertensive responses commonly observed with ESA.

**Effect of Allopurinol in Chronic Kidney Disease (CKD) Progression and Cardiovascular Risk** Jose Luno, Marian Goicoechea, Soledad Garcia de Vinuesa, Ursula Verdalles, David Arroyo, Abraham Rincon, Caridad Ruiz Caro, Jara Ampuero. *Nephrology, Hospital General Universitario Gregorio Marañon, Madrid, Spain.*

**Background:**

Hyperuricemia is associated with hypertension, inflammation, renal disease progression and cardiovascular disease. However, no data are available about the effect of allopurinol in patients with chronic kidney disease.

**Design, setting, participants and measurements**

We conducted a prospective, randomized trial of 113 patients with estimated glomerular filtration rate (e-GFR) < 60 ml/min. Patients were randomly assigned to treatment with allopurinol 100 mg/day (n=57) or to continue the usual therapy (n=56). Clinical, biochemical and inflammatory parameters were measured baseline and at 6,12 and 24 months of treatment. The objectives of study were: 1) renal disease progression, 2) cardiovascular events and 3) hospitalizations of any causes.

**Results:**

Serum uric acid and C.reactive protein levels were significantly decreased in subjects treated with allopurinol (p=0.016 and p=0.018, respectively). In control group eGFR decreased 3.3±1.3 ml/min/1.73 m$^2$ and in allopurinol group increased 1.3±1.2 ml/min/1.73 m2 after 24 months (p=0.018). Allopurinol treatment slowed down renal disease progression independently of age, gender, diabetes, C-reactive protein, albuminuria and renin-angiotensin system blockers use. (HR:0,53, p=0.048)

After a mean follow-up time of 23.4±7.8 months, 22 patients suffered a cardiovascular event. Diabetes mellitus (HR: 4,38 p=0.004), previous coronary heart disease (HR:4,49 p=0.005) and CRP levels (HR: 2.83, p=0.031) increased cardiovascular risk. Allopurinol treatment reduces risk of cardiovascular events in 71% (HR: 0.29, p=0.026) compared with standard therapy.

**Conclusions:**

Allopurinol decreases C-reactive protein and slow down progression of renal disease in patients with chronic kidney disease. Besides, allopurinol reduces cardiovascular and hospitalization risk in these subjects.

**Improved Renal Outcomes with a Calcium Channel Blocker Compared to a Thiazide Diuretic When Combined with an Angiotensin Converting Enzyme Inhibitor in Black Hypertensives** Matthew R. Weir, George L. Bakris, Michael A. Weber, Björn Lennart Dahlöf, Richard B. Devereux, Sverre E. Kjeldsen, Bertram Pitt, Jackson T. Wright, Roxzana Y. Kelly, Tsushung A. Hua, Robert Allen Hester, Eric J. Velazquez, Kenneth A. Jamerson. *Division of Nephrology, University of Maryland School of Medicine, Baltimore, MD.*

The Avoiding Cardiovascular events through Combination therapy in Patients Living with Systolic Hypertension (ACCOMPLISH) trial was a double-blind randomized event driven multi-center trial involving 11,506 patients with high cardiovascular risk randomized to benazepril + hydrochlorothiazide (B+H) or benazepril + amlodipine (B+A) and titrated in parallel to reach recommended blood pressure goals. There were 1,416 patients of self-described Black (AA) ethnicity. There was no overall difference in the primary composite cardiovascular outcome between treatment groups (B+H or B+A) in AA. The pre-specified kidney disease endpoint-defined as doubling in serum creatinine, endstage renal disease (ESRD), or death was also not different between treatment groups in AA patients. But, in view of the low event rates resulting from the early termination of the trial, this endpoint was modified to include a >50% sustained increased serum creatinine, ESRD or death. AA participants, despite having fewer primary cardiovascular events regardless of treatment assignment (7.8% vs 11.1%) than non-AA, were significantly more likely (12.5% vs 10.9% , p=.004) to develop a sustained >50% increase in serum creatinine. More AA (2.9 vs 1.0%, p=.001) had a greater than 50% increase in creatinine to a sustained level of 2.6 mg/dL or greater. Fewer patients on B+A compared to B+H developed sustained >50% increases in serum creatinine, both among AA (8.9% vs 16.0%) and non-AA (7.3% vs 14.5 %), both p<.0001). We conclude that in high risk patients with hypertension, AA patients have a much greater proclivity for renal disease progression even when having a lower rate of cardiovascular events. Combination antihypertensive treatment with B+A reduces kidney disease progression more effectively than B+H in both AA and non-AA patients.

## SA-FC419

**Dietary Sodium Restriction Is Superior to Dual Blockade in Enhancing the Antiproteinuric and Antihypertensive Effect of RAAS Blockade** Maartje C. J. Slagman,[1] Femke Waanders,[1] Marc H. Hemmelder,[2] Hiddo Jan Lambers Heerspink,[3] Gerjan Navis,[1] Gozewijn Dirk Laverman.[1] *[1]Nephrology, UMCG; [2]Nephrology, MCL; [3]Pharmacology, UMCG, Netherlands.*

**Background:** Persistent hypertension (HT) and residual proteinuria (UP) during single renin-angiotensin-aldosterone-system (RAAS) blockade predict unfavourable renal and cardiovascular outcome and thus implicate insufficient renoprotection. Dual blockade with ACE inhibition (ACEi) and angiotension receptor blockade (ARB) and/or dietary sodium restriction may be strategies to improve renoprotection. Their comparative efficacy, and the effects of their combination, were tested in the current study.

**Methods:** In a cross-over RCT 52 patients with non-diabetic nephropathies (83% male, 100% Caucasian, age 51±2 years) and residual proteinuria during single RAAS blockade at maximal dose (lisinopril 40 mg/d; LIS), were treated during four 6-week periods with LIS and dual blockade at maximal dose (lisinopril 40 mg/d and valsartan 320 mg/d; LIS+VAL), combined with consecutively a normal sodium diet (184±6 mmol $Na^+$/d) and a low sodium diet (LS; 104±5 mmol $Na^+$/d; p<0.001), in random order.

**Results:** At baseline (LIS) residual UP was 1.7 [1.3-2.1] g/24h. Addition of VAL reduced UP (-10±7%, p=0.003), but addition of LS diet was far more effective (-44±4%, p<0.001), while combination VAL+LS diet added to LIS was slightly but significantly more effective (-52±5%, p<0.001). Systolic blood pressure (SBP), which was high-normal (134±3 mmHg) at baseline (LIS), was not significantly altered by addition of VAL (131±3 mmHg, NS), whereas addition of LS diet normalized SBP (123±2 mmHg, p<0.001). Plasma $K^+$ levels (4.6±0.1 mmol/L) and creatinine clearance (83±6 mL/min) during LIS were unaffected by addition of VAL or LS diet, whereas both VAL+LS diet added to LIS increased plasma $K^+$ (5.0±0.1 mmol/L, p<0.001) and decreased creatinine clearance (69±6 mL/min, p=0.002).

**Discussion:** Dietary sodium restriction is superior to the addition of ARB for further reduction of HT and UP in renal patients already on ACEi. Our findings support the combined endeavours of patients and health professionals to accomplish satisfactory sodium restriction to enhance therapy response.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC420

**Add-On Aliskiren in Non-Dialysis CKD Patients Treated with Dual Blockade of Renin-Angiotensin System (RAS): A Prospective Pilot Study** Luca De Nicola,[1] Pasquale Zamboli,[1] Vincenzo Bellizzi,[2] Domenico Russo,[3] Felice Nappi,[4] Maristella Minco,[3] Giuseppe Conte,[1] Roberto Minutolo.[1] *[1]Nephrology Depts., Second Univ., Naples; [2]Hospital, Salerno; [3]Univ. Federico II, Napoli; [4]Hospital, Nola, Italy.*

The additive antiproteinuric effects of CEI+ARB are limited in most CKD pts possibly due to escape mechanisms. We evaluated antiproteinuric efficacy of direct renin inhibitor aliskiren in CKD pts with residual proteinuria after dual RAS blockade.

We selected consecutive adult CKD stage 1-4 (no transplant) pts with proteinuria >0.5 g/d treated with CEI+ ARB at maximal tolerated dose unchanged in the previous 3 months. Immunosuppressive therapy, sK >5.5 mEq/L and eGFR change >30% in the previous 6 months were exclusion criteria. Patients were evaluated before (baseline) and during 6 months of aliskiren at a dose titrated to 300 mg/d. Out of the 50 selected pts, 5 did not complete the study (immunosuppressive therapy, n=2; no assumption of aliskiren, n=3). Age was 57±15 yrs and BMI 30±6 kg/m$^2$; prevalence of males, diabetes and prior CV disease was 78%, 49% and 33%, respectively.

Main changes in the 45 pts studied

| | Basal | month 1 | month 3 | month 6 | P |
|---|---|---|---|---|---|
| Systolic BP (mmHg) | 146±13 | 139±13 | 139±16 | 141±19 | 0.0002 |
| Diastolic BP (mmHg) | 86±8 | 83±7 | 82±9 | 80±9 | 0.005 |
| eGFR (mL/min/1.73 m2) | 47.7±26.5 | 46.6±27.3 | 45.7±27.8 | 44.2±26.3 | 0.004 |
| sK (mEq/L) | 4.7±0.5 | 4.8±0.5 | 4.8±0.5 | 4.8±0.6 | 0.167 |
| Proteinuria (g/d) | 3.39±2.25 | 2.94±2.07 | 2.99±2.41 | 2.69±1.98 | 0.032 |

mean±SD

Median proteinuria decline (0.74 g/d, IQR 0-1.45) did not correlate with changes of either systolic (r=0.155, P=0.308) and diastolic (r=0.228, P=0.131) BP or eGFR (r=-0.015, P=0.922). No side effect requiring withdrawal of CEI/ARB or aliskiren occurred. Use of other antihypertensive drugs and UNaV did not differ from baseline (2.1±1.3 and 184±96 mEq/d, respectively).

Add-on aliskiren in CKD pts under dual RAS blockade allows an additional decline in proteinuria that is at least in part independent of its antihypertensive effect. While the drug appears to be safe in terms of hyperkalemia risk, long term evaluation of GFR is required.

Disclosure of Financial Relationships: nothing to disclose

**Cyclin Dependent Kinases (Cdks): New Players Controlling AQP2 Trafficking** Grazia Tamma,[1] Domenica Lasorsa,[1] Christiane Trimpert,[2] Lisa Mastrofrancesco,[1] Maria Grazia Mola,[1] Maria Svelto,[1] Peter M. T. Deen,[2] Giovanna Valenti.[1] *[1]Department of General and Environmental Physiology, University of Bari, Bari, Italy; [2]Department of Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Kidney water reabsorption is regulated by the hormone vasopressin (AVP) which exerts its effect on the water channel AQP2. AVP binds to its V2 receptors (V2R) and causes, via elevation of cAMP, activation of protein kinase A (PKA) and phosphorylation of AQP2 at serine 256 (pS256), AQP2 translocation to the plasma membrane. Besides S256, in vivo AVP action co-incides with phosphorylation of S264 and S269, and de-phosphoryation of S261, but the kinases involved are still unknown. Bio-informatical analysis suggests that cdk1/5 may phosphorylate S261 and their potential relevance in AQP2 regulation was investigated. Immunohistochemistry and immunoblot analysis indicated that cdk1 and cdk5 are both expressed in the AQP2-expressing principal cells. In *ex-vivo* kidney slices and MDCK-AQP2 cells, the cdk1/5 inhibitor roscovitine, increased pS256 and decreased pS261, while pS269 was unchanged. In MDCK-AQP2 cells, immunocytochemistry and cell surface biotinylation showed that roscovitine caused AQP2 translocation to the apical membrane in the absence of forskolin, resulting in increased osmotic water permeability (assessed by a FlexStation 3 fluorescence platereader). To investigate the possible signalling responsible for AQP2 relocation in response to roscovitine treatment, PKA activity was evaluated by FRET. MDCK-hAQP2 were co-transfeced with RII-CFP and Cat-YFP. Compared with non-treated cells, roscovitine treatment caused an increase in PKA activity, similar to that obtained with forskolin stimulation. Together, these data indicate that cdks are functionally involved in the regulation of AQP2 trafficking and suggest that inhibition of cyclin kinases may be an alternative approach for treatment of Nephrogenic diabetes insipidus due to vasopressin-2 receptor dysfunction.

**Simvastatin Regulates Aquaporin 2 Trafficking and Urinary Concentration: Role of Actin Modulation Via Rho GTPase** Wei Li, Richard Bouley, Ying Chen, Toshiyuki Matsuzaki, Paula Nunes, Udo Hasler, Dennis Brown, Hua Ann Jenny Lu. *Medicine, Massachusetts General Hospital /Harvard Medical School, Boston, MA.*

Statins are 3-hydroxyl-3-methyglutaryl (HMG)-coA reductase inhibitors that are commonly used to inhibit cholesterol biosynthesis. Emerging data have suggested that they also have "pleotropic effects" including modulating actin cytoskeleton reorganization. Here, we report the role of simvastatin in the trafficking of aquaporin 2. Specifically, simvastatin induced the membrane accumulation of AQP2 in cell cultures and kidneys in situ. The effect of simvastatin was independent of protein kinase A activation and phosphorylation at AQP2-ser256, a critical event involved in vasopressin (VP) regulated AQP2 trafficking. Further investigation showed that simvastatin inhibited endocytosis and induced actin reorganization in parallel with down regulation of RhoA activity. Overexpression of active RhoA abolished simvastatin's effect on AQP2 trafficking, suggesting the involvement of this small GTPase in simvastatin mediated AQP2 trafficking. Finally, the effect of simvastatin on urinary concentration was investigated in VP-deficient Brattleboro rats. Simvastatin acutely (3-6 hours) increased urinary concentration and decreased urine output in these animals. In summary, simvastatin regulates AQP2 trafficking in vitro and urinary concentration in vivo via events involving down regulation of Rho GTPase activity, modulation of the actin cytoskeleton, and subsequent inhibition of endocytosis. Our study provides an alternative mechanism to regulate AQP2 trafficking, bypassing the VP/vasopressin receptor signaling pathway.

### SA-FC423

**Reduced Rab5 Prenylation Might Explain the Lovastatin-Induced Accumulation of AQP2 at the Apical Plasma Membrane in Renal Cells** Giuseppe Procino, Claudia Barbieri, Monica Carmosino, Maria Grazia Mola, Giovanna Valenti, Maria Svelto. *Department of General and Environmental Physiology, University of Bari, Bari, Italy.*

We have previously shown that treatment with lovastatin accumulates the water channel AQP2 at the apical plasma membrane of cultured MCD4 renal cells by inhibiting its constitutive endocytosis. This observation might be of importance to rescue AQP2 apical expression in X-linked NDI. Here we propose a mechanism that might explain this effect.

In addition to inhibiting cholesterol synthesis, statins also inhibit the synthesis of other sterol and non-sterol intermediate compounds produced by the mevalonate pathway including the isoprenoids, farnesyl- (FP) and geranylgeranyl-pyrophosphate (GGP). Proteins of the Rab GTPase family must be post-translationally prenylated by addition of two geranylgeranyl moieties in order to be properly targeted to membranes and to be active. Members of the Rab family, including Rab5, were found associated with immunoisolated AQP2 storage vesicles. Rab5 is expressed in early endosomes and in chlatrin-coated endocytic vesicles suggesting a role in regulating AQP2 endocytosis at the plasma membrane.

In this study we found that, in MCD4 cells, mevalonate prevented apical accumulation of AQP2 induced by lovastatin incubation as demonstrated by confocal microscopy. Interestingly, similar results were obtained by provision of GGP, suggesting a role of prenylation in regulating AQP2 trafficking. Measurement of osmotic water permeability, obtained by a calcein-quenching-based assay on FlexStation, confirmed that the increase in water permeability induced by lovastatin treatment was completely abolished by mevalonate or GGP.

In agreement with these results, analysis of Rab5 prenylation under lovastatin treatment, showed that its electrophoretic mobility on SDS-PAGE was slightly reduced, consistent with a reduction of protein isoprenylation. Conversely, addition of mevalonate or GGP prevented Rab5 electrophoretic shift.

Taken together, these data suggest that statins might increase AQP2 apical expression by reducing Rab5 isoprenylation and its association to the apical plasma membrane where it regulates AQP2 endocytosis.

### SA-FC424

**E3 Ubiquitin-Protein Ligases Associated with Regulation of AQP2 Expression in Rat Kidney** Yu-Jung Lee,[1] Jeong Eun Lee,[2] Moon-Chang Baek,[2] Tae-Hwan Kwon.[1] *[1]Dept of Biochemistry and Cell Biology, School of Medicine, Kyungpook National University, Daegu, Republic of Korea; [2]Dept of Molecular Medicine, School of Medicine, Kyungpook National University, Daegu, Republic of Korea.*

Ubiquitination plays a role in the proteasomal degradation of AQP2. We aimed to identify E3 ubiquitin (Ub)-protein ligases in the kidney which are associated with AQP2 regulation. Sprague-Dawley rats were infused with vehicle (n=13), dDAVP for 5 d (n=13), or dDAVP was withdrawn for periods (15 min, 30 min, 1-, 3-, 6-, 12-, or 24-h) after 5 d-infusion (n=46). Total RNA was isolated from inner medulla (IM) for transcriptome analysis and plasma membrane (PM)- or intracellular vesicle (ICV)-enriched fractions of whole kidney were immunoisolated for LC-MS/MS analysis. dDAVP infusion for 5 d (D5d) significantly increased urine osmolality which was maintained during 3 h-withdrawal of dDAVP after 5 d-infusion (D5d-3h). Consistent with this, increased AQP2 expression was

seen in the PM-fractions of D5d and D5d-3h, whereas AQP2 expression in the ICV-fractions further increased after D5d-3h, indicating internalization of AQP2. Transcriptome analysis revealed eighty six genes of E3 ligases and LC-MS/MS analysis demonstrated 16 proteins of E3 ligases. Among them, seven E3 ligases (BRCA1, UBR4, BRE1B, UHRF1, NEDD4, CUL5, and FBX6) were shared. RT-PCR demonstrated mRNA expressions of all the seven E3 ligases in the kidney and immunoblotting demonstrated the changes in expression of the selected E3 ligases (BRE1B, NEDD4, and CUL5) in response to dDAVP stimulation/withdrawal or in lithium-induced NDI. Decreased rate of AQP2 degradation was observed in the mpkCCD cells with siRNA-mediated knockdown of CUL5 compared to control siRNA-transfected mpkCCD cells. Taken together, identified E3 ligases might play a role in the regulation of vasopressin-dependent AQP2 expression.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC425

**Vasopressin Independent Phosphorylation and Trafficking of Aquaporin-2 by Selective E-Prostanoid Receptor Agonists** Emma T. B. Olesen,[1] Helle A. Praetorius,[2] Robert A. Fenton.[1] *[1]The Water and Salt Research Center, Institute of Anatomy, Aarhus University, Denmark; [2]Institute of Physiology and Biophysics, Aarhus University, Denmark.*

Vasopressin increases the water permeability of the collecting duct (CD) acutely by $G_s$ protein-mediated targeting of aquaporin-2 (AQP2) to the apical membrane of principal cells. E-prostanoid receptor types 2 (EP2) and 4 (EP4) are alternative $G_s$ protein coupled receptors expressed in the CD. We investigated the effects of EP2 and EP4 stimulation on apical plasma membrane (APM) abundance and phosphorylation of AQP2 *in vitro*. MDCK cells stably transfected with AQP2 were stimulated with either PGE2, the EP2 receptor agonist butaprost (BUT) or the EP4 receptor agonist CAY10580 (CAY). The effects on AQP2 APM abundance were assessed by cell surface biotinylation. Compared to controls, PGE2 ($10^{-7}$M) increased abundance of AQP2 in the APM and phosphorylation at serine-264 (S264) and serine-269 (S269). The maximum effect on pS269 was reached after 5 minutes, whereas AQP2 accumulation in the APM and pS264 abundance further increased at later time points. The effect of BUT on AQP2 APM abundance and phosphorylation was concentration dependent. A significant increase in AQP2 targeting and phosphorylation occurred at $10^{-8}$M, both of which increased at higher doses of the agonist. Stimulation with either BUT or PGE2 (both $10^{-7}$M, 40 minutes) had similar effects on targeting, pS264 and pS269 abundance. Similarly, the effect of CAY on AQP2 targeting was concentration dependent in the range of $10^{-8}$M to $10^{-5}$M, with a significant increase in AQP2 membrane abundance observed at $10^{-7}$M. In conclusion, in MDCK cells, PGE2 increases phosphorylation of AQP2 at S264 and S269 and selective agonists for either EP2 or EP4 individually mimic the effect of PGE2 on AQP2 targeting. The EP2 selective agonist BUT additionally mimics the effect of PGE2 on pS264 and pS269 abundance. These results may provide further understanding of the concentrating mechanisms of the kidney collecting duct and could have implications for the treatment of nephrogenic diabetes insipidus.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC426

**mPGES-1 Deletion Potentiates Urine Concentrating Capability after Water Deprivation** Zhanjun Jia,[1,2] Gang Liu,[1,2] Tianxin Yang.[1,2] *[1]Internal Medicine, University of Utah, Salt Lake City, UT; [2]Medical Center, Veterans Affairs, Salt Lake City, UT.*

PGE2 plays an important role in regulation of fluid metabolism chiefly via antagonizing vasopressin-induced osmotic permeability in the distal nephron but its enzymatic sources remain uncertain. Among three prostaglandin E synthase (PGES) isoforms cloned thus far, including microsomal PGES-1 (mPGES-1), mPGES-2, and cytosolic PGES (cPGES), mPGES-1 is the only one processing the enzymatic activity in vivo. Present study was undertaken to investigate the potential role of mPGES-1 in regulation of urine concentrating ability after water deprivation (WD). After 24-h WD, wild-type (WT) mice exhibited a significant reduction in urine volume ($0.79 \pm 0.12$ vs.$1.22 \pm 0.22$ ml, $p<0.01$), accompanied by a significant elevation in urine osmolality ($2877.6 \pm 332.3$ vs. $2019.6 \pm 239.3$ mOsm/kg $H_2O$, $p<0.05$) as compared with control groups. In contrast, in response to WD, mPGES-1 KO mice had much less urine volume ($0.374 \pm 0.11$ $p<0.01$) and higher urine osmolality ($3836.3 \pm 523.3$ mOsm/kg $H_2O$, $p<0.05$). By qRT-PCR, renal medullary and cortical COX-2 mRNA in dehydrated WT mice was upregulated by 2.7- and 14-fold, respectively, contrasting to unaltered renal mRNA expression of COX-1 and mPGES-1. WD induced a 2-fold increase in urinary PGE2 output in WT mice ($p<0.05$ vs. WT control), which was completely blocked by mPGES-1 deletion. At baseline, the KO mice had a 30% increase in V2 receptor mRNA expression in the renal medulla but not the cortex as compared with WT controls; the expression was unaffected by WD irrespective of the genotype. In response to WD, renal medullary AQP2 mRNA exhibited a 60% increase in WT mice and an 110% increase in the KO mice ($p<0.05$ vs. WT) whereas the increases in renal cortical AQP2 mRNA were comparable between the genotypes so was NKCC2 mRNA. Immunoblotting confirmed increased renal medullary AQP2 protein abundance in the KO mice after WD. Taken together, these results suggest that mPGES-1-derived PGE2 via COX-2 activity inhibits urine concentrating ability during water deprivation likely through suppression of renal medullary expression of V2 receptors and AQP2.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC427

**Mice Lacking P2Y2 Receptor Are Resistant to Potassium (K)-Depletion Induced Polyuria** Bellamkonda K. Kishore,[1] Jeff M. Sands,[2] Yue Zhang,[1] Christopher F. Martin,[2] Janet D. Klein.[2] *[1]Medicine, Nephrology Div., VA Med Ctr & Univ. of Utah, Salt Lake City, UT; [2]Medicine, Renal Div., Emory Univ., Atlanta, GA.*

K-depletion and hypokalemia impairs urinary concentration ability. It is associated with decreased AQP2, NKCC2 and UT-B, but increased UT-A2 protein abundances in the medulla (Elkjaer et al, *AJP Renal* 283:F1376, 2002; Jung et al, *AJP Renal* 285: F1210, 2003). The P2Y2 receptor plays a significant overarching role in urinary concentration by apparently regulating the protein abundances of AQP2, NKCC2 and UT-A isoforms (Rieg et al, *FASEB J* 21:3717, 2007; Zhang et al, *AJP Renal* 295: F1715, 2008). Hence, we fed P2Y2 receptor knockout (KO) and wild type (WT) mice with normal or K-free diets for 2 weeks (N = 11/genotype/diet) with free access to drinking water. We assessed their sensitivity to K-depletion induced impairment of urinary concentration. There were no significant differences in the dietary K intake between the two groups. K-depleted WT mice showed a significant increase in urine output (5.2-fold) and decrease in osmolality (to 22%), associated with a marked increase in water intake. In K-depleted KO mice, these alterations were significantly less marked (urine output increased to 1.9-fold; urine osmolality decreased to 41%). Interestingly, K-depletion resulted in significant and comparable 136% increases in UT-A1 protein abundance in inner medulla in both groups, but did not alter the protein abundances of AQP1 in either group. However, K-depletion in KO mice caused a smaller decrease in NKCC2 (-28% in KO vs. -72% in WT; $P < 0.02$, N = 4) and AQP2 (-67% in KO vs. -80% in WT; $P$ = NS, N = 4) protein abundances. The apparent preservation of a K-depletion induced increase in UT-A1 coupled with lesser decreases in NKCC2 and AQP2 may be responsible for the observed resistance to polyuria in mice lacking P2Y2 receptor. Thus, these data suggest purinergic signaling may be involved in K-depletion-induced impairment of urinary concentrating ability.

### SA-FC428

**Regulation of UT-A1 by Phosphatases** Titilayo O. Ilori, Mitsi A. Blount, Jeff M. Sands, Janet D. Klein. *Department of Medicine, Renal Division, Emory University School of Medicine, Atlanta, GA.*

UT-A1 the urea transporter present in the apical membrane of the inner medullary collecting duct (IMCD), are crucial to the kidney's ability to concentrate urine. Phosphorylation of UT-A1 on serines 486 and 499 is key to its ability to traffic to the plasma membrane, since phosphomutants without these sites are unable to traffic and are unable to transport urea. Equally important is the dephosphorylation process and its impact on trafficking and regulation of urea transporter activity. UT-A1 is hyperphosphorylated in IMCDs that are treated with phosphatase inhibitors. We investigated whether calcineurin (protein phosphatase 2B, PP2B) was able to dephosphorylate UT-A1. IMCDs from Sprague Dawley rats were metabolically labeled with $^{32}$P-orthophosphate and treated with calyculin to inhibit protein phosphatases 1 and 2A (PP1, PP2A) or tacrolimus (FK506) to inhibit calcineurin. UT-A1 was immunoprecipitated from the lysates and proteins were separated by SDS-PAGE. Total phosphorylation of UT-A1 was assessed by autoradiography. The phosphorylation per unit protein was assessed with parallel western blots probed for UT-A1. We also probed western blots with a phospho-specific antibody to pSer486-UT-A1 to determine if serine 486 is a site of hyperphosphorylation in response to inhibition of the different phosphatases. Our findings show that the inhibition of PP1 and 2A resulted in overall increased phosphorylation of UT-A1. However, using the phopho-specific antibody, we did not detect any significant increase in phosphorylation at serine 486. Inhibition of calcineurin with tacrolimus, on the other hand showed an increased phosphorylation per unit protein at serine 486 compared with controls or calyculin treatment. We conclude that UT-A1 is a substrate for multiple phosphatases and that the PKA-phosphorylated serine 486 is dephosphorylated by calcineurin. This is the first documentation of the role of phosphatases, and of the specific site of phosphorylation of the urea transporter, in response to treatment with tacrolimus.

**Dissecting Microtubule-Dependent Vasopressin Type 2 Receptor Internalization and Trafficking Using a New High Affinity Fluorescent Vasopressin Ligand** Richard Bouley,[1] Sylvia Chen,[2] Matthew J. Webber,[1] Jean-Pierre Vilardaga,[2,3] Ashok Khatri,[2] Dennis Brown,[1] Dennis A. Ausiello.[1] *[1]Program in Membrane Biology, Nephrology Division, Massachusetts General Hospital, Boston, MA; [2]Endocrine Unit, Massachusetts General Hospital, Boston, MA; [3]Department of Pharmacology and Chemical Biology, University of Pittsburgh, Pittsburgh, PA.*

The vasopressin receptor type 2 (V2R) is the major target of vasopressin (VP). Understanding molecular mechanisms involved in V2R downregulation is, thus, important for human biology. Previously we showed that VP induces V2R internalization and degradation, as well as accumulation in a perinuclear area. The identification of proteins

modulating V2R intracellular pathways remains elusive. To address this question, we synthesized 9 fluorescent VP analogues tagged by tetramethylrhodamine (TMR) in position 8 of VP. One of these VP-TMR compounds has a high binding affinity (Ki =157±52 nM, n=3) and mediated V2R internalization in LLC-PK1 cells expressing either a FLAG-tagged receptor (FLAG-V2R) or V2R C- terminally tagged with GFP (V2R-GFP). Internalized VP-TMR colocalized with V2R-GFP in the perinuclear area suggesting that the hormone and receptor traffic along the same pathway. VP-TMR and V2R colocalized initially with early endosome markers such as early endosome antigen 1 (EEA1), small G-protein (Rab5), and later, with recycling and late endosome markers such as Rab11 and Rab25. We then investigated the mechanism by which VP-TMR is distributed to these compartments using total internal reflection fluorescence (TIRF) microscopy and real-time spinning disk confocal microscopy on LLC-PK1 cells expressing GFP tagged microtubules (MT). These live cell studies showed that VP-TMR-containing vesicles travel along the MT network, and remain attached to microtubules during metaphase and anaphase of cell mitosis. Colchicine, a MT depolymerizing agent, abolished perinuclear accumulation of VP-TMR, and western blotting showed that VP-induced V2R-GFP degradation is greatly reduced by colchicine (10μM). We conclude that VP induced V2R trafficking and downregulation is a microtubule dependent mechanism.

**Characterization of a Rat Model with Suppressed V2 Vasopressin Receptor Signalling in Thick Ascending Limb and Distal Convoluted Tubule** Kerim Mutig,[1] Michael Bader,[2] Turgay Saritas,[1] Tordis Ida Borowski,[1] Alexander Paliege,[1] Shinichi Uchida,[3] Sebastian C. Bachmann.[1] *[1]Department of Anatomy, Charité Universitätsmedizin, Berlin, Germany; [2]HELIOS Clinics and Max Delbrück Center for Molecular Medicine, Berlin, Germany; [3]Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan.*

Vasopressin (AVP) promotes urinary concentration by activating the vasopressin V2 receptor (V2R). Major expression of V2R was localized to the thick ascending limb (TAL), distal convoluted tubule (DCT), and collecting duct. Inactivating mutations in the V2R gene result in X-linked form of Nephrogenic Diabetes Insipidus (NDI) with loss of renal urine concentrating ability. To discriminate between the pathogenic mechanisms originating from the collecting duct and distal tubule a transgenic rat model with selective overexpression of a dominant-negative mutant of V2R (Glu242 stop; identified in human patients with NDI) in TAL and early DCT under the control of the Tamm-Horsfall protein promoter was generated. Overexpression of the mutated V2R was confirmed by immunohistochemistry and Western blot. Compared to control rats transgenic rats displayed polyuria (+50% at steady state and +250% under water deprivation for 18h; $p<0.05$); urine osmolality was decreased to half in both conditions ($p<0.05$). Kidneys had reduced medullary volume chiefly in inner stripe and revealed fibrotic foci within medullary rays. Transcriptional and protein levels of the major distal ion cotransporters were markedly reduced (NKCC2 -55% and –64% respectively; $p<0.05$) and NCC (-76% and -48%, respectively; $p<0.05$).

These data indicate that suppression of V2R signalling in TAL and early DCT results in impaired urine concentration and therefore contributes to the pathogenesis of X-linked NDI.

### SA-FC431

**Is Treating Transplant Glomerulopathy Futile?** Jack W. Galliford,[1] Candice A. Roufosse,[2] Vassilis Filiopoulos,[1] Kakit Chan,[1] Michelle Willicombe,[1] Christopher Lawrence,[1] Adam Mclean,[1] H. Terence Cook,[2] David Taube.[1] *[1]West London Renal and Transplant Centre, Imperial College Kidney and Transplant Institute, London, United Kingdom; [2]Department of Histopathology, Imperial College NHS Trust, London, United Kingdom.*

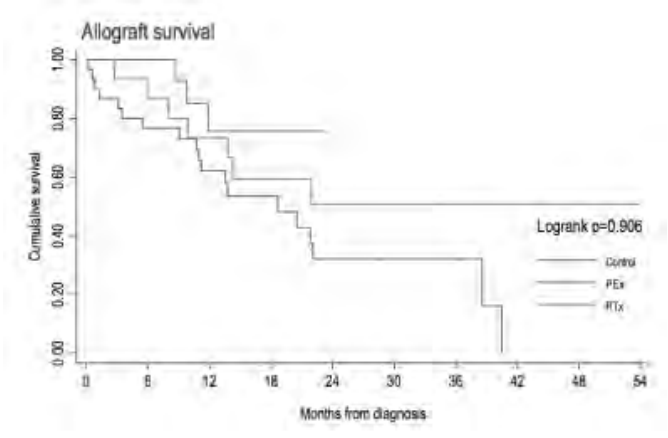
Transplant Glomerulopathy[TG] is a common cause of late allograft failure and there is no established treatment. Small studies have shown that enhanced immunosuppression, including Rituximab[Rtx], may slow progression of TG but with significant adverse events.

This study, the largest to date, describes our medium term experience of 3 treatment strategies for TG; defined after indication biopsy by double contours in gbm on light microscopy(cg1-3)without an immune complex GN or any other clear cause of TMA.

63 patients were diagnosed with TG [36M,27F;mean age 48±12 years].48% had class II DSAb,17% had class I+II and 8% class I alone.40/63 had a urinary PCR≥100;10/63≥300.

30 TG patients[19M,11F]receiving Tac[5-8ng/ml]and MMF[1.2-2.4 mg/l]without steroids acted as a control group. Fifteen patients[6M,9F]had Tac, MMF and Rtx[1g day 0&14]. A further 18 patients[11M,7F]had Tac, MMF and courses of plasma exchange[Pex] with ivIg.

Cumulative allograft survival shows none of the 3 strategies improved allograft survival; 15% overall at 4 years.



Control and Rtx groups had higher creatinines at diagnosis than Pex group [236±80&231±69vs169±53umol/l;p=0.002]but subsequent deterioration was the same in all groups at 3.3umol/l/month. There was no difference in outcome according to graft age, DSAb, proteinuria[logrank=0.63], %IFTA[logrank=0.35] or focal/diffuse C4d[logrank=0.28]. 1/30[3%]patients in control group had a serious infection,3/15[20%] in Rtx group with 1 death from sepsis and 2/18[11%]in Pex group.

This study shows that the addition of Rtx or Pex with ivIg does not alter the outcome of TG and may be associated with a significant risk of serious infection.

### SA-FC432

**Interstitial Fibrosis Evolution on Early Sequential Routine Renal Allograft Biopsies Using Quantitative Analysis** Aude Servais,[1] Vannary Meas-Yedid,[2] Laure-Helene Noel,[1] Panterne Clarisse,[3] Julien Zuber,[1] Marc-Olivier Timsit,[1] Christophe M. Legendre,[1] Eric Thervet.[1] *[1]Necker Hospital; [2]Institut Pasteur; [3]CENTAURE.*

INTRODUCTION. Renal interstitial fibrosis (IF) is the main histopathological feature of chronic allograft injury (CAI). Whereas currently assessed by semi-quantitative analysis, automatic color image analysis is more reliable and reproducible. The aim of this study was to assess quantitative IF on sequential routine renal biopsies (RB) after transplantation.

METHODS. We analyzed RB performed at day 0 (D0), month (M) 3 and M12 from 141 renal transplant recipients. For each biopsy, stained by light green trichrome, a cortical section was analyzed by a program of color segmentation imaging which automatically extracts green color areas characteristic of IF. Clinical and biological data between D0 and M48 were collected including estimated glomerular filtration rate (eGFR) by MDRD.

RESULTS. Mean IF score is 19±9% at D0, 27±11% at M3 and 34±11% at M12. We observe a progression of 8% from D0 to M3 and of 6% from M3 to M12. Mean eGFR is 57.3±19.5 ml/min/1.73m2 at M3, 56.7±19.2 at M12, and 50.6 ±17.9 at M48. IF at M3 is correlated with eGFR at M3, 12, and 24 ($p<0.03$) and IF at M12 with eGFR at M12 and 48 ($p<0.04$). IF evolution between D0 and M3 (ΔIF D0-M3) is correlated with eGFR at M24, 36, and 48 ($p<0.03$).

IF at M12 is significantly correlated with blood concentration of tacrolimus at M6 and M9 (P=0.05). Risk factors of IF at M12 are donor age (P=0.04), donor sex (female 29% vs male 34%, P=0.02), acute rejection episode (36 vs 30%, P=0.01). ΔIF D0-M3 is correlated with donor age (P=0.01), donor sex (female 5% vs male 10%, P=0.04), delayed graft function (13 vs 6%, P=0.02), acute rejection episode (15 vs 6%, P=0.002), and diabetes (13% vs 7%, P=0.03).

CONCLUSION. Significant IF score is already present before transplantation. Evolution of IF is more important between D0 and M3 vs M3 and M12. Initial quantified IF progression is predictive of 4-year allograft function. IF scoring as a continuous variable allows the use of more sensitive approaches to statistical analysis than semi-quantitative analysis.

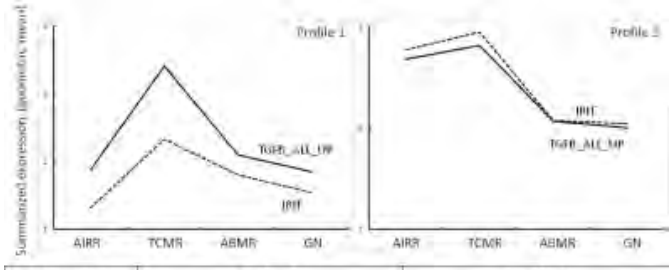
### SA-FC433

**Active Injury Repair Response in Human Kidney Transplants: Elevated Expression of Injury/Repair and Fibrogenesis Genes Associates with Good Recovery of Function and Prognosis** Konrad S. Famulski, Declan G. de Freitas, Philip F. Halloran. *Alberta Transplant Applied Genomics Centre, University of Alberta, Edmonton, AB, Canada.*

Repair of injured tissue reminisces the wound healing, where the pro-fibrotic processes and matrix remodeling play important role. We hypothesized that elevated expression of injury/repair induced transcripts will be accompanied by the emergence of TGFB-inducible transcripts and both will be the feature of healing grafts. Thus we studied expression of these genes and graft function in injured but non-rejecting human kidneys with early ATN (AIRR), in rejecting kidneys (acute TCMR, ABMR) and in non-rejecting with GN. Recovery of function and prognosis was best in the AIRR kidneys and kidneys with TCMR.

| Diagnosis | AIRR (ATN) | TCMR | ABMR | GN |
|---|---|---|---|---|
| Delta eGFR at 6 month post biopsy | 23.7 | 12.5 | -3.1 | -6.7 |
| Graft loss (censored) | 1/28 | 0/23 | 8/17 | 6/24 |

Gene expression studies revealed distinct expression patterns of genes involved in the injury/repair response (in house set: IRIT) and TGFB-inducible genes (MSigDB: TGFB_ALL_UP) across the four groups of transplants.



| Functions and genes | Profile 1 | Profile 2 |
|---|---|---|
| Diseases (IPA) | Cancer | Connective tissue disorder |
| Functions (IPA) | Cellular movement, cell death | Cell assembly and organization |
| Cellular component (GO) | Extracellular matrix | Collagen |
| Correlation with fibrosis | no | no |
| Top genes | C3, CP, MMP7, TNC , VCAN | COL1A1, COL1A2, COL3A1, COL6A3 |

Both profiles represent genes highly expressed in either TCMR or both AIRR and TCMR, but not in ABMR or GN. There was no correlation of the extent of fibrosis with the expression profiles. Thus similar active injury response takes place regardless of underlying insult and includes activation of genes related to cell death, matrix remodeling, TGFB effects and fibrogenesis. Importantly, restrained expression of these genes is observed in high risk kidneys with bad recovery, indicating stunned injury repair response in the presence of persistent stress. Thus elevated expression of injury/repair genes and profibrotic genes, and even of those associated with tissue disorders does not necessary lead to fibrosis and is beneficial in healing kidneys.

## SA-FC434

**Results of a Prospective Screening Protocol for *De Novo* Donor-Specific Antibody Development after Kidney Transplant** James E. Cooper, Ryan J. Goldberg, Jane Gralla, Laurence Chan, Alexander C. Wiseman. *Renal Division, Transplant Center, University of Colorado at Denver and Health Sciences Center, Denver, CO.*

Background: Development of *de novo* donor-specific antibodies (DSA) after kidney transplantation has been associated with poor long-term outcomes. Our study is the first to utilize a prospective DSA screening protocol to evaluate the timing, characteristics, and clinical outcomes associated with DSA development in transplant recipients.

Methods: All recipients of living or cadaveric kidney or cadaveric kidney/pancreas transplants from 9/07 to 9/09 were screened for class I and II DSA at 1, 6, 12, and 24 months post-transplant, in addition to whenever clinically indicated, using single antigen beads and Luminex® technology (LABScreen beads, One Lamda Inc.). A mean florescence intensity (MFI) of >500 was defined as positive DSA.

Results: Of 246 patients without pre-existing DSA that underwent kidney or kidney/pancreas transplant at our center from 9/07 to 9/09, de novo DSA was detected in 61 (24.8%). 29% of all DSA were class I and 71% were class II. DSA was first detected by protocol screening in 80%, and by clinical suspicion in 20%. In those first detected by protocol, 87% of all new DSA occurred in the first 6 months. Baseline characteristics between DSA (+) and DSA (-) groups were similar. The mean follow up time was 1.5 years. Clinical outcomes are shown in the table below.

Clinical Outcomes in DSA (+) and (-) Groups

| Outcome | All Patients (n=246) | DSA (-) (n=185 ) | DSA (+) (n=61) | P |
|---|---|---|---|---|
| Patient Survival (%) | 98 | 97 | 98 | NS |
| Graft Survival (%) | 96 | 98 | 92 | .05 |
| Rejection (all) (%) | 14 | 9 | 28 | <.001 |
| Rejection (Cellular) (%) | 12 | 9 | 20 | .03 |
| Rejection (Humoral) (%) | 2 | 0 | 8 | <.001 |
| 12 mo MDRD-GFR | 64 | 67 | 59 | .04 |

Conclusions: Prospective screening for de novo donor-specific antibody production in kidney allograft recipients during the first 6-12 months post-transplant can identify patients at risk for poor graft outcomes. These data support the use of prospective DSA screening as a means of risk stratification in kidney transplant recipients.

## SA-FC435

**Increase in Urinary IL-6 Levels after Kidney Transplantation Indicates Acute Rejection** Jens Gaedeke, Friederike Bachmann, Hans-Hellmut Neumayer, Klemens Budde. *Nephrology, Charité, Universitätsmedizin Berlin, Berlin, Germany.*

Increase in urinary IL-6 levels after kidney transplantation indicates acute rejection. Despite marked improvement in long term kidney transplant survival, acute rejection episodes remain an obstacle to longterm transplant survival.

Diagnosis (biopsy) and treatment can be delayed when the patient is taking oral anticoagulants (warfarin, aspirin, clopidogrel). Interleukin- 6 (IL-6) is a cytokine which is produced by infiltrating cells in the kidney. We investigated whether an increase in urinary IL-6 levels predicted an acute rejection.

We prospectively measured IL-6 levels in urine of 27 patients after de novo kidney transplantation. In addition, we analyzed patients referred from the outpatient clinic because of graft dysfunction (n= 73).

Twenty healthy individuals served as controls. Urine samples were collected as spot urine. All transplant patients received basic immunosuppressive therapy consisting of prednisolone, mycophenolic acid, cyclosporin or tacrolimus and induction with basiliximab.

The mean IL-6 concentration in healthy individuals was 2±4 pg/ml.

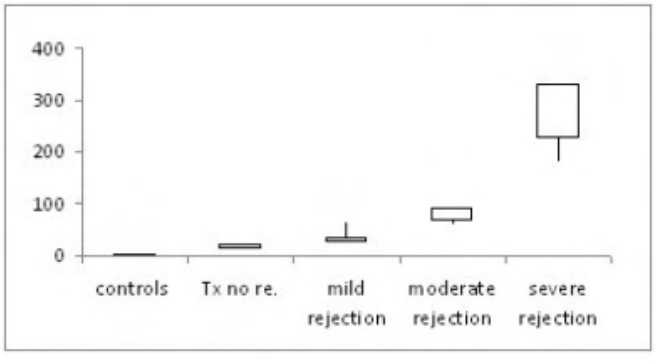
Patients with mild rejection (BANFF Ia) showed lower lower IL-6 concentrations (23,9 ±1,3 pg/ml) compared to moderate acute rejections (BANFF Ib / IIa 15.3±12.9 pg/ml ) and severe acute rejection (BANFF IIb/III, 363±303 pg/m).

After successful rejection treatment IL-6 concentrations returned towards baseline.

In case of therapy resistant rejection elevated IL-6 concentrations persisted.

Patients with non-rejecion-mediated graft dysfunction like CNI-toxicity had consistently low IL-6 concentrations (4.2±3.2 pg/ml).

Elevated urinary IL-6 concentrations are found in acute rejection. Persisting elevations indicated therapy- resistant rejection, while successful rejection treatment reduced IL-6 concentrations to normal. Urinary IL-6 is of diagnostic and prognostic value for acute rejections.



Disclosure of Financial Relationships: Honoraria: Shire.

## SA-FC436

**Protocol Biopsy Findings in Kidney Transplant Recepients in the Era of Modern Immunosuppression** Viresh Mohanlal, Emilio Ramos, Joseph M. Nogueira, David K. Klassen, Matthew R. Weir, Abdolreza Haririan. *Nephrology, University of Maryland Medical Center, Baltimore, MD.*

**PURPOSE**: The clinical utility of protocol biopsies in kidney transplant recipients remains controversial. The purpose of this study was to examine the prevalence of subclinical rejection and other histological features in renal allograft biopsies at 3 mo and 12 mo post-transplant with modern immunosuppresion (IS), and to assess the progression of histological changes within first year after transplant.

**METHODS:** We studied 114 patients who underwent protocol biopsies at 3.9±1.1 mo and 12.7± 2.7 mo. Biopsy findings were scored according to Banff 2005 criteria. Tacrolimus, MMF and early steroid withdrawal were used for maintenance IS. Biopsies performed for cause were not included in the analysis.

**RESULTS:** Baseline characteristics are summarized in Table 1.

Baseline characteristics

| | |
|---|---|
| Age (yrs) (mean ± SD) | 51.8 ± 13.0 |
| African American (%) | 61(53.5) |
| Male (%) | 70 (61.4) |
| Diabetes Mellitus (%) | 50 (43.8) |
| Preemptive transplant (%) | 39 (33.7) |
| Deceased donor (%) | 85 (74.6) |
| Alemtuzumab (%) | 63 (55.8) |
| Basiliximab (%) | 37 (32.7) |
| Thymoglobulin (%) | 13 (11.5) |
| PRA >40% | 14 (15.2) |
| HLA mismatch (mean ± SD) | 4.3± 1.6 |

Mean creatinine at 3 and 12 mo was 1.7 and 1.9 mg/dl respectively. The incidence of subclinical rejection was 15% at 3 mo and 9% at 12 mo respectively. IF/TA was noted in 60% of patients at 3 mo and 65% at 12 mo, with severe IF/TA in 5% at 3 and 12 mo. IF/TA progressed in 20% of patients and arteriolar sclerosis and hyalinosis progressed in 19% and 9% respectively. Glomerulitis was noted in 5 patients at 3 mo and 4 at 12 mo. 4

patients at 3mo and 3 at 12 mo had diffuse PTC C4D and DSA positivity. Interestingly. Transplant glomerulopathy was evident in 1 patient at 3mo and in 2 at 12mo. BKN was found in 2 patients at 3 mo and 12mo.

**CONCLUSIONS:** Our experience shows that even with modern IS, protocol biopsies reveal significant subclinical histological changes which could guide adjustment in maintainance IS. Further studies are needed to examine the impact of biopsy-guided IS modulation on long term renal allograft survival.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC437

**Complement Fixing Donor Specific Class II Antibodies Predict a High Rate of Rejection Episodes in Renal Retransplantation Patients** Anil Chandraker, Isabelle G. Wood, Nabil Mohsin, Nidyanandh Vadivel, Edgar L. Milford. *Renal Division, Brigham and Women's Hospital, Boston, MA.*

Aim: Retransplanted patients are at high risk for rejection. One known risk factor is the presence of anti-HLA antibodies. We investigated whether donor specific HLA antibodies (DSA) which bind complement predict rejection in these patients.

Method: We analyzed the likelihood of rejections during the first year in 103 renal retransplant patients between 1993 and 2000 in 13 centers in New England. Pretransplant sera were analyzed by standard solid phase screening for DSA class I and II (Luminex, One Lambda). Furthermore, we modified the single antigen (SA) solid phase screening technique (CmDSA I & II) to detect human complement binding. CmDSA was performed with the addition of a human complement source followed by mouse anti-C4d and anti-mouse phycoerythrin. The T cell anti-human globulin enhanced cytotoxic crossmatch (CDC) at the time of transplantation was the sole exclusionary test for transplantation. Rejection was defined as clinical or biopsy proven. Early loss of a previous transplant (PEL) was defined as graft failure within 3 months. Kaplan-Meier, Log-Rank was used for statistical analysis.

Results: Retranplant patients had significantly higher rates of rejection when their pretransplant sera contained complement binding anti-HLA class II (CompDSA II). Such difference was not noted for the CmDSA I.

% Likelihood of Rejection Episode at 1 Year

| | TFXM (+/-) | BFXM (+/-) | DSA ClassI (+/-) | DSA ClassII (+/-) | Cm DSA I (+/-) | Cm DSAII (+/-) |
|---|---|---|---|---|---|---|
| ALL (N=103) | 69/37* | 66/32** | 47/33* | 48/45* | 38/48 | 67/32* |
| PEL (N=41) | 100/41** | 89/36** | 52/42 | 66/36 | 50/50 | 89/40 |
| non-PEL (N=57) | 49/31 | 43/55 | 37/30 | 37/31 | 30/41 | 46/30 |

PEL:Previous early graft loss; **:p<0.01; *:p<0.05

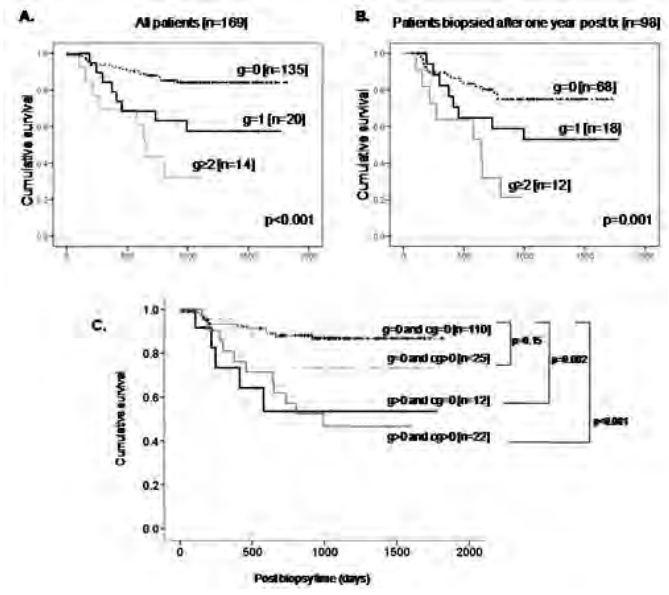
Conclusions: The modified CmDSA II may be useful in predicting increased risk of rejection in candidates for renal transplantation. Lack of significance in PEL patients p<.07 is likely due to small numbers. The CmDSA I was not significant most likely due to the exclusion of patients by CDC T cell crossmatches. The Flow crossmatch results TFXM and BFXM assay are also predictive of rejection.

Disclosure of Financial Relationships: Consultancy: T2 BiosystemsResearch Funding: Dialysis Clinic Incorporated; Other Relationship: Novartis – DSMB.

### SA-FC438

**Glomerulitis: Stronger Indicator of Molecular Rejection Than Tubulitis or Vasculitis, and Stronger Predictor of Outcome Than C4d or Transplant Glomerulopathy** Banu Sis,[1] Gian S. Jhangri,[1] Julie Riopel,[1] Jessica Chang,[1] Michael Mengel,[1] Declan G. de Freitas,[1] Luis G. Hidalgo,[1] Gunilla Einecke,[2] Bruce Kaplan,[3] Philip F. Halloran.[1] *[1]University of Alberta, Edmonton, AB, Canada; [2]Medizinishe Hohschule, Hannover, Germany; [3]University of Arizona, Tucson, AZ.*

The significance of glomerulitis in kidney transplants and its relationship to diseases remain obscure. We related glomerulitis to whole-genome microarrays, histopathology, and survival in 221 renal allograft biopsies for cause from 169 patients with a median follow-up of 32.1 months. We investigated the relationship between glomerulitis and probability of rejection assigned by a microarray-classifier. Glomerulitis was more frequent in late biopsies (>1 year), and in antibody-mediated rejection (ABMR), either C4d-positive (71%) or negative (52%), than in T cell-mediated rejection (TCMR) (25%) or other diseases (6-18%). IFNG-regulated transcript expression, capillaritis, and transplant glomerulopathy (TG) independently correlated with glomerulitis. Glomerulitis predicted poor survival if accompanied by alloantibody (C4d+/-), but not TCMR. Glomerulitis +/- TG predicted poor outcome, but TG without glomerulitis did not.



In a classification tree model, interstitial inflammation was the strongest predictor of molecular rejection and followed by glomerulitis within any given degree of interstitial inflammation, but not tubulitis or vasculitis. In multivariate logistic regression, interstitial inflammation (OR:3.01) and glomerulitis (OR:2.68) showed higher risk of molecular rejection compared to tubulitis (OR:1.79) or vasculitis (OR: 2.42). We conclude that glomerulitis is a stronger predictor of rejection than tubulitis or vasculitis and is better than C4d or TG to predict graft outcomes.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC439

**De Novo Donor Specific Antibodies Are Associated with Antibody Mediated Rejection in Patients Receiving Alemtuzumab Induction** Michelle Willicombe, Paul Brookes, Eva Santos, Jack W. Galliford, Adam Mclean, Candice A. Roufosse, Tom Cairns, David Taube. *Imperial College Kidney and Transplant Institute, London, United Kingdom.*

De novo donor specific antibodies [DSAbs] post renal transplant have been shown to be associated with rejection, allograft dysfunction and loss, in studies conducted in patients receiving a variety of induction and maintenance immunosuppressive agents with no reports referring to the use of Alemtuzumab. In this study we describe the significance of de novo DSAbs in patients receiving Alemtuzumab induction and Tacrolimus monotherapy.

435 patients [f:m=141:294, mean age: 47.44±13.14 yrs, mean HLA MM: 3.26±1.66, 1st graft: regrafts = 400:35] who were crossmatch and DSAb negative at the time of transplantation were included. Patients were screened for the development of DSAb post transplant using single antigen beads. Mean follow up was 1.69±1.16 yrs.

131/435 [30.11%] patients developed de novo anti-HLA antibodies post transplant, of which 78/435 [17.93%] developed DSAbs. Patient survival at 3 years was similar in the DSAb+ and DSAb- groups [98.0% vs 96.2%, p=0.42 (log rank)]. Patients with de novo DSAb were at increased risk of graft loss [RR DSA+ 3.5, p=0.0045]. 27/78 [34.62%] of DSAb+ patients experienced an episode of AMR. The relative risk of AMR following the development of DSAb was 17.13, p<0.0001. Allograft function was inferior in the DSAb+ group with a mean MDRD GFR at 12 months of 52.86 ±19.83mls/min and 58.49 ±17.51mls/min in the DSAb+ and DSAb- respectively [p=0.037].

Patients who developed both de novo anti-HLA Class I and Class II DSAb were at highest risk of developing AMR [RR 3.34, p=0.01] when compared with DSAb negative patients. Recipients who developed a DSAb with a mean fluorescence index [MFI] >1000 were also at higher risk of developing rejection [RR 1.74, p=0.01] when compared to patients with a DSAb with a MFI of <1000.

In patients receiving Alemtuzumab induction, the development of de novo DSAb is not uncommon and is associated with increased risk of AMR and inferior allograft survival. Patients should be screened post transplant for the presence of de novo DSAb and may benefit from augmented immunosuppression.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC440

**Pulsatile Preservation Reduces Apoptosis in a Porcine Model of Kidney Donation after Cardiac Death** Alkesh Jani, Jessica Martin, Kultigin Turkmen, Kameswaran Ravichandran, Danica Ljubanovic, Charles L. Edelstein. *U of Colorado.*

DCD kidneys suffer a high incidence of DGF due to warm ischemia (WI) and cold ischemia (CI). Clinical studies suggest pulsatile preservation (PP) of DCD kidneys may reduce injury. The mechanism of protection of PP is unknown. In a porcine model of DCD, we hypothesized that DCD kidneys have increased caspase-1 due to WI and increased caspase-3 and apoptosis due to CI. **Methods:** Male Yorkshire pigs subjected to cardiac death

were perfused with cold UW solution. Perfused kidneys were removed and stored in cold UW for 24 hrs. Kidney biopsies were obtained before cardiac death and at 0 and 24 hrs of CI. Apoptotic tubular cells/hpf were quantitated by a renal pathologist. Caspase activity was measured using fluorescent substrates. **Results:** Caspase-1 activity due to WI before cold preservation was significantly elevated vs normal (88.3±6.3 vs 59.3±3.6, $p<0.01$, n =5). CI was associated with a massive increase in apoptosis and caspase-3/7 activity.

| Time | 0 hrs | 24 hrs |
|---|---|---|
| Apoptotic tubular cells/hpf | 0.3±0.1 | 8.2±5.9* |
| Caspase 3/7 activity (nmol/min/mg) | 90.5±13.4 | 239.3±104.5* |

n=5; *P < 0.005 vs 24 hr

By immunoblot we determined that active caspase-3 was responsible for the caspase activity.Next we hypothesized that PP would protect against apoptosis.We compared DCD kidneys subjected to static preservation (SP) vs PP for 24 hrs CI. PP significantly reduced proximal tubular apoptosis and was associated with significantly increased anti-apoptotic BCL-XL and HIF-1α.Caspase-3/7 activity was not significantly different between SP and PP.

| | SP | | PP | |
|---|---|---|---|---|
| Time | 0 hrs | 24 hrs | 0 hrs | 24 hrs |
| Apoptotic tubular cells/hpf | 0.2 ±0.1 | 8±2.5 | 0.1 ±0.1 | 2.5 ±1.4* |
| Caspase 3/7 activity (nmol/min/mg) | 84.3 ±20.5 | 453.3 ±307.7 | 88.5 ±33.8 | 466.3 ±234.1 † |
| HIF-1 α activity | 283.8 ±14.7 | 345.9 ±28.2 | 301.8 ±12.6 | 494.4 ±23.4* |
| BCL-$X_L$ immunoblot | + | + | + | ++ |

n=5; *P < 0.05 vs 24 hr SP; †p = NS vs 24 hr SP

**Conclusion:** These findings suggest that in DCD kidneys, WI preferentially activates caspase-1 whereas CI activates caspase-3 and causes apoptosis. PP may protect DCD kidneys via activation of anti-apoptotic pathways involving BCL-XL and HIF-1α.

Disclosure of Financial Relationships: nothing to disclose

### SA-FC441

**Conversion to an Everolimus/Enteric-Coated Mycophenolate Sodium Regimen after Calcineurin Inhibitor Withdrawal in *De Novo* Renal Transplant Patients Improves Renal Function: 2 Years Follow-Up of the ZEUS Trial** Wolfgang Arns,[1] Thomas Becker,[1] Klemens Budde,[1] Ute Eisenberger,[1] Wolfgang Fischer,[2] Stefan Kramer,[2] Claudia Sommerer,[1] Petra Reinke,[1] Frank B. Pietruck.[1] *[1]ZEUS Study Group; [2]Novartis Pharma, Nuremberg, Germany.*

**Objective** In d*e novo* kidney allograft patients (pts) renal function, efficacy and safety was assessed after conversion to an Everolimus/Enteric-coated mycophenolate sodium (EC-MPS) regimen after Cyclosporine (CsA) withdrawal at M24 post-transplantation (tx)

**Methods** In this prospective, open-label, controlled, multi-center study renal allograft pts were randomized to a regimen consisting of either Everolimus/EC-MPS or CsA/EC-MPS at M4.5 after tx. After completion of the core study at M12, pts were included in an observational 12 Month follow-up study.

**Results** 300 pts were randomized to either Everolimus(n=155) or CsA(n=145), 258 (86.0%) pts completed the M24 visit. Renal function expressed as cGFR (Nankivell method) was similar in both groups at M4.5 post-Tx with an improvement by 7.84 mL/min in favor of the Everolimus regimen (p=0.0042) at M24 (61.3±17.2 vs. 69.2±19.0 mL/min). The observed GFR slope from M4.5 to M24 was +6.5[3.1,10.0] for Everolimus and -1.1[-4.8,2.5] mL/min for CsA pts. Similarly GFR slopes with MDRD(+9.0[4.2,13.8]) and Cockcroft-Gault formular (+6.7[3.2,10.3]) were significantly better ($p<0.001$) in the CNI-free regimen (CsA treated pts: MDRD: -1.3[-6.1,3.6]mL/min; Cockcroft-Gault: -1.4[-5.2,2.4]mL/min). Fewer pts in the Everolimus group had a decline of GFR compared to CsA pts (Nankivell: 31.7% vs 53.4%; p=0.0007). BPAR was reported in 17(11.0%) Everolimus vs. 7(4.8%) CsA pts between M4.5 and M24. After M12 two additional BPAR occurred in each group. Three death and one graft loss was observed in the CsA, none in the Everolimus group. Number of pts with infections (Everolimus 35(22.6%) vs. CsA 31(21.4%)) and hospitalization (Everolimus 45(29.0%) vs. CsA 52(35.9%)) in the follow-up period (M12-M24) was comparable.

**Conclusions** The conversion to Everolimus in *de novo* renal transplant pts after CNI withdrawal early after tx significantly maintains renal function over a period of 24 months without compromising efficacy and safety

**Safety Profile of Belatacept in Kidney Transplant Recipients from a Pooled Analysis of Phase II and Phase III Studies** Josep Grinyo,[1] Bernard Charpentier,[2] Jose Medina-Pestana,[3] Yves Vanrenterghem,[4] Flavio Vincenti,[5] Rebecca Shi,[6] Mamta Agarwal,[7] Dolca Thomas,[8] Christian Larsen.[9] *[1]Univ Hosp Bellvitge; [2]Bicetre Hosp; [3]Hosp do Rim; [4]Univ Hosp Leuv; [5]UCSF; [6]BMS; [7]BMS; [8]BMS; [9]Emory Univ.*

**Purpose:** This report focuses on safety outcomes of belatacept vs cyclosporine (CsA) in adult kidney transplant recipients.

**Methods:** Patients (pts) in 3 core studies (1 Phase II, 2 Phase III - BENEFIT & BENEFIT-EXT) were randomized to a more intensive (MI) or less intensive (LI) regimen of belatacept or CsA; all pts received basiliximab induction, and maintenance therapy with MMF and steroids. Safety data through 7/2009 from the 3 studies were pooled for the analysis.

**Results:** 1425 pts were included in the analysis (MI=477; LI=472; CsA=476). Median follow-up was ~2.4 yrs with some pts followed for ~7 yrs. Incidence of death (MI:7%; LI:5%; CsA:7%) and serious adverse events (MI:71%; LI:68%; CsA:69%) was lowest in the LI group. Overall incidence of malignancies remained low, but was slightly higher in the MI group (MI:10%; LI:6%; CsA:7%). Across the 3 studies, 15 PTLD cases occurred (n=8 MI; n=5 LI; n=2 CsA) including 8 involving the CNS (n=6 MI; n=2 LI). Excess PTLD risk was concentrated in EBV(-) recipients and in the MI group. No PTLD cases occurred after 18 mo in the belatacept groups. Frequency of serious infections was similar (MI:37%; LI:32%; CsA:36%). Rates of polyoma (MI:7%; LI:3%; CsA:6%) and fungal infections (MI:22%; LI:17%; CsA:21%) were lower in the LI vs MI or CsA groups. One case of progressive multifocal leukoencephalopathy was reported (MI group). Rates of herpes infections were higher with belatacept (MI:15%; LI:13%; CsA:10%). Tuberculosis occurred in 10 pts (n=5 MI; n=4 LI; n=1 CsA); mostly in endemic areas. No anaphylaxis or hypersensitivity reactions to belatacept were reported.

**Conclusions:** Longer-term treatment with belatacept-based regimens was generally safe. PTLD, including CNS presentation, was higher in belatacept vs CsA, especially in EBV(-) pts and the MI group. Incidence of death and serious infections was lowest in the LI group. The overall safety analysis favored the LI over MI regimen.

### SA-FC443

**Belatacept vs Cyclosporine in Kidney Transplant Recipients: Two-Year Outcomes from the BENEFIT Study** Christian Larsen,[1] Josep Grinyo,[2] Bernard Charpentier,[3] Jose Medina-Pestana,[4] Nassim Kamar,[5] Yves Vanrenterghem,[6] Chen-Sheng Lin,[7] Gregory Dirusso,[7] Pushkal Garg,[7] Flavio Vincenti.[8] *[1]Emory Univ School of Medicine; [2]Univ Hosp Bellvitge; [3]Bicetre Hosp; [4]Hosp do Rim; [5]Univ Hosp Toulouse; [6]Univ Hosp Leuven; [7]BMS; [8]UCSF.*

**Purpose:** To report the efficacy and safety of belatacept vs cyclosporine (CsA) in adult kidney transplant recipients after 2 yrs of treatment in the BENEFIT study.

**Methods**: BENEFIT is a 3-yr, randomized, phase III study in adults receiving a kidney transplant from a living or standard criteria deceased donor. Patients were randomized 1:1:1 to a more intensive (MI) or less intensive (LI) regimen of belatacept or CsA; all patients received basiliximab induction, MMF, and corticosteroids.

**Results**: 666 patients were randomized and transplanted (ITT population); 493 completed 2 years on treatment (n=164 MI; n=176 LI; n=153 CsA). At Yr 2, patient/graft survival was similar across groups (94% MI; 95% LI; 91% CsA). The renal benefit of belatacept was sustained through Yr 2 as evidenced by a 15–17 mL/min higher measured GFR ($p<0.0001$ MI or LI vs CsA) or calculated GFR in the belatacept groups vs CsA. Eight patients experienced an episode of AR between Yrs 1 and 2 (n=4 MI; n=4 CsA). Improvements in the CV and metabolic risk profile seen in Yr 1 with belatacept vs CsA were sustained and an additional beneficial effect on LDL-cholesterol emerged at Yr 2 ($p\leq0.002$ MI or LI vs CsA). The overall incidence rate of malignancies and serious infections remained comparable across groups. Two cases of PTLD (previously reported) occurred between Yr 1 and Yr 2 in the MI group (total cases through July 2009: n=3 MI; n=2 LI; n=1 CsA). The overall safety profile remained similar across groups.

**Conclusion**: At 2 yrs, a belatacept-based regimen demonstrated sustained better renal function and similar patient/graft survival vs CsA. No incremental efficacy was gained by using the MI vs the LI regimen. No new safety signals emerged. Belatacept is a promising therapeutic option in kidney transplant patients.

### SA-FC444

**Belatacept vs Cyclosporine in ECD Kidney Transplants: Two-Year Outcomes from the BENEFIT-EXT Study** Antoine Durrbach,[1] Christian Larsen,[2] Jose Medina-Pestana,[3] Yves Vanrenterghem,[4] Flavio Vincenti,[5] Sander Florman,[6] Jun Xing,[7] Alan Block,[7] Pushkal Garg,[7] Josep Grinyo.[8] *[1]Bicetre Hosp; [2]Emory Univ; [3]Hospital do Rim; [4]Univ Hosp Leuven; [5]UCSF; [6]Mount Sinai Med Cntr; [7]BMS; [8]Univ Hosp Bellvitge.*

**Purpose**: To report the efficacy and safety of belatacept vs. cyclosporine (CsA) after 2 yrs of treatment in the BENEFIT-EXT study.

**Methods**: BENEFIT-EXT is a 3-yr, randomized, phase III study in adults receiving ECD kidney transplant. Patients were randomized 1:1:1 to a more intensive (MI) or less intensive (LI) regimen of belatacept or CsA; all pts received basiliximab induction, MMF, and corticosteroids.

**Results**: 543 pts were randomized and transplanted (ITT); 347 completed 2 yrs on treatment (MI=116, LI=119; CsA=112). Patient/graft survival was similar across groups (83% MI, 84% LI, 83% CsA) at 2 yrs. The renal benefit of belatacept was sustained at Year 2 as assessed by the measured GFR (52 mL/min MI, 50 mL/min LI, and 45 mL/min CsA; p=0.028 MI vs CsA; p=0.108 LI vs CsA) and by the calculated GFR (8-10 mL/min higher in the belatacept groups vs CsA). Three additional episodes of acute rejection occurred after between Yr 1 and Yr 2 (n=1 LI; n=2 CsA). The CV and metabolic risk profile benefits of belatacept vs CsA on serum lipids and blood pressure were sustained. The overall incidence rates of malignancies and serious infections remained comparable across groups. Two previously reported cases of PTLD occurred between yrs 1 and 2 (n=1 MI; n=1 LI; total cases through July 2009 in BENEFIT-EXT: n=2 MI; N=3 LI; n=0 CsA). The overall safety profile remained similar across groups.

**Conclusions**: A belatacept-based regimen maintained better renal function, a better cardiovascular/metabolic risk profile, and similar patient/graft survival vs CsA at 2 yrs. No incremental efficacy was gained by using the MI vs LI regimen. No new safety signals emerged. Belatacept is a promising option in pts receiving ECD kidneys.

## SA-FC445

**ABO Incompatible Renal Transplantation with Conventional Immunosuppression Alone** Rosemary Masterson. *Nephrology, Royal Melbourne Hospital, Melbourne, Victoria, Australia.*

INTRODUCTION

We & others have reported successful ABO incompatible renal transplantation (ABOi) using conventional immunosuppression and removal of anti-blood group antibodies. We report outcomes of 17 patients undergoing ABOi using conventional immunosuppression without antibody removal, including a range of donor/recipient blood group incompatibilities.

METHODS

Patients with low anti-blood group antibody titres at baseline (diamed gelcard ≤ 8 (median 4), orthomed ≤ 32 (median 8), tube ≤ 128 (median 32)) were included in the study. Immunosuppression consisted of Mycophenolate Mofetil (MMF) initiated at Day 7 pre transplant, Basiliximab induction, Tacrolimus & Prednisolone. Median Tacrolimus levels were 7ng/ml, 6ng/ml and 4ng/ml at 1,3 and 12mths respectively. Prednisolone was tapered to 5mg and MMF to 1-1.5g per day by 3 months. No patients had antibody removal, splenectomy or Rituxumab therapy.

RESULTS

17 patients met study criteria with a median follow up of 18 months (1 week-33 months) post transplantation. Incompatibilities were B to A (n=7), $A_1$ to O (n=3), B to O (n=2), A1 to B (n=2), $A_2$ to O (n=1), AB to A (n=1), AB to A (n=1).

Excellent (100%) patient & graft survival was observed. Median serum creatinine: 98umol/l (80 -132 umol/l); median eGFR 66mls/min (48 - 91mls/min). One episode of subclinical borderline cellular rejection was found on 3 month protocol biopsy with no episodes of antibody mediated rejection being detected. Protocol biopsies performed on 14 patients at 3 and 12 months respectively showed all to be histopathologically C4d negative with no evidence of transplant glomerulopathy.

No opportunistic infections or malignancies were diagnosed and only one patient developed diabetes post transplantation.

CONCLUSION: Excellent patient and graft outcome can be achieved in selected patients with low titre anti-blood group antibodies using standard immunosuppression alone. In addition to cost saving benefits, this strategy reduces the risk of over immunosuppression in this selected patient cohort.

## SA-FC446

**Silent Development of *De Novo* Anti HLA Antibodies Following Transplantation Is Associated with Histological Changes in the Allograft. Interim Report on Behalf of the CTOT-02/CCTPT-02 Study** Sacha A. De Serres,[1] Bechara G. Mfarrej,[1] Indira Guleria,[1] Nader Najafian,[1] Yvonne R. Morrison,[3] Flavio G. Vincenti,[2] William E. Harmon,[1] Mohamed H. Sayegh,[1] Anil Chandraker.[1] *[1]Transplantation Research Center, Brigham and Women's Hospital and Children's Hospital Boston, Harvard Medical School, Boston, MA; [2]UCSF, San Francisco, CA; [3]NIH/NIAID/DAIT, Bethesda, MD.*

The clinical relevance of monitoring solid organ recipients for the development of anti-HLA alloantibodies (Abs) is unknown and the importance of class I *vs.* II Abs remains unclear. Over 650 subjects have been enrolled in the screening phase of the NIH CTOT-02/CCTPT-02 study, a multi-center prospective trial where unsensitized kidney transplant recipients are screened for development of *de novo* anti-HLA Abs post transplant. The aim of this report is to look at possible associations between Abs and gender, donor type, induction, HLA mismatch (MM) and DGF and correlate development with concurrent histology. Abs were detected by Luminex and the analysis was performed using log-rank statistics and univariate cox model.

49 subjects developed Abs: 22, 35 and 8 subjects developing class I, class II or both class I & II Abs. Unexpectedly, among the 75 zero MM subjects, 6 developed Abs, but only against class I (HR 2.9; p=0.03 *vs.* at least 1MM). Female gender was associated with class II conversion (HR 1.9; p=0.05). There was a trend for an association between class II conversion and the use of any induction therapy (p=0.09). This association was not confounded by MM status; 94% of subjects with zero MM received induction therapy, similarly to MM subjects. There was no association between Ab development and donor type or DGF. Biopsy results were available for 12 subjects prior to randomization to the treatment phase of the study. 5/12 showed evidence of borderline/acute rejection; all positive for class II, none for class I Abs (p=0.01).

This interim analysis of CTOT-02 suggests important differences in the baseline characteristics and the clinical impact associated with anti-HLA Abs. Longitudinal and mechanistic studies are underway to characterize the immunological profile and clinical outcome post-Ab conversion.

## SA-FC447

**The Influence of Co-Administered Omeprazole on the Bioavailability of Mycophenolate Mofetil (MMF) in Healthy Volunteers** Frieder Kees,[1] Korbinian Johannes Rupprecht,[1] Stefan Moritz,[2] Thomas Steinke,[2] Michael Bucher,[2] Lothar Faerber.[1,3] *[1]Dept. of Pharmacology, University of Regensburg; [2]Clinic of Anesthesiology and Surgical Intensive Care, University Hospital Halle; [3]Novartis Pharma, Nuremberg, Germany.*

**Aim** Prior studies showed co-administered pantoprazole decreases the bioavailability of mycophenolic acid (MPA) from MMF in healthy volunteers and in renal transplant patients. The aim was to investigate the interaction with omeprazole (OME), another member of proton pump inhibitors (PPIs), and to elucidate the mechanism of the drug-drug interaction

**Methods** In a cross-over study 12 healthy volunteers (6m/f) received one dose of 1000mg MMF with and without OME (20mg bid 4 days prior to MMF intake). Blood was sampled up to 48h and MPA concentrations were measured. PK parameters were evaluated for differences using the paired Student's t-test ($P<0.05$ significant) and treatments were tested for bioequivalence. Dissolution of MMF 500mg tablets was determined using an USP paddle apparatus (37°C, 50rpm) in 900ml aqueous buffer of pH1-7 and measured spectrophotometrically

**Results** *In vitro*, the dissolution of MMF decreased from 100% at pH1-4 to 47% at pH5, 25% at pH5.5, 15% at pH6 and 13% at pH7, respectively. Co-treatment of MMF with OME led to a significant decrease in MPA exposure. Mean $c_{max}$ of MPA decreased by 50% and $AUC_{12h}$ by 35%. Bioequivalence was not proven neither for $c_{max}$ nor for $AUC_{12h}$ of MPA. Due to remarkable enterohepatic cycling of MPA, resulting in long-lasting low MPA plasma concentrations, $AUC_{48h}$ were 10% lower and $AUC_{\infty}$ plus $c_{12h}$ were not altered.

| | MMF/OME | MMF | p |
|---|---|---|---|
| cmax(µg/ml) | 10.5±3.6 | 21.7±9.9 | 0.001 |
| tmax(h) | 1.2±0.5 | 0.6±0.2 | 0.003 |
| t1/2(h) | 17.7±5.4 | 12.2±2.8 | 0.006 |
| AUC12h(µg/ml*h) | 25.8±6.4 | 40.0±7.8 | 0.024 |
| AUC48h(µg/ml*h) | 51.3±17.7 | 56.0±16.8 | 0.052 |
| AUC∞(µg/ml*h) | 62.4±29.0 | 60.3±19.3 | 0.61 |
| c12h(µg/ml) | 1.1±0.5 | 1.0±0.4 | 0.54 |

**Conclusions** PPIs increase the intragastric pH resulting in poorer dissolution and reduced absorption of MMF. Administration of MMF with OME might result in insufficient MPA exposure in patients requiring dose adjustment

Disclosure of Financial Relationships: Research Funding: Novartis Pharma, Nuremberg, Germany; Honoraria: Novartis Pharma, Nuremberg, Germany.

## SA-FC448

**Cardiovascular Medication Use in Kidney Transplant Recipients** Eric D. Weinhandl,[1] Wendy L. St. Peter,[1,2] Jon J. Snyder,[1] Melissa Skeans,[1] Bertram L. Kasiske.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]University of Minnesota, Minneapolis, MN.*

**Background:** Pharmacological therapy for hypertension and hyperlipidemia in kidney transplant (tx) recipients may result in improved outcomes. Use of therapy is not well-characterized. **Methods:** We used data from the United States Renal Data System, including Medicare Part D event claims, to assess use of anti-hypertension (anti-HTN) agents (angiotensin-converting enzyme inhibitor [ACE-I] or angiotensin receptor blocker [ARB], beta blocker [βB], dihydropyridine calcium channel blocker [DP-CCB], diuretic) and lipid lowering (LL) agents (ezetimibe, fibrate, statin, other agent) during the first 6 mo post-tx. We analyzed adult US patients who received a kidney-only tx between Jan 1 and Jun 30, 2007, and who survived without graft failure and carried Part D coverage for 6 mo post-tx (N=3123). **Results:** Overall, 88% took ≥1 anti-HTN agent: 24, 73, 60, and 43% took an ACE-I/ARB, a βB, a DP-CCB, or a diuretic, respectively. Regarding combinations, 70% took at ≥2 agents, while 34% took ≥3 agents. Predictors of anti-HTN agent use included older age at transplant (odds ratio, 1.01 per yr), African-American (AA) *vs.* white race (1.33), both diabetes and HTN *vs.* other as primary end-stage renal disease (ESRD) cause (1.44 and 1.58, respectively), and living-donor status (0.76). Overall, 40% took ≥1 LL agent: 5, 3, 37, and 1% took ezetimibe, a fibrate, a statin, or another agent, respectively. Predictors of LL agent use included older age (1.03 per yr), AA *vs.* white race (0.74), and diabetes *vs.* other as primary ESRD cause (1.47). In those patients with 6 mo pre-tx Medicare coverage (N=2384), ischemic heart disease was positively associated with subsequent LL agent use (adjusted odds ratio, 1.61). **Conclusions:** Most recipients take at least one anti-hypertension agent post-transplant, and many take multiple; use of beta and calcium channel blockers is most common. In contrast, less than half of recipients take at least one lipid lowering agent; use of statins is predominant. Further research is needed to assess whether anti-hypertension regimens may be simplified without loss of efficacy, and whether use of lipid lowering agents is sub-optimal.

## SA-FC449

**Cyclosporine (CYA) Very Low Dose with Everolimus (E) High Dose Is Associated with Better Outcomes in Renal Transplant Patients with Respect to Standard Treatment with EC-MPS (M)** Elisabetta Bertoni, Maurizio Salvadori. *Renal Unit, Careggi University Hospital, Florence, Italy.*

Aim of this study was to compare in cadaveric renal transplant recipients the efficacy and safety of CyA "very low dose" with everolimus "high dose"respect to CyA standard dose with EC-MPS.

In a randomized, prospective, monocenter, open study, patients were enrolled to receive either everolimus (C0 8-10 ng/ml) + CyA (C2 250-300 ng/ml) + steroids or EC-MPS (1440/day) + CyA (C2 500-700 ng/ml) + steroids. 56 patients were enrolled in group everolimus, 50 in group EC-MPS. Efficacy was eveluated at 24 months.

106 patients have been enrolled. After 2 years 41 EC-MPS patients and 46 E patients were evaluated.Biopsy proven acute rejection rate was higher in standard CyA therapy 24% vs 18.8% in CyA very low dose therapy (RR=1.4). CMV infection rate was 27% vs 26%. The lenght of first period hospitalization was similar (24.67±12.20 vs 24.77±11.13 days). We observed a trend towards a better 2-year graft survival rate in patients with CyA very low dose (95% vs 85%; p=ns). Cya dose at 2-year was lower in E group (1.35±0.49 vs 2.3±0.64 mg/kg, p<0.0001). At 2-year eGFR (Cockcroft-Gault) was higher in Everolimus group (77.78±31.9 vs 54.76±18.76 ml/min). The 2-year systolic blood pressure was lower in Everolimus group (125.3±13.96 vs 129.8±16.23 mmHg, p=0.03). The 2-year serum cholesterol levels were higher in everolimus group (229.7±47.08 vs 206.7±42.2 mg/dL, p<0.01), even if everolimus patients used more statins (RR=1.72). 24 hours proteinuria was low and similar in both groups (387.6±42.5 in E vs 409.3±76.8 mg/24 hours in EC-MPS, p=ns).

Examining our population per protocol we observed a 2-year significant higher eGFR in patients with CyA very low dose. We documented systolic blood pressure in patients with lower CyA levels. Our prospective study confirmed the safety and efficacy of CyA very low dose associated with high everolimus dose. We obtained an higher 2-year eGFR with reduction of acute rejection rate. Our data confirm the efficacy of CNI minimization using high everolimus blood levels.

Disclosure of Financial Relationships: nothing to disclose

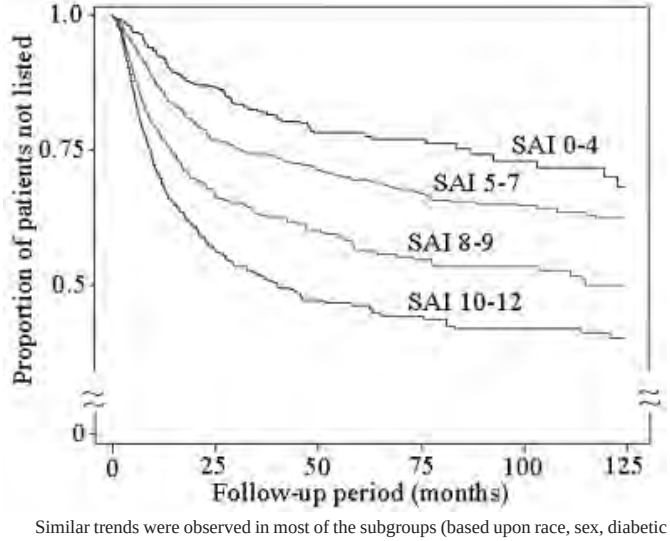
## SA-FC450

**Access to Kidney Transplantation: Role of Social Adaptability Index** Anna Barenbaum,[1] Gurprataap Singh Sandhu,[2] Martha Pavlakis,[2,3] Hongying Tang,[3] Preeti Rout,[2] Alexander S. Goldfarb-Rumyantzev.[2,3] *[1]Tel Aviv University, Tel Aviv, Israel; [2]Division of Nephrology, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA; [3]Transplant Institute, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA.*

Background. Identifying the group of subjects prone to disparities in access to kidney transplantation is important for developing potential interventions.

Methods. Data from the United States Renal Data System (1/1/1990-9/1/2007; n=4,583) were used to study association between the Social Adaptability Index (SAI; based upon employment, marital status, education, income, and substance abuse) and outcomes (time to being placed on the waiting list and time to being transplanted once listed).

Results. Patients were 52.2±17.3 years old, 55.3% males, 64.9% White, and 44.1% had diabetes. SAI was higher in Whites (6.8±2.2) than African Americans (6.2±2.4) [ANOVA, p<0.001], greater in men (6.8±2.3) than in women (6.4±2.3) [T-test, p<0.001]. In multivaiate model greater SAI (range 0 to 12) was associated with increased likelihood of being placed on the waiting list (HR 1.19 [95%CI 1.15-1.23] per each point of increase in SAI, p<0.001); and greater likelihood of receiving a transplant once listed (HR of 1.06 [95%CI 1.03-1.09] per point of increase in SAI, p<0.001). When SAI was divided into quartiles we observed gradual improvement in access to transplantation with increase in the SAI.



Similar trends were observed in most of the subgroups (based upon race, sex, diabetic status, age, comorbidites and donor type).

Conclusion. SAI is associated with access to renal transplantation in patients with ESRD; it may be used to indentify individuals at risk for healthcare disparities.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC451

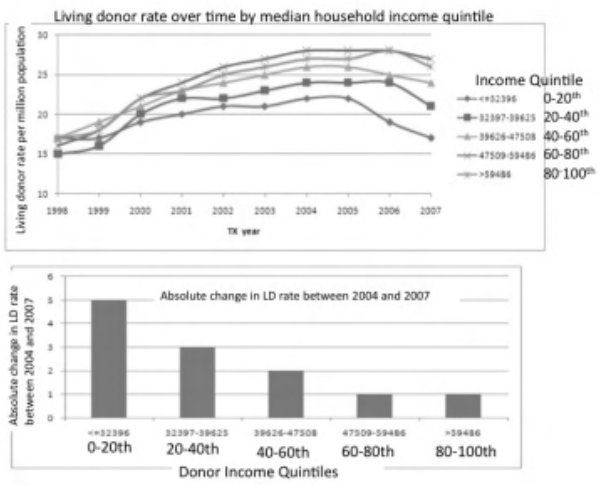
**The Retraction of Living Kidney Donation Is Most Marked among the Poor** Jagbir Gill, James Dong, Caren L. Rose, John S. Gill. *Nephrology, St. Paul's Hospital, University of BC, Vancouver, BC, Canada.*

Lower socioeconomic status is associated with a higher incidence of ESRD, yet reduced access to living donor kidney transplantation (Gore et al. AJT 2009). For reasons that are unclear, the number of living kidney donors in the US has decreased in recent years.

In this analysis we determine longitudinal changes in the rate of living donation (LD) as a function of median household income.

Methods: LD rates per million population, stratified by median household income, were calculated between 2000 and 2007 using data from OPTN/UNOS and the US 2000 Census.

Results: The figure shows that the rates of LD are inversely correlated with median household income. Rates of living kidney donation declined in all income groups over time, but the largest decline was seen in the lowest income group.



Conclusion: Living kidney donation decreased most rapidly among lower socioeconomic groups. Removing financial disincentives to living kidney donation may be an important strategy to prevent ongoing retraction of living kidney donation.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC452

**Race, Predialysis Transplant Discussion, and Preemptive Wait Listing in a National Cohort** Nancy G. Kutner,[1] Rebecca H. Zhang,[1] Yijian Huang,[1] Kirsten L. Johansen.[1,2] *[1]USRDS Rehabilitation/QoL Special Studies Ctr, Emory University, Atlanta, GA; [2]San Francisco VA Medical Ctr, UCSF, San Francisco, CA.*

Background. Preemptive listing for a kidney transplant can significantly reduce waiting time and improve patient outcomes, but previous research has shown that black patients are less likely than whites to be placed on the waiting list (WL) before beginning dialysis. It is not known if this race difference exists among patients with whom kidney transplantation has been discussed predialysis.

Methods. Incident dialysis patients aged ≥18 from 296 randomly selected clinics were surveyed in the USRDS Comprehensive Dialysis Study (CDS). Participants were asked "Was kidney transplantation discussed with you before you started your regular treatment for kidney failure?" and reported their education and employment status. Date of transplant WL, age, gender, race, medical insurance, diabetes, cardiovascular comorbidity, inability to ambulate or transfer, weight, and hemoglobin, serum creatinine and serum albumin values at treatment start were obtained from USRDS files.

Results. 813/1643 patients surveyed reported that transplantation was discussed with them predialysis, and within this group 7% were preemptively wait listed. In the preemptive WL group (n=58), 29.3% were black, compared to 26.6% of patients not preemptively WL (n=755). No gender, age or education differences were evident between the two groups, but preemptive WL patients were more often employed; had private insurance and higher average hemoglobin, serum albumin, and serum creatinine; and were less likely to have diabetes and cardiovascular comorbidity. Among the 813 patients reporting predialysis transplantation discussion, more preemptive WL patients had received early nephrology care (98.3% vs. 79.4%) and they were more likely than non-preemptive WL patients to begin renal replacement therapy on peritoneal dialysis (25.9% vs. 9.4%).

Conclusion. Black patients are frequently disadvantaged at multiple steps in the transplantation process. CDS data indicate that early discussion of transplant as a treatment option, linked with early nephrology care, may help remove barriers to preemptive WL for blacks.

Disclosure of Financial Relationships: nothing to disclose

**SA-FC453**

**Racial Disparities and Neighborhood Poverty in Pediatric Renal Allograft Survival** Rachel E. Patzer,[1] Nancy G. Kutner,[2] William M. McClellan,[1] Sandra Amaral.[3] *[1]Rollins School of Public Health, Emory University, Atlanta, GA; [2]Rehabilitation Medicine, Emory University; [3]Pediatrics, Emory University.*

**Background:** Racial and socioeconomic disparities exist in every aspect of kidney transplantation, from waitlisting to allograft survival. In pediatrics, the relationship of race and SES on graft survival remains poorly understood.

**Methods:** We explored this relationship among all pediatric (<21 yrs), incident ESRD patients in USRDS and UNOS who received a kidney transplant from Jan. 1, 2000 through Sept. 2006, and followed for transplant outcomes through Sept. 2008. Patients' residential zip codes were linked with poverty data from Census 2000. Cox models were utilized for multivariate analyses.

**Results:** Among 4,320 pediatric, incident ESRD patients, 37% received living donor kidney transplants. 18.4% experienced allograft loss within the median 3.6 yr follow-up time. In crude analyses, Blacks had nearly twice the risk of graft failure at any given time vs. White, Non-Hispanics (HR=1.87; 95% CI: 1.60-2.18). In contrast, Hispanic Whites were at a 23% reduced risk of graft failure vs. Non-Hispanic Whites (HR=0.77; 95% CI: 0.63-0.94). After controlling for demographic, clinical, and socioeconomic factors, this racial disparity remained highly significant, with Blacks at a 50% increased risk for allograft failure vs. White-NH. Increasing poverty was also associated with graft loss. Patients from the poorest neighborhoods had a risk of graft loss 20% greater than patients in the wealthiest neighborhoods (HR=1.20, 95% CI:1.01-1.43).

**Conclusion:** Racial and poverty disparities exist in pediatric kidney allograft survival, with Black pediatric ESRD patients and those living in poor neighborhoods having a shorter time to graft failure. These differences deserve further exploration to identify modifiable risk factors for graft loss and to ensure health equity.

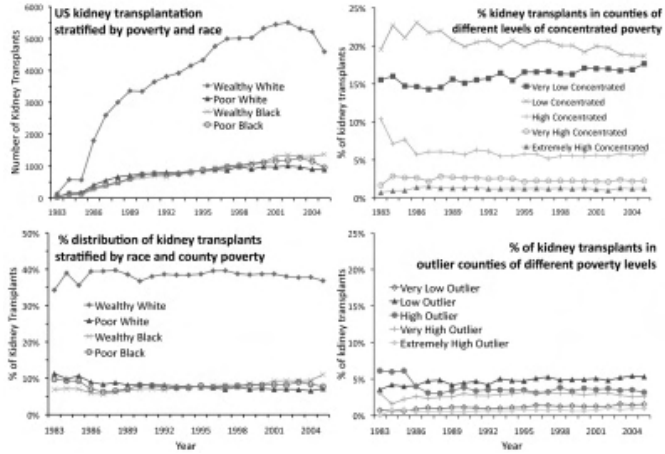
**Transplantation and Intensity of Poverty in the United States** Sumit Mohan,[1] Richard Mutell,[3] James B. Holt,[4] David J. Cohen,[1] William M. McClellan.[2] *[1]Dept of Medicine, Div of Nephrology, Columbia University, New York, NY; [2]Dept of Medicine, Div of Nephrology, Emory University, Atlanta, GA; [3]DaVita Clinical Research, Minneapolis, MN; [4]Centers for Disease Control, Atlanta, GA.*

Introduction: Racial disparities are reported to persist in renal transplantation in the United States. We attempted to study the impact of local poverty rates on transplantation rates over time in the US.

Methods: Transplantation data and the location of patients receiving transplantation between 1983 and 2005 were obtained from the UNOS standard analytic files. The 2000 Census data was used to develop a previously published 10-category index of spatial topography of poverty in the US (Holt JB. Prev Chronic Dis. 2007 Oct;4(4):A111). Transplant recipient zip codes were used to match patients to counties. Analysis was performed with SPSS 16.0

Results: Over this period, the largest increase in the absolute number of kidney transplantations was seen among white recipients living in wealthy counties with concentration of low poverty (≥1 standard deviations below the national mean poverty level). However, the relative percentage of transplants did not change significantly. Also, rates of transplantation of black recipients in these same areas were similar to that of white and black recipients in poorer counties (Figure). These differences were attenuated in counties whose poverty rates were spatial outliers (significantly different from the rates of surrounding/nearby counties). Statistically significant ($\chi^2$= 15190, p<0.001) ethnic disparities persist with the greatest present in the rich counties.



Conclusions: These results suggest that both race and economic factors are associated with disparities in the prevalence of renal transplantation in US and that these disparities have remained largely unchanged despite the growth in the number of transplantations being performed each year.

**SA-FC455**

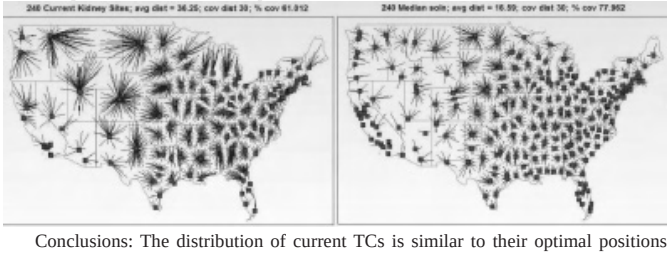
**Analysis of Kidney Transplant Center Locations in the United States** Daniela Ladner, Ashley E. Davis, John J. Friedewald, Mark S. Daskin, Sanjay Mehrotra, Vadim Lyuksemburg, Anton I. Skaro, Juan Carlos Caicedo, Michael Abecassis. *Northwestern University Transplant Outcomes Research Collaborative (NUTORC), Northwestern University Comprehensive Transplant Center, Chicago, IL.*

Purpose: The distance end stage renal disease (ESRD) patients must travel to a transplant center (TC) is predictive of listing and receiving a kidney transplant (KT). This study analyzes the geographic distance of the US and ESRD population to the existing 240 KT centers and compares the status quo to an optimal model maximizing geographic access to TCs.

Methods: Distribution of US and ESRD population was obtained from Census 2000 and ESRD Network data. US and ESRD population coverage within a 30 mile distance was computed for the current 240 KT centers. P-Median Facility Location Optimization (SITATION) was used to optimally locate 240 TCs with respect to every county's total and ESRD population. This technique locates TCs to minimize the total distance traveled by all individuals.

Results: Presently 61% of the country's population and 64% of ESRD patients live within 30 miles of a TC. Optimal TC distribution demonstrates that TCs are overall well distributed to serve either population with the exception of western and southern portions of the US.

Comparison of Current and Optimal Center Locations in the US.



Conclusions: The distribution of current TCs is similar to their optimal positions with underserved areas in the south and west. With approximately 40% of residents and patients living beyond 30 miles from a TC, this geographic disparity could be ameliorated by outreach clinics from existing TCs.

**SA-FC456**

**Risk Aversion in Renal Transplantation – An Unintended Consequence of Regulatory Oversight** Anton I. Skaro, Edward Wang, Colleen Jay, Daniela Ladner, Yaojen Chang, Olivia A. Ross, Vadim Lyuksemburg, Jane L. Holl, Michael Abecassis, Lorenzo G. Gallon. *Northwestern University.*

**Purpose:** Conditions of Participation (CoP) issued by the Centers for Medicare and Medicaid Services (CMS) on June 28, 2007 mandated that transplant center-specific survival be in accordance with expected outcomes, which are inadequately risk-adjusted specifically for cardiovascular disease. However, quality improvement through performance measurement may act as a disincentive to perform renal transplantation in high cardiac risk patients. We developed a cardiovascular risk index (CRI) and examined trends before and after implementation of the CoP.

**Methods:** We retrospectively examined 176,739 kidney transplant recipients from the United Network for Organ Sharing database between 1995 and 2009. Patient survival according to CRI was analyzed using Kaplan-Meier and log-rank tests. Cox regression, stratified analysis and Rothman synergy index were used to evaluate covariates.

**Results:** Patient survival was inferior for high CRI (≥2) renal transplant recipients. After risk adjustment, high CRI remained a predictor of patient mortality (HR 2.89, 95% CI 2.75-3.04). Diabetes (HR 1.80, 95% CI 1.75-1.86) was the strongest and hypertension (HR 1.01, 95% CI 0.97-1.04) the weakest predictors of mortality. Combination of diabetes and hypertension augmented risk of mortality (synergy index 1.11, 95% CI 1.05-1.17). Interestingly, the mean CRI score increased from 1.06 in 1995 to a peak of 1.57 in 2006, but declined immediately prior to and after the implementation of the CMS CoP (Figure 1).

**Conclusions:** A contemporaneous decline in CRI with enforcement of the CMS CoP implicates risk aversion as an unintended consequence of regulatory oversight. Modification of risk adjustment is necessary to preserve equal access to renal transplantation among high cardiac risk patients.

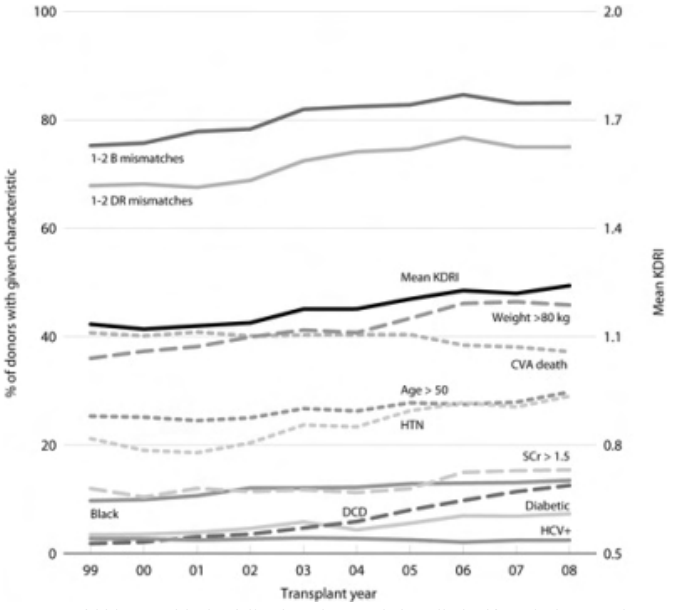
**Increasing Use of Riskier Deceased Kidney Donors in the US in the Past Decade** Jon J. Snyder, Sally K. Gustafson, Melissa Skeans, Bertram L. Kasiske. *United States Renal Data System, Minneapolis, MN.*

Survival of kidney transplants from deceased donors has remained fairly stable over the past decade, with a 5-year graft survival of 67% for transplants performed in 1999 and 69% in 2003, and first-year graft survival from 88% in 1999 to 91% in 2007. This is despite a 50% decline in the first-year incidence of acute rejection over the same 10-year period. Additionally, continued increases in the waiting list have lead to increased use of marginal kidney donors through the ECD program as well as increased use of DCD kidneys. We hypothesized that transplant programs were accepting higher risk deceased donor kidneys in many aspects of deceased donor quality. We examined trends in the kidney donor risk index (KDRI, Rao, Transplantation 2009) as well as trends in the individual components of the KDRI in first-time, adult, deceased donor kidney recipients in the US (N=83,901) using data from the United States Renal Data System (USRDS). Linear trends across transplant years were assessed using a logistic regression model. Mean KDRI increased significantly from 1.13 to 1.24 (Figure; p<0.0001).



Use of kidneys with the following characteristics all significantly increased over the 10-year period: black, diabetic, B/DR mismatches, age 50+, history of hypertension (HTN), DCD, weight 80+ kg, and terminal SCr > 1.5 mg/dL. Only a few risk characteristics decreased over the 10-year period: death due to CVA, HCV seropositive, and mean cold ischemia time (not shown, mean of 20 hours down to 19 hours). The KDRI supports the conclusion that use of higher risk deceased donors for kidney transplant has increased over the recent decade.

**Living-Donor Kidney Volume as a Predictor of Graft Function: Is There a Role for Proteinuria?** Hadim Akoglu,[1] Tolga Yildirim,[1] Gonca Eldem,[2] Aysun Aybal Kutlugün,[1] Mahmut Altindal,[1] Rahmi Yilmaz,[1] Tuncay Hazirolan,[2] Fazil T. Aki,[3] Mustafa Arici,[1] Cetin Turgan.[1] *[1]Nephrology, Medical Faculty of Hacettepe University, Ankara, Turkey; [2]Radiology, Medical Faculty of Hacettepe University, Ankara, Turkey; [3]Urology, Medical Faculty of Hacettepe University, Ankara, Turkey.*

**Introduction:** The proposed mechanisms by which graft size affects graft outcome are intraglomerular hypertension and hyperfiltration leading to proteinuria and nephron loss. We aimed to evaluate whether proteinuria had an impact on relationship between graft size and graft outcome in living donor kidney transplantation.

**Methods:** We analyzed 69 living donors (25 male, 44 female, mean age 42.0±9.5 years) and their organ recipients (45 male, 24 female, mean age 29.8±10.1years) who underwent transplantation from 2003 to 2007. Transplanted kidney volumes were measured by 3D helical CT scanning. A transplant kidney volume-recipient body weight (Vol/Wt) ratio was calculated for each donor-recipient pair. Glomerular filtration rate (GFR) and 24-hour proteinuria at 6 months, 1 year and 2 years after transplantation were recorded from recipients' charts. The subjects were divided into two groups according to the median of Vol/Wt ratio: low Vol/Wt ratio group (≤2.33 $cm^3$/kg) and high Vol/Wt ratio group (>2.33 $cm^3$/kg).

**Results:** GFR was positively correlated with Vol/Wt ratio at 6 month, 1 year and 2 years (r=0.49, p<0.0001; r=0.48, *P*<0.0001; r=0.42, *P*=0.0001, respectively). Mean GFRs in high Vol/Wt ratio group were significantly higher compared to low Vol/Wt ratio group at 6 months, 1 year, and 2 years after transplantation (78.58±20.2 vs 61.72±17.8 ml/dk/1.73 $m^2$, *P*<0.001; 75.27±18.3 vs 61.5±17.9 ml/dk/1.73 $m^2$, *P*=0.001; and 71.36±18.4 vs 60.47±17.5 ml/dk/1.73 $m^2$, *P*=0.006; respectively). Proteinuria did not differ between the two groups at 6 months, 1 year and 2 years after transplantation (226±201 vs 208±232 mg/d, *P*=0.74; 203±158 vs 213±195 mg/d, *P*=0.80; and 158±77 vs 191±166 mg/d, *P*=0.29; respectively).

**Conclusion:** Living donor kidney transplantation with a low Vol/Wt ratio is associated with significantly worse graft function. This association is unlikely to be affected by the degree of proteinuria.

Disclosure of Financial Relationships: nothing to disclose

**SA-FC459**

**Living Kidney Donation: Prediction of Glomerular Filtration Rate from Echographic Renal Dimensions** Carlo Donadio, Hesham Abdelkawy, Giulia Grassi. *Nephrology, Pisa University, Pisa, Italy.*

The gold standard to assess renal function is glomerular filtration rate (GFR). GFR is often estimated from serum creatinine (SCr), serum cystatin C (SCys) and creatinine clearance (CCr), or is predicted from SCr or SCys using formulas. Ultrasound scanning evaluates morphology and dimensions of kidneys.

Aim of this study was to evaluate the relationship among renal dimensions and renal function, and the possibility to predict GFR from echographic renal dimensions, in potential kidney donors (POTDON), in kidney donors (KDON) after donation, and in renal transplant recipients (RTR).

Patients. POTDON: 79 (52 females), SCr 0.5-1.3 mg/dL. KDON after donation: 33 KDON (28 females), SCr 0.81–1.90 mg/dL. RTR: 30 (8 Females), SCr 0.96 –2.42 mg/dL.

Methods. GFR was measured as $^{99m}$Tc-DTPA clearance. GFR was also estimated from SCr with Cockcroft&Gault (CG-CCr) and MDRD formula, and from SCys. Kidney dimensions were measured during bidimensional echography, and total and parenchymal kidney volumes were estimated with ellipsoid formula.

Results. Among sonographic measurements, in RTR and KDON, kidney length showed the best correlation with GFR, which was greater than that of SCr or SCys, and similar to that of CG-CCr or MDRD-GFR. Accuracy of kidney length as an indicator of GFR impairment was not different from laboratory tests. In POTDON the correlation with GFR was significant for SCys and for all prediction formulas, but not for Scr. The accuracy of CG-CCr and MDRD-GFR were better than Cys-GFR and CCr. However, their mean prediction errors versus GFR were relevant. Renal dimensions, particularly renal volume, showed a good correlation with GFR, higher than all prediction equations. Thus, we derived formulas to predict GFR from renal dimensions. These estimates of GFR were more closely correlated with true GFR than CG-CCr, MDRD-GFR, and Cys-GFR. GFR estimated from renal volumes had also a better agreement and a lower prediction error versus GFR than the other predictions.

In conclusion, renal echography provides also functional information, and it is possible to estimate GFR from renal volumes more accurately and with a lower prediction error than using formulas based on SCr and SCys or CCr.

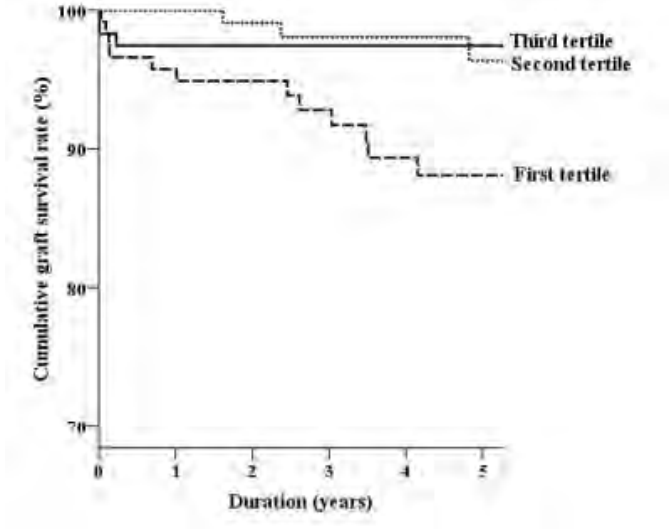
**Influence of Graft Volume on the Long-Term Outcome of Kidney Transplantation** Seung Seok Han, Jin Suk Han, Suhnggwon Kim, Yon Su Kim. *Internal Medicine, Seoul National University Hospital, Seoul, Korea.*

Purpose: Although the short-term outcome of kidney transplantation has improved, the long-term outcome is suboptimal. This is because in addition to immune factors, nonimmune factors also influence the graft outcome. Herein, we assessed the graft volume as a nonimmune factor and studied its effect on the long-term outcome in kidney transplant recipients.

Methods: We studied 354 living transplant recipients between April 2001 and December 2008. In all donors, preoperative helical computed tomography (CT) with 3D reconstruction had been performed. Graft volume was estimated using the prolate ellipsoid method. The graft outcome (development of acute/chronic rejection and glomerulonephritis, and graft survival) was calculated by studying patients separated into 3 groups on the basis of the adjusted kidney volume to the body surface area of the donor.

Results: During the follow-up period (55.7 ± 27.20 months), 18 grafts stopped functioning. Graft survival rates were significantly different among tertile groups (second group vs. first group, OR = 0.25 (0.07–0.89), $P$ = .032; third group vs. first group, OR = 0.24 (0.07–0.86), $P$ = .028).



The differences in graft survival rates remained significant after adjustment for the recipient's age, sex, and body surface area; donor type (living related vs. living unrelated); and donor's age, sex, and degree of human leukocyte antigen (HLA) mismatch (second group vs. first group, OR = 0.21 (0.06–0.76), $P$ = .017; third group vs. first group, OR = 0.23 (0.06–0.81), $P$ = .022). The rates of acute/chronic rejections and glomerulonephritis were also significantly low in the groups with large kidney volume, irrespective of adjustment for other variables.

Conclusion: Recipients with large kidney volume have the benefit of graft survival as well as low incidence of rejection and glomerulonephritis.

**Therapeutic Potential of Locked Nucleic Acid Modified Anti-microRNA-192 in Mouse Models of Diabetic Nephropathy** Sumanth Putta, Mitsuo Kato, Linda L. Lanting, Guangdong Sun, Rama Natarajan. *Diabetes, Beckman Research Institute of City of Hope, Duarte, CA.*

Diabetic nephropathy (DN), a major complication of diabetes is characterized by mesangial cell (MC) hypertrophy and increased extra cellular matrix (ECM) deposition. Transforming Growth factor-β (TGF-β) has been implicated in these events. We recently reported that micro-RNA-192 (miR-192) was upregulated by TGF-β in MC and in diabetic mice glomeruli, and increased collagen expression by downregulating E-box repressors, ZEB1 and ZEB2. miR-192 appeared to be a key upstream regulator of other renal miRs and downstream genes related to DN. Therefore, we hypothesized that miR-192 could be a potential therapeutic target for DN. Locked nucleic acid (LNA) modified anti-miRs are effective in inhibiting target miRNAs in animals but have never been tested in kidney. Our aim was to evaluate the efficacy of LNA based anti-miR-192 oligos in mice as a therapeutic approach for DN. We first delivered LNA-antimiR-192 (LNA) subcutaneously in normal mice and evaluated efficacy at 6 and 24hr post injection. Next, we tested various parameters of DN in Streptozotocin (STZ) induced type 1 diabetic mice at 2, 7 and 17 wks post LNA treatment to evaluate early molecular and later functional indices of DN. In situ hybridization showed efficient accumulation of anti-miR in renal compartments of LNA injected mice. miR-192 levels were significantly inhibited in kidneys from LNA injected mice, but not miR-194, suggesting specificity of the LNA in vivo. Significant decrease in miR-192 and reciprocal increase in ZEB1/2 (miR-192 target) levels in renal tissues from diabetic and non-diabetic mice were observed in long term LNA delivery (2-17 weeks). Further, significant decrease in pro-fibrotic ECM gene expression (Col1A2, TGF-β, and Fibronectin) was detected in LNA injected diabetic mice and the reduction was confirmed by immunostaining of renal sections. In addition, functional indices of DN such as proteinuria and albuminuria were decreased in LNA injected diabetic mice. No toxicity was observed in mice injected with LNA-anti-miR-192 compared to controls. Thus, the LNA-antimiR-192 treatment could be a novel therapeutic strategy for DN.

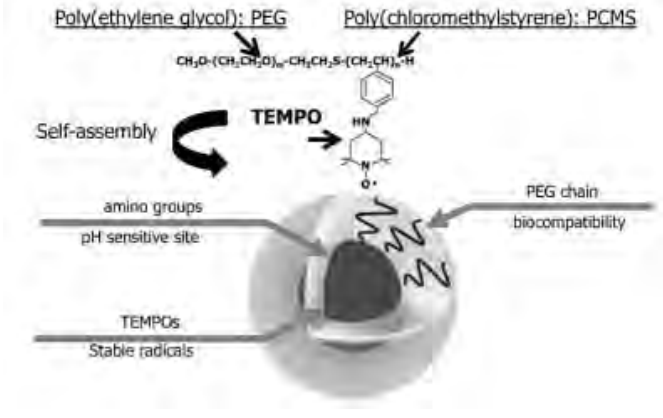
**Development of a pH-Sensitive Reno-Protective Nano-Particle for Relief of Ischemia-Reperfusion Acute Kidney Injury** Aki Hirayama,[1] Toru Yoshitomi,[3] Shigeru Owada,[5] Atsushi Ueda,[2] Hirofumi Matsui,[3] Kazumasa Aoyagi,[1] Yukio Nagasaki.[3] *[1]Center for Integrative Medicine, Tsukuba University of Technology, Japan; [2]Namegata District General Hospital, Japan; [3]University of Tsukuba, Japan; [4]Asao Clinic, Japan.*

We have developed a TEMPO containing nano-particle (RNP: radical containing nano-particle) which possesses high stability and antioxidative effects as was reported in Renal Week 2009. We improve this RNP as a reno-protective agent and apply it in acute kidney injury (AKI).

The RNP was synthesized as a micelle of poly(ethelenglycol)-poly(chloromethylstyrene) in which the later were converted to TEMPO (PEG-PCTEMPO, Figure 1). Controlling the repeating units of PCTEMPO, we synthesized a pH-sensitive RNP (N-RNP) which releases the inner TEMPO in acidic circumstances (pH 6 or lower) by a self-disintegration and pH-insensitive RNP (O-RNP). The renal protective effects were evaluated in a murine one kidney-one clip ischemia-reperfusion AKI model. O-/N-RNP, TEMPOL, 4-amino-TEMPO ($NH_2$-TEMPO) or PBS (control) was intravenously injected before the reperfusion procedure.



Following 50 min of ischemia and subsequent reperfusion, 3 mg/kg of N-RNP (containing 0.25 µmol/kg TEMPO) reduced the elevation of serum creatinine (Cre), blood urea nitrogen (BUN), oxidative stress markers and improved histopathological changes compared to the equivalent dose of TEMPOL or $NH_2$TEMPO, or control. The renoprotective effect of O-RNP was similar to that of TEMPOL or $NH_2$TEMPO. When the TEMPO concentrations were increased to 2.5 µmol/kg (RNP 30 mg/kg), N-RNP and $NH_2$TEMPO showed similar inhibition of the elevation of Cre and BUN. $NH_2$TEMPO, however, caused remarkable hypotension.

These results indicate that the pH-sensitive RNP is an effective renoprotector. The nano-particle structure and induction of pH-sensitivity are the crucial strategies responsible for this renoprotection.

**Assessment of Renal Perfusion in UUO Mice Using Retro-Orbital Injections of $^{99m}$Tc-MAG3 and NanoSPECT Imaging** Mohammed Noor Tantawy,[1] Rosie T. Jiang,[2] Feng Wang,[1] Keiko Takahashi,[2] Chuan-Ming Hao,[2] Raymond C. Harris,[2] Christopher Chad Quarles,[1] Takamune Takahashi.[2] *[1]Vanderbilt University Institute of Imaging Science, Nashville, TN; [2]Vanderbilt O'Brien Mouse Kidney Physiology and Disease Center, Nashville, TN.*

There is considerable interest and potential value in making available imaging methods that permit non-invasive assessments of renal function in mice. Here we optimized and evaluated the use of $^{99m}$Tc-MAG3 dynamic renal scintigraphy to detect decline in renal perfusion in a mouse model of unilateral ureteral obstruction (UUO). UUO mice were generated by complete ligation of the ureter of left kidney. The mice that underwent sham operation were used as a control. All the mice were imaged on days 0, 1, 3, and 6 post surgery using a NanoSPECT (Bioscan, Washington, DC) scan with planar dynamic mode and a parallel pin-hole collimator. On the days of imaging, the mice received ~37 MBq of $^{99m}$Tc-MAG3 retro-orbitally immediately before the start of a 45 min acquisition. Regions-of-interest were drawn in the left and right kidneys and time-activity curves were deduced. The peak activity of the kidneys and the time-to-peak were used as imaging metrics of renal perfusion. In UUO kidneys, the time-to-peak was significantly extended as early as day 0, exceeding 200 sec on any given day, while it was < 200 sec in the contra-lateral and sham kidneys. The peak activity of the UUO kidneys was equal to that in the contra-lateral kidneys on day 0 but was substantially reduced as the disease progressed (~3.5 times lower than the contra-lateral kidney at day 6). No significant differences were found in the peak activity between the contra-lateral kidney of the UUO mice and the kidneys of the sham operation mice.

In conclusion, our data demonstrate that reduction in renal perfusion in UUO mice can be reliably detected and quantified using retro-orbital injections of $^{99m}$Tc-MAG3. This method allows serial assessment of renal function in the same animals and could be effectively used for elucidating renal pathophysiology during the course of kidney disease.

## SA-FC464

**Ultrasonographic 2D Strain Imaging, a New Approach to the Evaluation of Vascular Stiffness in Patients with Chronic Kidney Disease** Shirley Yumi Hayashi,[1,2] Anna Bjällmark,[2] Marcelo M. Nascimento,[1] Bengt Lindholm,[1] Astrid Seeberger,[1] Britta Lind,[2] Miguel C. Riella,[3] Lars-Åke Brodin.[2] *[1]Baxter Novum & Renal Medicine Karolinska Institute, Stockholm, Sweden; [2]Royal Institute of Technology (KTH), Stockholm, Sweden; [3]Pontifícia Universidade Católica do Paraná.*

Arteriosclerosis and atherosclerosis are common complications in patients with chronic kidney disease (CKD), being the leading cause of mortality in this group of patients. Ultrasonographic 2D strain imaging of common carotid artery using speckle tracking technique has been recently described and showed to be superior to elastic modulus in the evaluation of arterial stiffness. The aim of this study was to evaluate carotid strain (CS) and carotid strain rate (CSR) in CKD patients. 156 CKD patients stages 3, 4 and 5 (97 men, 58.3±14.5 years) and 9 healthy controls (8 men, 51.1±10.5 years) were evaluated. Measurements of circumferential strain (%) and strain rate (1/s) were performed in common carotid artery using ultrasonographic 2D strain imaging. CS and CSR were significantly correlated with age (r2 -0.49, p<0.0001). and significantly lower in CKD patients in comparison with controls (3.2±1.8 vs. 5.3±1.8, p<0.0001) and (0.4±0.2 vs. 0.6±0.2, p<0.01). The patients were divided into tertiles according to the CS values (group 1: < 2%, group 2: > 2% to 4%, group 3: > 4%). Intima media thickness was significantly higher in group 1 in comparison with the 2 other groups (0.8±0.4* vs. 0.7±0.2 vs. 0.5±0.1, p<0.0001). Cholesterol (5.2±1.6 vs. 4.7±1.2 vs. 4.0±1.3*, p<0.01), triglycerides (2.9±1.6 vs. 2.6±1.4 vs. 2.2±2.6*, p<0.001) and calcium levels (3.4±1.4 vs. 3.2±0.2 vs. 2.5±0.2*, p<0.05) were significantly higher in groups 1 and 2 in comparison with group 3. In conclusion, carotid circumferential strain and strain rate appear to be lower in CKD patients which could indicate the presence of increased arterial stiffness. The decreased values of CS correlate with increased IMT and higher levels of cholesterol, triglycerides and calcium These results might indicate that CS and CSR measurements may be a valuable tool in the evaluation of vascular stiffness in CKD patients.

**Gene Expression Profiles in Different Venous Regions with Distinct Hemodynamic Environments in a Porcine Arteriovenous (AV) PTFE Graft Model** Li Li,[1] Randy Jay Christopherson,[2] Mary Carlson,[1] Donald Blumenthal,[3] Christi M. Terry,[1] Yan-Ting E. Shiu,[1,2] Alfred K. Cheung.[1,4] *[1]Internal Medicine, University of Utah; [2]Bioengineering, University of Utah; [3]Pharmacology, University of Utah; [4]Medical service, VASLC Healthcare System, SLC, UT.*

Implantation of a hemodialysis AV graft is often followed by the development of neointimal hyperplasia (NH) at the venous anastomosis (VA). The change of venous hemodynamic wall shear stress (WSS) caused by the graft likely plays a role in the NH formation. We monitored temporal changes in gene expression in different venous regions of different WSS levels through microarray analysis. Carotid-jugular PTFE grafts were placed in 4 pigs. Five days (n=2) or 14 days (n=2) after graft placement, the AV graft lumen geometry and blood flow data were obtained from MRI. These data were used as input for computational fluid dynamics (CFD) simulations of the AV graft flow field and contralateral non-operated jugular vein (JV) to identify average WSS in VA, proximal vein segments (PV, 2cm away from the VA) and JV. Subsequently, total RNA was isolated from these regions and analyzed by microarray. Statistical analysis (>2-fold change, p<0.001) was performed with GeneSifter software to identify altered gene expression in VA/or PV compared to JV. The average WSS in the VA, PV and JV regions at 5 post-operative days were 60 ± 28.3, 30 ± 14.1, and 7.5 ± 3.5 dyn/cm$^2$, respectively. Compared to JV, 55 genes were upregulated and 60 genes were downregulated at the VA. At 14 days, 13 genes were upregulated and 12 genes were downregulated at the VA. Using the same statistical criteria, 17 genes were upregulated and 14 genes were downregulated at the PV compared to JV at 5 days. At 14 days, 8 genes were upregulated and 3 genes were downregulated in PV compared to JV. These results showed a strong tendency for genes to be altered in VA which has the highest WSS environment. Detailed characterization of these genes and their individual associations with WSS over time are ongoing. Ultimately, these analyses may provide important insights into the role of mechanical force and molecular mechanisms leading to NH in hemodialysis vascular access.

**Uremic Ovine Model of End Stage Renal Disease (ESRD) for the Evaluation of the Bioartificial Renal Epithelial Cell System (BRECS)** A. Westover,[1] D. Buffington,[1] J. Jung,[2,3] L. Lou,[1] A. Rojas,[2] L. Charles,[1] P. Smith,[1] K. Johnston,[1] C. Pino,[1] David Humes.[1,3] *[1]Innovative BioTherapies; [2]Chungnam Nat Univ; [3]Univ of Michigan.*

Renal cell therapy incorporated into conventional CRRT has shown metabolic, immunologic and survival benefits in renal failure in preclinical and clinical studies. However, maintenance of a blood extracorporeal circuit for chronic renal cell therapy in ESRD is limited due to clotting and infectivity risks. To this end, a wearable renal cell therapy device continues to be developed using an ovine model of ESRD. The model employs a continuous-flow peritoneal dialysis (CFPD) circuit incorporating a BRECS allowing for uremic control, maintenance of cell viability and communication between the device and the host animal.

**Methods:** Two in/out-flow PD catheters were placed 2 weeks before the start of CFPD and sequential nephrectomies performed 2 weeks and one day before initiation of CFPD with commercially available 4.25% glucose. BRECS containing $10^8$ renal epithelial cells were incorporated into the CFPD circuit post equilibration to physiologic pH. Cell viability and functionality within the device were monitored using $O_2$ consumption and γ-glutamyltranspeptidase (gGT) metabolism. Parameters including blood chemistry profiles, nutrition, inflammation (CD11b expression by neutrophils) and leukocyte function (oxidative burst) of the animal were monitored and compared to acellular sham devices. Cell therapy continued up to seven days and animals were evaluated for an additional 48 hours post therapy.

**Results:** BRECS remained viable with detectable $O_2$ consumption and gGT activity for up to 7 days of CFPD period and post therapy. Uremic control by CFPD measured by small-solute uremic parameters was within acceptable ranges. For neutrophils, CD11b expression was reduced while oxidative burst potential was maintained with BRECS therapy. **Conclusion:** The ovine model of ESRD is an acceptable model to evaluate the therapeutic functionality in the BRECS. Preliminary studies have identified possible renal tubule cell therapy targets in the amelioration of inflammation and neutrophil function known to be dysregulated in ESRD.

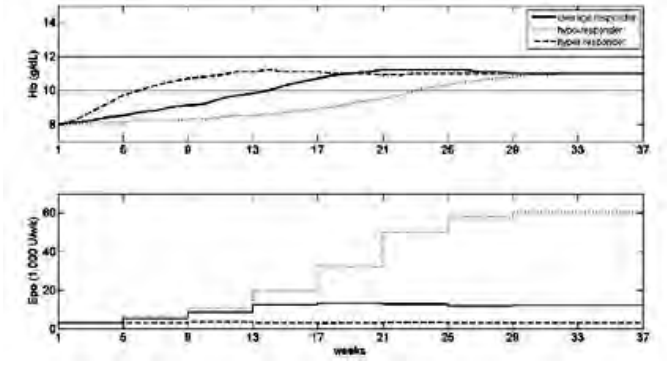
**Computer-Aided Personalized Anemia Management** Adam Gaweda,[1] Jordan Malof,[1] George R. Aronoff,[1] Alfred A. Jacobs,[1] Michael Brier.[2] *[1]Medicine, University of Louisville, Louisville, KY; [2]Department of Veterans Affairs.*

Erythropoiesis Stimulating Agent (ESA) dosing in ESRD anemia management is usually based on standard protocols applied to a diverse patient population. To enable dose individualization we developed software for ESA dosing, called Smart Anemia Manager™. We demonstrate its feasibility through *in silico* testing.

Using data from ESRD patients receiving Epoetin alfa (Epo) at University of Louisville, we developed three models representing typical pharmacodynamic (PD) Hemoglobin (Hb) response to Epo: hypo-, average, and hyper-responder. PD characteristics were represented by erythropoietic sensitivity (0.05, 0.25, and 1.0 g/dL per 1000 U/wk) and average

erythrocyte lifespan (60, 90, 120 days). Smart Anemia Manager™ is based on the concept of multiple Model Predictive Control (MPC). It uses multiple dose adjustment algorithms representing different PD profiles and automatically selects the correct algorithm for a given patient based on their response. Using the three response models, we simulated anemia management over a period of 37 weeks starting at baseline Hb=8g/dL.

Smart Anemia Manager™ drove Hb from the baseline value to the target range (10-12 g/dL) for all three test patients. The time to reach the target range was 23 (hypo-), 14 (average), and 7 (hyper-responder) weeks. The standard anemia management protocol used at our facility achieved the target Hb in 23 (hypo-) and 11 (average responder) weeks. For hyper-responder, the protocol resulted in Hb cycling and did not achieve a stable response.



Hb response (top) and Epo dose profiles (bottom) for the three representative patient models using Smart Anemia Manager™.

These test results demonstrate the feasibility of Smart Anemia Manager™ as a tool for personalized ESA dosing in anemia management, especially in reducing algorithmic Hemoglobin cycling.

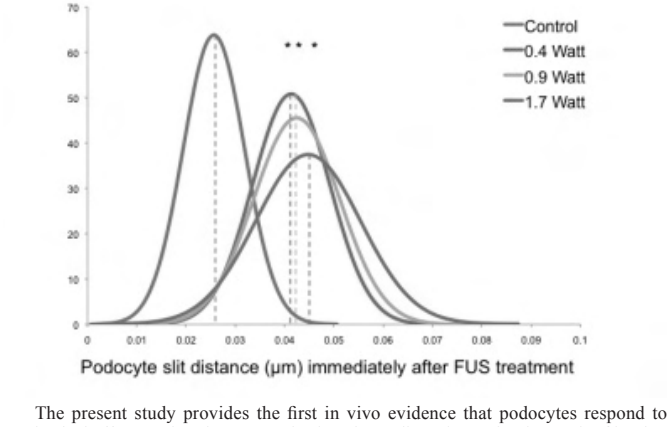
**Mechanical Stress Induced Functional and Structural Changes in the Glomerulus** Krisztina Fischer,[1,2] Nathan J. McDannold,[1] Gyorgy S. Reusz,[2] Ferenc A. Jolesz.[1] *[1]Radiology, Brigham and Women's Hospital/ Harvard Medical School, Boston, MA; [2]First Department of Pediatrics, Semmelweis University, Budapest, Hungary.*

Glomerular capillary pressure generates wall tension in glomerular capillaries that needs to be counterbalanced by the cellular layers. The podocytes are likely to predominantly stabilize the capillary wall and represent the dominant resistance to passage of large molecules. It is known that podocytes are sensitive to mechanical stress and fluidic shear stress in vitro. Focused ultrasound and microbubble contrast agents have proven to be able to change vascular permeability by mechanical effects on the vasculature.

In the present study we applied pulsed focused ultrasound exposures (10ms burst, 1Hz PRF, 30s duration) at three different power levels (0.4W;0.9W;1.7W) in the presence of microbubble contrast agent (Definity) as mechanical stress onto 19 healthy rabbits' kidneys. Five animals served as controls. The animals were either sacrificed immediately or one hour after the sonication treatment. Relative (treated versus non-treated kidney) creatinine clearance and protein to-creatinine ratios were calculated. Ultrafine structural analysis was performed using electronmicroscopy. Podocyte slit distance was measured using the AMT image capture engine software. A two-tailed t-test was applied to determine the statistical significance of the structural changes.

We have found a reversible, linear (proportional to the applied power level) increase in the relative creatinine clearance (R2= 0.998), protein to-creatinine ratio (R2= 0.983), and distance between podocyte foot processes (R2= 0.997, p<0.001) of the test subjects.



The present study provides the first in vivo evidence that podocytes respond to mechanical effects and such response leads to immediate change in glomerular filtration and proteinuria.

**Vesicle Associated Membrane Protein, VAMP2, Mediates cAMP-Stimulated Renin Release from Mouse Juxtaglomerular (JG) Cells** Mariela Mendez. *Hypertension and Vascular Research Division, Department of Internal Medicine, Henry Ford Hospital, Detroit, MI.*

Exocytosis of renin containing granules is involved in renin release from juxtaglomerular (JG) cells, a process stimulated by cAMP. The molecular mechanism and proteins involved in renin exocytosis are unexplored. In other endocrine cells, granule exocytosis is mediated by proteins of the soluble N-ethylmaleimide-sensitive factor attachment protein receptor (SNARE) family. From this family, vesicle associated membrane protein 2 (VAMP2) mediates cAMP-stimulated exocytosis. We hypothesized that cAMP-stimulated renin release from JG cells is in part mediated by VAMP2. We measured: a) expression of VAMP2 by Western blot and immunofluorescence; and b) the effect of VAMP2 silencing *via* adenoviral delivery of short hairpin RNA (VAMP2-shRNA) on cAMP-stimulated renin release from primary cultures of mouse JG cells. Intracellular cAMP levels were increased by treatment with Forskolin plus IBMX. By Western blot we found that VAMP2 is expressed in JG cell lysates at the expected molecular mass (n=8). Immunofluorescence and confocal microscopy showed colocalization of VAMP2 with renin containing granules in JG cells. JG cells were transduced with adenoviruses carrying a scrambled sequence (control) or VAMP2-shRNA and found that 48 hrs after transduction VAMP2 expression was reduced by 75% of control (n=6). In control cells Forskolin/IBMX stimulated renin release by 259±26 % (p<0,05) however in JG cells transduced with VAMP2-shRNA, Forskolin/IBMX increased renin release by 107±25%, a 58% blockade (p<0.05). We concluded that VAMP2 is expressed in JG cells and mediates part of the cAMP-stimulated renin release from mouse JG cells. These data identify for the first time a vesicle associated protein that mediates renin release.

## SA-FC470

**Kidney Damage-Induced Acceleration of Atherosclerosis Is Ameliorated by Pioglitazone Modulation of Macrophage Phenotype** Suguru Yamamoto,[1] Yiqin Zuo,[1, 2] Patricia G. Yancey,[3] Zhi-Qi Xu,[1] Iekuni Ichikawa,[1] Valentina Kon.[1] *[1]Vanderbilt University, Pediatrics, Nashville, TN; [2]Vanderbilt University, Pathology, Nashville, TN; [3]Vanderbilt University, Medicine, Nashville, TN.*

**Background:** We previously showed that angiotensin II (AII) has a role in uninephrectomy (UNx)-induced acceleration of atherosclerosis and that macrophage-specific deletion in peroxisome proliferator activated receptor g (PPARg) contributes to the proatherogenic effects of AII. We now examine if PPARg agonist benefits UNx-induced atherosclerosis and possible synergism with AII receptor antagonism.

**Methods and Results:** apoE-/- mice underwent UNx or sham operation (Sham). UNx were further subdivided into untreated UNx, UNx+Pioglitazone [Pio, n=10, 0.016% (w/w) in food], UNx+losartan (Los, n=10, 100mg/L in drinking water), or both (Pio+Los, n=10) for 10 weeks. There were no differences in body weight, creatinine clearance or triglycerides among the groups. Blood pressure was lower in Los and Pio+Los (90.0±3.3 and 87.1±2.8 vs UNx:108.1±4.4 mmHg, both $p<0.05$). Serum cholesterol was higher in Pio and Pio+Los (495.8±23.6 and 495.2±28.6 vs UNx 338.2±23.5 mg/dl, $p<0.05$). UNx significantly increased atherosclerosis assessed by Oil-red O (331385±25020 vs 197670±19131 $\mu m^2$ in Sham, $p<0.05$) which was lessened by Pio and Los (233408±17116 and 194250±25509 $\mu m^2$, p<0.05 vs UNx) but especially by the combination which was significantly less than Pio alone (Pio+Los: 146979±17046 $\mu m^2$, $p<0.05$). Assessment of plaque lesions revealed greater macrophage area in Pio+Los vs other treatments (80.7±11.4 vs Pio:50.3±4.2 and Los:57.2±6.5 %, $p<0.05$). The expanded macrophage area of Pio+Los had greater number of alternatively activated macrophages with anti-inflammatory/anti-atherogenic functions [Ym-1 positive macrophages (61.7±2.7 vs Pio:50.2±2.8 and Los:45.5±4.2 %, $p<0.05$)].

**Conclusion:** Despite elevated serum cholesterol, Pioglitazone lessens renal damage-induced amplification in atherosclerosis which is independent of blood pressure. This benefit is especially evident when combined with Losartan through an increase in the alternatively activated macrophages.

Disclosure of Financial Relationships: nothing to disclose

## SA-FC471

**Salt Sensitivity of the Aberrant Tubuloglomerular Feedback Responses after Subtotal Nephrectomy** Prabhleen Singh, Ali Kashkouli, Roland C. Blantz, Scott C. Thomson. *Nephrology, UCSD & VASDHS.*

We have repeatedly confirmed preserved tubuloglomerular feedback (TGF) responses in normal rats fed a high NaCl diet. We recently reported anomalous TGF responses in 50% of nephrons in rats after subtotal nephrectomy (STN) on a normal diet with moderate NaCl (AJP2009). Presently, we examined the microvascular basis for the latter phenomenon and tested it for salt sensitivity.

Rats were begun on low (commercial NaCl deficient diet) or high (1% NaCl in drinking water) salt diets from the time of STN and underwent micropuncture after 7 days. Mean body weights were similar in the two groups (267 vs.274 g), as was the food intake (7 vs.8 g/day). STN rats on high salt drank 2-fold more water than those on low salt (72 vs. 33 ml/day, p=0.002).

Group mean GFR was 1.25 ml/min in high salt and 1.0 ml/min in low salt (p=ns). Urine flow rates were higher in the high salt group 19μl/min vs. 10 μl/min in the low salt group (p=0.05). SNGFR and tubular stop flow pressure (PSF) were measured during

orthograde perfusion of Henle's loop (LOH) at 0 or 50 nl/min to characterize the TGF response. Glomerular capillary pressure (PGC) was calculated from PSF and plasma oncotic pressure.

Table 1

| Groups | SNGFR (nl/min) | | Late proximal flow (nl/min) | | PGC (mm Hg) | |
|---|---|---|---|---|---|---|
| | No LOH perfusion | Max LOH perfusion | No LOH perfusion | Max LOH perfusion | No LOH perfusion | Max LOH perfusion |
| Low salt STN | 42±2 | 31±3* | 30±2 | 21±2* | 75±3 | 69±3* |
| High salt STN | 46±4 | 54±3* | 30±3 | 35±2* | 73±2 | 73±2 |
| 2-way ANOVA cross term | | p=0.002 | | p=0.004 | | p<0.0005 |

*P<0.05 vs. No LOH perfusion by paired t-test

Both groups exhibited glomerular capillary hypertension. SNGFR and PGC responses to LOH perfusion in low salt STN were mundane. In high salt STN, SNGFR responses were frankly anomalous while PGC responses were nil, on average.

In STN rats on a high salt diet, the combined SNGFR and PGC response to LOH perfusion implies vasodilation of both afferent and efferent arterioles in order for SNGFR to increase while PGC remains constant. To facilitate salt balance on a high salt diet, the remnant kidney sacrifices stability of the early distal delivery by converting TGF from negative to positive feedback.

**A Mathematical Model of the Myogenic Response in the Rat Afferent Arteriole** Harold E. Layton,[1] Ioannis Sgouralis,[1] Leon C. Moore,[2] Anita T. Layton.[1] *[1]Department of Mathematics, Duke University, Durham, NC; [2]Deparatment of Physiology & Biophysics, SUNY Stony Brook, Stony Brook, NY.*

We have formulated a mathematical model of the rat afferent arteriole (AA). Our model consists of a series of arteriolar smooth muscle cells, each of which represents ion transport, cell membrane potential, cellular contraction, and wall mechanics. Blood flow through the AA lumen is described by Poiseuille flow. Model results suggest that interacting calcium and potassium fluxes, mediated by voltage-gated and voltage-calcium-gated channels, respectively, give rise to periodic oscillations in cytoplasmic calcium concentration, myosin light chain phosphorylation, and crossbridge formation with attending muscle stress mediating vasomotion. The AA model's representation of the myogenic response is based on the hypothesis that the voltage dependence of calcium channel openings responds to transmural pressure so that vessel diameter decreases with increasing pressure. With this configuration, the results of the AA model simulations agree well with findings in the experimental literature, notably those of Loutzenhiser et al., which showed that systolic blood pressure is an important determinant of renal vascular resistance (Am J Physiol Regul Integr Comp Physiol 290:R1153, 2006). The model can be incorporated into models of integrated renal hemodynamic regulation. This research was supported in part by NIH grant DK-42091 and by NSF grant DMS-0715021.

**The Anion Transporter Slc26a9 Plays an Important Role in Systemic Blood Pressure Control by Regulating Renal Chloride Excretion** Hassane Amlal,[1, 2] Sharon L. Barone,[1, 2] Jie Xu,[1, 3] Kamyar A. Zahedi,[1, 2] Manoocher Soleimani.[1, 2, 3] *[1]Center on Genetics of Transport, University of Cincinnati, Cincinnati, OH; [2]Medicine, University of Cincinnati, Cincinnati, OH; [3]Research Services, Veterans Administration, Cincinnati, OH.*

Slc26a9 (PAT4 = Putative Anion Transporter 4) ) is an electrogenic chloride transporter and is expressed in several epithelial tissues. However, its localization and role in the kidney remain unknown. RT-PCR experiments demonstrated the expression of Slc26a9 in the cortex and medulla and in cultured CCD and IMCD cells, and double immunofluorescence labeling co-localized Slc26a9 and AQP2 to the apical membrane of principal cells in the collecting duct. To ascertain the role of Slc26a9 in renal chloride excretion, wt and Slc26a9 ko mice were examined, before and after 24 hours of water deprivation. Wild type and Slc26a9 KO mice were placed in metabolic cages and after acclimation, were subjected to 24 hrs of water deprivation. The results indicated that mice with genetic deletion of Slc26a9 showed significant reduction in renal chloride excretion relative to wild type littermates when subjected to water deprivation (0.37 mEq/l/24 hrs in wt Vs. 0.185 in Slc26a9 ko; p<0.02). Food intake was comparable (2.84 +/- 0.12 and 2.40 +/- 0.43 gm/day in wt and ko animals, respectively, p>0.05) and baseline urine chloride excretion was not significantly different between the wt and mutant mice (0.44 +/- 0.08 and 0.32 +/- 0.045 mEq/l/24 hrs in wt and ko animals, respectively; p>0.05). Urine volume was lower (1.6 ml/24 hrs in wt animals and 0.80 in PAT4 ko animals, p<0.001), urine osmolality higher, and reduction in body weight was significantly less in water deprived Slc26a9 ko mice. Systemic blood pressure measurements by tail-cuff method at basal state demonstrated that Slc26a9 mice have elevated blood pressure, with systolic blood pressure being 117 +/- 7 mmHg in wt and 142 +/- 7 in Slc26a9 ko mice (p<0.02). We conclude that Slc26a9 is expressed in the collecting duct and plays an important role in renal salt excretion. We propose that diminished Slc26a9 function can impair the excretion of excess salt and result in salt-sensitive hypertension.

## SA-FC474

**Continued Renal Dysfunction after Percutaneous Transluminal Renal Angioplasty (PTRA) Is Associated with Microvascular Remodeling in Swine Atherosclerotic Renal Artery Stenosis (ARAS)** Alfonso Eirin,[1] Xiang-Yang Zhu,[1] Victor Urbieta Caceres,[1] James Krier,[1] John A. Crane,[1] Stephen C. Textor,[1] Amir Lerman,[2] Lilach O. Lerman.[1] *[1]Division of Nephrology and Hypertension, Mayo Clinic; [2]Cardiovascular Diseases, Mayo Clinic, Rochester, MN.*

Background: Revascularization fails to improve renal function in many patients with ARAS, but the mechanisms underlying irreversible renal injury have not been fully elucidated. This study tested the hypothesis that renal dysfunction after PTRA involves ongoing renal microvascular remodeling.

Methods: Pigs were studied after 10 weeks of ARAS, ARAS treated with PTRA and stenting 4 weeks earlier, and normal controls (n=10 each). Stenotic kidney blood flow and GFR were studied using multidetector CT. Renal microvascular architecture (micro-CT), fibrosis, oxidative stress, and angiogenic pathways were evaluated *ex-vivo*.

Results: Four weeks after successful PTRA mean arterial pressure decreased (from 179.116.48 to 105.216.5 mmHg, p<0.05 vs. ARAS, p=0.43 vs. Normal). However, stenotic kidney glomerular filtration rate (GFR) and renal blood flow remained decreased similar to untreated ARAS, and microvascular rarefaction and interstitial fibrosis did not change. The spatial density of outer cortical microvessels in ARAS and ARAS+PTRA correlated linearly with GFR (Figure). PTRA also failed to restore the expression of vascular endothelial growth factor or the fibrogenic factor Plasminogen Activator Inhibitor-1.

Conclusion: Tubulointerstitial injury in ARAS persisted 4 weeks after successful PTRA, and vessel loss correlated with the residual renal dysfunction. Microvascular loss and PAI-1-mediated fibrosis in swine ARAS, which might account for irreversible renal injury after PTRA, underscore the need for adjunct interventions beyond revascularization to restore stenotic kidney function.

## SA-FC475

**Succinate Activates the Collecting Duct Renin-Angiotensin System** Agnes Prokai, Anush Gevorgyan, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA.*

The TCA-cycle intermediate succinate is the ligand of the newly identified metabolic receptor GPR91, which is highly expressed in the juxtaglomerular apparatus (JGA) and in the collecting duct (CD). Tissue hypoxia and/or diabetic hyperglycemia causes mitochondrial stress, local accumulation of succinate in the kidney, GPR91-mediated glomerular hyperfiltration, JGA renin secretion, renin-angiotensin system (RAS) activation, and hypertension. CD renin is up-regulated in high angiotensin II states, and the CD is the major source of (pro)renin in diabetes (DM). In this study we investigated whether succinate and GPR91 signaling regulates the early elements of RAS in the CD.

M1 cells were treated with mannitol (5, 15, 25mM), glucose (5, 15, 25mM) and succinate (0.01, 0.1, 1mM) for 1 day. Acute treatment with 1mM succinate was performed for 6h. Western blot analyses and immunofluorescence were performed for extracellular signal-regulated kinases (ERK) 1/2 and p38, cyclooxygenase 2 (COX2), (pro)renin receptor [(P)RR], soluble (s) (P)RR, and (pro)renin. Urinary prostaglandin E2 (PGE2) excretion was measured in control and STZ-DM wild type (WT) and GPR91-/-mice.

Succinate treatment caused a significant, dose-dependent elevation in M1 cell pERK 1/2 levels. Similar increases in total (P)RR (1, 1.35, and 1.4-fold), s(P)RR (1, 1.5, and 2.65-

fold), pp38 (1, 4.6, and 1.75-fold), COX2 (1, 1.4, and 2.2-fold), prorenin (1, 2.1, 2.3-fold) and renin (1, 1.78, 2.73-fold) were observed 1 day after 25mM mannitol, glucose and 1mM succinate administration, respectively. Consistent with GPR91-mediated COX2-activation, the increased urinary PGE2 excretion (3 ng/24hr) observed in WT DM mice was abolished in DM GPR91-/-mice (1.3 ng/24hr, $p<0.05$).

These data support our hypothesis that succinate accumulation in diabetes activates the RAS in the CD, including the newly discovered (P)RR. Succinate and GPR91 signaling involves the activation MAP kinases and COX2, PGE2 release, and increased (pro)renin and (P)RR synthesis. Succinate-induced activation of the CD RAS may be important in controlling renal hemodynamics, systemic RAS, blood pressure in diabetes and in other kidney diseases that are associated with renal ischemia.

Disclosure of Financial Relationships: nothing to disclose

**SA-FC476**

**Effects of GLP-1 Receptor Activation on Renal Hemodynamics** Ali Kashkouli, Prabhleen Singh, Scott C. Thomson. *UCSD and VASDHS.*

Glucagon-Like-Peptide -1 (GLP-1) is a hormone secreted by the gut. GLP-1 receptors in gastrium, brain, and pancreas serve at multiple levels to stabilize blood glucose. GLP-1 receptors are also expressed in kidney cortex, where their function is poorly defined.

We recently examined the effects of the long-acting GLP-1 mimetic, exenatide, on glomerular and tubular function in the rat. In awake rats, exenatide infusion (1 nmol/h) increased whole kidney GFR from 2.2±0.3 ml/min to 4.3±0.2ml/min, $p=0.002$ and urine flow rate from 12±3 to 34+4 µl/min, $p=0.06$. Micropuncture experiments confirmed that exenatide is both a potent renal vasodilator and a proximal tubular diuretic and that it causes a rightward shift in the tubuloglomerular feedback response (EB 2010). Since this pattern resembles a test for renal functional reserve, which depends on nitric oxide, we presently tested the renal hemodynamic effects of exenatide for senstitivity to nitric oxide synthase (NOS) blockade in anesthetized rats.

Inulin and PAH clearances were measured before and during exenatide infusion in control and NOS blocked rats with standard L-NMMA infusion (0.5 mg/kg/min) begun 30 minutes prior to the onset of data collection.

L-NMMA increased blood pressure by 15 mmHg on average. Exenatide increased RBF, GFR, and urine flow rate despite the presence of NOS blockade (Table 1). Filtration fraction was unaffected by exenatide, suggesting no effect on glomerular capillary pressure. The differences in these parameters were of similar magnitude to that obtained with exenatide in the presence of placebo (normal saline).

Table 1

| Groups | Filtration Fraction | RBF(mL/min) | GFR(mL/min) | Urine flow rate(µL/min) |
|---|---|---|---|---|
| L-NMMA | 0.55±0.05 | 7.34±0.7 | 2.24±0.1 | 10±0.6 |
| L-NMMA + Exenatide | 0.49±0.03 | 11.31±1.2 | 3.14±0.14 | 35±9 |
| p values (by paired t-test) | 0.419 | 0.06 | 0.0032 | 0.06 |

Exenatide remains a potent renal vasodilator and diuretic in the presence of LNMMA, suggesting that its effects on the kidney are independent of nitric oxide.

Disclosure of Financial Relationships: nothing to disclose

**SA-FC477**

**Attenuated Tubuloglomerular Feedback (TGF) in Equilibrative Nucleoside Transporter 1 (ENT1)-Deficient Mice** Jurgen B. Schnermann, Lingli Li, Christoph Eisner, Yuning George Huang. *NIDDK, NIH, Bethesda, MD.*

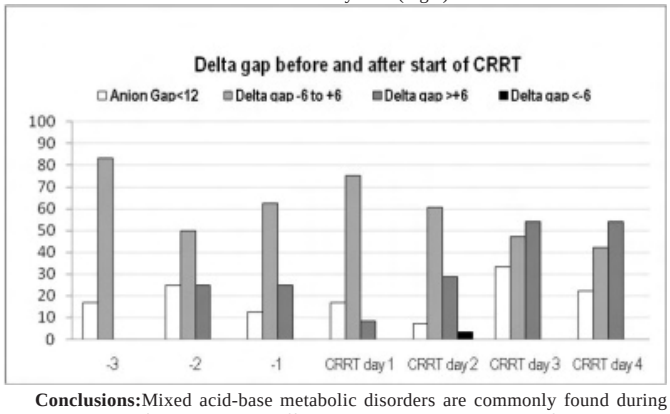
Previous evidence has indicated that adenosine 1 receptors (A1AR) are required for TGF responsiveness and that their ligand adenosine is at least in part derived from the extracellular metabolism of nucleotides. The present experiments were performed in ENT1-/- mice (C57BL/6 background) to test whether ENT1-mediated transmembrane movement of adenosine may also play a modifying role (breeder pairs of ENT1-/- mice were kindly provided by Doo-Sup Choi, Dept. Mol. Pharmacol. Psych, Mayo Clinic, Rochester, MN). Plasma concentrations of adenosine and inosine were markedly higher in ENT1-/- (1179±78 and 225±48 pmol/ml) than WT mice (179±24 and 47.5±9 pmol/ml). Telemetric measurements of 24-hour mean arterial blood pressure (mm Hg) and heart rates (bpm) were not significantly different between ENT1-/- and WT mice (114±14 and 557±39 vs. 114.3±8.1 and 594±46) despite the fact that spontaneous activity levels (6.5±5.7 vs. 9.3±8 movement cpm) as well as voluntary wheel running activity was lower in ENT1-/- animals. GFR of conscious female ENT1-/- mice averaged 347±59 ml/min (n=8; body weight 20.5±0.25 g) compared to 345±26 ml/min in WT mice (n=11; body weight 22.7±0.36 g). Responses of stop flow pressure (Psf) to maximum flow stimulation were significantly reduced in ENT1-/- compared to WT mice (1.63±0.4 mm Hg, n=28 vs. 5.8±1.1 mm Hg, n=17; $p<.0001$). Renal mRNA expression of A1AR, A2aAR, A2bAR, and A3AR were not significantly different between WT and ENT1-/- mice. In conclusion, TGF responsiveness is significantly attenuated in the absence of ENT1, and this effect may be related to A1AR saturation resulting from the marked increase of extracellular adenosine levels. The reduced spontaneous and voluntary locomotor activity is likely to result from the central inhibitory effect of adenosine.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO001**

**Clinical Utility of Delta Gap in Evaluating Mixed Metabolic Acid-Base Disorders in Acute Kidney Injury (AKI)** Rolando Claure-Del Granado,[1] Etienne Macedo,[1] Sharon Soroko,[1] Glenn M. Chertow,[2] Jonathan Himmelfarb,[3] T. Alp Ikizler,[4] Emil P. Paganini,[5] Ravindra L. Mehta.[1] *[1]University of California, San Diego; [2]Stanford University School of Medicine; [3]Kidney Research Institute, University of Washington; [4]Vanderbilt University Medical Center; [5]Cleveland Clinic Foundation.*

**Background:** Metabolic acid-base disorders are common in ICU pts with AKI however are often not well characterized. Mixed metabolic acid-base disorders are often unrecognized as they are influenced by multiple factors including the severity of AKI and the underlying disorders. We hypothesized that Δ gap would identify persistent alterations in acid-base balance. **Methods:** We analyzed data from 363 ICU pts with AKI who were dialyzed, from 5 centers included in the PICARD study. Mixed acid-base disorders were classified using the Δ gap (Δ anion gap- Δ bicarb), into the following groups: a) anion gap (AG) acidosis (Δ gap -6 to +6) b) AG acidosis + metabolic alkalosis (Δ gap >+6) c) non AG acidosis + AG acidosis (Δ<-6). Changes in Δ gap were assessed during consecutive days of IHD and CRRT. **Results:** At initiation of dialysis the mean values of $HCO_3$, pH and AG were similar for both modalities. After initiation of RRT, the % of pts with pure AG acidosis declined over consecutive days of RRT however there was an increase of metabolic mixed acid-base disorders which differed based on the modality used (Fig 1).



**Conclusions:** Mixed acid-base metabolic disorders are commonly found during consecutive days of RRT that can be effectively evaluated by Δgap. Use of saline solution and consequent hyperchloremia, citrate and other factors that are present during RRT could contribute to the persistence of mixed metabolic acid-base disorders. Therapy adjustments with dialysis should consider the effect on acid base status.

**TH-PO002**

**Efficacy of Glucose Versus Glucose Plus Insulin in the Treatment of Hyperkalaemia** Mogamat-Yyazied Chothia,[1] Mitchell L. Halperin,[4] Megan A. Rensburg,[2] Mogamat Shafick Hassan,[3] Mogamat Razeen Davids.[1] *[1]Stellenbosch University, Cape Town, South Africa; [2]Stellenbosch University & NHLS, Cape Town, South Africa; [3]Cape Peninsula University of Technology, Cape Town, South Africa; [4]University of Toronto & St Michael's Hospital, Toronto, Canada.*

**Introduction**

The emergency treatment of hyperkalaemia remains controversial. Most authors recommend the use of insulin plus glucose as first-line therapy. However, symptomatic hypoglycaemia remains a common complication of this treatment. This study examined the ability of a glucose bolus to cause insulin release and potassium shift into cells without the risk of hypoglycaemia.

**Methods**

A randomised cross-over study compared an IV glucose bolus alone to glucose plus insulin in 7 chronic haemodialysis patients. The primary endpoint was a significant difference K at 60 minutes. Hypoglycaemic episodes and serum insulin concentrations were also recorded.

**Results**

Baseline K was similar at 5.86 ± 0.66 mM in the insulin group and 5.83 ± 0.70 mM in the glucose-only group. Mean serum potassium at 60 minutes was 4.91 ± 0.50 mM in the insulin group versus 5.40 ± 0.87 mM in the glucose-only group (p=0.022). The absolute fall in K was 0.94 ± 0.56 mM in the insulin group versus 0.43 ± 0.25 mM in the glucose-only group (p=0.063). There were 6/7 subjects in the insulin group and only 3/7 in the glucose-only group who demonstrated a fall of at least 0.5 mM at the 60-min time point.

The range of blood glucose concentrations recorded was 3.0-26.8 mM in the insulin group and 3.8-29.3 mM in the glucose group. At all time points after baseline, the insulin group had higher plasma insulin concentrations and lower glucose/insulin ratios.

**Conclusion**

This study confirmed the superiority of glucose plus insulin for the emergency treatment of hyperkalaemia. Clinicians must attempt to prevent hypoglycaemia by infusing adequate amounts of glucose. A glucose-only bolus has a moderate effect, similar to that seen in some studies of inhaled beta-agonists, and may be considered as another therapeutic option in a situation when insulin is not immediately available.

**Assessing and Tracking Impact of Use of Sodium Polystyrene Sulfonate in an Inner City Hospital** Zaher Hamadeh, Pu Zong, Manish Ramesh, Anjali Acharya. *Department of Nephrology, Albert Einstein College of Medicine (Jacobi), Bronx, NY.*

***Introduction:*** Sodium Polystyrene Sulfonate (SPS) is a cation-exchange resin commonly used for treatment of hyperkalemia.SPS releases sodium ions in the acidic stomach, binds hydrogen ions and exchanges hydrogen ions for potassium in the intestine. Originally SPS was given mixed in water which caused constipation and fecal impaction.It was then mixed with 70% sorbitol, an osmotic cathartic agent which has been implicated in the associated complications of intestinal necrosis and other serious gastrointestinal adverse events. The formulation was then changed to 33% Sorbitol. Recently, there has been an interest again in the safety and effectiveness of SPS. Since SPS is a commonly used drug at our institution we looked at our experience with it. ***Methods***: Retrospective chart review using Electronic Medical Record (EMR). We obtained from the pharmacy a list of all patients who received SPS from 05/01/2009 until 04/30/2010. Billing data was retrieved from the database using the ICD 9 codes *of interest and gastrointestinal symptoms during the same period of time. Records of the 28 patients who were cross referenced on the two lists were reviewed for complications following each SPS dose.

Table 1

| | |
|---|---|
| Total number of patients received SPS | 988 |
| Total number of SPS doses given. | 2023 |
| Total number of patients with ICD codes * | 26 |
| Average dose of SPS (gram) | 22.4 |
| Average number of SPS doses per patient | 2.04 |
| Mean pre SPS K (mEq/L) | 5.76 +/- 0.08 |
| Mean post SPS K (mEq/L) | 4.98 +/- 0.07 |
| Number of patient who had serious GI events | 0 |

*569.83 Perforation of Intestine, 560 Intestinal Obstruction,560.89 Acute pseudo-obstruction of intestine 560.81 Intestinal or peritoneal adhesions with obstruction 560.1 Paralytic Ileus.

***Results***: No serious gastrointestinal adverse effects occurred after SPS dose. Mean pre and post SPS potassium values were 5.76 +/- 0.08 mEq/L and 4.98 +/- 0.07 mEq/L respectively(p value<0.0001). ***Conclusion:*** In our experience SPS is effective in lowering potassium levels and has not been associated with any severe adverse gastrointestinal complications.

**A Comparison of Serum Bicarbonate and Potassium Concentration Measurements in Arterial and Venous Samples** William G. Herrington,[1] Helen Nye,[1] Peter Watkinson.[2] *[1]Renal and General (Internal) Medicine, Oxford Radcliffe Hospitals NHS Trust, Oxford, United Kingdom; [2]Kadoorie Centre for Critical Care Research and Education, Oxford Radcliffe Hospitals NHS Trust, Oxford, United Kingdom.*

**Introduction**

Blood gas analysis is an important tool for the rapid assessment of critically ill patients. Previous studies do not consistently suggest that arterial and venous sites can be used interchangeably. Lack of duplication of each analysis in these studies means it is unclear whether perceived differences between sample sites reflects instrument imprecision.

**Aim**

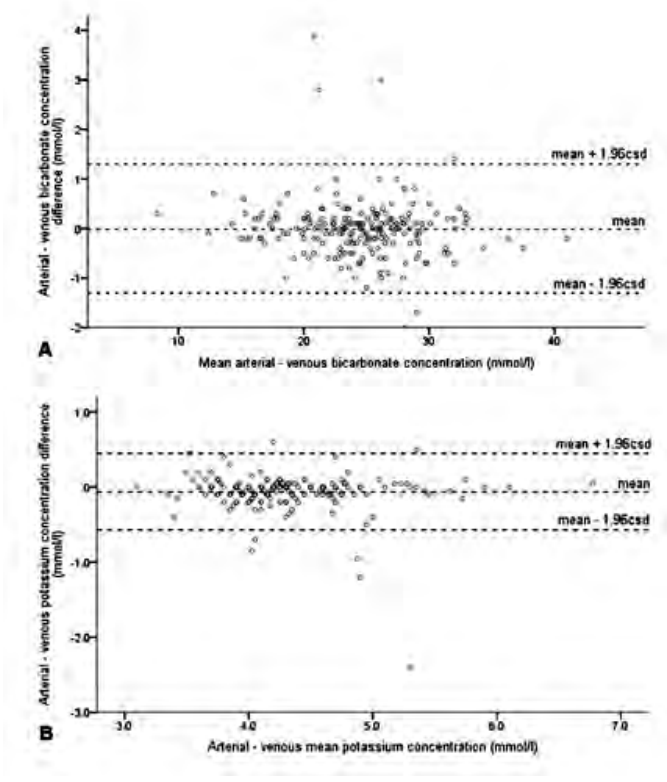
To assess the comparability of venous and arterial samples for bicarbonate and potassium measurements.

**Methods**

Simultaneous arterial and venous samples from 206 critically ill patients were analysed in duplicate. Coefficients of variation and 95% limits of agreement for duplicate measures were calculated for arterial and venous samples. Bland Altman plots (using the means of the two duplicates and the corrected standard deviation of the differences) were constructed to assess agreement between sampling sites.

**Results**

The median (range) of arterial bicarbonate concentrations and arterial potassium concentrations were 25 (9-41) mmol/l and 4.2 (3.1-6.8) mmol/l respectively. Coefficients of variation for arterial and venous bicarbonate results were 0.8 and 0.7% respectively, with bias (95% limits of agreement) of 0 (-0.5-0.5) mmol/l for both sample types (A). The bias between venous and arterial samples was 0 (-1.3-1.3) mmol/l. Coefficients of variation for arterial and venous potassium samples were 0.8 and 1.1% respectively, with bias of 0 (-0.1-0.1) for both sample types. The bias between venous and arterial samples was 0.1 (-0.4-0.6) mmol/l (B).



**Conclusions**

A venous blood sample is sufficiently accurate to assess bicarbonate and potassium concentrations in critically ill patients.

## TH-PO005

**Clinicogenetic Features of Korean Patients with Gitelman Syndrome** Kwon Wook Joo,[1] Ki Young Na,[1] Sejoong Kim,[2] Hye Ryoun Jang,[3] Jay Wook Lee,[5] Hae Il Cheong,[4] Jin Suk Han.[1] *[1]Internal Medicine, Seoul National University Hospital, Seoul, Korea; [2]Internal Medicine, Gachon University of Medicine and Science, Incheon, Korea; [3]Internal Medicine, Samsung Medical Center, Seoul, Korea; [4]Pediatrics, Seoul National University Hospital, Seoul, Korea; [5]Internal Medicine, Chung-Ang University Yong-San Hospital, Seoul, Korea.*

New classification of Bartter-like syndromes according to the underlying defective ion transporter is recently proposed due to diverse clinical features and genetic mutations of Gitelman syndrome(GS). Although mutations in *CLCNKB* as well as *SLC12A3* can also be the cause of GS, incidence and clinical differentiation in GS patients of the two mutations are still unclear. We investigated the clinical features and genetic variations of Korean patients with GS. 24 Korean GS patients(16 males and 8 females) were enrolled. Their clinical history, biochemical features, results of thiazide test, and mutation analysis of *SLC12A3* and *CLCNKB* were compared. Genes for *SLC12A3* and *CLCNKB* were directly sequenced and analyzed. All the subjects had hypokalemia, metabolic alkalosis, and normal blood pressure. Hypocalciuria was observed in 22 patients. 9 patients did not have hypomagnesemia. *SLC12A3* gene mutations were detected in 21 patients(9 compound heterozygous, 7 heterozygous, and 5 homozygous mutations). Mutations in *CLCNKB* were identified in 2 patients(1 heterozygous; W530L, 1 homozygous; W610X) with *SLC12A3* mutations and in 1 patient(homozygous; E199X) without *SLC12A3* mutations. Thiazide test was performed in 20 patients, of which results were compatible with GS except in 1 patient who had only homozygous *CLCNKB* mutation. The patient with mutations in *CLCNKB* showed relatively early onset and mild growth retardation, but biochemical abnormalities were not distinguishing. The patient with only homozygous *CLCNKB* mutation showed reduction of distal fractional chloride reabsorption in response to thiazide by more than 50%. Diagnosis of GS can depend primarily on the clinical criteria and thiazide test. The overlap between clinical presentations of *CLCNKB* and *SLC12A3* mutations was significant and mutation analysis of both *CLCNKB* as well as *SLC12A3* is necessary.

## TH-PO006

**Unusual Presentation of Gitelman's Syndrome: A Case Report** Smitha Reddy Anam,[1] Yangming Cao.[2] *[1]Internal Medicine, UCSF Fresno, Fresno, CA; [2]Nephrology, UCSF Fresno, Fresno, CA.*

**Background**: Despite advancement of genetic tests, the clinical diagnosis of Bartter's syndrome (BS) and Gitelman's syndrome (GS) can be challenging. Here we describe an unusual case of GS with hypercalciuria and hypocalcemia.

**Case Report**: A 45 year-old Hispanic male presented to the emergency room with a 3 day history of generalized weakness and muscle cramps. He had no significant past medical history and denied taking any medications or recent alcohol use. On physical exam he was normotensive, but he developed bilateral carpopedal spasm immediately after admission. He had hypokalemia (serum $K^+$ 2.7 mEq/L), hypomagnesemia (serum Mg 0.8 mg/dL) and metabolic alkalosis. He also had hypocalcemia (serum Ca 6.7 mg/dL and ionized $Ca^{++}$ 4.05 mg/dL) with 25(OH)Vit D deficiency (serum 16 ng/ml). Serum renin and aldosterone levels were normal. Twenty-four hour urinary electrolytes were consistent with renal wasting of $Na^+$ (405 mEq), $K^+$ (86.8 mEq), $Cl^-$ (459 mEq), Ca (376 mg) and Mg (694 mg). Surreptitious use of diuretics (bumetanide and furosemide) was excluded by test. The hypercalciuria with hypocalcemia made diagnosis of GS difficult. Hence a a 50 mg hydrochlorothiazide (HCTZ) challenge test after adequate hydration was performed. Compared with baseline FeCl (1.5%), FeCl increased to 1.9% (Δ FeCl 0.4%) at 30 min and 2.1% (ΔFeCl 0.6%) at 60 min after HCTZ. This demonstrated a blunted response of FeCl to HCTZ. A diagnosis of GS was made. Over a few days, his serum electrolytes normalized with replacement. His symptoms resolved and was discharged on oral supplements of K, Mg, Ca, Vit D and spironolactone.

**Discussion:** Diagnosis of GS over BS was favored because of age at presentation, hypomagnesemia and absence of overt polyuria. HCTZ challenge test showed a blunted response of FeCl (Δ FeCl 0.6%). From literature review, maximal increase of FeCl (Δ FeCl) of <2.3% after HCTZ indicates GS. Even though GS typically has hypocalciuria, our patient had significant hypercalciuria despite hypocalcemia. The hypocalcemia may be explained by vitamin D deficiency and hypomagnesemia.

**Conclusion**: HCTZ challenge test aids the diagnosis of GS.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO007

**Lowe Syndrome-Like Phenotype Caused by a Large Deletion That Includes CLCN5: A Novel Contiguous Deletion Syndrome** Mathieu Lemaire,[1,2] Hae Il Cheong,[3] Weizhen Ji,[1,2] Hyewon Park,[4] Jae Il Shin,[5] Richard P. Lifton.[1,2] *[1]Genetics, Yale School of Medicine, New Haven, CT; [2]HHMI; [3]Pediatrics, Seoul National University, Children's Hospital, Seoul, Korea; [4]Pediatrics, Seoul National University, Bundang Hospital, Seongnam, Korea; [5]Department of Pediatrics, Yonsei University College of Medicine, Severamce Children's Hospital, Seoul, Korea.*

Lowe syndrome is characterized by renal proximal tubule dysfunction, congenital cataracts, cryptorchidism, stunted growth, mental retardation and seizures. It is caused by mutations in OCRL1. Proximal tubule dysfunction observed in Dent's disease is analogous to that of patients with Lowe syndrome: at a minimum, low molecular weight proteinuria (LMWP) and either hypercalciuria or nephrocalcinosis are documented, with or without other tubular defects. Dent's disease is mainly caused by mutations in CLCN5, but a small number of patients also harbor OCRL1 mutations. We report the case of an orphaned 5-year-old Korean male with clinical features consistent with a diagnosis of Lowe syndrome: LMWP with hypercalciuria and nephrocalcinosis, cryptorchidism, stunted growth (< 3rd percentile), developmental delay and recurrent seizures. However, a number of unusual characteristics for Lowe syndrome were noted, such as hypothyroidism, micropenis, cleft palate and absence of cataracts. Since genomic analysis revealed no mutation in OCRL1, analysis of CLCN5 was attempted: only exon 1 of CLCN5 was successfully amplified by PCR. SNP genotyping on the 650K Illumina platform suggested a 3.5 Mb deletion at Xp11.22, and long-range PCR was used for fine mapping. Apart from CLCN5, the deleted interval also contains 14 genes. Of these, only SHROOM4 has a well-described association to a male-specific condition, namely Stocco dos Santos syndrome. Its typical features are reminiscent of our patient's: mental retardation, seizures and stunted growth. We posit that the unusual Lowe syndrome-like phenotype exhibited by our patient is due to a novel contiguous deletion and is in major part explained by the simultaneous loss of function of CLCN5 and SHROOM4. The remaining 13 genes are prime candidates to explain the characteristics that remain unaccounted for.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO008

**The Relationship between Arginine Vasopressin Levels and Hyponatremia in Children Receiving Hypotonic or Isotonic Intravenous Fluids Following a Percutaneous Renal Biopsy** Michael L. Moritz,[1] Kandai Nozu,[2] Kazumoto Iijima.[2] *[1]Pediatrics, Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [2]Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan.*

**Background:** Post-operative hyponatremia is a common complication in children which results from hypotonic fluid administration in the presence of arginine vasopressin (AVP) excess. There is increasing evidence to suggest that 0.9% sodium chloride could prevent post-operative hyponatremia.

**Purpose:** To evaluate the relationship between the change in serum sodium and AVP levels following a percutaneous renal biopsy in children receiving either hypotonic or isotonic fluids.

**Methods:** A prospective observational study was conducted in 60 children, ages 2 – 21 yrs, undergoing a percutaneous renal biopsy (PRB) from July 2006 to September 2008 at Kobe University Medical Center, Japan. Thirty-three patients received hypotonic fluids (90 mEq/l NaCl) and 27 patients received isotonic fluids (154 mEq/L NaCl) for 5 hours post PRB. AVP levels and biochemistries were obtained prior to (T0) and 5 hrs following (T5) the PRB. Patients were further subdivided into two groups based on the AVP level at T5, those with normal T5 AVP level (< 3.5 pg/ml) and those with an elevated T5 AVP level (> 3.5 pg/ml). The relationship between change in serum sodium in patients with elevated AVP levels were evaluated.

**Results:** A similar proportion of patients, whether receiving hypotonic or isotonic fluids, had elevated AVP levels at T5 ( 30% vs 26%, p = 0.71). Patients receiving hypotonic fluids with elevated T5 AVP levels had a 1.9 ± 1.5 mEq/l fall in serum, whereas patient receiving isotonic fluids with elevated T5 AVP levels had a 0.85 ± 0.34 mEq/l rise in serum sodium. There were no significant changes in serum sodium in patients with normal T5 AVP levels in either group**.**

**Conclusions:** Elevated AVP levels are common following a percutaneous renal biopsy. 0.9% NaCl prevents a fall in serum sodium in the presence of elevated AVP levels while hypotonic fluids do not.

Disclosure of Financial Relationships: nothing to disclose

**Maintenance Parenteral Fluid Prescribing Practices among Pediatric Residents** Michael A. Freeman,[1] Juan Carlos Ayus,[2] Michael L. Moritz.[1] *[1]Pediatrics, Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [2]Renal Consultants of Houston, Houston, TX.*

**Background:** The standard practice in pediatrics for over 50 years has been to prescribe hypotonic maintenance intravenous fluids (IVF) (Pediatrics 1957;19:123). In 2003, we questioned the safety of this practice (Pediatics 2003;111:2270) and since that time there has been mounting evidence that hypotonic IVF lead to hospital-acquired hyponatremia in states of AVP excess, whereas isotonic IVF effectively prevent it. There is no data evaluating whether IVF- prescribing practice has changed with increased awareness of this problem.

**Purpose:**To investigate sodium composition of IVF in use by pediatric residents throughout the United States in common clinical scenarios of AVP excess.

**Methods**: An internet survey was distributed to all pediatric residency programs in the US asking residents what type of IVF (0.2%, 0.45%, 0.9% NaCl or Lactated Ringers) they would administer in four common clinical scenarios (Table) in both a 6-mo-old and 13-yr-old child.

**Results:** Respondents selected a hypotonic IVF in78% of cases. The 0.2% NaCl solution was commonly used in infants (35.5%), yet rarely used in the older children (0.5%). The choice of IVF composition varied by both the age and illness of the child (Table), with isotonic IVF more likely to be used in children with meniningitis.

Percentage of Pediatric Residents Selecting Hypotonic Fluids

| Clinical Scenario | 13-yr-old pt | 6-mo-old pt |
|---|---|---|
| Gastroenteritis | 69% | 91% |
| Pneumonia | 75% | 92% |
| Meningitis | 51%* | 79%* |
| Post-surgical | 72% | 91% |

p < 0.01

Seventy-five percent acknowledged being aware of the clinical controversy regarding the use of isotonic IVF. Residents aware of the controversy were twice as likely to prescribe isotonic IVF than those unaware ( 24.5% vs 12.9%, P<0.001).

**Conclusions:** The majority of pediatric residents continue to use hypotonic IVF. However, a significant number of residents are using isotonic IVF. Awareness of this clinical controversy is prevalent and those residents who are aware of this controversy are more likely to use isotonic IVF.

## TH-PO010

**Stanniocalcin-1 Protects from Ischemia/Reperfusion Kidney Injury** Luping Huang, Tatiana Belousova, David Sheikh-Hamad. *Medicine, Baylor College of Medicine, Houston, TX.*

Inflammation, endothelial dysfunction, ROS production and MAPKs play critical roles in the pathogenesis of Ischemia/reperfusion kidney injury (I/R). Published data from our lab suggest that stanniocalcin-1 (STC1): blocks cytokine-induced rise in endothelial permeability; inhibits macrophage function; and suppresses superoxide generation in many systems (including endothelial cells and macrophages). We hypothesized that STC1 protects from ischemia/reperfusion kidney injury through inhibition of key pathways in its pathogenesis. Using wild type and STC1 transgenic mice which display high circulating STC1 levels and preferential expression of STC1 transgene in macrophages and endothelial cells, we examined the following at baseline, 24h, 48h, 72h, and 8d after I/R kidney injury (generated by clamping bilateral renal arteries for 30 min; Sham-treated controls were subjected to the same surgical procedure without renal aa clamping): creatinine clearance (CrCl); kidney morphology and infiltration with macrophages and T-cells; trans-endothelial permeability, measured using evans blue; NOS activity, measured as production of nitrates and nitrites. Results: following I/R and compared to sham-treated controls: WT mice displayed >65% drop in creatinine clearance (at 72h), coupled with severe tubular vacuolization and cast formation (at 24h, 48h and 72h); increased macrophage and T-cell infiltration (from 24h through day 8); higher trans-endothelial permeability to Evans blue; lower NOS activity (24h and 48h); but, greater pERK/pJNK+p-p38 activity ratio (at 24h and 48h). On the other hand, STC1 Tg mice displayed: no drop in creatinine clearance; no morhpological changes; no increase in macrophage or T-cell infiltration; no change in pERK/pJNK+p-p38; while NOS activity was preserved. Conclusions: 1) Transgenic overexpression of STC1 protects from I/R kidney injury; 2) Protection by STC1 from I/R is associated with stable NOS activity, preservation of endothelial permeability, and inhibition of inflammation.

## TH-PO011

**Activator of G Protein Signaling 3 Promotes Renal Epithelial Cell Proliferation Following Ischemia-Reperfusion Injury** Kevin R. Regner,[1] Michelle J. Kwon,[1] Sarah M. White,[1] Vani Nilakantan,[2] Frank Park.[1] *[1]Nephrology, Medical College of Wisconsin; [2]Surgery, Medical College of Wisconsin, Milwaukee, WI.*

Renal tubular epithelial cell (RTEC) proliferation plays a critical role in the regeneration of the kidney following ischemia-reperfusion injury (IRI). The mechanisms that regulate RTEC proliferation following IRI remain poorly understood. Heterotrimeric G proteins are pivotal molecular switches that can regulate epithelial cell biology. In genetic models of abnormal RTEC proliferation, our lab has identified elevated expression of Activator of G protein signaling 3 (AGS3), a novel receptor-independent regulator of G proteins. We therefore reasoned that AGS3 may regulate RTEC proliferation during the regenerative phase following experimental renal IRI. Sprague-Dawley rats underwent 30 min bilateral renal ischemia and reperfusion for 24 to 168 hours. During the reperfusion phase, there was a temporal increase in renal AGS3 protein expression reaching a peak level at 72 hours (60-fold increase compared to time-control sham-operated kidneys). This increase in AGS3 expression lagged the changes in serum creatinine. By 168 hours, AGS3 expression decreased to levels found in sham-operated kidneys. The increased AGS3 expression was exclusively localized to outer medullary RTECs and ~50% of all AGS3-positive RTECs were also positive for Ki-67, a marker of proliferation. Genetic knock-down of endogenous AGS3 in normal rat kidney epithelial cells using specific AGS3 shRNA significantly reduced cell proliferation by 26% through a cAMP-independent mechanism. Dose-dependent decreases in epithelial cell proliferation were observed following the incubation of renal epithelial cells with gallein (1.3-6.5 mM), a selective inhibitor of Gβγ subunit activity. Similar reductions in epithelial cell number (~30%) were observed using lentiviral overexpression of GRK2ct, a scavenger of Gβγ subunits, which confirmed our pharmacologic experiments. In conclusion, our data suggest that AGS3 participates in the process of RTEC proliferation during renal tubular regeneration by activating Gβγ subunits through a novel receptor-independent mechanism.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO012

**PGC-1α Is Transcriptionally Up-Regulated in Renal Tubules of Ischemia/Reperfusion AKI Via Hypoxia and AMPK** Yoshio Terada. *Department of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi University, Nankoku, Kochi, Japan.*

PGC-1α plays a central role in regulating the mitochondrial content and oxidative metabolism. Oxidative stress and mitochondrial damage were key factors in acute kidney injury (AKI). However, the regulation and functional roles of PGC-1α in renal tubules were poorly understood. Understanding the regulation and function of PGC-1α in renal tubules would provide important clues to the elucidation of the pathophysiology of AKI.

The aim of this study is to understand the roles of PGC-1α in AKI in vivo and in vitro, and the regulation of PGC-1α gene in renal tubular cells. To clarify the significance of PGC-1α and AMPK pathway in AKI, we used a rat AKI model in vivo and cultured renal tubular cells (NRK-52E cells) as an in vitro model. After clamping left rat renal artery for 1 h, kidney homogenate at 1-72 h after reperfusion was extracted. In Western blot analysis, PGC-1α expression and phosphorylation of AMPK were increased at 12-24h and 3-12h, respectively. In immunohistological examination, expression of PGC-1α and phosphorylation of AMPK were increased in proximal tubules. To understand the regulation of PGC-1α in renal tubular cells, we transfected PGC-1α-promoter-luciferase plasmid to NRK-52E cells. H2O2 and AICAR (AMPK activator) significantly increase promoter activity, mRNA and protein expression of PGC-1α. Overexpression of wild type of AMPK induced PGC-1α expression, and DN-AMPK reduced expression. Furthermore, overexpression of PGC-1α induced mitochondrial enzymes, such as UCP (uncoupling protein)-1.

In conclusion, PGC-1α is transcriptionally up-regulated in hypoxic condition in renal tubules via oxidative stress and AMPK. PGC-1α may regulate mitochondrial content and oxidative metabolism in AKI. The current study therefore unravels both pathophysiological significance of PGC-1α in ROS-induced cell damages of renal tubular cells in vivo and in vitro.

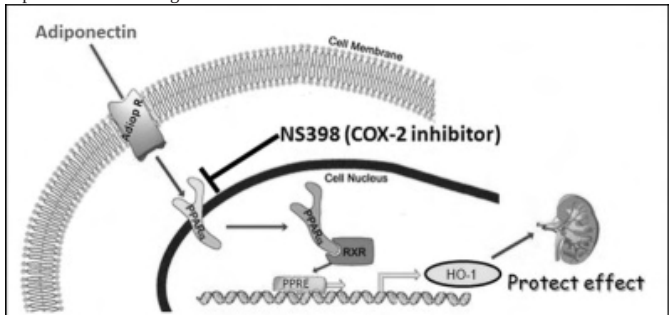
**TH-PO013**

**Protective Effects of Adiponectin Against Renal Ischemia-Reperfusion Injury Via Prostacyclin -PPARα- Heme Oxygenase-1 Signaling Pathway**
Wei-Shiung Lian, Hsiao-Fen Li, Ching-Feng Cheng, Heng Lin. *Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan.*

Adiponectin (APN), a circulating adipose-derived hormone that regulates inflammation and energy metabolism, has beneficial effects on the cardio- and cerebro-vascular disorders. Serum APN levels are lower in patients with coronary artery disease and type II diabetes, while hyper-adiponectinemia is found in patients with chronic kidney disease. However, the precise role and molecular mechanism of APN in acute reno-vascular disease is not clear. Results of the present study show that the serum concentration of APN decreased after ischemia /reperfusion (I/R) injury in mice. In addition, I/R-induced renal dysfunction (elevated serum creatinine and urea levels), inflammation (number of infiltrating neutrophils, myeloperoxidase activity, induction of IL-6 and P-selectin) and apoptotic responses (apoptotic cell number and caspase-3 activation) were attenuated in APN-treated compared to control mice. Molecular and biochemical analysis revealed that APN up-regulates heme oxygenase-1 (HO-1) via peroxisome-proliferator- activated-receptor-α (PPARα) dependent pathway which is mediated through the enhancement of COX-2 and 6-keto PGF1α expression. Chromatin immune-precipitation assay demonstrated that APN increases the binding activity of PPARα to the PPRE region of HO-1 promoter. Furthermore, APN induced HO-1 expression only found in wild type but not in PPARα gene deleted mice. This provides in vivo evidence that APN mediated HO-1 expression depends on PPARα regulation.



In conclusion, our results provide a novel APN mediated prostacyclin-PPARα- HO-1 signaling pathway that mediates its protective effects on renal I/R injury.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO014**

**The Renoprotective Mechanism of Autophagy Against Ischemia-Reperfusion Injury Is UCP2 Protein Dependent**
Yang Zhou, Ruoyun Tan, Junwei Yang. *Center for Kidney Disease, 2nd Affiliated Hospital of Nanjing Medical University, Nangjing, China.*

Recently, autophagy has been identified as a major pathway that delivers damaged proteins and organelles to lysosomes in order to maintain cellular homeostasis. The renoprotective role of Autophagy during ischemia and reperfusion (I/R) is not clear and is currently under intense investigation. Uncoupling protein 2 (UCP2) is a ubiquitously expressed mitochondrial carrier protein. It mediates proton leak across the inner mitochondrial membrane to decrease the yield of ATP from glucose. Here, we found that UCP2 expression was up-regulated after renal I/R injury. Meanwhile, renal specific UCP2-knockout (UCP2-/-) mice had higher renal I/R-induced mortality, kidney dysfunction, oxidative stress, and apoptosis compared with wild-type mice. Furthermore, mice administered with genipin, a specific chemical inhibitor of UCP2, also had more severe kidney dysfunction compared with vehicle treated mice. Analysis of pathophysiological conditions indicated that autophagy-mediated abnormal protein and organelle degradation mechanism was largely impaired in UCP2-/- mice. These findings highlight the importance of UCP2 as a key regulator of autophagy-mediated homeostatic mechanism to maintain renal parenchyma integrity. We postulate that UCP2-dependent autophagy is a major protective mechanism against renal tubule injury, representing a putative target to ameliorate human acute renal injury and I/R-related loss of renal function.

**Proximal Tubular Cells Acquire the Progenitor Markers CD24 and CD133 during Tubular Repair**
Bart Smeets,[1,2] Jurgen Floege,[1] Johan Van der Vlag,[3] Jack F. Wetzels,[3] Marcus J. Moeller.[1] *[1]Div. of Nephrology and Immunology, University Hospital Aachen, RWTH, Aachen, Germany; [2]Pathology, RUNMC, Nijmegen, Netherlands; [3]Nephrology, RUNMC, Nijmegen, Netherlands.*

Acute tubular necrosis is followed by regeneration of the injured renal tubular epithelial cells. It is has been shown that proximal tubuli are regenerated from intrinsic cells. Nonetheless, it is still unresolved whether intratubular stem/progenitor cells or the entire cell population contribute to the regeneration.

In this study, we identified a cell population localized in the proximal tubuli expressing the progenitor markers CD24 and CD133 using immuno-electron microscopy and immunofluorescent staining of normal human kidney sections and of biopsies showing acute tubular necrosis (ATN). Within normal human kidneys CD24 positive cells were scattered as single cells or in small groups of 2-4 cells throughout the proximal tubule and co-expressed the stem cells marker CD133. The morphology of CD24 positive cells differed from that of normal proximal tubular cells and contained less cytoplasma, fewer mitochondria and the brush border was absent. In contrast to normal proximal tubular cells, the cells expressed CD24, CD133, CXCR4, and other markers that are associated with epithelial dedifferentiation.

In ATN biopsies, the number of CD24 positive tubular cells was much higher compared to normal human kidneys. To establish whether the CD24 positive cells were regenerative, we co-stained for the proliferation marker Ki-67. We observed that in both normal human kidneys and in the ATN biopsies the majority (~85%) of the Ki-67 positive cells was also CD24 positive.

In conclusion, CD24 positive proximal tubular cells represent a novel distinct subpopulation of cells, which apparently participate in the regeneration after ATN.

**Telomerase Is Expressed in Renal Epithelia in Kidney Medulla and Papilla and Is Upregulated with Injury**
Jie Song,[1,4] Suzanne Czerniak,[1] Teresa Wang,[1] Wendy Ying,[1] Diana Carlone,[2] David Breault,[2,3] Benjamin D. Humphreys.[1,3] *[1]Renal, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Endocrinology, Children's Hospital, Harvard Medical School, Boston, MA; [3]Harvard Stem Cell Institute, Cambridge, MA; [4]Renal, Huashan Hospital, Fudan University, Shanghai, China.*

Telomerase, the enzyme responsible for maintaining telomere length and thus preventing cellular senescence, is highly expressed in embryonic stem cells but downregulated in adults, except in certain adult stem cells including those in intestine, testis, and hematopoietic system. We generated transgenic reporter mice in which the Telomerase promoter drives either GFP or CreERt2 (*mTert*-GFP, *mTert*-CreERt2) to analyze kidney Telomerase expression during homeostasis, acute injury and repair.

We report that renal papilla and inner medulla, areas of high oxidative stress in kidney, express high levels of both *mTert* mRNA and Telomerase activity. Using *mTert*-GFP reporter mice, we observe mosaic *mTert* expression restricted to a subset of tubular epithelial cells, co-localizing predominantly with collecting duct marker (AQP2) but also with thin and thick loop of Henle markers (AQP1, NKCC2 and THP). There was no co-localization of *mTert*-GFP+ cells with interstitial markers CD31, F4/80, $NG_2$ or PDGFRβ. Since Telomerase expression marks stem cells in other adult tissues, we examined whether *mTert*+ cells are slow cycling. After a two-day BrdU pulse at birth followed by an 8 week chase, 5% of *mTert*-GFP cells were long term label retaining. Ischemia-reperfusion injury (IRI) was performed to investigate a role for mTert+ cells in kidney repair. Both mTert mRNA and telomerase activity are upregulated in papilla after IRI. To examine the fate of mTert+ kidney epithelia, adult mTert-CreERt2; R26LacZ bigenic mice received a single tamoxifen pulse, resulting in genetic labeling of 5% of epithelia in papilla and inner medulla, and the fate of these cells was tracked after IRI.

These studies show, for the first time, the cellular localization of Telomerase expression, demonstrate 5% of these cells are slow cycling and suggest a novel role for Telomerase activity in kidney repair.

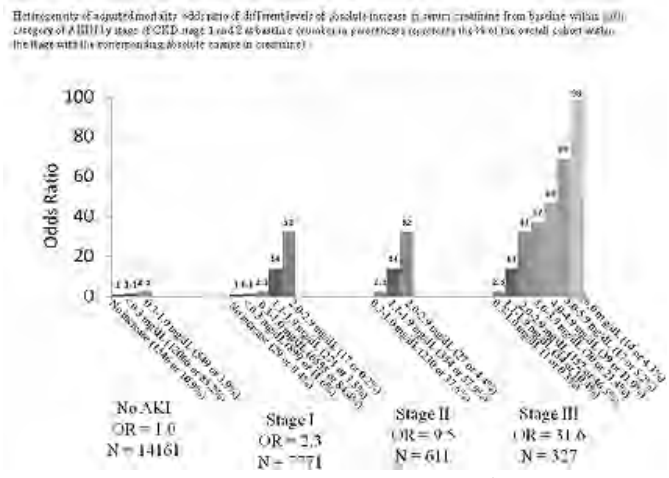
**TH-PO017**

**RIFLE and AKIN Misclassify the Severity of Acute Kidney Injury after Surgery**
Farsad Afshinnia,[1,2] Sean Nugent,[2] Tamara Schult,[2] Nancy Greer,[2] Areef Ishani.[1,2] *[1]University of Minnesota, Minneapolis, MN; [2]VA Medical Center, Minneapolis, MN.*

**Aims:** The prognostic improvement of RIFLE or AKIN compared to a continuous change in serum creatinine (Cr) to predict short-term mortality is unclear. Our study aim is to show the heterogeneity of risk of 30-day mortality after surgery within various stages of RIFLE and AKIN and their potential to misclassify the risk of mortality associated with acute kidney injury (AKI) when compared with continuous increase of Cr.

**Methods:** Using a nationwide VA database, 27204 patients with a baseline Cr corresponding to stages 1 to 3 of CKD who underwent surgery from 1999 to 2005 were identified. AKI after operation was defined according to RIFLE and AKIN. The outcome was 30-day mortality.

**Results:** In patients with CKD stage 1 or 2 at baseline, odds of mortality were 2.4, 9.7, and 29.3 in Risk, Injury and Failure, and 2.3, 9.5, 31.6 in stage 1 to 3 of AKIN, respectively, compared to no AKI ($P < 0.001$). There was also a graded increase in mortality from 2.3 to 98 by each 1 mg/dL increase of Cr from baseline when compared to no AKI in the same patients. As shown in the graph, there was a significant variability in odds of death within each stage of RIFLE or AKIN stratified by each 1 mg/dL increase of Cr, with the highest variability seen in category of Failure or stage 3 of AKIN. Similar results are noted in patients with CKD stage 3.



**Conclusion:** RIFLE and AKIN erroneously estimate the risk of mortality by collapsing wide range changes of Cr into similar categories. As a result, the risk of mortality is overestimated by lower levels of increase in Cr and underestimated by higher levels of increase in Cr within each stage of AKI.

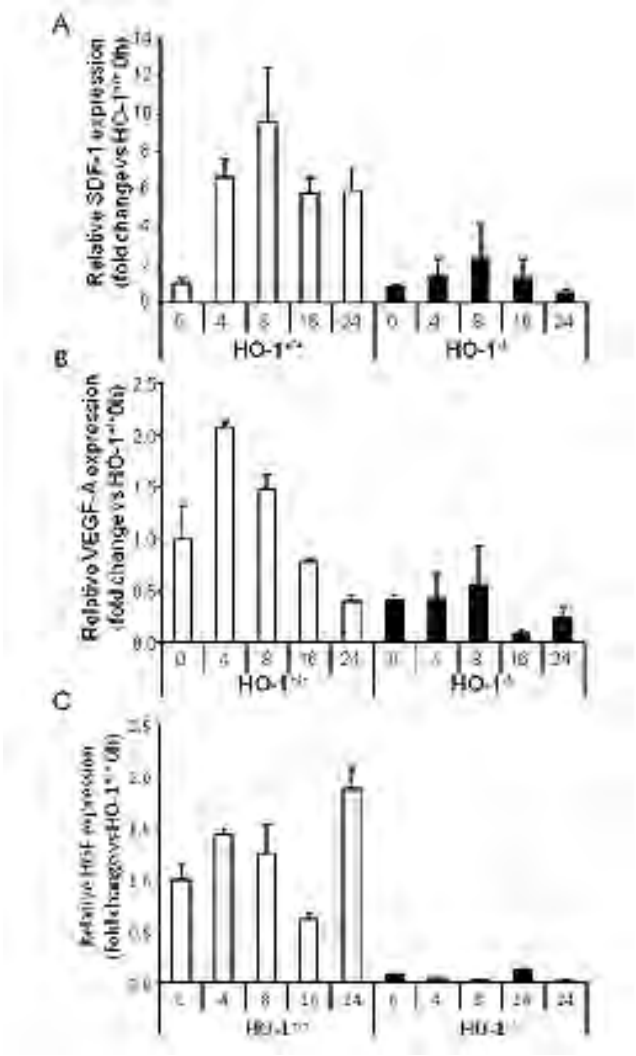
**Mesenchymal Stem Cells Induced Protection in Acute Kidney Injury (AKI) – Role of Heme Oxygenase-1 (HO-1)** Abolfazl Zarjou, Junghyun Kim, Carl A. Frizell, Amie Traylor, Anupam Agarwal, Lisa M. Curtis. *Medicine, University of Alabama at Birmingham, Birmingham, AL.*

Multipotent mesenchymal stem cells (MSCs) have become a popular and promising therapeutic approach in many clinical conditions. MSCs are beneficial in animal models of AKI, effects that are mediated by differentiation independent paracrine properties. MSCs have proven beneficial in cardiac surgery-related AKI and there is an ongoing clinical trial evaluating the safety and efficacy of MSCs. HO-1 is induced in response to stress and has important anti-apoptotic, anti-inflammatory and proagiogenic properties. We therefore examined whether HO-1 expression plays a role in the beneficial effects of MSCs. We isolated MSCs from bone marrow of age and sex matched HO-1$^{+/+}$ and HO-1$^{-/-}$ mice. Successful cultures were validated by differentiation into adipocytes, osteocytes and chondrocytes. Our studies indicate that differentiation of MSCs was not significantly different between cells isolated from HO-1$^{+/+}$ and HO-1$^{-/-}$ mice. However, when exposed to hypoxia MSCs derived from HO-1$^{-/-}$ mice demonstrate reduced expression and secretion of several important growth and proangiogenic factors when compared to MSCs derived from HO-1$^{+/+}$ cells. These factors include stromal cell-derived factor-1 (SDF-1), vascular endothelial growth factor (VEGF), hepatocyte growth factor (HGF) and insulin like growth factor-1 (IGF-1).



Conditioned media from HO-1$^{-/-}$ MSCs exposed to 24 h of hypoxia showed significantly lower levels of SDF-1 compared to HO-1$^{+/+}$ MSCs (HO-1$^{-/-}$ vs HO-1$^{+/+}$, 5.3±1.6 vs 19.5±0.65 ng/mg protein, $p<0.05$, n=4/group). Our studies indicate that HO-1 expression in MSCs is required for their optimal protective function and provide a basis for further studies to explore the effects of modulating HO-1 expression in MSCs in in vivo models of AKI.

**Adult Stem Cells from Foreign-Body Granulation Tissue Protect the Kidney and Accelerate Recovery from Acute Kidney Injury** Jilpa Patel,[2] Nishit Pancholi,[2] Krishnamurthy P. Gudehithlu,[1,2] George Dunea,[1,2,3] Jose A. L. Arruda,[3,1,2] Ashok K. Singh.[1,2] *[1]Nephrology, John H. Stroger Hospital of Cook County, Chicago, IL; [2]Nephrology, Hektoen Institute of Medicine, Chicago, IL; [3]Nephrology, University of Illinois at Chicago, Chicago, IL.*

In earlier studies we showed that granulation tissue induced by implanting polyvinyl tubes subcutaneously in rats is a source of mesenchymal stem cells (granulation tissue derived stem cells or GTSC). Here we tested the efficacy of GTSC to ameliorate acute kidney injury (AKI) in Fischer (F344) in-bred rats (baseline plasma creatinine 0.7 ± 0.06 mg/dL and plasma urea 50 ± 3.4 mg/dL). We induced AKI by unilateral (right) nephrectomy, occlusion of the left renal pedicle for 45 minutes followed by de-occlusion and reperfusion of the kidney. After inducing AKI, we divided the rats into two groups. Three hours after injury, group 1 (treated) rats received one intravenous injection of GTSC (2- 4 X $10^6$ cells in 0.7 ml saline) and group 2 (control) rats received vehicle. Twenty-four hours after injury, treated rats (versus controls) showed significantly lower plasma creatinine (1.0 ± 0.04 mg/dL vs. 1.6 ± 0.12 mg/dL) and plasma urea (71 ± 5.9 mg/dL vs. 138 ± 7.1 mg/dL) ($p<0.001$, N=8 in each group). In the treated group plasma creatinine and urea levels remained low, reaching baseline levels by day 4. In controls they did not reach baseline levels until day 7. On histology, there was less tubular dilatation, necrosis, congestion, and casts in the treated rats. PCNA immune-staining in the treated group showed a higher level of cell proliferation in the cortico-medullary region, suggesting that rapid cell renewal was responsible for the accelerated recovery in the treated rats. These results show that administration of GTSC protected the kidney and accelerated recovery from AKI.

**P2Y Receptors Mediate EGFR Activation and Renal Tubular Cell Proliferation during Acute Kidney Injury** Monika Gupta,[1] Peifeng Deng,[1] Peter Green,[1] Rick G. Schnellmann.[2] *[1]Medicine, Medical University of South Carolina; [2]Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC.*

While it is known that epidermal growth factor receptor (EGFR) is critical for repair and regeneration of renal proximal tubular cells (RPTC) following acute kidney injury (AKI), the sequence of events that lead to activation of EGFR are not known. Using primary cultures of rabbit RPTC, the aim of this study was to examine the role of P2Y receptors in activation of EGFR and RPTC proliferation following injury. P2Y1, P2Y2, P2Y4, P2Y12 and P2Y14 were expressed in RPTC using RT-PCR analysis. RPTC monolayers were scrape wounded and incubated for 24 h in the presence or absence of AG1478 (EGFR antagonist), RB-2 (non-selective P2Y receptors antagonist), AR-C66096 (P2Y12 antagonist), and MRS 2279 (P2Y1 antagonist). Cell proliferation was determined using a BrdU incorporation assay. At 24 h, 19% of the injured cells were proliferating compared to 2% of the cells incubated with AG1478. While MRS 2279 and AR-C66096 had no effect on proliferation, RB-2 decreased proliferation to 11%. Addition of exogenous EGF to RB-2 treated cells reversed the inhibition produced by RB-2, providing evidence that P2Y receptors are upstream of EGFR. Hence, one or more of P2Y2, P2Y4 and P2Y14 are required for approximately 50% of the proliferative signal after cell injury. We then examined the activation of EGFR at tyrosine 845 by P2Y agonists ATPγS, MRS2690, and UTPγS using immunoblot analysis and observed that all three agonists activated EGFR. We then examined the role of Src and ADAM 17 in P2Y-stimulated RPTC proliferation following scrape wounding. Src inhibition (PP-1), P2Y (RB-2) and ADAM17 inhibition (TAPI-1) decreased proliferation to 9%, 11% and 13%, respectively compared to 19% in injured RPTC. The combination of PP-1 and TAPI-1 was additive, supporting Src and ADAM17 as major but distinct pathways for EGFR activation. While inhibition of ADAM17 and P2Y receptors was not additive, inhibition of Src and P2Y receptors was additive. Hence, P2Y receptors mediate EGFR activation and RPTC proliferation via ADAM17.

**VEGF-Modified Human Embroyonic Mesenchymal Stem Cell Implantation Enhances Protection Against Cisplatin-Induced Acute Kidney Injury** Li Yuan,[1] Changlin Mei.[2] *[1]Division of Nephrology, Changzheng Hospital, Second Military Medical University, Shanghai, China; [2]Division of Nephrology, Changzheng Hospital, Second Military Medical University, Shanghai, China.*

**Objective:** Vascular endothelial growth factor (VEGF) is an important factor in renoprotection produced by MSC. We investigated the effects of VEGF modified human embryonic mesenchymal stem cells (VEGF-hMSC) in a cisplatin-induced tubular cell damage model in vitro and a nude-mouse model of cisplatin-induced AKI in vivo.

**Methods:** TCMK-1 were pretreated with cisplatin for 24 h and cocultured with hMSC, VEGF-hMSC and Ad-hMSC. Three days after cisplatin pretreatment, PCNA expression, regeneration and apoptosis of TCMK-1 were tested. AKI was induced by subcutaneous injection of cisplatin (18 mg/kg). 24 h after cisplatin administration, nude mice were divided into four groups and received a tail intravenous injection as follows: saline, VEGF-hMSC, Ad-hMSC, and hMSC. Normal control animals did not undergo cisplatin injection. Serum creatinine (SCr), blood urea nitrogen (BUN),HE staining, PCNA, TUNEL staining and CD34 were tested 4 days after cisplatin administration.

**Result:** Compared with TCMK-1 pretreatment with cisplatin alone, co-culturing with every kind of hMSC ceased the inhibitory effect of cisplatin on TCMK-1 growth, reduced apoptosis, and increased PCNA expression. These effects were most pronounced in VEGF-transfected hMSC. VEGF transfecton improved the ability of hMSC to impair cisplatin induce TCMK-1 injury. In addition, in a nude-mice model of cisplatin-induced kidney injury, administration of VEGF-hMSC offered more protective effects on renal function, tubular structure and survival. Cell proliferation increased, apoptosis decreased, and peritubular capillary density in the kidney improved in animals treated with VEGF-hMSC.

**Conclusion:** Implantation of VEGF-modified hMSC could provide advanced benefits in protection against renal tubular injury by anti apoptosis, improving microcirculation and proliferation .

**Impaired Proliferation and Mesenchymal Transition of Kidney Endothelial Cells Following Ischemic AKI: Role of VEGF** David P. Basile,[1] Jessica Friedrich,[1] Ellen Leonard,[1] Bruce A. Molitoris,[2] Robert L. Bacallao,[2] Timothy A. Sutton.[2] *[1]Cellular & Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN; [2]Medicine, Indiana University School of Medicine, Indianapolis, IN.*

AKI-induces the loss of renal microvessels and may lead to progressive CKD. Vascular rarefaction and progression to CKD is ameliorated by prior treatment with VEGF-121, but the fate of endothelial cells and the mechanism of VEGF protection is unknown. Endothelial proliferation was examined in kidneys of SD rats following 40 min of bilateral I/R injury and recovery for 1, 2, or 7 days post-ischemia. Cumulative cell proliferation was examined by repetitive administration of BrdU (twice daily) and colocalization in endothelial cells with CD31 or cablin. Regenerating tubules in the cortex and outer medulla accounted for >95% of BrdU + cells. Proliferating endothelial cells were not detected at 1 or 2 days post I/R and accounted for only ~ 1% BrdU+ cells at 7 days, which was not different than shams. VEGF-121 preserved vascular density post AKI at 7 days but did not affect BrdU incorporation in tubular, endothelial or perivascular cells. Potential endothelial mesenchymal transitions states were detected by localizing endothelial markers (CD 31, cablin or infused tomato lectin) with the fibroblast marker, S100A4. Endothelial transition states were prominent within 6 hours and sustained for at least 7 days following I/R and were 30-fold more prevalent than epithelial transition states. A transgenic mouse model with a Tie-2 promoter driving Cre crossed with a YFP reporter mouse was used to label endothelial cells and their progeny in response to kidney injury. Recovery from AKI for up to 14 days resulted in widespread distribution YFP+ interstitial cells, colocalized with S100A4 and SMA, further suggesting endothelial mesenchymal transition. Administration of VEGF-121 during the recovery period significantly attenuated the distributionYFP positive interstitial fibroblasts. These data indicate that capillary dropout post AKI results from low endothelial proliferative capacity and phenotypic transition, which can be minimized by VEGF activity.

**TH-PO023**

**Attenuation of Folic Acid-Induced Renal Inflammatory Injury in Sphingosine Kinase 2-Deficient Mice** Amandeep Bajwa, Hong Ye, Diane L. Rosin, Mark D. Okusa. *Medicine and the Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA.*

Epidemiological studies indicate some survivors of acute kidney injury (AKI) who regain renal function have a progressive decline in kidney function leading to end stage renal disease. Sphingosine 1-phosphate (S1P), a sphingolipid metabolite, is a mediator of numerous vital molecular processes, such as cell survival, differentiation, cytoskeletal rearrangements, and lymphocyte circulation. S1P is generated by phosphorylation of sphingosine by sphingosine kinases (SphK1 and SphK2). SphK1 and SphK2 have divergent cellular functions and intracellular localizations. SphK1, localized in the cytoplasm, promotes cell growth and survival, whereas SphK2, localized in the nucleus, induces apoptosis and hinders cell growth. The current study investigates the roles of SphK1 and SphK2 in folic acid (FA)-induced kidney fibrosis. WT, SphK1 KO and SphK2 KO mice were given FA (250mg/kg, ip) and followed for 14 days. SphK2KO mice exhibited significantly lower plasma creatinine at day 3 (48.54%, $p<0.01$) and fibrosis (Masson's trichrome staining) compared to WT and SphK1 KO mice at day 14 post FA administration. Compared to kidneys of SphK1 KO mice, kidneys of FA-treated SphK2 KO mice expressed lower mRNA levels of: TGF-β (15.79%, $p<0.001$), α-SMA (30.8%, $p<0.01$) and fibronectin (36.9%, $p<0.01$). Kidney sections of FA-treated SphK2 KO mice displayed lower levels of collagen, fibronectin, and α-SMA immunoreactivity compared to kidney sections of SphK1 KO mice. FA-treated SphK2 KO mice kidneys had reduced inflammatory leukocyte infiltration of macrophages (45.1%, $p<0.05$)) neutrophils (27.9%, $p<0.01$) and T cells (55.8%, $p<0.05$) compared to SphK1 KO mice. We conclude that: 1) FA induces fibrosis to a similar degree in WT and SphK1 mice, and 2) SphK2 deficiency attenuates FA-induced fibrosis. The discrete compartmentalization of SphK2 within the nucleus may contribute to its differential effect when compared to SphK1. Understanding the function of nuclear SphK2 may contribute further to our understanding of the pathogenesis of fibrosis of chronic kidney disease.

**Label-Retaining Cells Which Contribute to Tubular Regeneration after Renal Ischemia Are Not a Specific Minor Cell Population in the Kidney** Akito Maeshima, Masaaki Miya, Keiichiro Mishima, Noriyuki Sakurai, Hidekazu Ikeuchi, Takashi Kuroiwa, Keiju Hiromura, Yoshihisa Nojima. *Department of Medicine and Clinical Science, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan.*

Using an in vivo BrdU labeling, we previously identified label-retaining cells (LRCs) with renal progenitor-like property in renal tubules of normal rat kidney (JASN 14: 3138–3146, 2003). However, it remains unknown whether label-retaining potential is limited to a specific cell population or not. To address this issue, we examined the presence of LRCs in normal rat kidney using three kinds of thymidine analogues, BrdU, IdU, and CldU. 1) labeling experiment: Using osmotic pomp, BrdU was continuously given into 7-week-old Wistar rats for two, three, and four weeks and the number of BrdU-positive cells were analyzed. 2) Triple labeling experiment: BrdU, IdU, and CldU, were sequentially administered for 7 days into rats (100 mg/kg/day each). Two-week chase intervals were placed between administrations of each thymidine analogue. After the last chase, ischemia/reperfusion injury was induced in these rats and kidneys were removed for histological analysis at 24h after reperfusion. Using anti-IdU Ab (that recognizes BrdU and IdU, but not CldU) and anti-CldU Ab (that recognizes BrdU and CldU, but not IdU), three LRC populations with different chase periods were identified and the numbers of them were analyzed. Long labeling experiment demonstrated that the number of BrdU-positive tubular cells was increased according to labeling period. Majority of cortical tubular cells became BrdU-positive after 4-week labeling. Triple labeling experiment showed that LRC-BrdU (IdU+CldU+), LRC-IdU and LRC-CldU were scattered in renal tubules and the numbers of each LRC was decreased as the chase period got longer (LRC-BrdU<LRC-IdU<LRC-CldU). While the number of each LRC was significantly increased after injury, there was no significant difference in the ratio of cell division among these LRCs. These findings suggest that tubular LRCs are not restricted to a specific minor cell population in the kidney, which equally contribute to tubular regeneration after renal ischemia.

**TH-PO025**

**The Hormone Melatonine Augments Renoprotective Effects of Syngeneic Murine EPCs Via Stimulating Proangiogenic VEGF** Daniel Patschan, Susann Patschan, Johannes Wessels, Gerhard A. Mueller. *Department of Nephrology and Rheumatology, University Hospital Göttingen, Göttingen, Niedersachsen, Germany.*

Endothelial progenitor cells (EPCs) protect kidneys from acute ischemic damage. Recently, melatonine has been shown to agonize mesenchymal stem cells. Aim of the present study was (I) to evaluate whether melatonine would mediate beneficial effects on EPCs in the setting of acute ischemic renal failure, and, if so, (II) to analyze the cellular/molecular mechanisms involved herein.

EPCs, isolated from C57BL/6N mice were preincubated with melatonine and systemically injected into recipient animals with acute ischemic renal failure (40 minutes of ischemia). In some experiments cells were pretreated with combined melatonine and the melatonine antagonist luzindole. Two days later animals were sacrificed and renal function and histology were analyzed. In order to investigate melatonine-mediated cellular effects on EPCs, cultured murine EPCs were analyzed for apoptosis, necrosis, and production/secretion of VEGF in the presence of TGF-β with and without simultaneous melatonine treatment.

Systemic injection of $0.5\times10^6$ untreated EPCs did not protect mice from acute ischemic renal failure. Animals that were injected with melatonine-pretreated cells did not develop acute renal failure. These effects could be reversed by combined cell pretreatment with melatonine and luzindole. In vitro analysis did not show reduced TGF-β-induced EPCs apoptosis/necrosis in the presence of melatonine; nevertheless, the cells secreted significantly more VEGF into the culture medium if they had been preincubated with combined TGF-β and melatonine as oposed to pretreatment with TGF-β alone.

In summary, the data indicate melatonine as new therapeutic tool in stimulating EPC-mediated renoprotective effects in acute ischemic renal failure. In this process, increased production/secretion of vasostabilizing VEGF by EPCs is potentially pathogenetically relevant.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO026**

**EPC Regeneration in Sepsis with Impaired Renal Function** Susann Patschan, Daniel Patschan, Johannes Wessels, Gerhard A. Mueller. *Department of Nephrology and Rheumatology, University Hospital Göttingen, Göttingen, Niedersachsen, Germany.*

Endothelial progenitor cells (EPCs) are involved in vasculogenesis under various circumstances. Aim of the study was to evaluate EPC numbers and regeneration in patients with sepsis with and without impaired renal function.

Blood samples from sepsis patients (defined as infectious SIRS) were analyzed for total circulating EPCs (cytometric analysis) and EPC proliferation (colony forming unit-assay). For clinical evaluation, age, gender, mean serum creatinine, the AKIN score, necessity of dialysis treatment, and CRP were assessed.

Twenty-three patients (10 female [67.8 ±13.9 years] and 13 male [64.5 ±13.8 years]) were included into the study. The mean serum creatinine of all patients was 1.99 ±1.44 mg/dl, 15 patients underwent transient or permanent dialysis treatment during the course of the disease. In 17 patients the AKIN score was 3. Eight patients displayed 10 or more EPC colonies (CFU-ECs) (35.3 ±21.6). Patients with <10 EPC colonies (4.2 ±2.2, $p<0.0001$) showed significantly higher mean serum creatinine levels (2.4 ±1.5 mg/dl vs. 1.1 ±0.7 mg/dl, $p=0.04$) than patients with ≥10 colonies. There were no differences in the percentages of total circulating EPCs between the two groups.

In summary, the data indicate that EPC regeneration in sepsis is less affected in patients with lower creatinine levels. Thus, prevention of renal function or, if necessary, effective dialysis treatment in sepsis stabilizes the EPC system as an essential functional element of vascular homeostasis.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO027**

**Tunicamycin, an Established Endoplasmic Reticulum (ER) Stress Inducer, Cause Causes a Proteinuric Form of Proximal Tubular Injury** Ling-Mei Chiang,[2] Pu Duann.[1] *[1]Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Pediatrics, Chang-Gung Memorial Hospital, Keelung, Taiwan.*

The unfolded protein response (UPR) is a cellular recovery mechanism activated by endoplasmic reticulum (ER) stress. The UPR is coordinated with the ER-associated degradation (ERAD) to regulate the protein load at the ER. ER stress is currently believed to be an independent stress pathway which regulates inflammatory process and the autophagy/repair response to injury. The CHOP gene (encoding C/EBP homologousprotein-10, also known as GADD153) is regulated tightly by stress in a wide variety of cells. Studies on CHOP-knock mice point to CHOP as the core modulator molecule in the UPR pathway. Tunicamycin is a specific ER stress inducer ex vivo. Mice injected with tunicamycin (TN), develop tubular injury and renal dysfunction resembling human AKI. Using this model, we demonstrated (Nat Cell Biol 11(12), 1473-80, 2009) that CHOP was predominantly upregulated in proximal tubular cells (PTCs). PTC cell death and renal dysfunction in this model were ameliorated in CHOP knockout mice, suggesting that CHOP plays a critical role in ER stress-induced renal dysfunction. In this present studies we correlated tubular histopathological changes with proteinuria (Up/Uc) prior and 1, 2, 3 and 4 days after TN injection (intraperitoneal, 1 mg/Kg weight). We observed proteinuria, Up/Uc values: 0.69±0.23, 1.72±0.44, 3.46±0.98, 6.46±2.58, and 1.07± 0.33, prior and on days 1, 2, 3 and 4 after TN injection. Histologically, the extent of tubular injury, in terms of percentage of injured tubular area, correlated with changes in Up/Uc: 10%, 35%, 70% and 4% on days 1, 2, 3 and 4, respectively, after TN injection. Pretreatment with the TN chemical chaperone, 4-phenyl butyrate (4-PBA), reduced proteinuria and extent of tubular injury. These observations, coupled with our previous studies, suggest that TN-induced ER stress causes a proteinuric form of injury specific for proximal tubules and may provide a new model for ER stress-mediated AKI. TN chaperones may provide powerful tools to study mechanisms of ER stress-mediated AKI.

**TH-PO028**

**miR-127-3p Induced by HIF Is a Cytoskeleton Protector Mechanism in the Proximal Tubule Response to Ischemia/Reperfusion** Elia Aguado Fraile,[1] Edurne Ramos,[1] David Saenz Morales,[1] Elisa Conde,[1] Ignacio Blanco Sanchez,[1] Marta Martinez,[1] Angel M. Candela-Toha,[3] Fernando Liano,[2] Laura Garcia-Bermejo.[1] *[1]Pathology, Hospital Univ. Ramon y Cajal; [2]Nephrology, Hospital Univ. Ramon y Cajal; [3]Anesthesiology, Hospital Univ. Ramon y Cajal.*

microRNAs are small RNA molecules (20-25 nucleotides) that play important regulatory roles in the cell. Among other functions, they are regulators of cellular homeostasis, and they control cell response to different stress, such as ischemia. Ischemic injury is underlying most of the Acute Renal Failure (ARF) cases and contributes to kidney delayed graft function. Identification of microRNAs involved in renal ischemia/reperfusion (I/R) response could allow designing new therapeutic strategies to prevent organ injury or accelerate recovery.

Using and *in vitro* protocol of Hypoxia/Reoxygenation (H/R) in proximal tubule cell lines of Rat (NRK-52E) and Human (HK-2), and an *in vivo* protocol of Ischemia/Reperfusion (I/R) in Rat, we have found that miR-127-3p is up-regulated after ischemia but also in reperfusion. This induction is dependent on Hypoxia Inducible Factor alpha subunit (HIF-1α), a key regulator of cell response to low oxygen conditions, among other mechanisms. Knockdown of HIF-1α by siRNA transfection in HK-2 prevents miR-127-3p upregulation during hypoxia and also in reperfusion. Moreover HIF-1α overexpression in the same cell line, increases miR-127-3p levels.

H/R leads to cytoskeleton alterations, including actin and tubulin depolimerization. Modulation of miR-127-3p by transfection of specific Pre-miR and anti-miR molecules in NRK-52E submitted to H/R demonstrated that cells with overexpressed miR-127-3p present better microtubule and actin organization after hypoxia. Using different databases (Microcosm, Pictar and TargetScan 5) for target gene prediction, we have found that some of the putative targets for miR-127-3p are involved in microtubule organization and trafficking.

In summary, miR-127-3p is modulated during cell response to H/R regulating cytoskeleton dynamics. Maintenance of tubular cell structure through miR-127-3p would assure correct tubular function and might be contributing to ATN recovery.

Disclosure of Financial Relationships: nothing to disclose

**Urinary Biomarkers for the Early Detection of Recovery Phase in Patients with Acute Kidney Injury** Sang Choel Lee,[1] Eawha Kang,[2] Hyung Bok Park,[1] Soo Young Yoon.[1] *[1]Department of Internal Medicine, College of Medicine, Kwandong University, Goyang, Gyeonggi-do, Korea; [2]Department of Internal Medicine, NHIC Ilsan Hospital, Goyang, Gyeonggi-do, Korea.*

AKI is a common and serious complication in hospitalized patients. Several biomarkers including NGAL, KIM-1 and cystatin C have been suggested as useful markers for AKI. However, it is unknown whether such biomarkers are also helpful in detecting recovery of kidney function from established AKI. We measured urine NGAL and cystatin C levels every 2 days for 8 days in 30 patients with AKI. AKI was defined as a 50% or greater increase in serum creatinine from baseline. In addition, patients with a 50% or greater decrease in serum creatinine from peak level within 8 days after development of AKI were classified as recovery group. Exclusion criteria were pre-existing CKD or renal replacement therapy during admission. Urine NGAL and cystatin C levels were determined by ELISA. At day 0, there were no significant differences in serum creatinine, BUN, fractional excretion of sodium, urine NGAL and cystatin C levels between recovery (n=18) and non-recovery group (n=12). Compared to non-recovery group (4.6±0.6 mg/dL, mean±s.e.), serum creatinine concentrations in recovery group (3.9±0.6 mg/dL) started to decrease from day 2, but it did not reach statistical significance. The difference in serum creatinine levels between the two groups became evident only after day 6 (5.2±0.9 vs. 2.1±0.9 mg/dL, $p<0.001$). In contrast, urine NGAL (204.6±42.1 vs. 371.1±60.1 ng/ml, $p<0.05$) and cystatin C (0.15±0.03 vs. 0.26±0.07 mg/L, $p<0.05$) concentrations were significantly lower in recovery group than non-recovery group from day 2 until the end of the study. When urine NGAL and cystatin C were normalized with urine creatinine concentrations, these two biomarkers also decreased earlier than serum creatinine from day 2. In conclusion, this study showed that urine NGAL and cystatin C levels declined faster than serum creatinine levels in recovery phase in patients with AKI. Our findings suggest that urine NGAL and cystatin C may be more reliable biomarkers in the early detection of recovery from AKI.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO030**

**Gentamicin (G) Nephrotoxicity: Prevention and Repair by Bone Marrow-Derived Mesenquimal Stem Cells (BMSCs)** Luciana Aparecida Reis,[1] Fernanda Teixeira Borges,[1] Manoel De Jesus Simoes,[2] Nestor Schor.[1] *[1]Medicine, UNIFESP/EPM, Sao Paulo, SP, Brazil; [2]Morphology, UNIFESP/EPM, Sao Paulo, SP, Brazil.*

The aim of this study is to investigate if BMSCs can prevent and or attenuate renal damage induced by G. Female Wistar rats received G (40mg/Kg/BW, *ip*) or water (CTL) for 10, 11, 12, 15 or 20 days. In the 10$^{th}$ day of G, the rats received IV male BMSCs (1X10$^6$). After 24, 48 hr or 5 days from BMSCs, blood and 24 hr urine were collected for creatinine (Cr), urea (U) and $FE_{Na}$. Prevention groups (P) rats received IV BMSCs 24 hr (P-24h) before or after the 5th day (P+5d) of G. Kidneys were evaluated for HE, KI67, caspase 3 and Y chromosome. It was observed that Cr, U and $FE_{Na}$ increased in all groups when compared to CTL. Rats that received BMSC, Cr and U as well as $FE_{Na}$ decreased when compared to G groups. There was no significant difference in Cr, U and $FE_{Na}$ in P groups, suggesting that renal injury homed BMSCs.

| GROUPS | Cr [mg/dl] | U [mg/dl] | FENa [%] |
|---|---|---|---|
| CTL | 0.5±0.03 | 24±2 | 0.6±0.02 |

G induced ATN and no KI67 marker. Animals treated with G+BMSCs did not present ATN, KI67 marker was observed . It was noted the presence of Y chromosome in the rats treated with BMSCs, suggesting additional mechanisms other than paracrine actions. This latter effect could indicate the permanence of BMSC in situations where the aggression persists, as in this model. These results suggest that BMSCs have a potential effect to minimize the nephrotoxicity induced by G.

**TH-PO031**

**The Effect of Conditioned Medium (CM) of Mesenquimal Stem Cells Derived from Bone Marrow (BMSC) in Acute Kidney Injury (AKI) Induced by Gentamicin (G) in Rats** Luciana Aparecida Reis,[1] Fernanda Teixeira Borges,[1] Manoel De Jesus Simoes,[2] Nestor Schor.[1] *[1]Medicine, UNIFESP/EPM, Sao Paulo, SP, Brazil; [2]Morphology, UNIFESP/EPM, Sao Paulo, SP, Brazil.*

Cell therapy using BMSC seems to be a new alternative for the treatment of nephrology diseases, including AKI. Thus, we evaluate the effects of CM on AKI induced by G. Female Wistar rats received G (40mg/Kg/BW, *ip*, daily) or water (CTL) for 15 or 20 days. On 10$^{th}$ day with G, animals received 500µl, iv in only one dose of CM (BMSC cultured for 24 hr with DMEM) or CM+TPS (BMSC cultured for 24 hr with DMEM+tripsin, 100ug/ml) or CM+RNAse (BMSC cultured for 24 hr with DMEM+RNAse, 40 ug/ml). Blood and 24 hr urine were collected for creatinine (Cr), and $FE_{Na}$ dosages for all. Cytokines (IL10, TNFα and INTγ) were analyzed for the 15 days group. Kidneys were evaluated for HE, KI67 and caspase 3.

| GROUPS | Cr [mg/dl] | FENa [%] |
|---|---|---|
| CTL15d | 0.5±0.03 | 0.6±0.02 |
| CTL20d | 0.7±0.02 | 0.5±0.01 |
| G15d | 2.9±0.04* | 1.7±0.03* |

| G20+CM10 | 0.9±0.01# | 1.2±0.04# |
| G15+CMRNAse10 | 3.1±0.03* | 1.4±0.03* |
| G15+CMTPS10 | 1.0±0.1* | 1.2±0.02* |
| G15+RNAse10 | 3.4±0.08*,# | 2.2±0.03*,# |
| G15+TPS10 | 2.1±0.09*,# | 1.9±0.04*,# |

*p<.05 vs. CTL; #p<.05 vs.G15 or 20

G15 or G20 groups presented an important nephrotoxicity. CM induced decreases in Cr and $FE_{Na}$ indicating effect of CM at glomerular and tubular levels. G alone caused ATN and mild KI67. Surprisingly, CM showed no ATN and intensely KI67 observation. The association of CM and RNAse blunted the protective effects of CM alone. In groups $G_{15}$ ,$G_{15}$+$RNAse_{10}$ and $G_{15}$+$TPS_{10}$ caused pro-inflammatory cytokines increases, with decreases on IL10 when compared to $G_{15}$+$MC_{10}$. Results suggest that CM would act via paracrine effects, probably by releasing factors (among than mRNA and RNA) that activate resident cells. CM minimized inflammatory responses and the AKI induced by G, indicating CM is a potential tool to modify this nephrotoxicity.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO032**

**Effects of Bone Marrow Mesenchymal Stem Cells (BMSC) in Rats with Acute Kidney Injury (AKI) Due to Sepsis Induced by Lipopolysaccharide (LPS) Administration and E.coli Infection** Luciana Aparecida Reis,[1] Fernanda Teixeira Borges,[1] Manoel De Jesus Simoes,[2] Nestor Schor.[1] *[1]Medicine, UNIFESP/EPM, Sao Paulo, SP, Brazil; [2]Morphology, UNIFESP/EPM, Sao Paulo, SP, Brazil.*

Female Wistar rats received LPS (6mg/Kg/BW) (LPS group) or water (CTL) in a single dose *i.v.* (N=10). After 24, 48 or 72 hr, rats received a single dose iv of BMSC (1X10$^6$cells). For the E. coli protocol, both kidneys were punctured, one time each, with a human nephritogenic *E. coli* solution at a dose of 10$^9$ per 5 ml. Then, the animals received 1X10$^6$ BMSC iv, 24 hr after renal punction. Blood and urine were collected 24, 48 or 78 hr and measured creatinine (Cr), urea (U) and $FE_{Na}$. Kidneys were analyzed for HE, KI67, caspase 3 and for Y cromossome. In the LPS 24, 48 or 72 hr vs CTL the Cr (1.65±0.14; 2.4±0.05; 2.2±0.04 vs. 0.66±0.08; mg/dl), U (50.3±2.9; 70.3±2.9; 87.7±2.1; 146±465 vs. 15.4±3.1; mg/dl) and $FE_{Na}$ (2.18±0.01; 1.80±0.03; 2.0±0.03 vs. 0.6±0,2; %) increased when compared to CTL, respectively. The LPS+BMSC 24, 48 or 72 hr caused a decrease on Cr (0.75±0.01; 0.82±0.02; 0.80±0.03; mg/dl), U (42±3.7; 54±3.6; 51±1.8; mg/dl) and $FE_{Na}$ (0.58±0.01; 0.5±0.02; 0.53±0.03; %; p<0.05) comparing with LPS groups. In LPS-groups, the kidneys showed a small marked KI67 and intensive caspase 3 expression but differently, it was highly marked for KI67 and lower expression for caspase 3 in LPS+BMSC groups. However, a striking difference in the BMSC treated animals where the presence Y chromosomes were detected and no histological ATN lesions were observed. E. coli Protocol: After 24 hr we observed a significant increases (p<0.05) on Cr (1.3±0.1*vs.*0.9±0.1) and U (92.1±0.2*vs.*40.6±0.1), comparing with CTL groups. A significant protective effect (p<0.05) on the Cr and U were observed after 24hr (0.8±0.3 and 76.1±0.1) and 48hr (0.9±0.2 and 46.5±0.2). These results strongly suggest that BMSC minimize AKI in both sepsis models. The BMSC administration have a significant impact on renal function observed and thus, holds substantial promise for its use on sepsis for these protocols.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO033**

**Alterations in Mitochondrial Proteins, Dynamics, and Biogenesis Following Acute Kidney Injury** Jason A. Funk, Rick G. Schnellmann. *Pharmaceutical and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

Mitochondrial dysfunction is a pathological process that occurs in a number of acute organ injuries, including acute kidney injury (AKI). In response to energy depletion or injury, mitochondrial biogenesis is initiated to aid in recovery of cell and organ function. We investigated mitochondrial biogenesis in a non-lethal rat model of myoglobinuric AKI. AKI was induced by glycerol injection (50% solution, 10 mL/kg, im) into the hind limbs of Sprague-Dawley rats. After glycerol injection, rats had reduced kidney function as determined by a rise in SCr levels from 0.5 to 2 mg/dL at 24h. Recovery of kidney function began around 72h with SCr levels decreasing to 1.3 mg/dL, and continued to decrease to control levels 120h post-injection. Cleaved caspase-3 expression, a marker of apoptosis, was observed in glycerol-treated rats between 24 and 120h post-injury. Mitochondrial respiratory proteins NDUFB8, ATP synthase β, and cytochrome c oxidase subunit I (COXI) were decreased 24h after glycerol injection and remained decreased throughout the study period, suggesting loss of mitochondrial function. Interestingly, expression of mitochondrial fission and fusion processes, including dynamin-related protein (Drp1) and mitofusin 2 (Mfn2), were elevated at 24h and throughout the course of the study. We observed increases in markers of mitochondrial biogenesis, including elevations in peroxisome proliferator-activated receptor coactivator (PGC)-1α, PGC-1 related coactivator (PRC), and nuclear respiratory factor (NRF)-1 mRNA and elevations in PGC-1α, NRF-1, and mitochondrial transcription factor A (mtTFA) proteins at 24h and throughout the study in glycerol treated rats. In summary, AKI with apoptosis occurred within 24h of glycerol injection and resulted in 1) loss of mitochondrial proteins/function, 2) increases in mitochondrial fission and fusion proteins and 3) initiation of mitochondrial biogenic signaling early after injury and was sustained throughout the study period. These findings reveal that persistent mitochondrial dysfunction occurs after AKI and mitochondrial biogenesis may play an essential role during recovery from injury.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO034**

**Adipose Tissue Contributes to Renal Lipotoxicity during Acute Kidney Injury** Kiran Nagothu, Syed M. Ali, Shenyang Li, Neriman Gokden, Gouri Ranganathan, Judit Megyesi, Didier Portilla. *Medicine, University of Arkansas for Medical Sciences, Little Rock, AR.*

We have shown increased accumulation of nonesterified fatty acids and triglycerides (TG) in serum and kidney tissue of mice undergoing cisplatin (CP)-mediated Acute Kidney Injury (AKI). We hypothesize that adipose tissue may contribute to the observed dyslipidemia during AKI. Epididymal fat tissue mass from CP-treated mice was significantly reduced (43±5%) when compared to controls. Adiponectin synthesis, adipose tissue mRNA levels of hormone sensitive lipase, lipoprotein lipase (LPL), and fatty acid synthase were also reduced. In contrast, there was a 10-fold increase in serum adiponectin levels in CP-treated mice measured by western blotting and ELISA. These results suggest: 1) that CP-mediated increased serum adiponectin levels relate to reduced degradation of circulating adiponectin rather than increased synthesis from adipose tissue, 2) that down-regulation of LPL in adipose tissue may account for the observed increase in serum TG levels in CP-

treated mice. Adiponectin receptors 1 and 2 are the major receptors for adiponectin in vivo and play an important role in the regulation of lipid metabolism. To better understand the effects of increased serum adiponectin levels in kidney tissue during AKI we examined the effects of CP and PPARα ligand like fibrate on the expression of renal adiponectin receptor-1 (AdipoR1). CP treatment caused a significant reduction (93%) in mRNA and protein levels of AdipoR1. Fibrates prevented CP-mediated reduced expression of renal AdipoR1, reduced renal lipotoxicity and ameliorated renal function. These changes were substantiated by immuno-histological studies that localized AdipoR1 to proximal tubules and thick ascending limb cells, with reduced expression of AdipoR1 in proximal tubules of CP-treated mice. We conclude that reduced expression of AdipoR1 in proximal tubules during AKI may account for reduced fatty acid oxidation and increased renal lipotoxicity. Increased serum adiponectin levels and reduced expression of renal AdipoR1 during AKI may represent a state of resistance to adiponectin previously described in patients with chronic kidney disease.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO035**

**Development of a Zebrafish Model of Acute Kidney Injury** Rebecca A. Wingert. *Department of Biological Sciences, University of Notre Dame, Notre Dame, IN.*

Acute kidney injury (AKI) is a devastating and often-lethal condition, and patients who survive are at risk for developing numerous non-renal complications. In recent years it has become appreciated that the nephron can regenerate following epithelial cell damage incurred from ischemia or toxin exposure. However, there is only a rudimentary knowledge of the cellular events that transpire and the molecular controls are unknown. Determining how the regenerative process is accomplished will establish a foundation of core knowledge that will be vital for engineering new options for AKI treatment. The zebrafish model is an attractive system to study the molecular pathways responsible for nephron regeneration. Zebrafish nephrons share a number of similarities with mammals, and it is likely that essential mechanisms responsible for kidney regeneration will be conserved between these species. Zebrafish embryos possess a pair of nephrons that are anatomically situated such that they can be manipulated with laser ablation technology. Laser ablation was focally administered to a discrete patch of proximal tubule epithelial cells in one nephron, leaving the other nephron unperturbed to provide renal function. Following cell ablation, there was a rapid and robust regenerative response that restored epithelial intergrity of the tubule within several days. Regenerated nephrons display several hallmarks of the unperturbed control nephrons: for example, they showed expression of the proximal tubule specific solute transporter genes slc20a1a and nbc1. In addition, regenerated nephrons exhibited active uptake of fluorescent-labeled dextrans, suggesting restoration of epithelial function. These studies demonstrate that zebrafish nephrons can regenerate and that the zebrafish model can now be used to dissect the fundamental molecular signals that orchestrate kidney epithelial regeneration.

**Sirtinol, SIRT1 Inhibitor, Attenuates LPS-Induced Renal Inflammation in Mice** Yujin Jung,[1] Aesin Lee,[1] Duk Hoon Kim,[1] Jung Eun Lee,[1] Ki Dong Lee,[1] Mi Jeong Sung,[2] Kyung Pyo Kang,[1] Sik Lee,[1] Sung Kwang Park,[1] Won Kim.[1] *[1]Chonbuk National University Medical School, Jeonju, Republic of Korea; [2]Korea Food Research Institute, Songnam, Republic of Korea.*

Sepsis, characterized by depressed function in nearly all organs, has a high mortality when associated with acute kidney injury. Renal inflammation is characterized by activation of numerous common pro-inflammatory pathways.

SIRT1 is a mammalian $NAD^+$-dependent deacetylase that belongs to class III histone deacetylase. SIRT1-protein levels have been reported to be modulated during different cellular and disease conditions. There are controversies whether increased expression of SIRT1 might offer a protective mechanism or represent the disease progress. Recently, it has been reported that sirtinol, SIRT1 inhibitor, reduces antigen-induced airway inflammation and attenuates trauma-hemorrhage-induced lung inflammation. However, the role of sirtinol on kidney inflammation is not elucidated. Hence the present study was attempted to investigate the effect of sirtinol in preventing acute kidney injury during lipopolysaccharide (LPS)-induced endotoxemia.

In *in vivo* experiment, sirtinol suppressed LPS-induced increase of fractalkine and ICAM-1 expression in the kidney interstitial area and also decreased CD11b-positive macrophage infiltration. We further confirmed that, ICAM-1 protein level in the kidney tissue was significantly decreased after sirtinol treatment in the endotoxemic mice by immunoblot analysis. LPS-induced increase of pro-inflammatory cytokine such as TNF-α and IL-1β expression was significantly decreased by sirtinol treatment in the kidney tissue. In addition, we found that Sirtinol decreased TNF-α-induced increase of fractalkine, ICAM-1, and VCAM-1 in human umbilical vein endothelial cells (HUVECs).

In conclusion, sirtinol, SIRT1 inhibitor, has an anti-inflammatory effect on LPS-induced renal inflammation in endotoxemic mice.

**Factors Predicting the Severity of Acute Renal Failure Following Influenza A (H1N1) Infection** Rupesh Raina. *Department of Nephrology and Hypertension, Cleveland Clinic Foundation, Cleveland, OH.*

We describe the clinical course and risk factors for acute kidney injury (AKI) in patients with influenza A (H1N1) infection.

Between August 1st and December 5th of 2010, 2160 individual subjects were tested for influenza A infection; 1607 (74%) ambulatory, and 553 (26%) hospitalized, of which 203 (37%) required critical care. Among subjects who tested positive for influenza A, hospitalization was associated with older age (male gender (29 vs. 17%, $p$=0.01), but not pre-existing CKD (64 vs. 64%, $p$=0.99).

CKD or kidney transplant recipient status was a predisposing factor for kidney injury both by AKIN (acute kidney injury) diagnosis (43% vs. 9%, $p$=0.004), as well as severe renal failure requiring RRT (renal replacement therapy) (42% vs. 8%, $p$=0.05).

Critically ill patients, however, incurred greater injury reflected by higher peak creatinine (4.6±2.6 vs. 1.8±0.7 mg/dl, $p$=0.0001), creatinine change from baseline (3.5±2.6 vs. 0.8±0.4 mg/dl, p=0.0001), and need for dialysis (33% vs. none, $p$=0.0001), compared to regular nursing floor patients compared to those either on a regular nursing floor or treated as outpatients.

Critically ill patients with influenza A infection, had a higher likelihood of developing renal failure requiring dialysis if they were obese, had CKD, elevated CK and coagulopathy .CK levels ≥2000 U/L were noted only among obese patients (29% vs. none, $p$=0.01), but not severe hypoxia (38% vs. 50%, $p$=0.4). Provision of dialysis was associated with two-fold increase in mortality (50% vs. 24%, $p$=0.05).

The incidence of AKI among patients with influenza A infection was not higher than the general population matched per location of care. Obesity, elevated CK levels, and pre-existing CKD were associated with AKI requiring dialysis; the latter was associated with two-fold increase in hospital all-cause mortality. Information about the incidence of influenza A-related complications and their risk factors will aid in better care delivery, and resource allocation.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO038**

**Is an Angiotensin-Converting Enzyme Inhibitor (ACE-I) or Angiotensin Receptor Blocker (ARB) an Independent Predictor for Post-Operative Acute Kidney Injury (AKI) in Non-Cardiac Surgery?** Miho Murashima, Ai Ogata. *Department of Nephrology, Kyoto Katsura Hospital, Kyoto, Japan.*

**Objective:** ACE-I or ARB might be an independent predictor for post-operative (post-op) AKI in cardiac surgery. This study is to evaluate whether ACE-I or ARB is an independent predictor for post-op AKI in non-cardiac surgery.

**Methods:** This is a retrospective cohort study of patients who underwent surgeries under general anesthesia from 2007 to 2009 at our hospital. The outcome variables is post-op AKI as defined by AKI network (increase in creatinine by >0.3mg/dL or >150% compared to baseline within 48 hours or urine output < 0.5ml/kg/hour for > 6 hours). The predictor variable is the pre-operative (pre-op) use of ACE-I and/or ARB. The covariates are age, sex, kinds of surgery (intrathorasic, intraperitoneal, and others), pre-op creatinine (Cre), body mass index (BMI), diabetes mellitus (DM), hypertension (HTN), chronic obstructive pulmonary disease, atrial fibrillation, peripheral arterial disease, cerebrovascular disease, coronary artery disease (CAD), prothrombin time (INR) >1.5, platelet <150X10$^3$/ml, emergent surgery, pre-op hematcrit (Hct), the use of vasopressors, diuretics, non-steroidal anti-inflammatory drugs or iodine contrast within 48 hours preoperatively, smoking and left ventricular ejection fraction < 40%.

**Results:** Interim analysis of 686 patients was performed. By univariate logistic regression analysis, age, sex, kinds of surgery, pre-op Cre, BMI, DM, HTN, emergent surgery, pre-op Hct, CAD, the use of vasopressors, diuretics, iodine contrast were significant predictors for post-op AKI. By multivariate logistic regression analysis, the use of ACE-I and/or ARB was not an independent predictor for post-op AKI.

| | Odds Ratio (95% CI) | p |
|---|---|---|
| Age | 1.02 (0.98-1.05) | 0.30 |
| Sex | 1.53 (0.69-3.42) | 0.29 |
| ACE-I/ARB | 0.55 (0.23-1.30) | 0.17 |
| Pre-operative creatinine | 2.83 (1.05-7.61) | 0.04 |
| BMI | 1.12 (1.02-1.24) | 0.02 |

**Conclusions:** In the interim analysis, only pre-op Cre and BMI were independent predictors for post-op AKI and the use of ACE-I and/or ARB is not an independent predictor. Further analysis may alter the results.

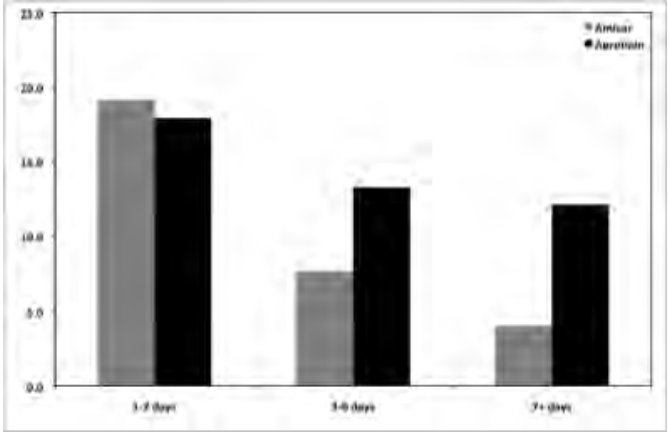
Disclosure of Financial Relationships: nothing to disclose

**TH-PO039**

**Acute Kidney Injury Duration Varies by Anti-Fibrinolytic Agent in Cardiac Surgery** Jeremiah R. Brown,[1] Robert Kramer,[2] Steven G. Coca,[3] Chirag R. Parikh.[3] *[1]The Dartmouth Institute for Health Policy and Clinical Practice, Dartmouth Medical School, Lebanon, NH; [2]Cardiothoracic Surgery, Maine Medical Center, Portland, ME; [3]Department of Internal Medicine, Yale University School of Medicine, New Haven, CT.*

Background: Aprotinin has been shown to be nephrotoxic when given to patients undergoing cardiac surgery, however results have been inconsistent and variable. We hypothesized aprotinin results in longer acute kidney injury (AKI) duration than Amicar (Epsilon-aminocaproic acid).Methods: Consecutive patients undergoing cardiac surgery

between 2002-2007 were followed for post-surgery AKI. Patients with a history of chronic dialysis were excluded. Duration of AKI was calculated by the number of days AKI was present as defined as a ≥0.3 (mg/dL) or a ≥50% increase in serum creatinine from baseline, or new onset of acute dialysis. Kaplan-Meier and Cox's proportional hazard modeling was conducted to evaluate five year mortality. Results: Fifty-three percent of patients received Amicar (N=2,333) and 47% received high dose aprotinin (N=2,093). Patients receiving aprotinin were more likely to develop longer durations of AKI than Amicar (Figure, P<0.001): 7.0 ± 11.5 versus 3.8 ± 6.0 days (P<0.001). Nearest-neighbor propensity matching demonstrated aprotinin had significantly worse 5-year mortality compared to Amicar (relative risk [RR] 2.09, 95% CI 1.65-2.65). The findings were consistent among each duration category of AKI, as aprotinin was associated with increased risk of 5-year mortality compared to Amicar: AKI for 1-2 days (RR 2.47, 1.45-4.21); AKI for 3-6 days (RR 1.90; 0.98-3.67); and AKI for ≥7 days (RR 1.56; 0.88-2.76).



Conclusions: Aprotinin is associated with longer duration of AKI compared to Amicar. AKI duration may provide the sensitivity and specificity for evaluating renal outcomes in clinical trials.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO040

**Determinants for Duration of Acute Kidney Injury after Cardiac Surgery** Jeremiah R. Brown,[1] Robert Kramer,[2] Steven G. Coca,[3] Chirag R. Parikh.[3] *[1]The Dartmouth Institute for Health Policy and Clinical Practice, Dartmouth Medical School, Lebanon, NH; [2]Cardiothoracic Surgery, Maine Medical Center, Portland, ME; [3]Department of Internal Medicine, Yale University School of Medicine, New Haven, CT.*

Background: Acute kidney injury (AKI) duration following cardiac surgery is associated with poor survival. However, it is not known what risk factors contribute to prolonged AKI and delayed recovery. We sought to identify perioperative risk factors that are associated with duration of AKI.

Methods: A cohort of 4,987 cardiac surgery patients from 2002 through 2007. AKI was defined as a ≥0.3 (mg/dL) or ≥50% increase in serum creatinine from baseline. We used multinomial logistic regression. Results: AKI developed in 39% of patients; 19% 1-2 days, 11% 3-6 days, 9% ≥7 days. Risk factors of AKI duration included older age, male sex, diabetes, hypertension, estimated glomerular filtration rate<60 (mL/min), preoperative red blood cell transfusion, blood prime, total heparin given on pump, nadir hematocrit<20 on pump, and pump time ≥120 minutes.

| Risk Factors | AKI 1-2 Days (OR) | AKI 1-2 Days (95%CI) | AKI 3-6 Days (OR) | AKI 3-6 Days (95%CI) | AKI 7+ Days (OR) | AKI 7+ Days (95%CI) |
|---|---|---|---|---|---|---|
| Age 60-69 | 1.25 | (1.03-1.53) | | | 2.11 | (1.47-3.04) |
| Age 70-79 | 1.61 | (1.31-1.97) | 2.54 | (1.95-3.32) | 4.40 | (3.10-6.23) |
| Age 80+ | 2.03 | (1.51-2.73) | 3.27 | (2.29-4.67) | 8.32 | (5.52-12.54) |
| Female | | | 0.64 | (0.51-0.80) | 0.68 | (0.53-0.88) |
| Diabetes | | | 1.57 | (1.28-1.91) | 1.39 | (1.10-1.74) |
| Hypertension | 1.22 | (1.04-1.44) | 1.78 | (1.43-2.23) | 1.27 | (1.00-1.61) |
| eGFR<60 (mL/min) | | | 2.39 | (1.93-2.96) | 2.82 | (2.23-3.56) |
| IABP use | | | | | 2.29 | (1.63-3.22) |
| Number of pRBCs | | | | | 1.41 | (1.14-1.73) |
| Blood prime | | | 1.22 | (1.04-1.43) | 1.43 | (1.23-1.66) |
| Cold cardioplegia | 0.74 | (0.63-0.86) | 0.69 | (0.56-0.84) | 0.75 | (0.60-0.94) |
| Heparin>= 50,000 (USP) | 1.21 | (1.02-1.43) | | | | |
| Nadir HCT<20 | | | 1.39 | (1.06-1.83) | 1.41 | (1.05-1.90) |

Conclusion: Risk-factors for AKI may be useful to evaluate a patient's risk for the rate of recovery from AKI after cardiac surgery and subsequent long-term survival.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO041

**Preventing AKI with a Hemoconcentration (HC) Strategy in Cardiac On-Pump Surgery (CS). A Risk-Adjusted Cohort Study** Alejandro Ferreiro,[1] Raul Lombardi.[2] *[1]Statistics, National Institute for Cardiac Surgery (INCC), Montevideo, Uruguay; [2]Medicina Crítica, SMI IMPASA, Montevideo, Uruguay.*

**Introduction:** The extracorporeal circulation is an etiologic factor for AKI in CS. Hemodilution (HD) is a newlly potentially modifiable risk factor for AKI. Hemoconcentration (HC) should protect kidneys in this setting. **Material and Methods:** to evaluate the impact of HD and the potential favorable effect of HC on AKI incidence, all patients submitted to CS between 1/1/2000 and 12/31/2009 were enrolled (n=7773; 6026 On-Pump (77.9%)). The INCC prospectively-collected database was used for analysis. Demographics, comorbidities, intraoperative and postoperative (PO) variables, and 30-day mortality (OM) were registered. A previously described priming redution strategy or in-pump ultrafiltration were used for HC. HD (preO - lowest on-pump Hct), AKI (RIFLE criteria), or RRT were registered. eGFR was calculated with the Cockroft-Gault formula. The PO RRT risk was estimated with the preO multivariable-adjusted Mehta score. ***Statistical analysis***. t test or Mann-Whitney test, $\chi 2$ and multivariate logistic regression analysis were used when appropriately, p<0.05 (*). **Results:** 6026 patients were included: age 65±11yrs (16-91). 61,9% HC strategy (94% priming reduction). No differences between groups in: comorbidities, preO SCr and eGFR. A U-shaped relationship between lowest Hct, AKI and RRT was observed, (lower rates in Hct 24-28%), in all eGFR spectrum. An excess (score) multivariable adjusted incidence of RRT was observed in the under 24% Hct group. AKI: 28 vs 31%, RRT: 1.9% vs 3.4%; PO Δ eGFR: 15.3 ml/min vs 17.9 ml/min, and OM (4.3% vs 5.8%) (*) were lower in the HC group, despite lower PreO Hct (36% vs 38%), but higher on-pump Hct (25,5% vs 23,9%) and lower HD (12,5% vs 14,6%) (*). The benefit of HC was observed in all the eGFR (*) spectrum, mainly in patients with preO Hct less than 34% (RRT: 2,7% vs 6%) (*). **Conclusion**: A direct relationship between lowest on-pump Hct and AKI was observed, with a 2-fold reduction of RRT incidence with the HC strategy, resulting in a lower 30-day mortality. Few other preventive strategies described in the literature demonstrated such impact on PO AKI after CS.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO042

**Impact of Statin Use on Incidence of Acute Kidney Injury in Critically Ill Patients with Sepsis** Ravish Shah,[OSUMC] Anil K. Agarwal.[OSUMC] *[1]Division of Nephrology, The Ohio State University Medical Center, Columbus, OH; [2]Division of Nephrology, The Ohio State University Medical Center, Columbus, OH.*

**Background:** Sepsis is the leading cause of death in critically ill patients. Development of sepsis related acute kidney injury (AKI) significantly increases the mortality. Cellular mechanisms for AKI include generation of oxygen free radicals and inflammatory cytokine production. Hydroxy-3 methylglutaryl co-A reductase inhibitors (statins) directly influences these inflammatory mechanisms. The aim of the study was to determine the impact of statin use on incidence of AKI, need for renal replacement therapy (RRT) and mortality in patients with sepsis.

**Methods:** This retrospective study was performed at a university affiliated tertiary care center and approved by the institutional review board. Patients admitted to ICU with a diagnosis of sepsis were included. They were then divided into two groups based on statin use. Demographics, co-morbid conditions and laboratory data were obtained. Statistical analyses were performed after adjusting for all the co-variables.

**Results:** A total of 302 patients met the inclusion criteria. Of those, 74 patients were in statin group and 228 were in no-statin group. Patients in statin group were older and had higher incidence of diabetes mellitus, hypertension, dyslipidemia, coronary artery disease (P < 0.01). Those with chronic kidney disease and systolic heart failure were more likely to develop sepsis related AKI (P< 0.01). Statin group had significantly less mortality (61%) compared to no-statin group (90%) (P<0.01). No statistically significant differences were noted in incidence of AKI or the need for RRT between both the groups.

**Conclusion:** Despite of higher incidence of co-morbid conditions, the statin group had significantly lower mortality. Statin use had no impact on incidence of sepsis related AKI or need for RRT. The reason for disparities in the outcome related to mortality and AKI may be related to differences in the disease severity, which could not be assessed given the retrospective nature. Prospective randomized controlled trials are warranted to investigate the potential benefit of statin in sepsis related AKI.

**Performance of Three Generations of Severity Scoring Systems Sequentially Evaluated in Acute Kidney Injury (AKI) Critically Ill Patients** Veronica T. Costa e Silva,[1] Isac Castro,[1] Fernando Liano,[2] Luis Yu.[1] *[1]Nephrology Service, Unversity of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Nephrology Service, University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Validated scoring systems are necessary to guarantee adequate randomization in clinical trials. The third generation of illness severity models (SAPS 3, APACHE IV and MPM III) have never been assessed in AKI non-dialysis patients. The aim of this study was to compare the performance of three AKI specific and nine general intensive care unit (ICU) scoring systems, including the new third generation models, for AKI patients in the ICU. A prospective study was done in six ICUs in a brazilian academic tertiary care center.

AKI was defined as an increase ≥ 50% in baseline serum creatinine. Scores discrimination and calibration were expressed by the area under the receiver operating characteristic curve (AUCROC) and Hosmer-Lemeshow (HL) goodness-of-fit tests, respectively. The observed-to-predicted mortality ratio (SMR) was calculated whenever possible. Scores were applied on AKI diagnosis day, on the day when AKI specific criteria were met and on the day of nephrology consultation (NC). Three hundred sixty six patients were analyzed. SAPS II and SHARF scores presented good performance at all evaluated time points (AUCROC curves over 0.80 on the third day and sustained-HL test ($p > 0.20$) over time). Customized SAPS 3 had good discrimination (AUCROC curve: 0.81 on third day), the best SMR (range over time: 1.09 – 1.13), but showed unsatisfactory HL test results on the third day (p: 0.025). APACHE IV presented similar discrimination and satisfactory HL tests over time but underestimated mortality (SMR range over time: 1.69 – 1.72). All scores presented progressive performance improvement over time. On the third day of analysis, most scores presented AUROC values over 0.70, and six models demonstrated AUCROC around 0.80. In conclusion, a sequential evaluation in early AKI improved the models' performance, demonstrating that severity scoring systems could perform well in critically ill AKI patients. The third generation models presented good discrimination but calibration difficulties were observed.

## TH-PO044

**Validation of RIFLE Criteria across Different Categories of Preoperative Estimated Glomerular Filtration Rate (eGFR) in Cardiac Surgery Patients**

Raul Lombardi,[1] Alejandro Ferreiro.[2] *[1]Sanatorio IMPASA, Montevideo, Uruguay; [2]Instituto Nacional de Cirugia Cardiaca, Montevideo, Uruguay.*

Purpose: to validate serum creatinine-based RIFLE criteria across different stages of chronic kidney disease.

Methods: all adult patients submitted to cardiac surgery in INCC-IMPASA between 1/1/2000 and 12/31/2008 were enrolled. Patients with an eGFR less than 15 ml/min/m2 were excluded. The INCC prospectively-collected database with more than 490 variables was used for analysis. Demographics, comorbidities, intraoperative and postoperative (PO) variables, and 30-day mortality (OM) were registered. Acute kidney injury (AKI) was defined according to RIFLE criteria based on changes in serum creatinine. For estimation of GFR the modified MDRD formula was used. Patients were categorized into four categories of chronic kidney disease (CKD): 1) ≥ 90 ml/min/$m^2$; 2) 60 to 90 ml/min/$m^2$; 3) 45 to 60 ml/min/$m^2$; 4) 30 to 45 ml/min/$m^2$; 5) 15 to 30 ml/min/$m^2$. Incidence of AKI as well as mortality rate was established for each CKD category. The model was adjusted for preoperative risk (EuroSCORE) using logistic regression analysis.

Results: 6231 patients were included in the analysis. Mortality rate of AKI and non-AKI patientes are shown in Table 1.

Mortality rate across preoperative eGFR

| eGFR | AKI | Non AKI | |
|---|---|---|---|
| Cat 1 | 6.4 | 2.4 | 0.000 |
| Cat 2 | 8.9 | 2.5 | 0.000 |
| Cat 3 | 12.9 | 2.5 | 0.000 |
| Cat 4 | 22.0 | 4.3 | 0.000 |
| Cat 5 | 29.9 | 7.0 | 0.000 |

value are expresed in percentages

Relative risk for Eusroscore was (1.17); CKD cat 1: (1.47); CKD cat 2: (1.48); CKD cat 3: (2.40); CKD cat 4 (3.70); CKD cat 5 (11.9); whereas for RIFLE R (2.30); RIFLE I (4.61) and RIFLE F (14.1). As seen, AKI is associated to a higher mortality which rises as preoperative renal function falls, even when adjusted for preoperative risk.

Conclusions: the present study showed that AKI defined by RIFLE criteria is independently associated to mortality rate in all categories of preoperative renal funcion.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO045

**Reappraising the Urine Output Criteria of AKI Consensus Definitions**

Dinna N. Cruz, Francesco Garzotto, Pasquale Piccinni, Gramaticopolo Silvia, Claudio Ronco. *S Bortolo Hosp, Vicenza, Italy.*

The consensus definitions RIFLE and AKIN use two criteria: change in serum creatinine (sCr) from a baseline or reference value, and urine output (UO). Experts have noted that the UO criteria may not match well with respective sCr criteria. Furthermore, UO is affected by diuretic use. Our aim was to evaluate the concordance between sCr and UO criteria on a daily basis, in the presence or absence of diuretics.

**Methods**

We enrolled 601 ICU patients from 10 centers; we recorded daily the worst 6hr & 12h UO, total 24h UO, diuretic use and sCr during the entire ICU stay. The sCr was compared to baseline sCr values from old records whenever possible. These data were used to determine RIFLE class on a daily basis. Agreement between RIFLE class based on sCr criteria (RIFLE-Cr) or on UO criteria (RIFLE-UO) was evaluated with the Kappa test.

**Results**

We evaluated a total of 6101 patient-days, excluded 536 days when RRT was performed, leaving 5565 days for analysis. RIFLE class was: NonAKI in 4490, Risk in 700, Injury in 241 and Failure in 134 of 5565 days. Diuretics were used in 2923/5565 days.

On the whole, agreement between RIFLE-Cr and RIFLE-UO was very poor (k=0.07, p<0.001). It was slightly better on no-diuretic days (k=0.11, p<0.001), and worse on days with-diuretic (k=0.05, p<0.001).

RIFLE-UO criteria for Risk (<0.5 ml/kg/h x 6h) were fulfilled in only 21% of all RIFLE-Cr-Risk days (Fig 1); this proportion was slightly higher on no-diuretic days (24%) vs with-diuretic days (18%). Findings were qualitatively similar for 12h (not shown) & 24h UO (Fig 2, RIFLE-Cr-Failure, no-diuretic 37% vs with-diuretic 7%, p<0.001).

**Conclusion**

Agreement between RIFLE-Cr and RIFLE-UO is poor. Diuretic use, which is common in the ICU, further worsens this inconsistency. Revision of UO criteria may help to harmonize the two sets of criteria.

## TH-PO046

**Performance of a New Definition of Acute Kidney Injury Based on Creatinine Kinetics in Cardiac Surgery**

Fernando Liano,[1] Angel M. Candela-Toha,[2] Jose Del Rey,[3] Laura Garcia-Bermejo,[4] Jose Garrido.[5] *[1]Nephrology, Hospital Universitario Ramón y Cajal, Madrid, Spain; [2]Anesthesiology; [3]Biochemistry; [4]Pathology; [5]Cardiac Surgery, .*

A new definition of AKI based on creatinine kinetics (CK) models has been published recently (1). This definition and classification system uses absolute increases in sCr over clearly defined periods of time, instead of relative changes. The rationale under this proposal is that absolute increases should provide earlier diagnosis, specially in CKD patients.

Aim: Compare the CK definition of AKI with the RIFLE system in a cardiac surgery setting.

Methods: Retrospective analysis of a cardiac anesthesia database. We analyzed sCr data for the first postoperative week of 2103 patients operated of major cardiac surgery with CPB. Baseline sCr was considered the nearest value to the surgical date. Patients were assigned to the highest category of AKI by both definitions. Time to diagnosis was measured as the number of days elapsed till the first time a sCr value fullfilled criteria to be classified as AKI in any of the systems. We use weighted kappa coefficient to assess agreement across categories and nonparametric tests to compare time to diagnosis. Discrimination for outcomes (need for RRT and in-hospital mortality) was explored calculating and comparing AUC ROC.

Results: A significant greater proportion of patients were classified as AKI by the CK system as compared with RIFLE (28.5% vs 14.3%). Diagnosis of AKI by the CK scheme was earlier (1.8 d vs 2.5 d; p<0.001) for the 268 patients diagnosed of AKI by both systems. While need for RRT discrimination was excellent for both definitions (AUC 0.884 for CK vs 0.852 for RIFLE; p=n.s.) discrimination for in-hospital mortality was good (AUC 0.801 for CK vs 0.781 for RIFLE; p=n.s.)

Conclusion: The AKI definition and classification system based on CK models was more sensitive than RIFLE, detected AKI earlier and had a similar prognostic value in terms of need for RRT and in-hospital mortality.

**Definition of Iodinated Radiocontrast Agent Toxicity by Creatinine Elevation Alone Appears Questionable (BICAH Study: CRG010700102)**
Simon Desmeules, Mohsen Agharazii. *Medicine, CHUQ, Quebec, Qc, Canada.*

Introduction: Radiocontrast induced nephropathy (RCIN) is usually defined by an elevation of baseline creatinine (Cr) level by 0.5 mg/dL or 25%. Cystatin C (CyC) blood levels are well correlated with kidney function and can detect more rapidly subtle change of glomerular filtration rate (GFR). In theory, CyC should detect more RCIN than Cr alone. Our study evaluated RCIN incidence using Cr (0.5 or 25% elevation) and CyC (25% increase). Method: 170 patients with GFR<60 mL/min exposed to iodixanol were randomized to normal NaHCO3 (Bic), normal saline (NaCl) or NS+n-acetylcystein 600 mg BID x48h started the day before (NAC). Hydration protocols were identical in the 3 groups (3mL/kg x1H pre + 1mL/kg X6h post). Blood samples were drawn at T=0 and T=48H. Table shows baseline characteristics of the patients.

| | total | BIC | NAC | NaCl | p |
|---|---|---|---|---|---|
| n | 170 | 56 | 61 | 53 | |
| Age (y) | 63.7 | 65.1 | 63.1 | 63.1 | ns |
| Men (%) | 66.5 | 60.7 | 63.9 | 75.5 | ns |
| Weight (kg) | 75.5 | 77.3 | 72.3 | 76.9 | ns |
| Height (cm) | 168 | 169 | 168 | 169 | ns |
| BSA | 1.87 | 1.90 | 1.83 | 1.89 | ns |
| BMI | 26.4 | 26.9 | 25.6 | 26.9 | ns |
| DM (%) | 28.8 | 32.1 | 32.8 | 20.8 | ns |
| Transplant (%) | 31.6 | 26.8 | 37.7 | 30.2 | ns |
| Creat (µmol/L) | 158 | 163 | 150 | 161 | ns |
| MDRD (mL/min) | 41 | 41 | 42 | 42 | ns |
| Contrast vol (mL) | 144 | 143 | 137 | 153 | ns |
| Cont/bw (mL/kg) | 2.0 | 1.9 | 2.0 | 2.1 | ns |
| Hydratation (mL) | 668 | 658 | 653 | 695 | ns |
| Hydrat/bw (mL/kg) | 8.9 | 8.6 | 9.0 | 9.1 | ns |

Results: RCIN incidence was lowest in the NS group but no statistical difference was detected.

RCIN incidence (%)

| **RCIN def** | **Intervention** | | | |
|---|---|---|---|---|
| | Bic | NAC | NaCl | p |
| **Cr0.5** | 3.6 | 3.3 | 0 | ns |
| **Cr25** | 5.4 | 6.6 | 0 | ns |
| **CyC25** | 5.4 | 9.8 | 3.8 | ns |

No patient required dialysis. As expected, CyC diagnosed more cases of RCIN but concordance between the two methods was poor. 3/7 cases detected by Cr25% were also detected by CyC25% while Cr0.5 and CyC25% were in agreement on 2 of 4 cases. Overall, Cr and CyC were in agreement in less than 50% of cases. Conclusions: RCIN incidence in our study was low when defined with Cr elevation. Prevention with NS does not appear inferior to NAC or BIC and is less cumbersome. Finally, RCIN needs to be better defined in order to prevent clinically significant events.

**TH-PO048**

**Episode Duration and Improvement Status Influence Outcomes from Acute Kidney Injury (AKI)**
Rakesh Malhotra,[1] Etienne Macedo,[1] Josee Bouchard,[2] Ravindra L. Mehta.[1] *[1]University of California, San Diego, San Diego, CA; [2]Université de Montréal, Montréal, QC, Canada.*

Background: AKI stage is well recognized as influencing outcomes. However,the duration of AKI episode and the completeness of renal functional improvement have not been evaluated as factors related to outcomes. We hypothesized that duration and completeness of improvement in renal function would correlate with clinical outcomes.

Methods: We studied 716 ICU patients screened for a prospective observational study on incidence of AKI from June 2006 to December 2008. AKI was defined by AKIN sCr criterion (≥0.3mg/dl absolute change within 48 hr). AKI patients were categorized based on the rate and completeness of change in sCR into three groups: "Transient Elevation" sCR return to reference within 72 hr; "AKI Slow Improvement": sCr improvement ≥ 0.3 mg/dl in > 72 hr without return to reference within 72 hr) and "Persistent AKI"(sCr change <0.3 mg/dl through ICU stay with no return to reference). ICU and hospital mortality, need for renal replacement therapy (RRT) and length of stay were compared among these groups stratified by AKIN stage.

Results: AKI patients had a significantly higher ICU and hospital mortality than No AKI subjects (19.8% vs. 2.1%; P <.0001 & 24.0% vs. 2.4%; P<.0001). Patients with persistent AKI had the worst outcomes followed by patients with slow improvement and transient elevation (Table). This effect was evident controlling for AKI stage (AKI Stage 1 mortality 11.8% vs. 15.8% vs. 19.7% in Transient, Slow and Persistent AKI).

Conclusion: Transient rise of sCr is associated with increased risk of mortality. Slow renal improvement or no improvement after an AKI episode contributes to worse outcomes. Future studies should focus on targeting early improvement in renal function to improve outcomes.

Clinical Outcome by AKI Groups

| | No AKI | AKIN AKI | | |
|---|---|---|---|---|
| | | Transient elevation | AKI slow Improvement | Persistent AKI |
| Total N | 374 | 42 | 28 | 122 |
| % ICU Mortality | 2.1 | 9.5 | 17.9 | 23.8 |
| % Hospital Mortality | 2.4 | 11.9 | 21.4 | 28.7 |
| % Need for RRT | 0.5 | 0 | 0 | 31.1 |
| Length of ICU stay (days) | 3 (2-4) | 5 (4-8) | 7 (5-13) | 4 (3-6) |
| Length of Hospital stay (days) | 5 (3-10) | 10 (6-18) | 11 (6-19) | 7 (4-15) |

Disclosure of Financial Relationships: nothing to disclose

**TH-PO049**

**Decline in Serum Creatinine: A Potential Criteria for Refining Diagnosis and Staging of Acute Kidney Injury (AKI)**
Rakesh Malhotra,[1] Etienne Macedo,[1] Josee Bouchard,[2] Ravindra L. Mehta.[1] *[1]University of California, San Diego, San Diego, CA; [2]Université de Montréal, Montréal, QC, Canada.*

Background: Diagnostic criteria for AKI (AKIN and RIFLE) rely on increments in serum creatinine(sCR) to define AKI. However, several patients present with an elevated sCr at hospital admission that subsequently declines during hospitalization. These patients cannot be classified as AKI based on current criteria and it is unclear if this decline in sCR represents an episode of AKI. We studied the prognostic significance of sCr decline in ICU patients who did not meet AKIN criteria during ICU stay.

Methods: We studied 716 patients admitted to ICU's who were screened for a prospective observational study on incidence of AKI from Jun 06 to Dec 08. Patients were stratified in three groups. "AKIN AKI": defined by AKIN sCr criterion (≥0.3mg/dl absolute change within 48 hours) ; "Presumed AKI": patients who did not meet AKIN criteria but had sCr decline ≥0.3 mg/dl during the ICU stay; "No-AKI": patients who did not meet either criteria. We compared ICU and hospital mortality, need for renal replacement therapy (RRT) and length of stay among these groups.

Results: 192 (26.8%) patients met the AKIN criteria. Presumed AKI patients had a trend towards higher ICU mortality (4.0% vs. 2.1%; P=0.37) compared with No AKI but lower ICU mortality (4.0% vs. 19.8%; P=<.0001) compared with AKIN AKI group (Table). Presumed AKI patients had significantly longer length of stays as compared to No AKI (P<.0001).

Conclusion: Patients with elevated sCr at ICU admission who have a decline during the course of ICU stay have an increased risk for mortality. Future studies are required to evaluate whether a decline in Scr should be a criterion to diagnose and stage AKI.

| | No AKI | Presumed AKI | AKIN AKI | P value |
|---|---|---|---|---|
| Total N | 374 | 150 | 192 | |
| % ICU Mortality | 2.1 | 4.0 | 19.8 | <.0001 |
| % Hospital Mortality | 2.4 | 6.0 | 24.0 | <.0001 |
| % Need for RRT | 0.5 | 0 | 19.8 | <.0001 |
| Length of ICU stay (days) | 3 (2-4) | 5 (3-6) | 5 (3-8) | <.0001* |
| Length of Hospital stay (days) | 5 (3-10) | 8 (5-15) | 8 (5-16) | <.0001* |

**TH-PO050**

**Transient Changes in Renal Function and Outcomes in ICU Patients: A Prospective Cohort Study**
Etienne Macedo,[1] Rakesh Malhotra,[1] Josee Bouchard,[2] Ravindra L. Mehta.[1] *[1]University of California San Diego; [2]Université de Montréal.*

Prerenal failure is used to designate a transient increase in sCr, however, the time frame for reversibility as well as volume or hemodynamic improvement required to rule out the syndrome are not clearly designated. We assessed the influence of a transient decrease in urine volume or increase in sCr on outcomes of surgical ICU patients. We hypothesized that transient changes would be associated with better outcomes than prolonged azotemia and/or oliguria. Methods: We analyzed surgical ICU patients screened in study on incidence of AKI from Jun06 to Dec08. We characterized transient changes as an increase in sCr (at least 0.3 mg/dL or 50% from reference) that returned to reference within 72 h or a single episode of urine volume less than 3mL/kg for 6h. Patients were classified as sustained AKI by sCr if sCr did not returned to reference values within 72 h, or an episode of 12h with urine output < 6mL/kg; and AKI by both criteria when they met sustained UO and sCr criteria. Results: Of 315 patients, 168 (53%) were classified as AKI of which 43 (28%) met transient criteria, and 125 (82%) sustained AKI. Oliguric patients without increase in sCr were less often exposed to diuretic (20%) than patients that reach only sCr criteria (40%) or both criteria (70%). There was no difference in the use of vasopressor or diuretics between prerenal and sustained AKI patients. Length of ICU and hospital stay, as well as ICU and hospital mortality were different among the groups. Among survivors, AKI patients had a longer length of ICU stay compared to the prerenal group (p=0.05).

| | No AKI | Transient changes by sCr or UO | AKI by UO | AKI by sCr | AKI by UO and sCr |
|---|---|---|---|---|---|
| N | 147 | 43 | 55 | 36 | 34 |
| % ICU mortality | 2 | 4.6 | 2 | 11 | 24 |
| % Need for RRT | 1 | 0 | 0 | 8 | 12 |
| ICU stay (days) | 2(2-3) | 3(2-8) | 3(2-7) | 4(3-15) | 5(3-13) |
| Hospital stay (days) | 5(3-11) | 8(4-14) | 8(4-17) | 10(5-19) | 16(5-23) |

Conclusion: Patients with transient changes in urine flow and or sCr have worse outcomes than non AKI patients and may identify patients at risk for adverse events. Further studies are needed to assess whether transient alterations in renal function have a similar effect in non-surgical patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO051**

**Pattern of Serum Creatinine Decline Is Associated with Renal Recovery from Acute Kidney Injury in ICU Patients** Etienne Macedo,[1] Rakesh Malhotra,[1] Josee Bouchard,[2] Ravindra L. Mehta.[1] [1]*University of California San Diego;* [2]*Université de Montréal.*

Recovery of kidney function following an episode of AKI is influenced by several factors including the severity of renal functional change. The rate, magnitude and duration of change in sCr have been identified as potential factor associated with outcomes. We hypothesized that a rapid improvement in renal function characterized by early and persistent decline in sCr would be associated with higher level of renal recovery. **Methods:** We studied a cohort of 716 ICU patients screened from Jun06 to Dec08. AKI was defined by the AKIN sCr criterion (>= 0.3mg/dL within 48 hours). The slope of Scr change was computed from the last sCr value prior to its decline in non-dialyzed patients for 24, 48 and 72h time points from ICU admission. Percent recovery was calculated based on the last value at ICU discharge in comparison to the first sCr at ICU admission and time to recovery was computed as the time duration between the last peak sCr value and that at ICU discharge. Patients were stratified based on percentage change of recovery from; 25-49%, 50-99% and >=100%. We evaluated the relationship of the slope to level of and time to recovery. **Results:** Of 192 (26.8%) patients that met AKIN criteria, 38 were dialyzed and not included in this analysis. In 37%, sCr returned to reference during ICU stay, in half the last sCr was between 50 to 99% from the reference sCr %, and in 11% from 25 to 49%. The level and time to recovery were correlated (r=-.399; p=<.0001).

Serum creatinine slopes and renal recovery during ICU stay

| Recovery category | N | Slope 24 | Slope 48 | Slope 72 |
|---|---|---|---|---|
| 25-49% | 17 | .35(.3-.47) | .25(.2-) | .3(.2-) |
| 50-99% | 78 | .4(.15-.5) | .1(.1-.25) | .13(.06-.16) |
| >=100% | 57 | .4(.3-.6) | .25(.15-.35) | .2(.13-.23) |
| Correlation with final % of renal recovery - r (p) | 152 | .428(<0.001) | .449(0.001) | .323(0.051) |

*p for difference among groups

**Conclusion:** In this cohort, a rapid decline in Scr was associated with higher levels of renal recovery during the ICU stay. Future studies should target the time to improvement as a modifiable factor for improving renal functional recovery and other outcomes from AKI.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO052**

**How Effective Is a Time-Independent Creatinine Change Criteria in Identifying Patients Developing Acute Kidney Injury as Defined by RIFLE/AKIN?** Andrew J. P. Lewington,[1] Ashley Garner,[2] Julian Barth.[2] [1]*Department of Renal Medicine, Leeds Teaching Hospitals, Leeds, West Yorkshire, United Kingdom;* [2]*Department of Clinical Biochemistry, Leeds Teaching Hospitals, Leeds, West Yorkshire, United Kingdom.*

Introduction

The NCEPOD AKI report identified a significant gap in the quality of care received by patients who died from AKI. Specifically there was an unacceptable delay in recognising patients who developed AKI post-admission. This clearly illustrates the need to improve the detection of AKI in hospitalised patients.

AKI can be detected by increases in serum creatinine using the RIFLE or AKIN definitions. However current UK hospital laboratory systems cannot apply these definitions to real-time changes in serum creatinine. An alternative criterion is to use a time independent laboratory Delta check to identify patients who experience a rise in creatinine.

Methods

The laboratory clinical biochemistry database was interrogated retrospectively for creatinine results for adult in-patients admitted to a teaching hospital (880 in-patient beds) during October 2008. Only in-patients were included, all out-patients were excluded. All creatinine results for these patients reported within 30 days following the day of admission were collected. The data was analysed using the RIFLE, AKIN and a Delta check criterion defined as an increase of >26 umol/L in two successive creatinine results over a period up to 30 days.

Results

A total of 10019 serum creatinine results were reported on 2822 adult in-patients. Of the 1315 patients who had multiple creatinine results 149 (73 males; 76 females) were identified as potentially suffering from AKI in accordance to either the RIFLE, AKIN or Delta check criteria. These 149 patients represented 5.3% of all patients with creatinine results and 11.3% of patients who had multiple creatinine results.

Conclusion

Utilisation of the Delta criterion detected most of the patients identified by both RIFLE and AKIN. This criterion could be easily incorporated into a routine Clinical Biochemistry alert system to identify patients developing AKI. Diagnosis of AKI would then be based on the application of the RIFLE/AKIN definitions.

**Hypertension, Cardiovascular Diseases and Multiple Organ System Failure: Flip Sides for an Acute Kidney Injury Outcome** Milan M. Radovic.[1,2] [1]*Clinic of Nephrology, Clinical Center of Serbia, Belgrade, Serbia;* [2]*University of Belgrade, School of Medicine, Belgrade, Serbia.*

BACKGROUND: Viewpoint on binomial acute kidney injury (AKI) outcome and factors that influence lack of complete recovery have not been elucidated.

AIM: The aim of the study was to compare impact of comorbidities and complications on fatal outcome and incomplete AKI stage 3 recovery.

METHODS: Retrospective, observational, single centre study was done in 825 AKI stage 3 patients (age 50.3 ± 15.8 years, 604 male) treated by hemodialysis, assigned to one out of 4 groups according to in-hospital outcome: 1 = no AKI recovery and death (N =369, 44.7%), 2 = AKI recovery but death (N=9, 1.1%), 3 = incomplete AKI recovery and survival (N=43, 5.2%), 4 = complete recovery and survival (N=404, 49%, p < 0.001). Individual severity score (ISS), age and frequencies of comorbidities and complications were compared between groups (ANOVA, logistic regression and Cox proportion hazard model).

RESULTS: Patients in group 1 were older than in group 4 and had greater ISS than other (p<0.001). Hypertension and cardiovascular diseases (p< 0.001) were more frequent in groups 1 and 3 than other groups. Sepsis (p = 0.038), ARDS and MOSF (p < 0.001) were more frequent in group 1 than group 4, and MOSF than in group 3 (p < 0.001). Patients with hypertension (OR 2.72, CI 1.2 - 6.2, p=0.018) and ischaemia (OR 6.49, CI 1.98 - 21.3, p=0.002), were likely not to recover AKI completely. Neoplasia (OR 1.62, CI 1.01 - 2.61, p = 0.045) and cardiovascular diseases (OR 2.43, CI 1.48 - 3.97, p< 0.001) were related with fatal outcome. Cox regression (p = 0.011) showed impact of hypertension (OR 4.66, CI 1.95 - 11.1, p=0.01) on incomplete AKI recovery. Patients with cardiovascular (OR 1.67, CI 1.2 - 2.3, p = 0.003) or hepatic (OR 1.52, CI 1.06 - 2.17, p = 0.024) comorbidities and ARDS as a complication (OR 2.23 , CI 1.37 - 3.67, p = 0.01) had greater hazard risk for fatal outcome.

CONCLUSIONS: Hypertension had the greatest impact on AKI stage 3 incomplete recovery. Cardiovascular diseases are the most important comorbidity and ARDS and MOSF complications related with fatal outcome.

**TH-PO054**

**Second Episode of AKI: An Infrequent but Deadly Outcome** Raul Lombardi. *On Behaf of the VENTILA Group, Getafe, Spain, IMPASA, Montevideo, Uruguay.*

Purpose: to establish the clinical profile and the outcomes of a second episode of acute kidney injury (AKI) in mechanically ventilated (MV) patients.

Methods: The VENTILA Group database was used for the study. Clinical and laboratory data were recorded daily until death, ICU discharge, or day 28, whichever came first. AKI was defined according to AKIN criteria. Regression of AKI (AKI-R) was considered when a sustained and progressive reduction of SCr ≥0.3 mg/dl was observed during more than 2 consecutive days. Persistence of AKI (AKI-P) was defined by the absence of regression. Second episode of AKI (AKI-2) was defined by a sustained rise in SCr≥0.3 mg/dl for two or more days in patients with AKI in regression. The remainder ptes were grouped as No-AKI. Study period: 10 days from start of MV. Primary outcome: in-hospital mortality; secondary outcome: days of MV, ICU-LOS and hospital-LOS.

Main results are in Table 1.

| | AKI-R | AKI-P | AKI-2 | No-AKI | TOTAL |
|---|---|---|---|---|---|
| Cases n, % | 330 (12.0) | 391 (14.1) | 49 (1.8) | 1991 (72.1) | 2761 |
| Age yrs (SD) | 60.0 (16.4) | 61.8 (17.1) | 55.9 (16.2) | 58.3 (17.4) | 59.0 (17.5) |
| Male % | 67.9 | 63.2 | 57.1 | 59.2 | 60.8 |
| SAPS II median,range | 48 (12-108) | 49 (5-109) | 41 (2-94) | 42 (2-109) | 44 (2-109) |
| Days of MV mean (SD) | 9.6 (7.1) | 6.5 (3.5) | 14.5 (16.2) | 8.1 (7.7) | 8.2 (7.8) |
| ICU-LOS mean (SD) | 16.1 (13.8) | 12.0 (11.6) | 25.1 (27.5) | 14.5 (13.7) | 14.6 (13.90 |
| Hospital-LOS mean (SD) | 30.1 (34.3) | 24.5 (26.7) | 36.1 (40.2) | 28.5 (29.7) | 28.3 (30.1) |
| Observed mortality % | 49.1 | 59.1 | 67.3 | 38.6 | 43.2 |
| Expected mortality % | 44.8 | 47.0 | 35.3 | 35.7 | 38.4 |
| Variation % (rate) | 8.8 (1.09) | 20.5 (1.25) | 47.3 (1.90) | 7.5 (1.08) | 11.1 (1.12) |

Kaplan-Meier analysis showed a drop in survival curve for AKI-2 ptes by day 6, in coincidence with the onset of AKI-2: 6.6 (1.9) d. $PaO_2$, plateau pressure, PEEP, MAP worsened 3 days before AKI-2 onset.

Conslusions: 1) a second episode of AKI almost doubled the expected mortality and prolonged MV time and LOS. 2) timing of onset of AKI-2 and drop in survival suggest a relationship between both events. 3) hemodynamic derangement and injurious MV seems to be risk factors. 4) protective ventilation and close hemodynamic support could prevent this deadly complication.

**Clinical Characteristics and Outcomes of Septic Acute Kidney Injury** Eunjung Cho, Sang-Kyung Jo, Won-Yong Cho, Hyoung-Kyu Kim. *Department of Internal Medicine, Division of Nephrology, Korea University Anam Hospital, Seoul, Korea.*

**Purpose**: This study aimed to determine the clinical characteristics and outcomes of critically ill patients with septic acute kidney injury (AKI) in comparison with non-septic AKI.

**Methods**: We retrospectively collected data of patients with AKI who were ≥18 years of age and admitted to the intensive care unit (ICU) for ≥24 hours between 1 April 2007 and 31 December 2009, and compared the clinical characteristics and outcomes of patients with and without sepsis. Outcome measures were in-hospital mortality, renal replacement therapy (RRT) requirements, duration of ICU and hospital stays, and renal recovery. We analyzed predictors of mortality using logistic regression.

**Results**: Of the 1075 patients, 333 (30.9%) had AKI, as defined by the RIFLE criteria, and 134 (40.2%) of them had AKI with sepsis. The predominant septic foci were thoracic (46.3%) and abdominal (29.9%). Septic AKI had significantly higher SAPS II and SOFA scores, and required more mechanical ventilation and vasoactive drugs than non-septic AKI. Furthermore, a significantly greater proportion of patients with septic AKI progressed to the failure category of the RIFLE classification compared to patients with non-septic AKI (62.7% versus 44.7%). Septic compared with non-septic AKI had a higher in-hospital mortality and required more RRT (63.2% versus 35.7%, p<0.001; 44.7% versus 23.2%, p<0.001, respectively). Amongst survivors, patients with septic AKI were more likely to recover renal function. Finally, a higher SAPS II score, and a greater requirement for vasoactive drugs and RRT were independently associated with increased in-hospital mortality in septic AKI after adjustment for other covariates.

**Conclusion**: The incidence of AKI in ICU patients is high, for which sepsis is a leading contributing factor. Patients with septic AKI are sicker and have a higher burden of illness with an increased risk of death compared to patients with non-septic AKI, but renal function recovers better in survivors of septic AKI. Further studies are necessary to determine the clinical factors and actual pathophysiology related to outcomes and also to find valid treatment modalities in septic AKI.

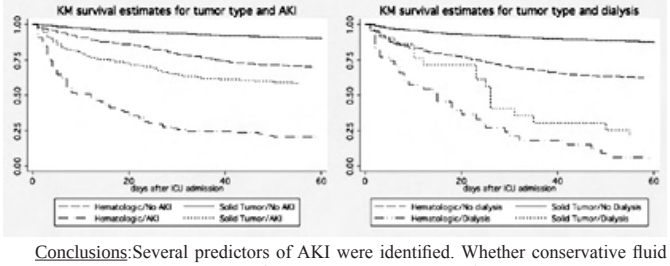
### TH-PO056

**Predictors, Costs, and Outcomes of Acute Kidney Injury in Critically Ill Patients with Cancer** Amit Lahoti, Abdulla K. Salahudeen. *General Internal Medicine AT/EC, Section of Nephrology, University of Texas M D Anderson Cancer Center, Houston, TX.*

Purpose:To identify predictors and the associated costs of AKI and dialysis in critically ill patients with cancer. Methods:Retrospective analysis of 2398 patients admitted to the ICU from Dec 2005 through Dec 2006 with a baseline serum creatinine (Scr)<=1.5 mg/dL. Primary endpoint was AKI defined as a minimum 50% increase in Scr from baseline at any point during the ICU admission. Regression analysis was used to determine predictors of AKI as well as the economic impact of AKI and dialysis on total hospital cost. Kaplan-Meier estimates of survival stratified by tumor type were determined. Results:Predictors of AKI included (Odds Ratio): vasopressors(2.7), mechanical ventilation(2.2), medical vs surgical service(2.0), IV diuretics(3.0), amphotericin(2.3), sepsis(1.9), and diabetes(1.4). There was a 2.1-fold increase in odds of developing AKI in patients receiving both mechanical ventilation and vasopressors (interaction). After adjusting for covariates, dialysis was associated with an increase of $76,911 in hospital cost. Independent of dialysis, each 1% increase in creatinine was associated with a $92 increase in hospital cost. Pts with hematologic malignancies who developed AKI had the lowest short-term survival. The need for dialysis in these patients was associated with a dismal 60-day prognosis (figure).



Conclusions:Several predictors of AKI were identified. Whether conservative fluid strategies decrease the incidence of AKI by reducing the need for mechanical ventilation and diuretics is of interest. Amphotericin should be reserved for patients who have a strong indication. Given the cost implications and poor survival, the utility of dialysis in critically ill patients with hematologic malignancies should be carefully examined. A limited trial of early goal directed therapy might be considered.

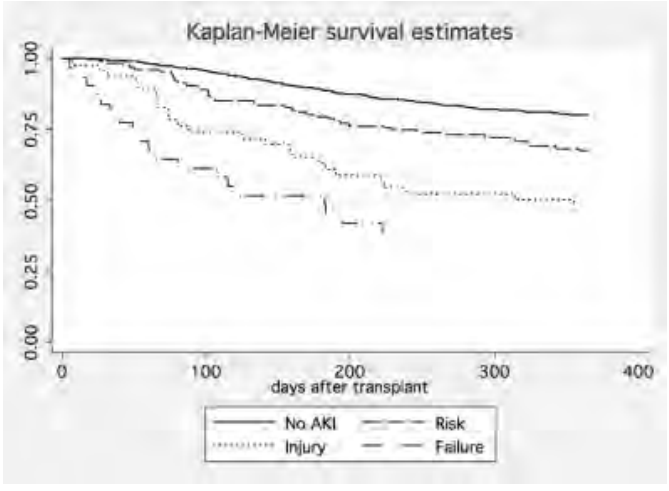
### TH-PO057

**Acute Kidney Injury Occurs in a Significant Number of Patients Undergoing Stem Cell Transplant and Is Associated with Decreased Survival** Amit Lahoti,[1] Abdulla K. Salahudeen.[1] *[1]General Internal Medicine AT&EC, Section of Nephrology, University of Texas M D Anderson Cancer Center, Houston, TX; [2]Houston, TX; [3]Houston, TX.*

Purpose:To determine the incidence and outcome of acute kidney injury (AKI) in patients undergoing stem cell transplant. Methods:Retrospective analysis of 1048 patients who underwent stem cell transplant at M D Anderson Center from Sept 2004 to Sept 2006. AKI was defined by the RIFLE criteria using the maximum SCr within 60 days of transplant compared to baseline. Cox Proportional Hazards model was used to examine the effect of AKI on survival. Kaplan-Meier estimates of survival were determined by RIFLE category. Results: Demographics included average age 50 years, 60% male gender, and 76% Caucasian. 48% of patients underwent allogeneic transplant. 19% of patients had acute GVHD grade I-II, and 4.4% had acute GVHD grade III-IV. 12%, 4.4%, and 3% of patients were classified into the Risk, Injury, and Failure categories, respectively. AKI was significantly associated with mortality in an adjusted Cox proportional hazard model (hazard ratio): Risk (1.4), Injury (1.9), and Failure (2.7).



Conclusions: AKI develops in a significant number of patients undergoing stem cell transplant and is associated with decreased overall survival. Whether strategies that help to mitigate the incidence of AKI also translate to improved survival are of interest.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO058

**Acute Kidney Injury (AKI) in Cancer Patients: Incidence, Risk Factors and Outcomes** Abdulla K. Salahudeen, Amit Lahoti. *UT MD Anderson CC, Houston, TX.*

Purpose of Study: AKI appears to be on the rise in the cancer population, but its incidence, risk factors or influence on patient-outcomes is not known.

Methods: Electronic patient records were prospectively collected in 5491 patients hospitalized to UT MD Anderson Cancer Center for 3 months between May 1, 2006 and July 31, 2006. For each patient, demographic information and laboratory and pharmacy data were obtained. Descriptive, survival and logistic regression analyses were performed.

Results: The incidence of AKI defined as an absolute increase in serum creatinine ≥ 0.3 mg/dl was 28% among the 5013 patients. Preexisting AKI was noted in 14% patients admitted to hospital where as 14% patients acquired AKI in the hospital. The mean (±SD) age was 54±18 y, and men were 52%. In univariate analysis, frequency of AKI was significantly higher in patients on chemotherapeutic, anti-diabetic and antibiotic medications. Patients admitted to ICU were 50% more likely to develop AKI. AKI in cancer patients was found to be associated with 1) a high blood sugar of over 200 mg/dl (p<0.001), 2) admission through Emergency Center or admission to ICU (p<0.001), and 3) admission Service Group or Cancer types (p=0.001), for example, admission to Stem Cell Transplant Department or hematological malignancy. Patient with AKI had a mortality rate of 15% compared to patients without AKI who only had a mortality rate of 2.3 (p<0.001). In multivariate regression analysis, patient who had AKI had higher rates of hospital stay (OR 2.1, CI: 1.7-2.6; P<0.0001) and mortality (OR 6.0 , CI: 4.3-8.2; P<0.0001).

Conclusions: 1) the AKI incidence rate of 28% among patients admitted to cancer hospital is higher than the rate known for patients admitted to a community hospital, 2) the risk factors for AKI include diabetes, type of cancer and cancer therapy and 3) both mortality and hospital stay are adversely affected by the development of AKI in hospitalized cancer patients.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO059

**The Incidence and Clinical Course of Acute Renal Failure in Patients with Severe Acute Pancreatitis** Young Soo Kim, Hyun Gyung Kim. *Nephrology, Uijeongbu St. Mary's Hospital, The Catholic University of Korea, Uijeongbu-si, Kyunggi-do, Republic of Korea.*

**Purpose** : Although acute renal failure (ARF) commonly develops in patients with severe acute pancreatitis (SAP), the impact of ARF on disease severity is rarely reported in Korea. This study was performed to compare the clinical findings, morbidity and mortality between SAP patients with ARF and normal renal function (NRF). **Method** : We retrospectively evaluated the medical records of 102 patients with SAP between january 2001 and June 2008 in 3 Hospitals. We defined SAP by the 1992 International Symposium on Acute Pancreatitis in Atlanta. **Results** : Of the total 102 SAP patients, ARF was observed in 39 patients (38.2%). Eight of the 39 ARF patients (20.5%) received hemodialysis and ten patients (25.6%) died. When compared to NRF patiens, ARF patients (n=39) had higher incidence of loss of consciousness (17.9% vs 1.6%, p=0.003), and APACHE II scores more than 8 (92.3% vs 0%, p<0.001). The ARF group had also higher incidences of sepsis (35.9% vs 7.9%, p<0.001), multiorgan failure (15.4% vs 0%, p=0.001), respiratory failure (28.2% vs 4.7%, p=0.001) and mortality (25.6% vs 3.2%, p=0.001). In our study, thrombocytopenia (p=0.037), Hemoconcentration (p=0.023), high LDH (p=0.040) were significant predictors of ARF in patients with SAP.**Conclusion** : The incidence of ARF was high (38.2%) and ARF patients showed higher mortality, compared to NRF patients. We suggest that early management of ARF should be performed for reducing the mortality in SAP patients.

Multivariate analysis of risk factors for ARF in patients with severe acute pancreatitis

| | Regression coefficient | Regression Standard error | p value | Adjusted odds ratio | 95% C.I |
|---|---|---|---|---|---|
| Thrombocytopenia | 2.083 | 1.000 | 0.037 | 8.026 | 1.130-56.991 |
| Hemoconcentration | 1.526 | 0.673 | 0.023 | 4.602 | 1.229-17.226 |
| Hyponatremia | 0.741 | 0.643 | NS | 2.098 | 0.589-7.476 |
| Abnormal LFT | -0.301 | 0.674 | NS | 0.740 | 0.198-2.770 |
| High LDH | 1.646 | 0.801 | 0.040 | 5.188 | 1.080-24.913 |
| Sepsis | 1.188 | 0.792 | NS | 3.281 | 0.695-15.492 |
| Respiratory failure | 1.098 | 0.892 | NS | 2.997 | 0.521-17.228 |

Disclosure of Financial Relationships: nothing to disclose

## TH-PO060

**Predicting Kidney Recovery in Patients with Acute Kidney Injury Requiring Renal Replacement Therapy** Benjamin R. Bell,[1] Neill Adhikari,[1] Sean M. Bagshaw,[2] Jan O. Friedrich,[1] Michelle A. Hladunewich,[1] David Klein,[1] Stephen Lapinsky,[1] Ron Wald.[1] *[1]Department of Medicine, University of Toronto, Toronto, ON, Canada; [2]Critical Care Medicine, University of Alberta, Edmonton, AB, Canada.*

**Introduction:** A significant minority of patients with acute kidney injury (AKI) who require renal replacement therapy (RRT) go on to chronic dialysis. There is limited information on factors present at RRT initiation that may predict a favorable kidney prognosis in AKI.

**Methods:** This is a cohort study of consecutive patients admitted to critical care units at St. Michael's Hospital (Toronto, Canada) who required dialysis for AKI from April 2007-January 2010. We collected demographic (age, sex) and clinical variables (baseline and admission creatnine, diagnostic category, laboratory data, RRT modality, urine output, Charlson and Sequential Organ Failure Assessment scores) at RRT initiation and followed patients to 30 days. Factors associated with RRT independence at 30 days among survivors (analysis 1) and RRT-independent survival at 30 days (analysis 2) were determined using logistic regression/stepwise covariate selection.

**Results:** 256 critically ill patients with AKI required RRT, of whom 118 (46%) died within 30 days. Among the 138 survivors, 40 (29%) were dependent on RRT and 98 (71%) were RRT-free at 30 days. Factors that were independently associated with RRT independence among survivors (analysis 1) and RRT-free survival (analysis 2) are shown below.

| Analysis 1 | | Analysis 2 | |
|---|---|---|---|
| | OR (95% CI) | | OR (95% CI) |
| CCI | 0.80 (0.66-0.97) | CCI | 0.81 (0.70-0.95) |
| Nonoliguria | 2.55 (1.06-6.06) | Nonoliguria | 1.71 (0.91-3.20) |
| baseline eGFR (per 10 unit increase) | 1.14 (0.99-1.30) | SOFA score (per 1 unit increase) | 0.85 (0.78-0.92) |

CCI=Charlson comorbidity index (per 1 unit increase), Nonoliguria=>400cc urine in 24h period after RRT initiation. SOFA=sequential organ failure assessment

**Discussion:** Recovery of kidney function in AKI is associated with a lower preexisting comorbidity, greater urine output and premorbid kidney function. This information may inform clinical decision-making and discussions with patients and their families.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO061

**Prognosis of Acute Kidney Injury in Chronic Kidney Disease** Seung Yeup Han, Mi Hyun Jang, Choong-Hwan Kwak, Eun-Ah Hwang, Sung Bae Park, Hyun Chul Kim. *Internal Medicine, Keimyung University Dongsan Medical Center, Daegu, Korea.*

**Purpose** : In studies of acute kidney injury(AKI) in hospitalized patients, the prevalence of preexisting chronic kidney disease(CKD) has been estimated to be about 30%. This study performed to ascertain the incidence, causes and outcomes of AKI in CKD.

**Methods** : We reviewed medical records of 211 consecutive cases of AKI admitted in our hospital between Jan. 2003 and Dec. 2006.

**Results**: Altogether, 211 patients of AKI were identified. The mean age of the patients was 60.8±17.3 years, and there was a male predominance (1.6:1). The mean follow up duration was 18.9±24.1 months. During an average hospitalization of 15.2±16.4 days, 32 patients(15.2%) died. There were 48 patients (22.7%) with AKI in CKD. The causes of AKI were 77 infections including sepsis patients constituted the largest group(36.5%). The second common cause of the AKI was hypovolemia (39 patients, 18.5%), and then nephrotoxic drugs or contrast induced AKI (38 patients, 18.0%), cardiac problem (18 patients, 8.5%), malignancy (8 patients, 3.8%), post-operative (8, patients 3.8%). When the groups with AKI only (n=163) and AKI with preexisting CKD (n=48) were compared, the rates of dialysis requiring patients in hospitalization was significantly higher in those with underlying CKD than AKI only (22.1% Vs 58.3%, p=0.000). There were no statistically significant difference in age, blood pressure, hospital duration, cause of AKI between two groups. In AKI only, serum creatinine level was recovered known before the episode of AKI in 42.3%, compared with 8.3% for patients with CKD, and 4.9% of patients with AKI only progressed to end-stage renal disease(ESRD); 37.5% of patients with preexisting CKD progressed to ESRD (p=0.000). In hospital mortality rates were no difference between two groups, but renal survival rates with AKI only were 98% in 3month, 97% in 1year, 96% in 3years; AKI with preexisting CKD were 72.7%, 50.8%, 46.2% (p=0.000). **Conclusion**: AKI with preexisting CKD was an important part of AKI and at significantly increased risk for ESRD. So enough attention and prevention should be paid to this entity and causes such as infection or drugs.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO062

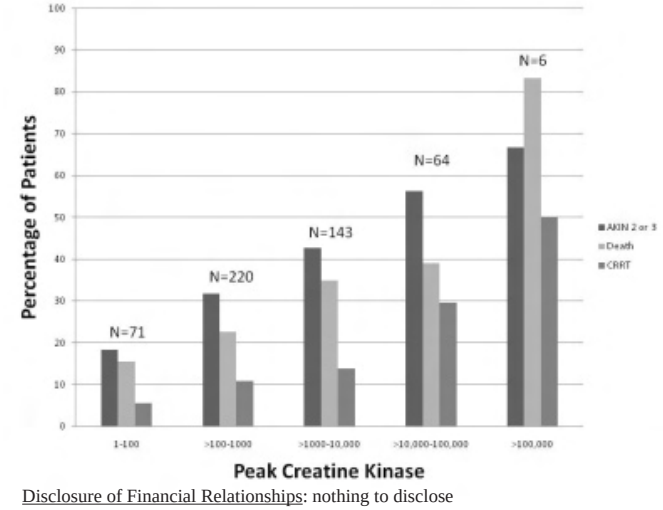
**Association of Rhabdomyolysis with Renal Outcomes and Mortality in Burn Patients** Ian J. Stewart,[1] Casey Cotant,[1] Molly A. Tilley,[1] Todd F. Huzar,[2] James K. Aden,[2] Jesse Sherratt,[1] Clinton K. Murray,[1] Kevin Chung.[2] *[1]San Antonio Military Medical Center; [2]United States Army Institute of Surgical Research.*

Purpose: The contribution of rhabdomyolysis to acute kidney injury (AKI) in the context of burn injury is poorly studied. We sought to determine the impact of rhabdomyolysis on AKI (defined by the AKIN classification), renal replacement therapy (RRT) and death.

Methods: Consecutive admissions to the burn intensive care unit at our institution from January 2003 to October 2008 were examined. Patients were included in the analysis if they had a serum creatine kinase (CK) measured anytime in the course of their hospitalization. Patients were excluded from the analysis if they had a diagnosis of myocardial infarction. Independent variables included gender, age, inhalation injury, electrical burn, percentage total body surface area burned (%TBSA), percentage of full thickness burns (%FT), injury severity score (ISS), log CK at admission and log peak CK. These variables were examined via multivariate logistic regression analysis against AKIN stage, RRT and death.

Results: Of 1,124 consecutive admissions, 306 met our eligibility criteria. Both log CK at admission (OR 1.5, 95% CI 1.1-2.2; p=0.02) and log peak CK (OR 2.0, 95% CI 1.5-2.6; p<0.0001) were found to be associated with AKIN stage 2 or greater. For RRT, log CK at admission (OR 1.9, 95% CI 1.2-3.0; p=0.007) and log peak CK (OR 1.7, 95% CI 1.2-2.3 p=0.003) achieved statistical significance. Finally, log peak CK (OR 1.8, 95% CI 1.3-2.6; p=0.003) was associated with an increased risk of mortality.

Conclusion: Each ten-fold increase in admission CK nearly doubles the probability of AKI and RRT while each ten-fold increase in peak CK nearly doubles the probability of AKI, RRT and death.



Disclosure of Financial Relationships: nothing to disclose

## TH-PO063

**Baseline Serum Markers Are Associated with Future Severe Rhabdomyolysis in Non-Whites** Lisa K. Prince, Kevin C. Abbott, Stephen W. Olson. *Internal Medicine, Nephrology Service, Walter Reed Army Medical Center, Washington, DC.*

Rhabdomyolysis can cause significant morbidity. Metabolic and electrolyte disorders may increase the risk of rhabdomyolysis. Known ethnic differences in baseline creatinine kinase (CK) levels suggest a potential difference in other serologic risk factors. No previous studies evaluate baseline serology prior to rhabdomyolysis. We hypothesize that non-white subjects with severe rhabdomyolysis have different baseline serology prior to diagnosis compared to matching controls.

**Methods**:Fourteen cases of severe rhabdomyolysis with acute kidney injury in non-whites were identified in the military database. The Department of Defense serum repository (DoDSR) sent serum samples for each study subject from *prior* to diagnosis and 3 age, sex, race, and age of serum matched controls to Quest Diagnostics© for measurement of CK, renal panel, lactate dehydrogenase (LDH), coenzyme Q10 (CoQ10) and aldolase levels.

**Results**:Study cases and matching healthy controls had a significantly different mean CK (341 vs. 158 U/L; p = 0.004), CoQ10 (0.52 vs. 0.66 U/L; p = 0.01), aldolase (9.35 vs. 8.11 U/L; p = 0.01), and phosphorus level (3.78 vs. 3.46 mg/Dl; p = 0.01). A greater number of study cases than matching controls met the combined thresholds of CoQ10<0.6 U/L & Aldolase>7.1 U/L (79% vs. 29%; p=0.002) and LDH>93 U/L & CoQ10<0.57 U/L (64% vs. 8%; p<0.0001). Combined thresholds of aldolase > 9.3 U/L & CoQ10 of < 0.6 U/L (43% vs. 0%; p=0.0001) was 100% specific for future severe rhabdomyolysis.

**Conclusions:**Lower baseline levels of coenzyme Q10, and higher levels of phosphorus, CK, and aldolase are associated with future severe rhabdomyolysis in non-whites. Combinations of serologic markers establish a more sensitive and specific evaluation for future severe rhabdomyolysis. These novel findings could provide a screening tool to identify those at risk for rhabdomyolysis in physically demanding or extreme environments. Targeted education of this population could provide early symptom recognition and therapeutic intervention to prevent further exacerbation of disease. The potential prophylactic benefit of CoQ10 replacement also warrants investigation.

Disclosure of Financial Relationships: nothing to disclose

**Time Is Tubule. Consequences of Referral Delay in Acute Kidney Injury** Prasad Rajendran, Thangavelu Chandrasekar, Christopher Federick Wong, Kottarathil Abraham Abraham. *Department of Nephrology, University Hospital Aintree, Liverpool, United Kingdom.*

Aim: The purpose of our study was to determine in patients with Acute Kidney Injury(AKI), whether a delay in referral to a nephrologist, by more than 1 day was associated with worsening of the AKIN stage or poor outcome and to evaluate prognostic factors for AKI mortality.

Method: Hospitalized patients referred to our renal service from July 2007 to January 2008 were studied. Serial S.Creatinine values through the hospital stay at 48 hour intervals were used to estimate the AKIN stage prior to referral, at referral and post referral. Statistical analysis was performed on demography and outcome**.** Multivariate analysis was performed on various prognostic factors.

Results: Among the 135 patients referred with AKI, 60% were males. Pre-existing CKD was present in 73%.

| Referral Delay | AKI Stage Pre-referral | AKI Stage at Referral | AKI Stage post referral | In Hospital Outcome | Outcome at 2 years |
|---|---|---|---|---|---|
| < 1 day n=27 (20 %) | Stage 1 n=8(30%); Stage 2 n=5(18%); Stage 3 n= 14(52%) | Stage 1 n=8(30%); Stage 2 n=5(18%); Stage 3 n= 14(52%) | Stage 1 n=7(26%); Stage 2 n=5 (18%); Stage 3 n= 15 (56%) | Death 8(30%); Dialysis Dependant 0; Full Recovery 13(48%); Partial Renal Recovery 5(19%); No Renal Recovery 1(4%) | Dialysis Dependant 0; Death 16(59%) |

**Presence of sepsis (OR 2.6, p<0.05) and being on diuretics at the onset of AKI (OR 2.8, p<0.05) were strong independent predictors of 1 year mortality.**

Conclusion: Early referral in less than 24 hours of AKI is associated with less patients progressing to higher AKI stages and having poor outcomes at discharge. Mortality outcomes at 2 years was similar but dialysis dependancy was minimised. Attention to the treatment of sepsis and avoidance of diuretics in those at risk can potentially minimize mortality in AKI.

**TH-PO065**

**Delayed Nephrology Consultation (NC) and the Outcome of Acute Kidney Injury (AKI) Patients in the Intensive Care Unit (ICU)** Veronica T. Costa e Silva,[1] Isac Castro,[1] Fernando Liano,[2] Luis Yu.[1] *[1]Nephrology Service, University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Nephrology Service, Hospital Ramon y Cajal, Madrid, Spain.*

Delayed NC is supposed to affect the prognosis of AKI ICU patients. The aims of this study were to analyze: 1) factors related with early NC in critically ill AKI patients; 2) the impact of delayed NC on outcome of these patients. A prospective study was performed in 6 ICUs of University of São Paulo School of Medicine (Pneumology, Internal Medicine, Trauma, Surgery, Infectious Diseases and Emergency). Data were collected by an independent single observer, non-member of the ICU or nephrology staff, by daily visits looking for new AKI cases. NC was solicited by the ICU physician. AKI was defined as an increase of 50% in the basal serum creatinine (SCr). AKI was classified as Surgical or Clinical. Renal function recovery was defined as return to baseline SCr level. A total of 366 patients were included for analysis. AKI incidence was 18%. General mortality was 68%. NC was carried out in 196 (53%) pts and NC occurred 2.8 +/- 3.5 (mean +/- SD) days after diagnosis day (DD) as requested by the ICU physician. NC were done in the first 2 days after DD (66%, early- NC group). The remaining were considered as delayed-NC group which presented higher mortality (OR:4.04/CI:1.60-10.17) and reduced renal function recovery (OR:0.22/0.08-0.60). A PS for early-NC was created. The 6 variables retained on the model were: AKI of clinical origin (OR:2.62/CI:1.14-5.99), D (OR:0.99/CI:0.99-1.00), SCr (OR:2.04/CI:1.38-3.02), pH (OR:0.008/CI:0.001-0.20), Pneumology (OR:3.58/CI:1.06-12.06) and Internal Medicine (OR:5.95/CI:1.80-19.59) ICUs. After correction by the PS, Delayed NC was still associated with higher mortality (OR: 4.04/CI: 1.60 – 10.17) and reduced renal function recovery (OR: 3.61/CI: 1.14 – 11.40). In conclusion, factors influencing early NC were SCr, D, pH, ICU pt's origin and clinical AKI. Delayed NC was associated with higher mortality and worse renal function even after correction by confounders variables.

**Acute Kidney Injury (AKI) Management in the Intensive Care Unit (ICU): A Survey of Current Practice in the United Kingdom** Sarah L. Jones, Mark A. J. Devonald. *Nottingham Renal Unit, Nottingham University Hospitals NHS Trust, Nottingham.*

**Study Purpose**

To ascertain current UK ICU practice for investigating and managing AKI.

**Methods**

An online survey was distributed to all UK general adult ICUs between December 2009 and May 2010. We asked about details of renal replacement therapy (RRT) and investigation of AKI.

**Results**

188/233 ICUs (81%) started the survey and 167 (72%) completed it.

In over 40% of units a nephrologist is never or rarely consulted about AKI. 88% of responding units refer to nephrology if a primary renal disease is suspected. Only 19% of units routinely use the AKIN or RIFLE criteria. 57% of respondents always request a renal tract ultrasound scan but only 46% have 24 hour access to renal ultrasound scanning.

CVVH is the most frequently used form of RRT (56%) followed by CVVHDF (37%). Intermittent RRT is the main method in only 5% units. CRRT is managed exclusively by intensivists in 94% of units, whereas IHD is managed predominantly by nephrologists (57%).

The most frequently used criteria for initiating RRT are hyperkalaemia, fluid overload and pH (acidaemia). 66% of respondents have a lower threshold for commencing RRT in patients with severe sepsis. A satisfactory or improving urine output is the most commonly used indication for discontinuing RRT followed by normalisation of pH.

73% of units have a standard protocol for RRT with 35mls/Kg/hr as the most frequently prescribed dose (59%). In only 51% of units is delivered dose of RRT assessed.

**Conclusions**

There is considerable variation in the management of AKI in UK Intensive Care Units. This is presumably attributable to a lack of consensus on optimal practice.

**Can Trimetazidine Prevent Contrast Induced Nephropathy in Patients with Renal Impairment?** Muhammad Rafiqul Alam,[1] Abdul Wadud Chowdhury,[2] Kazi Shahnoor Alam,[3] Asia Khanam.[1] *[1]BSMMU; [2]DMCH; [3]NIKDU, Dhaka, Bangladesh.*

***Background:***

Contrast Induced Nephropathy (CIN) is an increasing cause of hospital acquired kidney injury and leads to a significant increase in mortality. With the increasing use of radiographic contrast media in diagnostic and interventional procedures, CIN has become an important cause of iatrogenic acute renal impairment. CIN is defined as a 25% increase in SCr from the baseline value or an absolute increase of at least 0.5 mg/dl (44.2 mmol/L), with 48 hours after the administration of radiographic contrast media that is not attributable to other causes.

**Objective:**

To estimate the prevalence of CIN in patients undergoing coronary procedure with pre-existing renal impairment.

To evaluate the efficacy of TMZ as an adjunct to saline infusion for prevention of CIN in patients with renal impairment.

**Method:**

This was a prospective randomized controlled trial comparing hydration therapy to additional TMZ for the prevention of CIN. A total of 90 patients with a SCr between 1.4 to 2.5 mg/dl undergoing elective coronary procedure in a specialized cardiac hospital were studied. Patients were randomly divided into 2 groups: TMZ (n=44) and control (n=46). Echocardiography was done in all patients. Hydration with isotonic normal solution (0.9%) at a rate of 1ml/kg/hr starting 12 hr before the coronary procedure and up to 12 hr there after was done in patients of both groups. TMZ was administered as a dose of 20 mg thrice day orally for 72 hr starting 48 hr before the procedure. Iopamiro-370 was used during all of the coronary procedure. Volumes of contrast agent were different depending upon the coronary procedure. SCr and urea concentration were measured 24 hr before, 48 hr and 7 days after the coronary procedure.

**Result:**

Out of 90 patients with pre-existing renal impairment 44 were in TMZ group and 46 in control group. There was no statistically significant difference in age, sex, blood pressure, baseline SCr, calculated creatinine clearance rate and presence of co-morbid condition between the two groups. Diabetes mellitus was found as predominant co-morbid condition.

***Conclusion:***

Trimetazidine cannot prevent CIN significantly in renal impaired patients.

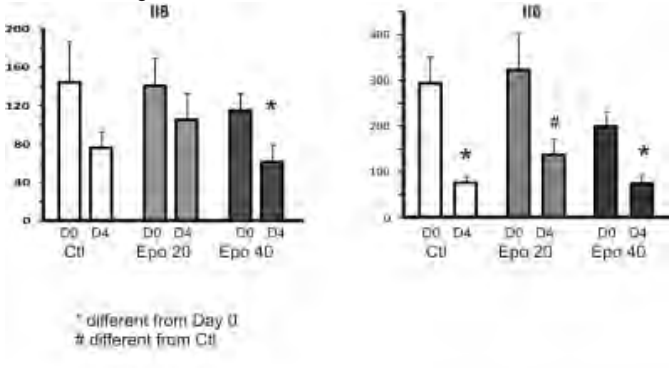
**Epoetin Does Not Demonstrate Anti-Inflammatory Properties after Cardiac Surgery** Sophie M. De Seigneux, Belen Ponte, Jerome Pugin, Patrick Saudan, Pierre-Yves F. Martin. *Department of Nephrology, University Hospital of Geneva, Geneva, Switzerland.*

Introduction : The inflammatory state is deleterious for the mortality in the acute setting. Erythropoietin has been thought to have nephroprotective as well as antiinflammatory properties. We have previously demonstrated that a-epoetin (EPO) does not modify renal function after cardiac surgery (ASN 2009). In the same patients, we measured the cytokines blood levels and compared the levels between the groups.

Subjects and Methods: From June 08 to June 09, 80 patients having cardiac surgery were randomised to receive either 40 000 IU a-Epoetin (n=20) or 20000 IU a-Epoetin (n=20) or a normal saline injection after cardio-pulmonary bypass (CBP). To assess acute inflammatory response serum cytokines ( IL6, IL8, IL1beta, IL10, TNFalpha, IL12p70) were measured using a luminex technique at day 0 before Epoetin infusion and at day 4.

Results: Patient groups did not differ in terms of age, gender, comorbidities and baseline renal function. IL6, IL8, IL1beta, IL10, TNFalpha, IL12p70 were measured at day 0 and similar between groups. Only IL 6 and IL8 decreased at day 4 and this decrease was observed in all groups. However in the group treated with EPO 20000 units, the decrease of IL6 was significantly less important than in the control ( 77+/-12 vs 135+/-34pmol/ml, p<0.05). IL8 also appeared to decrease less with EPO treatment but this trend did not reach statistical significance.



Conclusions: A single administration of either 20000 or 40000 IU a-Epoetin after cardiac surgery does not alleviate the inflammation observed in the post operative state and rather appeared to impede the spontaneous decrease in pro inflammatory cytokine post-operatively, mostly IL6. These results, associated with the negative results on renal function do not support the use of EPO in acutely ill patients for nephroprotection.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO069**

**AKI: Are We Biased Against Peritoneal Dialysis?** Sergio Gaiao,[1,2] Massimo De Cal,[1] Fredric O. Finkelstein,[3] Claudio Ronco,[1] Dinna N. Cruz.[1] *[1]S Bortolo Hosp, Vicenza, Italy; [2]Sao Joao Hosp, Porto, Portugal; [3]St Raphael Hosp, New Haven, CT.*

**Introduction:**

Peritoneal Dialysis (PD) is employed for Acute Kidney Injury (AKI) management in developing countries. However, in developed countries, this modality is rarely used in this context.

This is a relevant issue in the AKI field, in part related to the cost and infrastructure needs for hemodialysis. In disasters, PD is also the simplest method for RRT.

Our aim was to evaluate actual practice as well as practitioner opinion regarding PD use in AKI.

**Methods**

A questionnaire was distributed to selected attendees of 3 PD meetings held in 2009 (International Course on PD in Vicenza, ISPD in Hong Kong and North American Chapter of ISPD in Vancouver).

**Results**

We analyzed 484 completed questionnaires. Responders were from Europe (74%), followed by Asia Pacific (14%) and North America (11%). Most work in nephrology departments (88%).

Thirty-six percent think that PD is a suitable therapeutic option in most cases of AKI in ICU, while 51% think that PD is suitable for AKI in the wards (Fig 1a). In contrast, only 16% actually use PD for AKI management in the ICU, while 22% use it in the wards (Fig 1b). The most common modality used is Acute Intermittent PD, 39% in the ICU and 36% in the wards, followed by Tidal PD (24% in ICU and 30% in wards).

Overall 66% responders were not certain of the most appropriate PD dose for AKI in the ICU, while 61% were uncertain in the wards. However, among actual users of PD, a smaller number (34-50%) were uncertain about appropriate dose.

**Conclusions**

Although 36-51% of respondents feel that PD is suitable for AKI, only 16-22% actually use it. This is similar to the disparity between opinion and practice regarding PD in chronic kidney disease. There is much uncertainty about the appropriate PD dose for AKI. Further studies on barriers to implementation of acute PD are needed.

**Impact of Acute Renal Failure on Nosocomial Infections Prevalence in Critically-Ill Patients** Jean-Sebastien Rachoin, Daniel Fabius, Christa Schorr, Jean-Pierre El-Khoury, David R. Gerber, Lawrence S. Weisberg. *Medicine, UMDNJ-RWJ Medical School, Camden, NJ.*

Critically-ill patients with dialysis-dependent ARF have a high mortality rate which may be due, in part, to acute infection. We hypothesized that ARF itself, and not just renal failure, increases the risk for nosocomial infection. We studied nosocomial infection and mortality in critically-ill patients on dialysis for either ARF or end-stage renal disease (ESRD). We performed a retrospective observational study of all patients admitted to a medical/surgical ICU from 2003 through 2009. We defined ARF as that requiring RRT (A-RRT). We recorded the following nosocomial infections: pneumonia, bacteremia and UTI. Patients with onset of nosocomial infection before RRT were classified as not having ARF. 9441 patients were initially considered for inclusion, of whom 7202 had complete data available. 256 patients (3.6%) had A-RRT, of whom 27 had nosocomial infection before RRT, leaving 229 evaluable patients with A-RRT. 403 patients (5.2%) were receiving RRT for ESRD (E-RRT). 446 of 7202 patients (6.2%) had one or more nosocomial infection. 34 patients with A-RRT (15%) had at least one nosocomial infection, compared with 41 patients (10%) with E-RRT and 368 of 6570 patients (5.6%) receiving no RRT. After adjusting for comorbid conditions and severity of illness, patients with A-RRT were significantly more likely to develop nosocomial infection than patients with E-RRT (OR 2 [1.3-3.0],p=0.001). In patients with A- RRT, nosocomial infection was associated with a trend towards increased mortality (OR 2 [0.9-4.5], p=0.087). Thus, critically-ill patients with dialysis-dependent ARF are at higher risk of nosocomial infections than patients with dialysis-dependent chronic kidney disease, even after adjustment for severity of illness. The effect of modality of RRT remains to be determined.

**TH-PO071**

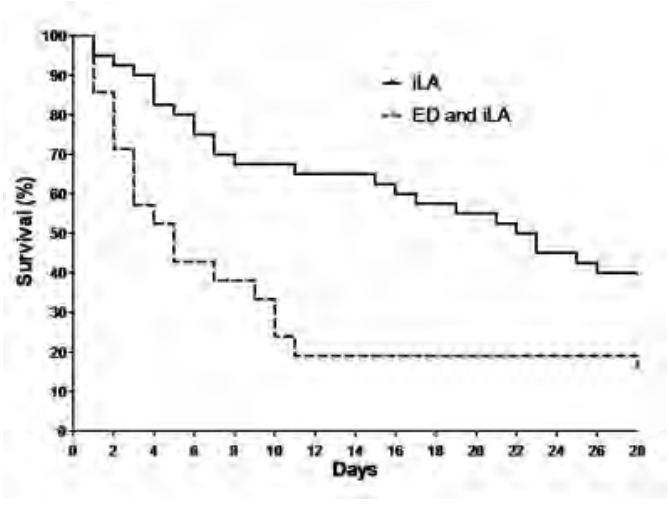
**Effect of Acute Kidney Injury Requiring Extended Dialysis on Survival of Patients Undergoing Interventional Lung Assist Membrane Ventilator Treatment** Jan T. Kielstein,[1] Sören Tolk,[1] Olaf Wiesner,[2] Hermann G. Haller,[1] Carsten Hafer,[1] Marius M. Hoeper.[2] *[1]Department of Nephrology and Hypertension, Medical School Hannover, Hannover, Germany; [2]Department of Pulmonary Medicine, Medical School Hannover, Hannover, Germany.*

**Background:** Extracorporeal lung assist devices are increasingly used in the intensive care unit setting to improve extracorporeal gas exchange mainly in patients with acute respiratory distress syndrome (ARDS). In the setting of multi-organ dysfunction syndrome ARDS is frequently accompanied by acute kidney injury. It is unknown how the combination of these two conditions affects survival of critically ill patients.

**Patients and Methods:** At a tertiary care centre we retrospectively evaluated all patients undergoing interventional lung assist (iLA membrane ventilator) treatment between January 1st 2005 and December 31st 2009. 61 patients (31F/30M), median age 40 (28 to 52) years were followed up to one year.

**Results:** Of the 61 patients undergoing iLA membrane ventilator treatment 21 patients had acute kidney injury network (AKIN) stage 3 treated by extended dialysis. The mean 28 day survival of all patients was 33 %. While patients without extended dialysis showed a mean 28 day survival of 40%, the survival of patients with extended dialysis was only 19%. Patients on extended dialysis were not different in respect to age, weight, Horowitz index and underlying disease.

**Discussion:** The concomitant necessity for extended dialysis (ED) in patients undergoing iLA membrane ventilator treatment is associated with increased mortality in ICU patients.



Patients in whom iLA was placed as a bridge to lung transplantation and that were successfully transplanted showed the best outcome. Future studies have to clarify whether it is possible to identify patients that benefit from the combination of these two extracorporeal treatment methods.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO072**

**Prognosis of Patients on Extracorporeal Membrane Oxygenation: The Impact of Acute Kidney Injury on Mortality** Yung-Chang Chen,[1] Feng-Chun Tsai,[2] Ya-Chung Tian,[1] Ming-Yang Chang,[1] Chang-Chyi Jenq,[1] Chih-Wei Yang.[1] *[1]Kidney Research Center, Department of Nephrology, Chang Gung Memorial Hospital, Taipei, Taiwan; [2]Division of Cardiovascular Surgery, Chang Gung Memorial Hospital, Taipei, Taiwan.*

**Purpose:** Extracorporeal membrane oxygenation (ECMO) has been utilized for patients in critical condition such as those with life-threatening respiratory failure or post-cardiotomy cardiogenic shock. This study analyzed the outcomes of patients treated with ECMO and identified the relationship between prognosis and the Acute Kidney Injury Network (AKIN) obtained at post-ECMO support 48 h (AKIN 48-hour). Additionally, AKIN 48-hour is compared with other acute kidney injury scoring systems.

**Methods:** This study reviewed the medical records of 82 critically ill patients on ECMO support at a specialized intensive care unit (CVSICU) at a tertiary care university hospital between March 2002 and February 2006. Demographic, clinical and laboratory variables were retrospectively collected as survival predicators.

**Results:** Overall mortality rate was 59.8%. The most common condition requiring ECMO support was cardiogenic shock. Goodness-of-fit was good for AKIN 48-hour criteria. The Risk of renal failure, Injury to the kidney, Failure of kidney function, Loss of kidney function, and End-stage renal failure (RIFLE) 48-hour and AKIN 48-hour scoring systems had excellent areas under the receiver operating characteristic curve (0.845+/-0.048 and 0.881+/-0.041, respectively). Furthermore, AKIN 48-hour correlated strongly with RIFLE 48-hour scores for individual patients ($r^2$=0.608, $p$<0.001). Finally, cumulative survival rates at 6-month follow-up after hospital discharge differed significantly ($p$<0.05) for AKIN 48-hour stage 0 *vs.* AKIN 48-hour stage 1,2 and 3, and AKIN 48-hour stage 1 and 2 *vs.* AKIN 48-hour stage 3.

**Conclusions:** During ECMO support, the AKIN 48-hour scoring system proved to be a reproducible evaluation tool with excellent prognostic abilities for these patients.

**TH-PO073**

**The Acute Flank Pain Syndrome: A Common Presentation of Acute Renal Failure in Young Adults in Iceland** Margret Arnadottir,[1] Helga Margret Skuladottir,[1] Sverrir Hardarson,[2] Margret B. Andresdottir.[1] *[1]Department of Nephrology, Landspitali University Hospital, Reykjavik, Iceland; [2]Department of Pathology, Landspitali University Hospital, Reykjavik, Iceland.*

**Purpose**: The acute flank pain syndrome (AFPS) was a common side effect of the NSAID suprofen which was withdrawn in the eighties. Since then, only a few reports of AFPS have been published, in association with intake of other NSAIDs and/or binge drinking. The goal of the present study was to calculate the incidence and describe the cases of AFPS in Iceland during a 10 year period.

**Methods**: AFPS was defined as severe flank and/or abdominal pain in combination with acute renal failure, both features unexplained except for the possible consumption of ethanol and/or an NSAID. The hospital records of the patients that fulfilled the following criteria were reviewed with regard to AFPS: age 18-41 years, acute renal failure, and admission during the period January 1998 – December 2007. Information about the sales figures of ibuprofen and diclofenac were also collected.

**Results**: One-hundred and six patients received the diagnosis acute renal failure, of which 21 (20%) had AFPS. The incidence of AFPS increased during the study period but the average countrywide incidence was 20.2/million/year. There was a history of recent consumption of ethanol in 15 patients, an NSAID in 15 patients, either in 20 patients and both in 9 patients. Eighteen of 21 patients were males. The maximal serum creatinine concentration was 251 (137-529) micromol/L. In all cases, spontaneous regression of pain and renal failure was observed. In 2007, 29.8 DDD of ibuprofen and 20.7 DDD of diclofenac were sold. The increase in the incidence of AFPS was parallel to that of the over-the-counter sales of ibuprofen.

**Conclusions**: The study revealed a high incidence of AFPS and the largest case series of AFPS that has been reported since the suprofen experience. As in previous reports, almost all the patients had a history of recent consumption of ethanol and/or an NSAID. The incidence of AFPS in Iceland may be explained by heavy consumption of NSAIDS in combination with binge drinking pattern. AFPS may be underreported in other countries.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO074**

**Retrospective Evaluation of the Renal Effect of Phosphate Soda Enema in Hospitalized Patients** Bruce S. Spinowitz, Prince Mohan, Gabriel EL-Kass, Wing Fun Leo-To, Bessie Vardianos, Chaim Charytan. *Nephrology & Pharmacy, NY Hospital Queens, Flushing, NY.*

Acute phosphate nephropathy has been reported in patients who have received oral sodium phosphate products. Patients who have received phosphate soda via enema have been reported to experience severe hyperphosphatemia, hypocalcaemia, seizures and coma. Acute kidney injury(AKI) has not been reported in adults. Our objective was to explore a relationship between sodium phosphate enema administration in the hospital setting and subsequent rise in serum creatinine, which might suggest the possibility of AKI consequent to this laxative use.

Methods: Data was collected from our hospital pharmacy patient profiling system from September 2008 through September 2009. 1347 patients had an order for phosphate enema. 510 patients were excluded (pediatric patients, ER patients, patients with fewer than three days of post-dose data). Of the remaining 837 patients, 364 received a phosphate enema. 473 who did not receive an enema served as the control group. AKI was defined as an increase of 25% from baseline serum creatinine or an absolute serum creatinine increase of 0.5 mg/dl. Serial creatinine and eGFR were analyzed post enema administration in all patients. Concomitant medications and selected co-morbidities were analyzed.

Results: 32 of the 364 patients (8.8%), who received sodium phosphate enema, were found to have AKI. 17 out of 473 patients (3.6 %) who never received enema, had AKI(OR=2.58,p<0.002). 26 of 32 patients with AKI in enema group returned to baseline renal function in an average of 6.3 days. In the control group 12 of 17 patients returned to baseline renal function in an average of 2 days. The two groups were comparable with respect to age and baseline eGFR.

Conclusions: The temporally related increase in serum creatinine associated with phosphate soda enema administration suggests, but does not prove, a causal relationship. This data, plus the association of oral phosphate use and acute renal failure, warrant caution when prescribing phosphate enemas as a purgative. To further evaluate this relationship, studies are needed with serum phosphate levels measured pre/post enema administration.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO075**

**Incidence and Predictors of Acute Kidney Injury in Hospitalized Clostridium Difficile Infected Patients (Pts)** Venkata A. Suda, Lalathaksha Murthy Kumbar, Paul A. Fein, Ashwini M. Shadakshari, Sara Asadi, Parampreet S. Ghuman, Jyotiprakas Chattopadhyay, Morrell M. Avram. *Avram Division of Nephrology, Long Island College Hospital, Brooklyn, NY.*

Clostridium difficile infection (CDI) is recently becoming more frequent, severe and difficult to treat. Medical literature about the relationship between CDI and development of acute kidney injury (AKI) is minimal. The objective of this study was to examine the incidence and predictors of AKI (serum creatinine >0.3 mg/dL above baseline) in hospitalized pts with CDI. One hundred forty two pts who were diagnosed with CDI between November 2008 and September 2009 were enrolled in this study. Demographics, clinical, and biochemical data were recorded. Sixty one percent of the pts (n=87) developed AKI. Pts with AKI were older than those without AKI (67 vs. 59 years, p=0.02). Pts with hypertension (p=0.004), diabetes (p=0.002), cardiovascular disease (p=0.008), chronic kidney disease (p=0.03), and those who received pressors (p<0.0001) were significantly higher in AKI group compared to those without AKI. At the time of admission, the patients who developed AKI had higher serum creatinine (p<0.0001), urine specific gravity (p=0.013) proteinuria (p=0.002), hematuria (p=0.07), low serum albumin (p=0.016) and serum bicarbonate (p=0.002). By univariate logistic regression analysis, the above factors were significantly associated with AKI. The administration of intravenous contrast was lower in AKI group compared to non AKI (16 vs.31 p=0.037). Using multivariate logistic regression analysis, controlling for other confounding variables, admission creatinine (odds ratio: 26.2, p=0.001), CVD (odds ratio: 5.63, p=0.059), diabetes (odds ratio: 9.66, p=0.009) and proteinuria (odds ratio: 6.36, p=0.03) were significant predictors of AKI in these pts. Twenty seven percent (n=24) of pts with AKI expired during the study period compared to 2% in pts without AKI. In conclusion, AKI is highly prevalent in pts with CDI and carries a high mortality. Further studies are needed to assess these risk factors and interventions aimed at decreasing the high mortality.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO076**

**Risk Factors of Colistin Induced Nephrotoxicity** Sung Chang Bae, Sung Jin Moon, Sang Hun Lee, Hyeong Cheon Park, Sung-Kyu Ha. *Internal Medicine, Gangnam Severance Hospital, Seoul, Korea.*

In recent years, colistin was increasingly reused into clinical practice despite its nephrotoxicity, depending on the multidrug-resistant (MDR) gram-negative bacteria is becoming more prevalent. But only limited data are available to prevent its nephrotoxicity. In this study, the incidence, clinical characteristics and risk factors of colistin-induced nephrotoxicity was investigated. The data was obtained retrospectively from 57 cases receiving colistin sodium methanesulfonate for treatment of MDR gram negative bacterial infections between March 2009 and May 2010 at Gangnam Severance Hospital, 900-bed tertiary care facility located in Seoul, South Korea. The study excluded the patients who used the colistin for less than two days or who was creatinine concentration more than 4.0 mg/dL. Thirty five (61.4%) of the 57 cases developed nephrotoxicity and 9 (15.8%) of whom underwent renal replacement therapy. By Acute Kidney Injury Network, AKI stage 1 (R), stage 2 (L) and stage 3 (F) were 13 (22.8%), 14 (24.6%) and 8 (14%), respectively. In the univariate analysis, old age, hypoalbuminemia, septic shock, malignancy and concominanat use of prepenem or vancomycin were more frequent in the patients with AKI. However, multivariate logistic regression analysis showed that the malignanacy (OR=67.8; 95% CI 1.34 – 3426.13; P = 0.035) and concominant use of vancomycin (OR = 20.7; 95% CI 1.09–391.95; P = 0.043) were independently associated with a colisin induced nephrotoxicity. In conclusion, maliganancy and concomitant use of vancomycin were risk factors of colistin induced nephrotoxicity. Colistin may have to be used with caution in these patients.

**TH-PO077**

**Outcomes of Critically Ill Patients with Acetaminophen Induced Acute Liver and Kidney Injury Requiring Renal Replacement Therapy** Andrew J. P. Lewington,[1] Simon Lines,[1] Ashley Wood,[1] Mark Bellamy.[2] *[1]Renal Department, Leeds Teaching Hospitals, Leeds, West Yorkshire, United Kingdom; [2]Department of Intensive Care Medicine, Leeds Teaching Hospitals, Leeds, West Yorkshire, United Kingdom.*

Introduction:

We report here on the outcomes of patients with acetaminophen (paracetamol) induced liver and kidney injury necessitating renal repacement therapy (RRT) admitted to the intensive care unit (ICU) of a tertiary referral liver unit. We analysed which admission variables predicted mortality.

Methods:

We performed a retrospective review of all patients admitted to the ICU over a 6 year period. A subgroup of these with acetaminophen induced liver injury and requiring RRT were identified for further analysis.

Results

Of the 5582 admissions during this period, 73 patients met study criteria. Mean age was 37 years (s.d. ± 13.9 yrs) with a 60% female preponderance; overall hospital mortality was 58%. The ten patients who underwent a liver transplant had a lower mean age of 28 years ($p<0.05$); 8 of the 10 survived. Using logistic regression modeling, low pH and higher MELD score were predictive of mortality ($p<0.05$); age, gender, albumin, serum transaminase and sodium, hemoglobin, platelet count and APACHE2 score were not. Admission pH was the best discriminator of survival; all patients with an admission of pH of ≤ 7 died (n=8) and those with a pH of > 7.3 (n=14) fared best with a mortality of 35%.

Conclusion

These data add to the small body of evidence on acetaminophen-induced acute kidney injury in critically ill patients. A low admission pH, a likely surrogate for liver dysfunction and global disease severity, is the most useful parameter measured on admission for predicting outcome. Traditional ICU prognostic scores, such as APACHE2, seem to perform less well in this subset of patients. These prognostic criteria are similar to the King's College (UK) prognostic criteria for acute acetaminophen poisoning.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO078**

**Acute Kidney Injury (AKI) in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD) and Pneumonia** Qi Qian,[1] Carlos R. Franco-Palacios,[1] Robert Hartman,[2] Ladan Zand,[3] Xiangling Wang,[1] Guangxi Li,[2] Rodrigo Cartin-Ceba.[2] *[1]Division of Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [2]Department of Radiology, Mayo Clinic, Rochester, MN; [3]Division of Internal Medicine, Mayo Clinic, Rochester, MN; [4]Pulmonary & Critical Care Medicine, Mayo Clinic, Rochester, MN.*

**Background:** ADPKD is a common inherited disease, leading to kidney failure in >50% affected individuals. AKI occurs in patients with pneumonia, leading to an increase in one-year mortality. We compared the occurrence and severity of AKI in pneumonia patients with and without ADPKD.

**Methods:** Mayo Clinic Rochester in-patient database from 1998 to 2008 were screened. A total of 45 pneumonia episodes (by chest x-ray and clinical presentations) in ADPKD patients and 112 consecutive non-ADPKD patients with pneumonia and with a comparable eGFR were identified. Patients with end stage renal failure, with organ transplantation or on chronic immunosuppressants were excluded. The remaining pneumonia episodes, 26 in ADPKD and 82 in non-ADPKD, were analyzed.

**Results:** ADPKD patients were younger than non-ADPKD patients, mean age of 61.9 and 84.3 years, respectively, $P < 0.01$. Seventeen of the 26 (65.5%) pneumonia episodes in ADPKD and 26 of the 82 (31.7%) episodes in non-ADPKD were associated with the development of AKI ($P < 0.01$). In both groups, those who developed AKI had a lower baseline eGFR (mil/min/BSA) than those who did not (49.2 vs. 60 in ADPKD and 41.1 vs. 54.4 in non-ADPKD). One year mortality rate in ADPKD with or without AKI was 41.1% (7 of 17) vs. 11.0% (1 of 9), odds ratio 5.6 (95% confidence interval: 0.6-55.4). The one year mortality rates in non-ADPKD with and without AKI were 42.3% vs. 30.4%, odds ratio 1.7 (95% confidence interval: 0.6-4.4). In both ADPKD and non-ADPKD groups, pneumonia patients with AKI had more frequent ICU admission and mechanical ventilation and a longer hospital stay than those without AKI.

**Conclusion:** ADPKD patients with pneumonia show a higher occurrence of AKI than those without ADPKD (with comparable eGFR), suggesting that ADPKD patients are more susceptible to kidney injury in the context of infection.

Disclosure of Financial Relationships: nothing to disclose

**Clinical Manifestations of Renal Dysfunction Are Associated with Low Individual Awareness of Chronic Kidney Disease** Delphine S. Tuot,[1] Laura C. Plantinga,[1] Chi-Yuan Hsu,[1] Regina Jordan,[2] Nilka Rios Burrows,[2] Elizabeth Hedgeman,[3] Jerry Yee,[4] Neil R. Powe.[1] *[1]University of California, San Francisco, San Francisco, CA; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]University of Michigan, Ann Arbor, MI; [4]Henry Ford Hospital, Detroit, MI.*

Background: Awareness of chronic kidney disease (CKD) among primary care providers and persons with CKD is low. We examined whether well-known complications of kidney disease that should trigger CKD recognition among providers are associated with high individual CKD awareness.

Methods: CKD awareness was assessed in 2323 adults with CKD stages 1-4 using 1999-2006 National Health and Nutrition Examination Survey data. CKD awareness was a "yes" answer to "Have you ever been told you have weak or failing kidneys?" A clinical manifestations score (CMIS) ranging from 0-7 and consisting of equally weighted indicators of abnormal values of serum potassium, serum bicarbonate, serum phosphate, blood urea nitrogen, anemia, proteinuria and uncontrolled hypertension, was created. Multivariable logistic regression was used to estimate odds and percentages of awareness by CMIS, adjusted for demographic characteristics and diabetes, weighted to the US population.

Results: Among individuals with CKD, those with proteinuria or hyperkalemia had a 3-fold greater odds of CKD awareness ($p<.01$ & $p=.03$) than those without. Patients with a CMIS of 2, 3-4 and >5, had higher odds of being aware of their CKD status than those without measurable complications of renal dysfunction, independent of eGFR (adjusted odds ratio 2.1 $p=.01$; 3.9 $p<.001$; 5.0 $p=.02$). There was a linear trend of greater CKD awareness with an increasing CMIS ($p =.003$). Nonetheless, 86.5% of individuals with a CMIS score >5 were unaware of their disease.

Conclusions: CKD awareness is low, even among individuals who manifest many complications of renal dysfunction. A better understanding of mechanisms of awareness, such as physician recognition of clinical manifestations and provider-patient communication, is required to intervene and improve risk factor modification, facilitate earlier detection of CKD to slow its progression, and minimize associated complications.

**TH-PO080**

**An Easily Administered Self-Report Depression Scale Can Predict Poor Outcomes in Patients with CKD** Susan Hedayati,[1,2] Masoud Afshar,[2] Abu T. M. Minhajuddin,[2] Robert D. Toto,[2] Madhukar Trivedi,[2] Augustus John Rush.[3] *[1]Nephrology, Dallas VA Medical Center; [2]Nephrology, Clinical Sciences, and Psychiatry, University of Texas Southwestern Medical Center at Dallas; [3]Duke-NUS, Singapore.*

We previously demonstrated that a major depressive episode (MDE) as assessed by a structured psychiatric interview is associated with excessive morbidity and mortality in patients with CKD (*JAMA* 2010; 303: 1946). To investigate whether an easily administered patient self-report scale of depression is associated with poor outcomes, we administered the 16-item Quick Inventory of Depression Symptomatology Self-Report Scale (QIDS-SR) to 260 consecutive VA outpatients with CKD. Scores on the QIDS-SR range from 0 to 27, with higher scores indicating a greater severity of depressive symptoms. A cutoff of ≥10 was validated to indicate a MDE in CKD patients. Patients were followed prospectively for 12 months for a composite outcome of progression to ESRD, hospitalization or death. Cox proportional hazards models were used to explore the associations of both the QIDS-SR score and the QIDS-SR cutoff of ≥10 with the composite outcome. Models were adjusted for age, race, eGFR, serum albumin, hemoglobin, calcium-phosphorus product, medical comorbidities and drug and alcohol abuse.

Mean age was 64.5 ±12 years. Thirty-seven percent were African American and 55% had diabetes mellitus. Six percent had stage 2, 38% stage 3, 41% stage 4 and 15% predialysis stage 5 CKD. Mean QIDS-SR score was 7.1 ±4.9. There were 126 composite events. The risk for ESRD, hospitalization or death was 6% higher for each one point increase in QIDS-SR score, HR 1.06 (95% CI 1.02-1.09). This association remained statistically significant in adjusted models, HR 1.05 (1.01-1.09). QIDS-SR score ≥10 was also significantly associated with the composite outcome, HR 1.52 (1.05-2.21) in unadjusted and 1.55 (1.05-2.28) in adjusted models.

The score on a short and easily administered depression questionnaire was independently associated with an increased risk of CKD progression, death or hospitalization. The QIDS-SR may be used to screen patients with CKD for depression in the outpatient setting and predict clinical outcomes.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO081**

**Ethnic Differences in ESRD and Death in the Diabetes Mellitus Treatment for Renal Insufficiency Consortium (DIAMETRIC) Study** Tahira P. Alves,[1] David K. Packham,[2] Jamie P. Dwyer,[3] Dick De Zeeuw,[4] Julia Lewis,[3] Robert C. Atkins,[5] Hiddo Jan Lambers Heerspink.[4] *[1]Medicine, Nephrology Division, University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]Melbourne Renal Research Group and Royal Melbourne Hospital, Melbourne, Australia; [3]Medicine, Nephrology Division, Vanderbilt University Medical Center, Nashville, TN; [4]Clinical Pharmacology, University of Groningen, Groningen, Netherlands; [5]Medicine, Nephrology Division, Vanderbilt University Medical Center, Nashville, TN; [6]Monash University, Melbourne, Australia; [7]Clinical Pharmacology, University of Groningen, Groningen, Netherlands.*

In recent studies, black patients with non-diabetic chronic kidney disease appear to be more likely to reach ESRD than die from any cause. The purpose of this study was to compare the risks for ESRD, CVD death and all cause mortality among different ethnic groups with established type 2 diabetic nephropathy and CKD in the DIAMETRIC database. Data on 3228 adult patients with type 2 diabetic nephropathy from the IDNT and RENAAL trials were combined to establish the DIAbetes MEllitus Treatment for Renal Insufficiency Consortium (DIAMETRIC) database established in 2009. Mean follow-up for the trials was 2.8 years. There were 628 ESRD events and 576 deaths ( 304 CV related and 272 non-CV related) during the follow-up period. The rates for ESRD, CV death and all cause mortality were significantly higher ($p<0.05$) for Hispanics (11.7/100 pt yr, 2.2/100 pt yr, and 4.8/100 pt yr, respectively) followed by Asians (8.8/100 pt yr, 1.7/100 pt yr, and 3.3/100 pt yr, respectively) and blacks (7.6/100 pt yr, 1.4/100 pt yr, and 2.2/100 pt yr, respectively), when compared to white patients (5.8/100 pt yr, 1.3/100 pt yr, and 2.1/100 pt yr, respectively). The incidence rate ratio (IRR) of ESRD to mortality was significantly higher ($p<0.05$) for blacks (IRR 3.5) and whites (IRR 2.8) closely followed by Asians (IRR 2.7) and Hispanics (IRR 2.4). In conclusion, all ethnic groups with type 2 diabetic nephropathy were significantly more likely to reach ESRD than die from any cause.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO082**

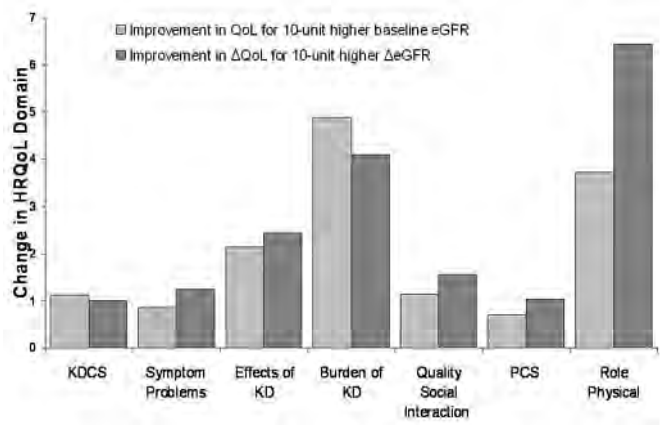
**Change in Health Related Quality of Life (QoL) with Progression of Chronic Kidney Disease (CKD): The Study of Treatment for Renal Insufficiency: Data and Evaluation (STRIDE)** Anca Tilea,[1] Brenda W. Gillespie,[1] Fredric O. Finkelstein,[2] George Eisele,[3] Margaret A. Kiser,[4] Rajiv Saran,[1] Peter Kotanko.[5] *[1]U. of Michigan, Ann Arbor, MI; [2]Hospital St Raphael Yale University, New Haven, CT; [3]Medical College of Albany, Albany, NY; [4]University of North Carolina, Chapel Hill, NC; [5]RRI, New York, NY.*

Declining renal function may result in deterioration in QoL.We examined the association between change (Δ) in QoL domain score and progression of CKD in a multicenter CKD cohort.

STRIDE is a national prospective cohort of 2,162 CKD patients (median follow-up 3 years).The Kidney Disease QoL Short Form-36 was administered at baseline and follow-up visits. ΔQoL and ΔeGFR were calculated as the difference between the baseline visit and the last visit with both QoL and eGFR(n=991).Pearson correlation and linear regression were used to assess the associations between each QoL domain and baseline eGFR,and between ΔQoL domains and ΔeGFR.Models were adjusted for age, gender, race, diabetes and hypertension.

The average age was 63±14 yr, mean eGFR was 25±11 ml/min/1.73m$^2$, with 52% males, 23% black, 38% diabetics and 54% hypertensives.The average ΔeGFR was -0.6±8.7 ml/min/1.73m$^2$/year.Results showed significant associations ($p<0.05$) between ΔeGFR and ΔKidney Disease Component Summary score, Δ(symptom problems), Δ(effects of kidney disease, Δ(burden of KD), Δ(quality of social interaction), Δ(Physical Component Summary score), Δ(role-physical) and marginal association with Δ(energy/fatigue) ($p=0.06$).The figure shows the significant associations of baseline eGFR predicting baseline QoL, and ΔeGFR predicting ΔQoL domains.

Declining eGFR is associated with a decline in a variety of QoL domains.Understanding mechanisms of these associations and implications for patient management require further investigation.



Disclosure of Financial Relationships: nothing to disclose

**TH-PO083**

**Racial Disparity in Mortality by Identified CKD Stages in Elderly Medicare Patients** Suying Li,[1] Jiannong Liu,[1] David T. Gilbertson,[1] Robert N. Foley,[1,2] Allan J. Collins.[1,2] *[1]U. S. Renal Data System Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, U of MN, Minneapolis, MN.*

The United States Renal Data System has shown that mortality rates for African Americans (AAs) are lower than those for Whites in dialysis patients. A study using the Third National Health and Nutrition Examination Survey data showed that in patients with early CKD stages (1-5) AAs had significantly higher risk for death than Whites among persons who were < 65 yrs old, but this was not seen among those who were >= 65 yrs old.

Beginning October 2005, new ICD-9 codes were introduced to identify CKD by stage in the Medicare population. This study includes point prevalent Medicare patients on January 1, 2008, aged > 65 yrs old. CKD stages and comorbidities were identified from 2007 claims. Patients were excluded if they were enrolled an HMO, Medicare as secondary payor, or diagnosed with ESRD in 2007. Patients were followed from January 1 to December 31, 2008 censored at ESRD date or the end of Medicare entitlement. Adjusted mortality rates by CKD stages were based on Cox regression and adjusted for age, gender, and comorbidities with the all CKD cohort as reference. The relative risks (RRs) were adjusted for age, gender, comorbidities, and CKD stages. These comorbidities included anemia, cancer, GI bleeding, liver disease, hypertension, and all cardiovascular diseases.

There were total 37,320 patients with specific CKD stages codes and identified as Whites or AAs included in this study. Overall, AAs had higher risk of death than Whites (RR=1.10; p=0.0486). More results by CKD stages are reported in the following table.

| CKD stages | Race | N | Percent of death | Adjusted mortality (per 1000 pat-yrs) | Adjusted RR |
|---|---|---|---|---|---|
| 1-2 | Whites | 5694 | 10.5 | 124 | 1.00 |
| | AAs | 68 | 7.9 | 115 | 0.95 (0.74-1.23) |
| 3-5 | Whites | 27683 | 13.5 | 151 | 1.00 |
| | AAs | 3875 | 12.2 | 172 | 1.12 (1.02-1.23) |

In Medicare 5% random sample, we have found that AAs with CKD had significantly higher risk of death, especially with stages 3-5. We conclude that the improved AA survival on dialysis may reflect a survival bias compared to Whites.

**TH-PO084**

**Predicting Loss of eGFR in Patients with Diabetes Mellitus – What Is the Impact of Ethnicity?** Gavin Dreyer,[1] Rohini Mathur,[2] Sally Hull,[2] Alistair Chesser,[1] Magdi Yaqoob.[1] *[1]Renal Unit, Royal London Hospital, United Kingdom; [2]Centre for Health Sciences, Queen Mary University, United Kingdom.*

Introduction

In patients with diabetes mellitus (DM), South Asian ethnicity is associated with a greater prevalence of severe CKD (stages 4-5) compared to Afro-Caribbean or Caucasian ethnicity. The effect of ethnicity on the progression of CKD in patients with DM has not been studied. We conducted a prospective study of 2,305 patients to examine the impact of ethnicity on the yearly change in eGFR of patients with DM.

Methods

Computer databases in 138 primary care facilities in London were searched for patients with a diagnostic code for DM and concomitant CKD (eGFR <60ml/min/m$^2$, 4 variable MDRD equation adjusted for ethnicity). Patients aged 30-75 years with a recording of ethnicity at study entry in April 2006 were included. The mean follow up was 4.4 years. Progression of CKD was measured as change in eGFR per year.

Results

At study entry, 1,970 patients had CKD stage 3 compared to stage 4 (n=110) and stage 5 (n=45). In a logistic regression analysis for patients with CKD stage 3 (adjusted for age, gender, clustering, mean arterial pressure, cholesterol, HbA1c, use of ACE/ARB), South Asian and Afro-Caribbean patients had a faster rate of decline in eGFR compared to the Caucasian population. In stage 4 CKD, only South Asian patients had a significant reduction in eGFR.

Mean change in eGFR by ethnic group per year

| | | Change in eGFR (ml/min/year) | 95% confidence interval |
|---|---|---|---|
| | White | -0.55* | -0.89, -0.21 |
| Stage 3 | South Asian | -0.91* | -1.29, -0.13 |
| | Afro-Caribbean | -0.91* | -1.43, -0.39 |
| | | | |
| | White | 0.38 | -0.84, 1.62 |
| Stage 4 | South Asian | -1.51* | -2.61, -0.57 |
| | Afro-Caribbean | -1.01 | -2.40, 0.38 |

*=p<0.001

Conclusions

Ethnicity significantly affects the change in eGFR in patients with DM. South Asian and Afro-Caribbean patients progress faster than Caucasian patients which may in part explain higher numbers of non-Caucasian patients receiving dialysis or transplants in the UK. Further studies are required to determine the optimal treatment strategy for each ethnicity to minimise loss of kidney function and reduce health disparities between ethnic groups.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO085

**Socioeconomic Factors and Low Albumin Levels in Rural CKD Patients** Rebecca J. Schmidt, Bethany S. Pellegrino. *Nephrology, West Virginia University, Morgantown, WV.*

The prognostic value of serum albumin for dialysis patients is well known and low levels are due to both the 'chronic inflammatory state' and nutritional factors. Albumin levels of patients starting dialysis in the US have changed little since 1996 (3.1-3.2 g/dl), suggesting the problem prior to the start of dialysis. Nutrition may be equally as important as the 'chronic inflammatory state,' particularly in patients whose poor nutritional habits are longstanding.

Laboratory values from 4623 patients with Stages 3-5 chronic kidney disease (CKD ) seen between January 1, 2001 and May 31, 2010 were analyzed by county of residence. Values at first presentation to the CKD clinic were utilized. Census statistics for the percent of residents living below the federal poverty level (%<FLP) ($10,827 and $18,346 for an individual and family of 3, respectively), were ranked for each county.

The majority (4299 or 93%) of patients represented 18 of West Virginia's 55 counties. Mean albumin levels were similar for all CKD patients of both genders (mean±SE: 3.58±0.023 g/dl for females vs. 3.54±0.025 g/dl for males) and did not correlate with age or year of visit. Almost half (45%) of all CKD patients presented with albumin levels ≤3.5 g/dl and for Stages 3-5, 34%, 42% and 70% of patients presented with albumins ≤ 3.5 g/dl. Albumin levels (mean±SD) ranged from 3.66±1.00 for Stage 3 to 3.14±0.79 for Stage 5.

Albumin levels (mean±SE) ranged from 3.38±0.08 to 4.23±0.13 with 17 of 18 counties having a mean albumin level below 3.92±0.09 and a single county having a mean albumin level exceeding 4 g/dl (p<0.0001). Mean albumin in this county (4.23±0.13) was higher than the mean albumin for the 17 other counties, though statistically different from only 11 (p<0.0001). The %<FLP ranged from 15.5 to 25.2% in these 17 counties, the county with the highest albumin having the lowest %<FLP (12.9%).

Among our rural CKD patients, mean albumin levels were highest in the county with the lowest %<FLP. Additional study of the impact of socioeconomic status on nutritional forces throughout the continuum of CKD may shed light on the stagnant and low albumin levels seen in patients starting dialysis.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO086

**Racial and Ethnic Differences in the Onset of CKD as Defined by Proteinuria** Stephen F. Derose,[1] Jean Q. Wang,[1] Peter W. Crooks,[2] Jiaxiao Shi,[1] Mark P. Rutkowski.[3] *[1]Research & Evaluation, Kaiser Permanente Southern California, Pasadena, CA; [2]Renal Program, Kaiser Permanente Southern California, Pasadena, CA; [3]Baldwin Park Medical Center, Kaiser Permanente Southern California, Baldwin Park, CA.*

Racial disparities in the onset of CKD as defined by proteinuria are not well characterized. We conducted a retrospective cohort study to determine the risk of developing proteinuria among a diverse population with an initially normal urine protein test and eGFR >60 mL/min/1.73m$^2$.

Subjects were members of Kaiser Permanente Southern California from 1st Jan 1998 to 31st Dec 2006 and had equivalent health insurance coverage. Proportional hazards regression was used to estimate risk associated with race after adjustment for age and sex. Study entry was defined by a negative urine test. The outpatient serum creatinine test closest in time and prior to the entry urine test was used to estimate eGFR based on the CKD-EPI equation. The primary endpoint was proteinuria as defined by two quantitative urine tests >6 days apart without concurrent evidence of UTI by ICD-9 codes or positive leucocyte esterase or nitrites. Censoring events were death, disenrollment, or the end of the study period. Members with unknown race or multiple race were excluded (26% of those who were otherwise eligible).

Subjects were 42.5% male, median age 49.2 years, with 42.4% White, 34.7% Hispanic, 13.1% Black, 8.1% Asian and Pacific Islander, 0.12% Native American, and 1.62% for all other race and ethnicity. Compared to Whites, the hazard ratios and 95% CI's for the 769,915 subjects were: Black 1.32 (1.28-1.36); Hispanic 1.57 (1.53-1.61); Asian and Pacific Islander 1.59 (1.54-1.65); and Native American 1.77 (1.32-2.37).

Compared to Whites, the other major racial and ethnic groups were at higher risk of developing proteinuria after a normal test and when eGFR was in the normal to mildly decreased range. Blacks, who are often observed to be at higher risk for ESRD, were at slightly lower risk than other non-White groups.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO087

**Deprivation but Not Rurality Is Associated with Increased Incidence of End-Stage Renal Disease: A Spatial Analysis** Cécile Couchoud,[1] Chantal Guihenneuc-Jouyaux,[2] Florian Bayer,[1] Benedicte Stengel.[3] *[1]REIN Registry, Biomedicine Agency, Saint Denis La Plaine, France; [2]MAP5 CNRS UMR 8145, Paris 5 University, Inserm U780-IFR69, Villejuif, France; [3]Paris-Sud University, Inserm U780-IFR69, Villejuif, France.*

Objective. To quantify the extent to which deprivation and rurality may explain the spatial pattern of ESRD incidence, after adjustment for several confounders and application of geographically appropriate methods.

Methods. The association between ESRD incidence in France in 2006-2007 and 6 district-level indicators of socioeconomic environment (percentage of people aged 20-59 years receiving minimum guaranteed income allowances, percentage unemployed, percentage receiving free health care, percentage receiving minimum guaranteed income allowances for the elderly, gross domestic product (GPD) per capita, and educational level) and 2 indicators of rurality was explored at the district level. Confounders included diabetes prevalence, cardiovascular mortality (competitive risk), and indicators of health-care supply and clinical practices.

Results. Crude ESRD incidence by district ranged from 80.4 to 238.6 per million inhabitants. Each 1.3% increase in those receiving minimum guaranteed income allowances was associated with a 14% increase in ESRD incidence before and an 11% increase after adjustment for 9 potential confounders. Similar increase was found with % unemployed and % receiving free health care, but not with other socioeconomic or rurality indicators. The association between rurality and ESRD incidence seemed to be explained largely by the deprived environment, and much less by other confounders.

Conclusion. Living in deprived areas may explain some between-area variation in ESRD incidence rates. Better understanding of the local geography of these rates might help public officials to adjust supply and demand at the district level. It may also prove useful for devising and monitoring strategies for prevention, especially among subgroups with low socioeconomic status.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO088

**Racial and Ethnic Differences in Mortality among Individuals with Chronic Kidney Disease (CKD): Results from the Kidney Early Evaluation Program (KEEP)** Stacey Jolly,[1] Nilka Rios Burrows,[2] Shu-Cheng Chen,[3] Suying Li,[3] Claudine T. Jurkovitz,[4] Keith C. Norris,[5] Michael Shlipak.[6] *[1]Cleveland Clinic, Cleveland, OH; [2]Centers for Disease Control, Atlanta, GA; [3]Chronic Disease Research Group, Minneapolis, MN; [4]Christiana Care Health System, Newark, DE; [5]Charles R. Drew University, Los Angeles, CA; [6]University of California San Francisco, San Francisco, CA.*

*Objective:* To estimate associations of race/ethnicity with all-cause mortality among those with early and late stage CKD.

*Methods:* Cross-sectional analysis; KEEP participants from 2000-2008 with CKD, not on dialysis, nor with prior kidney transplant who self-reported race/ethnicity. Early stage CKD defined as urinary albumin to creatinine ratio ≥ 30 mg/g among those with eGFR ≥ 60 mL/min/1.73 m$^2$. Late stage CKD defined as eGFR < 60. Covariates: age, sex, obesity, DM, HTN, smoking, family history, education, health insurance, geographic region, year screened.

*Results:* 19,205 participants with prevalent CKD, 55% ($n$ = 10,560) were white, 27% ($n$ = 5237) African American, 9% ($n$ = 1638) Hispanic, 5% ($n$ = 951) Asian, and 4% ($n$ = 813) American Indian/Alaska Native (AIAN). There were 1043 deaths (5%) among those with CKD; 214 (3.5%) among those with early stage CKD; 829 (6%) among those with late stage CKD.

Adjusted Hazards Ratios of Risk of Death for KEEP Participants with CKD by Race/Ethnicity, 2000-2009

| | CKD | Albuminuria (eGFR >=60) | eGFR <60 |
|---|---|---|---|
| | N= 19,205 | N = 6068 | N = 13,137 |
| | HR (95% CI) | HR (95% CI) | HR (95% CI) |
| White | 1.00 | 1.00 | 1.00 |
| African American | 1.01 (0.87 – 1.18) | 1.03 (0.75-1.42) | 0.99 (0.83-1.17) |
| Hispanic | 0.65 (0.48 – 0.88)* | 0.62 (0.33-1.14) | 0.64 (0.45-0.91)* |
| Asian | 0.72 (0.50 – 1.04) | 0.44 (0.20-0.95)* | 0.84 (0.56-1.27) |
| AIAN | 1.41 (1.10 – 1.18)* | 1.32 (0.80-2.18) | 1.39 (1.04-1.84)* |

*p-value <0.05

*Conclusions:* Hispanics and Asians had better survival prognosis compared with Whites; AIAN had the worst prognosis. Further research is needed to understand these disparities and create novel interventions to address them among those with CKD.

**TH-PO089**

**Health Related Quality of Life (HRQoL) Predicts Mortality and ESRD in Chronic Kidney Disease (CKD): The Study of Treatment for Renal Insufficiency: Data and Evaluation (STRIDE)** Anca Tilea,[1] Brenda W. Gillespie,[1] Fredric O. Finkelstein,[2] Margaret A. Kiser,[3] George Eisele,[4] Peter Kotanko,[5] Rajiv Saran.[1] *[1]U. of Mich., Ann Arbor, MI; [2]Hosp. of St. Raphael Yale U., New Haven, CT; [3]U. of N. Carolina, Chapel Hill, NC; [4]Med. College of Albany, Albany, NY; [5]RRI, New York, NY.*

Poor patient outcomes are a major concern in CKD. However, previous studies have mainly investigated these outcomes in relation to HRQoL in the End Stage Renal Disease (ESRD) population only. We examined the association between HRQoL and patient outcomes (death, dialysis and transplantation) in a multi-center CKD cohort.

The STRIDE is a prospective cohort study of 2,162 CKD patients (median follow-up 3-years) at 79 US renal clinics. The Kidney Disease and Quality of Life Short Form (KDQoL SF-36) was administered at enrollment and follow-up visits. The Kidney Disease Component Summary (KDCS), Mental Component Summary (MCS), and Physical Component Summary (PCS) scores were calculated. Cox regression was employed to assess the associations between mortality and ESRD with each of the baseline HRQoL domain score, adjusted for age, gender, race, diabetes, hypertension, hemoglobin, serum albumin and eGFR.

The average age was 63±15 years. The average eGFR (MDRD) was 24±10ml/min/1.73m$^2$. Fifty-four percent were males, 23% were black, 39% with diabetes and 53% with hypertension.There were 85 deaths and 278 ESRD events. In general, higher HRQoL scores were significantly associated with lower risk of mortality,and ESRD. In particular, the PCS score and KDCS score showed the strongest association. Our results show significant associations between low HRQoL and poor patient outcomes. Systematic monitoring of HRQoL could become a useful tool in risk stratifying CKD patients and thus might improve their management.

| | Death | | ESRD | |
|---|---|---|---|---|
| HRQoL-SF36 Domains** | HR | P | HR | P |
| KDCS | 0.83 | 0.01* | 0.99 | 0.78 |
| Symptom Problems | 0.89 | 0.02* | 0.94 | 0.01* |
| Effects of KD | 0.95 | 0.28 | 0.97 | 0.16 |

**Depressed Mood, Usual Activity Level, and Continued Employment on Dialysis** Nancy G. Kutner,[1] Rebecca H. Zhang,[1] Yijian Huang,[1] Kirsten L. Johansen.[1,2] *[1]USRDS Rehabilitation/QoL Special Studies Ctr, Emory University, Atlanta, GA; [2]San Francisco VA Medical Ctr, UCSF, San Francisco, CA.*

**Background**. Employment is valued in American society, and individuals' ability to engage in productive activity provides a marker of the effectiveness of care. Many chronic kidney disease (CKD) patients leave the labor market when they start dialysis, however. **Methods**. We investigated the association of depressed mood and usual activity level with patients' continued employment after starting dialysis, independent of disability income and patient characteristics. 1643 incident dialysis patients aged ≥18 from 296 randomly selected clinics were surveyed in the USRDS Comprehensive Dialysis Study (CDS). Participants provided information about current and prior employment, disability income receipt, education, depressive symptoms (Patient Health Questionnaire-2, i.e. PHQ-2), and usual activity level/energy expenditure (Human Activity Profile, i.e. HAP). Age, gender, race, medical insurance, diabetes, inability to ambulate or transfer, COPD, cardiovascular comorbidity, and hemoglobin and serum albumin values at treatment start were obtained from USRDS files. Dialysis modality was defined at time of interview, i.e. approximately 4 months post treatment start. **Results**. 32.6% of patients who worked in the year before dialysis (191/585) continued working. Patients who stopped working were almost three times more likely to report probable or possible depression (PHQ-2 ≥3; P < 0.0001). Mean (sd) HAP scores were 46.1 (18.6) among patients who stopped working vs. 60.2 (14.8) among those who continued working; P < 0.0001. Lower PHQ-2 scores (P = 0.06) and higher HAP scores (P < 0.0001) remained associated with increased likelihood of continued employment in logistic regression analyses adjusted for disability income, socioeconomic and clinical characteristics, and patient clustering in facilities. **Conclusion**. Screening and management of depressive symptoms and encouragement of increased activity in CKD patients are mutually reinforcing interventions that could facilitate individuals' continued employment in addition to generally improving overall quality of life on dialysis.

**Genetic Ancestry, Poverty and Albuminuria among African Americans: The Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) Study** Deidra C. Crews,[1] Edgar R. Miller,[1] Neil R. Powe,[2] Mike Nalls,[3] Andrew Singleton,[3] Alan B. Zonderman,[3] Michele Kim Evans,[3] Wen Hong Linda Kao,[1] Carmen A. Peralta.[2] *[1]Johns Hopkins University; [2]University of California, San Francisco; [3]National Institute on Aging, National Institutes of Health.*

A susceptibility gene for non-diabetic proteinuric ESRD was recently identified and found to be more common among African Americans. However, whether genetic ancestry, environmental factors (i.e. poverty), or their interaction account for most of the risk for albuminuria at early stages of kidney disease is unknown. We examined the relation of genetic African ancestry and poverty with albuminuria among African Americans in a community-based study of adults aged 30-64 years living in Baltimore, MD, and selected to have socioeconomic diversity. Percent African ancestry was estimated with STRUCTURE using 2000 ancestry informative markers. Poverty (annual household income <125% of 2004 Poverty guideline) and 3 income categories were examined. Urinary albumin/creatinine ratio (ACR) was log transformed, then back transformed to a relative difference (RD) in multivariable linear regression models. Among 474 participants, 53% were women, 31% lived in poverty. African ancestry ranged from 46% to 99%. ACR ranged from 0.10 to 279 mg/g. Overall, the correlation between ACR and percent African ancestry was -0.07 (P= 0.15), and each 10% increase in African ancestry was not associated with higher ACR, RD -2.6 % (95% CI, -8.7% to 4.0%). In contrast, poverty (compared to non-poverty) was independently associated with higher ACR [RD 16.6% (95% CI, 2.8% to 32%)] after adjustment for African ancestry, age, sex, diabetes, hypertension, obesity, total cholesterol, and estimated GFR; and there was no significant interaction between poverty and African ancestry. Additionally, with adjustment, there was a graded, independent association between greater income and lower ACR [RD -20.4% (95% CI, -33.3% to -4.9%), when the highest annual income (>$40,000) was compared to the lowest income (<$17,500) category]. Poverty, an environmental factor, is associated more strongly than genetic ancestry with early kidney damage among African Americans.

**TH-PO092**

**Racial and Ethnic Differences in the Onset of CKD as Defined by eGFR Loss** Stephen F. Derose,[1] Mark P. Rutkowski,[3] Jean Q. Wang,[1] Jiaxiao Shi,[1] Peter W. Crooks.[2] *[1]Research & Evaluation, Kaiser Permanente Southern California, Pasadena, CA; [2]Renal Program, Kaiser Permanente Southern California, Pasadena, CA; [3]Baldwin Park Medical Center, Kaiser Permanente Southern California, Baldwin Park, CA.*

Racial disparities in the onset of kidney disease as defined by GFR loss are not well characterized. We conducted a retrospective cohort study to determine the risk of losing half of initial kidney function among a diverse population with eGFR >90 or >60 mL/min/1.73m$^2$.

All subjects were members of Kaiser Permanente Southern California and had equivalent health insurance. Two or more outpatient serum creatinine tests >90 days apart from 1st Jan 1998 to 31st Dec 2006 were used to estimate eGFR based on the CKD-EPI equation. Proportional hazards, including competing risks, regressions were used to determine risk asociated with race after adjustment for age and sex. Study entry was defined by the first available eGFR. The primary endpoint was the eGFR after which all subsequent eGFR's were less than half the entry value. Censoring occurred for death (the competing event), disenrollment, or the end of the study period. Members with unknown race or multiple race were excluded (30% of those who were otherwise eligible).

Subjects were 41% male, median age 51 years, with 47.9% White, 31.3% Hispanic, 12.6% Black, 7.8% Asian and Pacific Islander, 0.1% Native American, and 0.4% for all other race and ethnicity. Compared to Whites, the hazard ratios (HR) and 95% CI's for 1,054,696 subjects with entry GFR >60 were: Black 3.4 (3.1-3.8); Hispanic 2.9 (2.6-3.2); Asian and Pacific Islander 1.9 (1.6-2.2); and Native American 4.4 (1.8-10.6). For the 742,260 subjects with entry eGFR >90, the HRs were: Black 2.5 (2.1-3.0); Hispanic 2.9 (2.6-3.2); Asian and Pacific Islander 1.4 (1.1-1.8); and Native American 4.4 (1.8-10.6).

Compared to whites, the other major racial and ethnic groups had a greater risk of losing half their entry eGFR from a starting point of normal (>90), or normal to mildly decreased (>60), kidney function. Blacks, Hispanics and Native Americans were at highest risk.

Disclosure of Financial Relationships: nothing to disclose

**Is Awareness of Chronic Kidney Disease Associated with Greater Receipt of Evidence-Based Medical Therapies?** Delphine S. Tuot, Laura C. Plantinga, Chi-Yuan Hsu, Neil R. Powe. *University of California, San Francisco, San Francisco, CA.*

Background: Awareness of chronic kidney disease (CKD) is low. Efforts are underway to increase recognition of CKD among providers and patients, assuming that they will lead to better outcomes in CKD patients through wider application of, and adherence to, proven therapies. However, few studies have tested this assumption.

Methods: Blood pressure (BP) control, use of Angiotensin Converting Enzyme Inhibitors (ACEI) or Angiotensin Receptor Blockers (ARB) and glycemic control were assessed in 3200 adults with CKD stages 1-4 using 1999-2006 National Health and Nutrition Examination Survey data. BP control was defined as an average BP <140/90 in subjects without proteinuria and <130/80 in the presence of proteinuria; ACEI/ARB use was self-reported; glycemic control was a hemoglobin A1C <7mg/dl. CKD awareness was a "yes" answer to "Have you ever been told by a healthcare provider you have weak or failing kidneys?". All estimates were weighted to the US population.

Results: Fewer than 50% of individuals with kidney dysfunction attained BP control and only 18% were treated with an ACEI/ARB, regardless of CKD awareness. Among diabetics with CKD, glycemic control was achieved in 30% of those aware of their CKD and 50% of those unaware. Odds of BP control and ACE/ARB use according to evidence-based guidelines were not different among subjects aware and unaware of their CKD (p=.08 and p=.77), regardless of proteinuria (p=.54 and p=.3), CKD stage (p=.58 and p=.51) or diabetes (p=.38 and p=.73). Those aware of their CKD status had lower odds of glycemic control compared to those who were unaware, independent of eGFR and severity of diabetes (adjusted odds ratio =.23; p=.01).

Conclusions: Contrary to expectation, awareness of CKD was not associated with greater odds of BP control or ACEI/ARB use and was actually associated with decreased odds of glycemic control. Inference regarding causality is limited by the cross-sectional nature of the analysis but our results suggest that future policy in this area should be guided by a more sophisticated understanding of physician and patient behavior.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO094

**Sources of Drug Coverage among Medicare Beneficiaries with End-Stage Renal Disease** Wendy L. St. Peter,[1,2] Diane L. Frankenfield,[3] Christopher Powers,[3] Eric D. Weinhandl,[1] James P. Ebben,[1] Benjamin L. Howell.[3] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Pharmacy, U of MN; [3]ORDI, CMS, Baltimore, MD.*

**Background:** Drug coverage sources in end-stage renal disease (ESRD) patients since Medicare Part D inception are unknown. Objectives were to describe 1) distribution of drug coverage in the ESRD patient population, and 2) which types of stand-alone Part D plans ESRD patients voluntarily enrolled in during 2007. **Methods:** Data from the Chronic Condition Warehouse linked with administrative data from the United States Renal Data System were used. A 20% random sample of Medicare beneficiaries who were alive and had ESRD in December 2007 were identified. Patients were classified as having no known coverage, Part D coverage (with or without the low-income subsidy [LIS]), coverage from a former employer, or coverage from other creditable sources. To describe the stand-alone Part D plans in which ESRD patients voluntarily enrolled, we considered only patients who self-enrolled into plans and excluded patients eligible for auto-enrollment via LIS. Plan characteristics considered included deductibles (Y/N), gap coverage (Y/N), and premiums (by quartile). **Results:** Among ESRD patients, 16.9% had no known source of drug coverage, 17.9% had Part D without LIS, 45.7% had Part D with LIS, 8.8% had coverage from former employer, and 9.5% had other creditable coverage (compared to 15.4%, 33.9%, 21.9%, 15.8%, and 12.9% in general Medicare population, respectively). ESRD patients who self-enrolled in Part D were more likely to choose more comprehensive plans, with 70.8%, 38% and 22.6% choosing plans with no deductible, with gap coverage, and with higher premium and superior benefits, respectively (compared to 68.9%, 33.7%, and 12.0% among all Part D program self-enrollees, respectively). **Conclusions:** In 2007, a large number of ESRD beneficiaries still lacked a known source of creditable drug coverage; reasons for this are unclear. Auto-enrollment into the Part D benefit via LIS appeared to be an important mechanism for many ESRD patients to obtain prescription drug coverage. ESRD beneficiaries who self-enrolled into Part D plans tended to prefer plans with more comprehensive benefits.

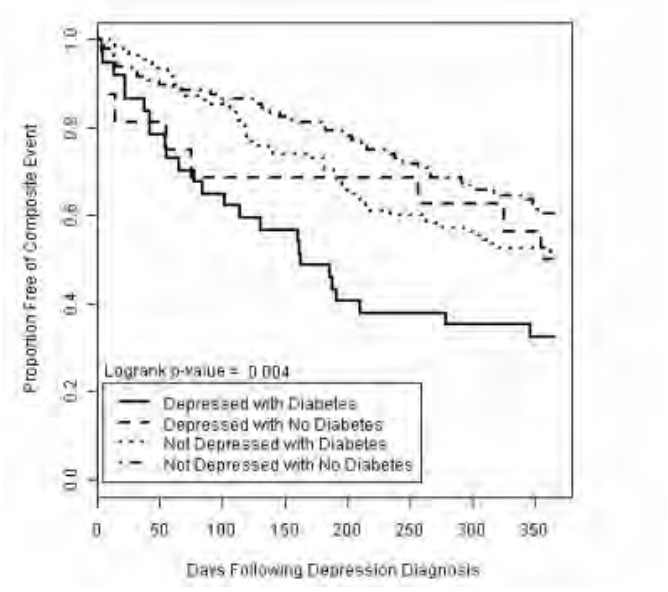
## TH-PO095

**Major Depressive Episode Increases Risk for Kidney Disease Progression, Hospitalization and Death in Type 2 Diabetics** Susan Hedayati,[1,2] Masoud Afshar,[2] Abu T. M. Minhajuddin,[2] Robert D. Toto,[2] Madhukar Trivedi,[2] Augustus John Rush.[3] *[1]Dallas VA Medical Center; [2]UT Southwestern Medical Center at Dallas; [3]Duke-NUS, Singapore.*

Depression is associated with treatment nonadherence and poor glycemic control in diabetics. To determine if patients with type 2 diabetes, CKD and a Major Depressive Episode (MDE) are at a higher risk for progression to ESRD, death or hospitalization, we prospectively studied 267 outpatients with stages 2-5 predialysis CKD recruited from a single VA Medical Center and followed for a year. The primary outcome was the composite of ESRD, death or hospitalization. Kaplan Meier survival curves were used to compare event-free survival times, and Cox proportional hazards to assess adjusted hazard ratios. Subjects were grouped by diabetes and MDE status: **Group A**: 39 had diabetes and MDE; **Group B**: 17 had MDE but no diabetes; **Group C**: 109 had diabetes but no MDE; **Group D** (referent group): 102 had neither MDE nor diabetes. Event-free survival based on the composite outcome was shortest in **Group A** (187 ±22 days), vs. 245 ±40 days in **Group B**; 261 ±12 days in **Group C**; and 280 ±12 days in **Group D**, Log-rank p =.004.



After adjusting for age, race, eGFR, serum albumin, hemoglobin, calcium-phosphorus product, cardiovascular disease, other comorbidities and drug and alcohol abuse, those with diabetes and depression (**Group A**) were twice as likely to progress to ESRD, die or become hospitalized than those without diabetes or depression (**Group D**), HR 2.1 (95% CI 1.2-3.6). Adjusted hazard ratios were statistically non-significant for **Group B** (1.9, 95% CI 0.9-4.3) and **Group C** (1.2, 95% CI 0.8-1.9).

Depression in patients with type 2 diabetes and CKD increases risk for kidney disease progression, hospitalization and death due to diabetic complications. Identification and treatment of depression in these patients may improve outcomes.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO096

**Racial Disparity in CKD Progression and Risk Factor Control: A Longitudinal Analysis of the Kidney Early Evaluation Program** Suying Li,[1] Shu-Cheng Chen,[1] Allan J. Collins,[1,2] Peter A. McCullough,[3] George L. Bakris,[4] Joseph A. Vassalotti.[5,6] *[1]Chronic Disease Research Group, MMRF, Minneapolis, MN; [2]Medicine, Univ. of Minnesota; [3]William Beaumont Hospital, Northville, MI; [4]Univ. of Chicago, Pritzker School of Medicine, Chicago, IL; [5]National Kidney Foundation, New York, NY; [6]Mt. Sinai School of Medicine, New York, NY.*

Starting in June, 2008, the Kidney Early Evaluation Program participants (KEEP) were asked to return annually. To examine differences in CKD progression and risk factor control between Whites (Ws) and African Americans (AAs), we studied KEEP participants who had a 2nd screening between 6/15/08 and 12/31/09. The overall returning rate was 9%.

This study included 2451 Ws with mean age of 63.8 and 1286 AAs with mean age of 58.3 years old. The mean and median screening interval in days between assessments was 642 and 408. The CKD prevalence at the 1st and 2nd screening was 30.0% and 35.6% for Ws and 17.7% and 21.5% for AAs. The MDRD-eGFR declined 4.8 mL/min/1.73 $m^2$ in Ws and 6.6 mL/min/1.73 $m^2$ in AAs between the two screenings. The blood pressure (BP) control (systolic BP<140 mm Hg and diastolic BP<90 mm Hg) at the 1st and 2nd screening was 42.4% and 43.6% for Ws and 37.9% and 42.6% for AAs. Among hypertensive participants who had not achieved BP control at the 2nd screening, AAs declined faster in eGFR than Whites.

As product of the KEEP program, BP control was improved on the 2nd screening. Despite this improvement, the rate of decline of eGFR was greater for AAs than Ws. These data suggest that more intensive intervention and care is needed with additional education on risk factor awareness and control.

| | Whites | AAs | p-value |
|---|---|---|---|
| **N** | 2451 | 1286 | |
| **Mean difference in eGFR between 2 screenings** | -4.8 | -6.6 | <0.0001 |
| **CKD prevalence at 1st screening, %** | 30.0 | 17.7 | <0.0001 |
| **CKD prevalence at 2nd screening, %** | 35.6 | 21.5 | <0.0001 |
| **BP control at 1st screening, %** | 42.4 | 37.9 | 0.0211 |
| **BP control at 2nd screening, %** | 43.6 | 42.6 | 0.6127 |
| **eGFR decline for those BP controlled at 2nd screening** | -5.8 | -6.5 | 0.4105 |
| **eGFR decline for those BP not controlled at 2nd screening** | -4.5 | -6.6 | 0.0053 |

## TH-PO097

**Ethnic- and Gender-Specific Cut-Offs for Urinary Albumin-Creatinine Ratio When Detecting Microalbuminuria in Han Chinese** Xiaohong Fan, Jianfang Cai, Lijun Mou, Bixia Gao, Xuejiao Liu, Xuemei Li, Xue-Wang Li. *Nephrology, Peking Union Medical College Hospital, Beijing, China.*

**Background** As Asian people tend to be smaller than Caucasians, establishing accurate cut-off values for simple screening tests of kidney injury, such as urinary albumin-creatinine ratio(ACR), is important.

**Methods** We analyzed a population based sample of 1056 people(50.2±12.1years, no known renal disease) from the epidemiological investigation of metabolic syndrome and chronic kidney disease in Pinggu district, Beijing. 8-hour overnight urinary albumin excretion(UAE) was regarded as the standard for defining the albuminuria. The ROC curve analysis was used to determine the ACR cut-off value for microalbuminuria, the 95$^{th}$ percentile method was then used to determine an ACR reference value in the healthy Han Chinese, both of which were compared to previously published data.

**Results** The discriminator value of ACR for microalbuminuria by ROC curve analysis was 1.95mg/mmol(sensitivity 97.6% and specitivity 88.6%)for men, 3.62mg/mmol(sensitivity 83.8% and specitivity 89.1%)for women and 2.78mg/mmol(sensitivity 88.7% and specitivity 85.9%)for overall. The upper boundary of ACR (the 95$^{th}$ percentile ) in healthy was 2.11mg/mmol for men,2.52 mg/mmol for women, 2.23 mg/mmol for overall. Compared with the ACR cut-off by KDOQI, the result of ROC curve analysis in this study had better agreement with the standard criteria(K value is 0.637 vs 0.568 of KDOQI), .

The kappa statistics and diagnostic test of calculated in this study and previously published ACR cut-off values for MA

| ACR cut-offs values for MA | Male | Female | K- value | Sensitivity (%) | Specitivity (%) | Positive likelihood ratio | Positive predictive value (%) |
|---|---|---|---|---|---|---|---|
| ROC curve analysis | 1.95 | 3.62 | 0.637 | 91.3 | 88.2 | 7.96 | 56.9 |
| 95th percentile | 2.11 | 2.52 | 0.536 | 90.7 | 83.3 | 5.44 | 47.4 |
| Beijing CKD STUDY | 1.58 | 2.26 | 0.479 | 94 | 78.6 | 4.39 | 42.1 |
| INTERMAP STUDY | 2.79 | 3.9 | 0.649 | 83.3 | 91.3 | 9.56 | 61.3 |
| KDOQI | 1.92 | 2.83 | 0.568 | 92.7 | 84.6 | 6 | 49.8 |

**Conclusions** Using a population sample, we report ethnic differences in cut-off values for detecting microalbuminuria using ACR. Ethnic difference must be considered when evaluating results using these methods.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO098

**Screening for CKD in Homeless Individuals in Mexico** Guillermo G. Garcia,[1] Jaime A. Gonzalez,[1] Alfonso Gutierrez,[1] Ma. Concepcion Ocegueda,[1] Salvador Plascencia,[1] Mario Marquez,[2] Marcello Tonelli.[3] *[1]Division of Nephrology, Hospital Civil de Guadalajara, Guadalajara, Jal, Mexico; [2]Secretaria de Salud, Jalisco, Mexico; [3]Nephrology Division, University of Alberta, Canada.*

CKD is a major cause of morbidity and mortality in Mexico. Data from other nations suggests that risk factors for CKD are disproportionally higher among the poor.

Since 1998, the Fundacion Hospitales Civiles de Guadalajara has used mobile units to provide health care for the poor in Jalisco, with emphasis on disease prevention and early detection. In partnership with IJAS, a state welfare agency, we screened homeless individuals in Guadalajara. We excluded individuals with known CKD and < 18 years of age. Trained personnel collected demographic and clinical data and collected blood samples for selected tests. In 02/2006, 260 individuals were screened. Findings were compared with the National Health Survey 2006 (ENSANUT), and with our own reported data on CKD in poor communities in Jalisco.

Results

| | Homeless n = 260 | ENSANUT n=33,624 | Homeless vs ENSANUT p | Jalisco n = 3742 | Homeless vs Jalisco p |
|---|---|---|---|---|---|
| Age (y) | 50.75 ±17.93 | NA | | 57.3±13.2 | 0.0001 |
| Male (%) | 193 (74.2) | 16,139 (49.7) | 0.0001 | 1097 (29.3) | 0.0001 |
| Known DM (%) | 15 (5.8) | 2,554(7.0) | 0.29 | 1625 (43.4) | 0.0001 |
| Blood Glucose>126 mg/dL (%) | 48 (18.9) | NA | | 1528 (41.6) | 0.0001 |
| Known HTN (%) | 9 (3.5) | 5,044 (15.0) | 0.0001 | 2217 (59.2) | 0.0001 |
| SBP≥140 or DBP≥90 (%) | 76 (31) | 10,423 (30.8) | 0.58 | 2128 (57.1) | 0.0001 |
| eGFR < 60 ml/min/ 1.73 m² (%) | 57 (22.4) | NA | | 593 (17.4) | 0.05 |
| BMI ≥ 30 (%) | 39 (17.6) | 10,444(31.1) | 0.0001 | 1580 (43.1) | 0.0001 |
| Current smoker (%) | 90 (34.6) | 2419 (21.5) | 0.0001 | 569 (15.2) | 0.0001 |

We conclude that 1) the prevalence of CKD and its risk factors are high among homeless individuals 2) Consideration should be given to target this high risk population in programs aimed to prevent CKD and its risk factors in Mexico.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO099

**Impact of Socioeconomic Factors to the Incidence of ESRD in DM Patients** Yafei Yang,[1] Fung-Chang Sung,[2] Chiu-Ching Huang.[1] *[1]Nephrology, China Medical University Hospital, Taichung, Taiwan; [2]School of Public Health, China Medical University, Taichung, Taiwan.*

**Objective** Diabetes mellitus (DM) is the major risk leading to the end stage renal disease (ESRD) in Taiwan. Studies investigating the relationship between socioeconomic status and incidence of ESRD in DM are limited. We investigated whether socio-demographic factors and comorbidity interact with DM in developing ESRD.

**Design and setting** Cohort study assembled from the National Health Insurance claims data of Taiwan and followed up to 2008.

**Study subjects** In 1997-2000, a cohort of 26,352 new diagnosed DM patients and a non-DM cohort of 131,694 controls were sampled from the claims data.

**Results** The incidence of ESRD was 29.9 per 10,000 person-years in the DM cohort, which was much higher than that in the non-DM cohort of 2.0 per 10,000 person-years. The incidence of ESRD increased from 8.0 per 10,000 person-years in the DM cohort for less than 20 years old to 29.5 per 10,000 person-years of 40-59 years old and 34.6 per 10,000 person-years of 60 years of age and older. There was a reversed dose-response relationship between the age-specific incidence rate ratio and age; the younger DM patients had a ratio of 47.2 while the oldest group had a ratio of 2.7. More DM patients lived in rural area. However, the adjusted hazard ratio of living in suburban and urban area to rural area were 1.18 and 1.08. All comorbidities contributed to develop ESRD.

Cox proportional hazard regression analysis for estimating risk of end stage renal disease by socio-demographic status and comorbidity

| | Crude Hazard ration (95% CI) | Adjusted HR (95% CI) |
|---|---|---|
| Population/km2 | | |
| Low | 1 | 1 |
| Moderate | 1.01(0.73-1.39) | 1.18(0.85-1.62) |
| High | 0.78(0.57-1.07) | 1.08(0.79-1.48) |
| Comorbidity | | |
| None | 1 | 1 |
| Hypertension | 9.94(7.68-12.9) | 2.67(2.01-3.54) |
| Kidney disease | 10.3(7.63-14.0) | 4.79(3.51-6.52) |
| Heart disease | 2.05(1.18-3.54) | 0.86(0.50-1.50) |
| Stroke | 2.86(1.51-5.43) | 1.32(0.69-2.52) |

**Conclusions** Patients with DM are at high risk of developing ESRD. Residential place and insured group didn't show significant interference to the development of ESRD in Taiwan.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO100

**Low Awareness of Chronic Kidney Disease in Japanese Health-Check Subjects** Yoshinari Yasuda,[1] Kinuko Komada,[1] Kiyoshi Shibata,[2] Shoichi Maruyama,[1] Enyu Imai,[1] Seiichi Matsuo.[1] *[1]Department of Nephrology/CKD Initiatives, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan; [2]Kasugai City Health Care Center.*

*Background:* Chronic kidney disease (CKD) has been increasingly highlighted as a public health issue, worldwide. CKD prevalence in Japan is very high and estimated CKD patient number is 13.3 million in adult. However it is worried that the vast majority of CKD patients do not recognize their CKD, because CKD was the recently defined disease which usually lacks a subjective symptom.

Objective: To estimate awareness of CKD in Japan, past and present renal diseases were interviewed among health check subjects in relation to CKD and life-style related diseases.

Methods: The study subjects were 8,674 people (4,382 men and 4,292 females), who underwent health check in Kasugai City Medical Care Center, from 2006 to 2007. Medical interview was conducted by 10 nurses, and the awareness was defined by any past and present renal diseases. Estimated GFR (eGFR) was calculated by the Japanese eGFR equation, and cases with eGFR less than 60 (mL/min/1.73m²) or with proteinuria in urine dipstick were diagnosed as CKD. CKD awareness was compared in eGFR category, with/without proteinuria and treatment for hypertension, diabetes mellitus or hyperlipidemia.

Results: CKD awareness rate was 6.4% (555/8,674) in all and 10.0% (141/1,413) in CKD patients. The CKD awareness increases as CKD stage advances. CKD patients on treatment for lifestyle-related diseases recognize renal diseases at 9.2% in eGFR45-60, 22.4% in eGFR 30-45 and 60.0% in eGFR<30, which shows no statistical significance in comparison to CKD without treatment (7.7%, 22.4%, 100%, respectively). Even among CKD with proteinuria, treatment for lifestyle-related disease has no statistical impact for CKD awareness.

Conclusions: CKD awareness was low in Japanese CKD patients regardless of treatment for lifestyle-related disease which associate with CKD onset and/or progression.

**High Normal Levels of Albuminuria and Risk of Hypertension in Indo-Asian Population** Saleem Jessani,[1] Andrew S. Levey,[2] Nish Chaturvedi,[3] Tazeen H. Jafar.[1,2,3] *[1]Aga Khan University, Karachi, Pakistan; [2]Tufts Medical Center, Boston; [3]Imperial College London, United Kingdom.*

Urine albumin excretion even in the high normal range (10-29 mg/g) as assessed by urine albumin to creatinine ratio (UACR) predicts hypertension in European-origin populations. Indo-Asians have lower muscle mass and reduced urine creatinine excretion, but also greater risk of elevated blood pressure (BP). However, the prognostic significance and clinical utility of UACR in the high normal range for incident hypertension is unclear in this population.

We conducted a nested cohort study within a cluster randomized controlled trial in Karachi, Pakistan on 1272 normotensive, non-diabetic adults aged ≥40 years with UACR <30 mg/g to examine the relationship of high normal levels of UACR and incident hypertension (defined as initiation of antihypertensive therapy during two years of follow-up or new onset of systolic blood pressure (SBP) ≥140 mm Hg or diastolic ≥90 mm Hg, confirmed at subsequent visit). BP was measured in the sitting position with a calibrated Omron 737 Intellisense device. Multivariable models were built. Logistic regression analysis was performed to determine the relationship of UACR with incident hypertension.

A total of 920 (72.3%) participants completed the 2-year final follow-up visit. During this time, 105 participants (8.3%) developed incident hypertension. In the multivariable model, participants with UACR values in the highest quartile (≥6.1 mg/g) had a 3-fold (adjusted OR: 2.72 (95% CI: 1.37 to 5.40), and those in the third quartile (3.8 to 6.0 mg/g) had 2-fold (adjusted OR: 2.11(1.06 to 4.22), greater risk of hypertension compared to those in the lowest quartile (<2.8 mg/g). The overall positive predictive value (PPV) of high normal UACR (≥6 mg/g) was (12.3% (9.1 to 16.3%) which was not different from PPV of 12.0% (9.8 to 14.5) of high normal baseline SBP (≥120 mm Hg) for incident hypertension.

Conclusion: Albuminuria as measured by UACR in the high normal range predicts hypertension in non-diabetic Indo Asians. Further research including economic evaluation is needed to assess the clinical application of these findings.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO102**

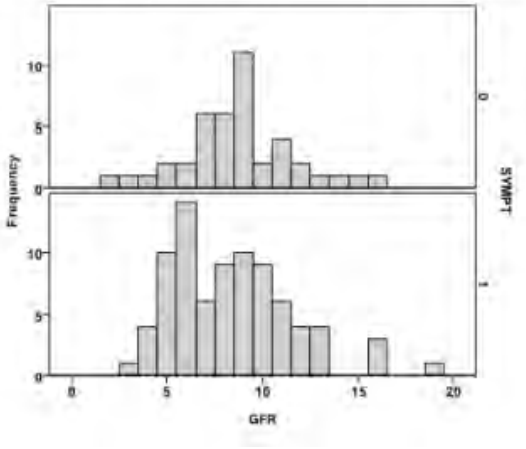
**Earlier Initiation of Dialysis in Males and Older Patients May Be Due to Poorer Tolerance of Uraemic Symptoms** Damien Ashby, Wendy Brown, Lynn Dahri, Elizabeth M. Dalby, Debra J. Gifford, Marie S. Henriksson, Samantha Ross, Claudia C. Schmalzhaf, Helen E. Watts, Peter Hill, Megan Griffith. *Imperial College Kidney & Transplant Institute, London, United Kingdom.*

There is wide variation in opinion and practice patterns regarding the timing of dialysis initiation. Age and sex influences have previously been noted, but the reasons are poorly understood.

To investigate this, data was prospectively collected on all patients starting dialysis from a group of low clearance clinics over a 2 year period to examine the effect of age and sex on GFR at dialysis initiation.

128 patients (aged 28 – 90, 66% male) commenced dialysis with a mean GFR +/-sd of 8.5+/-3.1ml/min. The primary reason for initiation was biochemical in 53.5%, fluid overload in 7% and uraemic symptoms in 39.5%, (although symptoms contributed to the decision in 67%). Mean GFR in symptomatic and asymptomatic patients was similar (8.4+/-3.1 vs 8.7+/-2.9ml/min p=0.3) but, as expected, there was a difference in the shape of the distributions with GFR in symptomatic patients being clearly skewed with greater variance and a long right sided tail.

Fig 1 Distribution of GFR at initiation of dialysis in asymptomatic and symptomatic patients



GFR was significantly higher at dialysis initiation in patients over 65 (9.0+/-3.1 vs 7.9+/-2.9ml/min p=0.041) and also in males (9.1+/-2.7 vs 7.4+/-3.3ml/min p=0.003) despite tending to be younger in this group. Analysing symptomatic and asymptomatic patients separately, both the age and gender effects were seen to be restricted to those patients with symptoms at dialysis initiation.

Males and older patients tend to start dialysis at a higher level of GFR when symptoms contribute to the decision but not when dialysis is initiated for biochemical reasons. These data suggest that gender, as well as age, influences the tolerance of uraemic symptoms. Whether this is the result of stoicism or differences in uraemic pathophysiology is unclear.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO103**

**Trend of Prevalence of Chronic Kidney Disease along with the Change in Pattern of Health-Related Behavior in the Korean Adult Population: Data from Korea National Health and Nutrition Examination Survey (KNHANES)** Seong-Woo Lee,[1] Sewon Oh,[2] Ho Seok Koo,[1] Ki Young Na,[1,2] Kwon Wook Joo,[1] Yon Su Kim,[1] Curie Ahn,[1] Dong Wan Chae,[1,2] Jin Suk Han,[1] Suhnggwon Kim,[1] Ho Jun Chin.[1,2] *[1]Internal Medicine, Division of Nephrology, Seoul National University College of Medicine, Seoul, Korea; [2]Internal Medicine, Seoul National Bundang Hospital, Seongnam, Korea.*

Background: Chronic kidney disease (CKD) is an increasing public-health problem. However, there have been limited data on the prevalence and trend of CKD in Korean adult population. Method: Data from 3rd and 4th KNHANES were used. A total of 14,938 participants with an age ≥20 years, with creatinine data, and with estimated glomerular filtration rate (eGFR) ≥15 ml/min/1.73m$^2$ were included for the analysis. Result: In the whole population, the proportion of CKD defined as eGFR < 60 ml/min/1.73m$^2$ was 7.5%. In 3rd KNHANES, the proportion of CKD was 8.8%, while 6.7% in 4th KNHANES (p <0.001). Mean age of participants in 3rd KNHANES was 47.2±15.3 years, while 49.3±16.3 years (p<0.001) in 4th KNHANES. In 3rd KNHANES, mean systolic and diastolic blood pressure were 119.3±17.9 mmHg and 77.3±10.8 mmHg, while 116.6±17.4 mmHg (p<0.001) and 75.1±10.7 mmHg (p<0.001) in 4th KNHANES, respectively. In 3rd KNHANES, 48.0% of participants walked over 60 minutes a day, while 57.5% did in 4th KNHANES (p<0.001). 14.1% of participants did strenuous exercise in 3rd KNHANES, while 15.4% did in 4th KNHANES (p=0.036). Total energy intake (1996.0±834.9 kcal/day vs. 1768.3±751.7 kcal/day; p<0.001) and sodium intake (5.7±3.3 g/day vs. 4.6±3.0 g/day; p<0.001) significantly decreased over the time. However, prevalence of hypertension (25.6% vs. 26.6%; p=0.200), diabetes (8.9% vs. 9.7%; p=0.101), obesity (32.6% vs. 31.9%; p=0.340) and proteinuria defined as dipstick ≥ 1+ (2.2% vs. 2.0%; p=0.479) were not changed over the survey period. Conclusion: In Korean adult population, proportion of CKD was deceased. This might be largely due to improved pattern of health-related behaviors, decreased blood pressure and stabilized prevalence of the other chronic diseases.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO104**

**Withholding Renal Replacement Therapy Does Not Explain the Low Incidence of ESRD in Iceland** Thorbjorg Karlsdottir,[1] Runolfur Palsson,[1,2] Olafur S. Indridason.[2] *[1]University of Iceland; [2]Division of Nephrology, Landspitali University Hospital, Reykjavik, Iceland.*

The incidence of treated ESRD in Iceland is lower than in most other Western countries. The aim of this study was to examine if this might be explained by withholding of renal replacement therapy (RRT) in a substantial proportion of patients with ESRD.

This was a retrospective study of all patients with ESRD in Iceland during the years 2000-2007, who did not receive RRT. We gained information from all health care institutions in Iceland on patients with serum creatinine levels >280 µmol/L (3.2 mg/dl) identified through electronic laboratory reports. Medical records of the patients were studied and death certificates examined. Primary care physicians and nephrologists were contacted for information on patients with advanced CKD. ESRD was defined as eGFR <15 ml/min/1.73 m$^2$, calculated by the MDRD study equation.

We identified 78 patients (43 males) who developed ESRD during the study period but did not receive RRT. In contrast, 164 patients initiated RRT yielding a total incidence of ESRD of 102.5/million/year. Thus, 32.2% of patients with ESRD did not receive RRT. Their mean age was 79.3 ±9.59 years, 73.1% were >75 years of age and they had on average 4 comorbid diseases. The last known eGFR averaged 9.6 ±3.44 ml/min/1.73 m$^2$ and 31 patients had eGFR between 10 and 15. A nephrologist was involved in the care of 76% of patients. In 36% of cases, the treating physician did not recommend RRT, 23% of the patients declined RRT and in 18% the decision not to use RRT was made jointly by the patient and the physician. Six patients (8%) were prepared for RRT but died before it could commence and in 10 patients (13%) with well compensated stage 5 CKD, no decision regarding RRT had been made as it was not considered necessary. Nine patients were alive at the end of the study. The most common causes of death were cardiovascular diseases (54%) and kidney failure (23%).

One third of patients who develop ESRD in Iceland do not receive RRT. However, the total incidence of ESRD remains low compared to other Western nations. Most of the untreated patients are elderly and burdened by comorbidity and, thus, may not benefit from RRT.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO105**

**Propensity Score Matched Evaluation of Epoetin Alfa and Darbepoetin Alfa Utilization in Patients with Chronic Kidney Disease Not on Dialysis**
Robert A. Bailey,[1] Ozgur Tunceli,[2] Joseph Singer,[2] Judith Stephenson,[2] Mekre Senbetta.[1] *[1]Health Economics and Outcomes Research, Centocor Ortho Biotech Services, LLC, Horsham, PA; [2]HealthCore, Inc., Wilmington, DE.*

**Purpose:** To examine epoetin alfa (EPO) and darbepoetin alfa (DARB) treatment patterns and corresponding erythropoiesis stimulating agent (ESA) costs in patients with chronic kidney disease not on dialysis (CKD-NOD). Additionally, we compared the results observed in the total study population with a propensity score matched population to account for potential baseline difference that may affect ESA use.

**Methods:** A medical claims analysis was conducted from 1/1/2004-7/31/2009 using the HealthCore Integrated Research Database. Patients were age ≥18 years, newly initiated on EPO or DARB, received ≥2 doses, and had ≥1 claim for CKD prior to treatment. Patients with cancer, receiving chemotherapy or dialysis, or treated with both agents were excluded. Mean cumulative ESA dose and drug costs were evaluated in the total population and a propensity score matched population. Propensity score matching was used to identify similar populations in the EPO and DARB groups for comparison. January 2010 Wholesale Acquisition Cost was used to calculate drug cost.

**Results:** In the ESA-treated, CKD-NOD population, 1,660 EPO patients and 1,175 DARB patients were identified. Mean (SD) cumulative EPO dose was 300,596 (468,371) units for EPO and 1,205 (1,824) mcg for DARB. The mean drug cost was $4,554 for EPO and $6,279 for DARB (27% higher cost for DARB). The observed dose ratio (EPO units/ DARB mcg) was 244:1. The propensity score analysis identified 1,083 ESA treated CKD-NOD patients in each of the EPO and DARB groups that were not clinically different. Mean (SD) cumulative ESA dose was 299,194 (456,467) units for EPO and 1,185 (1,776) mcg for DARB. The mean drug cost was $4,533 for EPO and $6,174 for DARB (27% higher cost for DARB). The observed dose ratio (EPO units: DARB mcg) was 253:1.**Conclusion:** This study of ESA use in CKD-NOD observed higher drug costs for DARB compared with EPO. The observed cost difference and dose ratios were similar between the total study population and propensity score matched population.

**Assessing Which Clinical Parameters Nephrologists Use When Predicting Rapid Progression of Chronic Kidney Disease**
Darren Green, Richard Hoefield, Aaron Poppleton, David I. New, Philip A. Kalra. *Dept. of Renal Medicine, Salford Royal Hospital, Salford, United Kingdom.*

For patients with chronic kidney disease (CKD) approaching dialysis, modality choice and timing of vascular access can affect survival and patient satisfaction. Accurate prediction of time to dialysis is therefore an important tool for the renal clinician.

The CRISIS prospective epidemiological investigation of CKD stages 3-5 has reported which clinical factors are associated with rapid progression of CKD. In this study, we analyzed which clinical factors most strongly influence physicians' assessment of when a patient will need dialysis. By comparing these data with data from CRISIS, factors which physicians over or undervalue when predicting time to dialysis can be evaluated.

Nephrologists seeing patients in a pre-dialysis clinic were asked to predict the time to dialysis for each patient, based on clinical information available during the consultation. The clinic was held at the hospital where CRISIS patients had been enrolled to give similar demographics. Multi-variate regression was used to define which factors were associated with the predictions of time to dialysis.

During the study, 6 clinicians assessed 124 patients. Baseline data compared to CRISIS were as follows: mean age = 64.8 years (vs. CRISIS = 65.1 years), gender = 62.9% male (vs. 63.7%), diabetes = 31.5% (vs. 32.0%). Factors associated with perceived likelihood of rapid progression to dialysis by clinician were MDRD calculated eGFR ($p<0.001$), and the presence of proteinuria ($p<0.001$), hypoalbuminemia ($p=0.002$), hyperphosphatemia ($p<0.001$) and anemia ($p=0.044$). Of these, multi-variate analysis of >1300 CRISIS patients has shown eGFR, anemia and proteinuria to be significant in predicting rapid progression of CKD. CRISIS also showed that younger age, male sex, current smoker, and hypertension were significant.

This study suggests that not all predictive parameters are used by clinicians when assessing time to dialysis but that only hyperphosphatemia and hypoalbuminemia are overvalued as predictors. Highlighting these discrepancies may improve physicians' judgement in the pre-dialysis setting and improve patient outcome and satisfaction.

**TH-PO107**

**Hypertension Awareness, Treatment, and Control in the Korean Adult Population with and without Diabetes or Chronic Kidney Disease: The Fourth Korea National Health and Nutrition Examination Survey 2008**
Sang-Woong Han,[1,5] Ho-Jung Kim,[1] Joo-Hark Yi,[1] Ju-Hyun Lee,[1] Hyeong Cheon Park,[2] Sang Youb Han,[3] Bumsoon Choi,[4] Bo Youl Choi.[1,5] *[1]Hanyang University College of Medicine, Korea; [2]College of Medicine,Yonsei University, Korea; [3]Inje University, Ilsan-Paik Hospital, Korea; [4]The Catholic University of Korea, Korea; [5]Center for Healthy Aging and Longevity, Hanyang University Institute of Aging Society, Korea.*

Hypertension (HTN) is a well-established risk factor for cardiovascular disease and is common in diabetic or chronic kidney disease (CKD) patients. We aimed to analyze HTN awareness, treatment, and control in adults with and without diabetes or CKD, according to recent guidelines which recommend more stringent blood pressure (BP) control in high risk patients. A cross-sectional study of a representative sample of the Korean adult population (≥30 years old) was conducted using 5,923 participants in the 2008 KNHANES IV-2. HTN was defined as a BP of ≥140/90 mmHg for those without diabetes or CKD and as ≥130/80 mmHg for those with diabetes or CKD (an estimated GFR of <60 mL/ min/1.73 $m^2$ calculated by the MDRD equation). In 2008, the estimated prevalence of HTN, diabetes and CKD were 27.7%, 10%, and 5.9%, respectively. The estimated prevalence of HTN among the population with diabetes or CKD were 70% and 68.1%, respectively. Awareness, treatment, and control of HTN in the Korean adult population without diabetes or CKD were 59.2%, 51.6%, 36.8 % and 65 %, 59.9%, 22.6% in those with diabetes or CKD, respectively. Compared to the hypertensive population without diabetes or CKD (n=1,193), those with diabetes or CKD (n=625) were older (64±11.6 vs 59.4±13.3 yrs, $p<0.0001$), in lower education ($p=0.0018$) and in lower BP (systolic BP, 131.8±16.5 vs 134.3±16.5 mmHg, $p=0.0039$; diastolic BP, 79.6±10.8 vs 84.6±11.4 mmHg, $p<0.0001$) This study suggested that despite higher awareness and treatment of HTN, and lower level of BP in addition to higher prevalence, HTN remains poorly controlled in the Korean adult population with diabetes or CKD. Therefore, optimal management of HTN by health care personnel in this high risk population is strongly recommended.

**The Incidence of Pauciimmune Glomerulonephritis in Lancashire and South Cumbria (North-West of England)**
Sophie Louise Bennett, Alexander Woywodt, Ajay Prabhakar Dhaygude. *Renal Medicine, Royal Preston Hospital, Preston, Lancashire, United Kingdom.*

Pauciimmune glomerulonephritis (PIGN) is the most common cause of rapidly progressive glomerulonephritis in adults. Most of these patients produce Anti Neutrophil Cytoplasmic Autoantibodies (ANCA). Incidence of PIGN varies according to geographical region and ethnicity. This study investigated the incidence of PIGN in North-West England over a 5-year period. The population of adults in this area in the 2001 census was 1.2million; 95.3% were Caucasian, 3.7% were Indo-Asian and 0.2% were Afro-Caribbean.

**Methods** Data from archived records was used to identify patients with histological evidence of PIGN between 1st January 1999 and 31st December 2003. The criteria for inclusion were cellular or fibrocellular crescents, tuft necrosis or vasculitis. Only patients with PIGN first detected within the study period and who were aged >17-year were collected.

**Results** Sixty-four cases were identified over 5-years with an overall annual incidence of 10.5 patients per million of the adult population. Thirty-five of these were under 65-years at diagnosis and 29 patients were at least 65-years old. Of the younger group, 20 were alive at 5-years compared to 12 in the older group (6 patients were lost to follow up). The male to female ratio was 37:27. Most patients (44) were Caucasian; 2 were Indo-Asian and 1 patient was Afro-Caribbean (ethnicity data unavailable for 17 patients). Forty-two patients were ANCA positive; 22 cANCA/PR3-ANCA. Fifteen patients were ANCA negative and data was not available for 7 patients.

**Conclusions** Our results are very similar to those found in a study in Greater Manchester over the same time period (ASN 2007 poster by Dhaygude et al). Estimates in the latter were of 9.8 per million of the adult population; this is in contrast to findings in South-West USA where the estimate was 3.1 per million population (13th International ANCA Workshop poster by Hogan et al). This supports the findings of other studies concerning regional variation and an increase in incidence with further distance north. Further studies are needed to determine the importance of environmental and genetic factors in affecting this distribution of cases.

**Canadian Pediatric IgAN/HSP: Baseline Patient Characteristics from the REDDCAPP Registry** Maury N. Pinsk,[1] Chantal Bernard,[5] Janusz Feber,[7] Ian W. Gibson,[2] Aviva M. Goldberg,[2] Christoph Licht,[3] Aicha Merouani,[6] Andrew W. Wade,[4] Tom D. Blydt-Hansen.[2] *[1]University of Alberta, Edmotnon, AB, Canada; [2]University of Manitoba, Winnipeg, MB, Canada; [3]University of Toronto, Toronto, ON, Canada; [4]University of Calgary, Calgary, AB, Canada; [5]McGill University, Montreal, QC, Canada; [6]Universite de Montreal, Montreal, QC, Canada; [7]University of Ottawa, Ottawa, ON, Canada.*

The Renal Disease Database in the Canadian Pediatric Population (REDDCAPP) is a multicentre effort to track the incidence and characteristics of IgA nephropathy (IgAN) and Henoch Schoenlein purpura nephropathy (HSPN) in Canadian children. Methods: Pediatric patients with biopsy-proven IgAN/HSPN were enrolled from four Pediatric Nephrology centres across Canada from 2008-2010. Results: 30 patients (47% were males) with complete data sets were included in the analysis. 53% were self-declared Aboriginal/ First Nations, 27% were Caucasians, and the remainder were from South Asian/East Asian or Latin American Countries. The mean age at biopsy was 10.8 ± 3.8 years. 36.7% of the patients had a BMI>26 kg/m$^2$, and 37% of patients presented with hypertension (7% >90th percentile, 30% >95th percentile). Presentation as HSPN occurred in 47%. Presenting signs were macrohematuria (63%) and microhematuria (33%). One patient without hematuria presented with nephrotic syndrome. Urine protein creatinine ratio (UPCR)was < 20 mg/mmol in 6%, 20-200 mg/mmol in 33% and >200 mg/mmol in 61% . The average UPCR was 631 mg/mmol (range 11-2641) compared to normal value of <20 mg/mmol. Renal function was abnormal in 20% with 7% CKD II, 10% CKD III and 3% CKD IV. No patients presented with a GFR < 15 ml/min/1.73m$^2$. No patient presented with low serum C3, although 38% had C4 levels below 0.16 g/L. Conclusion: A significant proportion of Canadian children who were biopsied with IgAN/HSPN suffer from hypertension (37%), proteinuria (94%) and decreased renal function (20%).

Disclosure of Financial Relationships: nothing to disclose

**TH-PO110**

**Low Serum Albumin Associated with Death in Patients with Chronic Kidney Disease** Rebecca J. Schmidt, Bethany S. Pellegrino. *Nephrology, West Virginia University, Morgantown, WV.*

Serum albumin is known to correlate with survival in patients on dialysis. Albumin levels of patients starting dialysis in the United States have changed little since 1996 (3.1-3.2) g/dl) and in our rural West Virginia dialysis patients low albumin levels are the norm.

Albumin values from 5406 patients with Stages 3-5 chronic kidney disease (CKD) seen between January 1, 2001 and May 31, 2010 were analyzed. Values at first presentation to the CKD clinic were utilized. Age of the patient population (mean±SD ) was 65.7±16.67 and 57% of the group was older than 65. Less than 3% of the group was African American, the predominant race being white (93.41%).

Mean albumin levels were similar for gender (mean±SE: 3.58±0.023 for females vs. 3.54±0.025 for males) and did not correlate with age. Almost half (44%) of Stage 3-4 patients presented with albumin levels ≤3.5 g/dl and for Stages 3-5, 34%, 42% and 70% of patients presented with albumin levels ≤3.5. Mean±SD for WV CKD patients ranged from 3.37±0.75 for Stage 3 to 3.16±0.74 for Stage 5.

Albumin levels for patients who ultimately died prior to starting dialysis were significantly less than for those who did not (3.21±0.05 vs. 3.61±0.02 (mean±SE); P< 0.0001.

The prognostic value of low albumin in non-dialysis-dependent CKD patients has been suggested to portend similar adverse outcomes, though prevalence of albumin levels ≤ 3.5 among those with higher levels of renal function is not widely reported.

In our patient population, a low serum albumin at first presentation was associated with a higher likelihood of death and perhaps represents an adjunctive marker of prognosis in CKD patients moving toward dialysis.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO111**

**Low Serum Albumin Common in Rural Patients with Chronic Kidney Disease** Rebecca J. Schmidt, Bethany S. Pellegrino. *Nephrology, West Virginia University, Morgantown, WV.*

Serum albumin is known to correlate with survival in patients with on dialysis and low levels are an Achilles heel for many caregivers of dialysis patients. Albumin levels of patients starting dialysis in the United States have changed little since 1996 (3.1-3.2) g/dl) and in our rural West Virginia dialysis patients, low albumin levels are the norm.

Albumin values from 5406 patients with chronic kidney disease (CKD 3-5) seen between January 1, 2001 and May 31, 2010 were analyzed. Values at first presentation to the CKD clinic were utilized. Age of the patient population (mean±SD ) was 65.7±16.67; 57% were older than 65. Less than 3% were African American, the predominant race being white (93.41%).

Mean albumin levels were similar for all CKD patients of both genders (mean±SE: 3.58±0.023 for females vs. 3.54±0.025 for males) and did not correlate with age or year of visit. Mean levels ≤ 3.5 g/dl were highly prevalent (45%) in all stages of CKD among our rural patients and also among those < 65 years of age. Albumin levels for WV CKD patients are shown with NHANES data for the US general population by stage below, along with percents of WV CKD patients with albumin levels ≤ 3.5 g/dl compared with data from a large integrated health system (Go 2004) below:

CKD Albumins

| | WV CKD Patients | US General Population | WV CKD with Albumin ≤ 3.5 (%) | Large Health Care System with Albumin ≤ 3.5 (%) |
|---|---|---|---|---|
| Stage 3-45-59 | 3.66±1.00 | 4.2±0.01 | 10.6% | 2.8% |
| Stage 3-30-44 | 3.63±0.58 | 4.1±0.03 | 21.5% | 5.8% |
| Stage 4-15-29 | 3.54±0.67 | 4±0.04 | 41.8% | 13.7% |
| Stage 5 <15 | 3.14±0.79 | 4.1±0.02 | 70.4% | 24% |

p < 0.0001 for WV CKD vs. NHANES IIII population and large health care system

Compared to the NHANES III population and members of a large health care system, WV CKD patients had significantly greater prevalence of hypoalbuminemia at varying levels of renal function. Low albumin levels present earlier in the continuum of CKD likely contribute to the persistently low albumin levels seen in patients starting dialysis and the particularly high prevalence of hypoalbuminemia in WV dialysis patients.

**Effect of Statin on Muscle Sympathetic Nerve Activity in Patients with Chronic Kidney Disease** Laima Siddiqi,[1] Liam P. Oey,[2] Peter J. Blankestijn.[1] *[1]Nephrology and Hypertension, University Medical Center Utecht, Utrecht, Netherlands; [2]Neurophysiology, University Medical Center Utecht, Netherlands.*

Background: Hypertensive chronic kidney disease (CKD) patients often have sympathetic hyperactivity which appears to contribute to the pathogenesis of hypertension and cardiovascular organ damage. Experimental studies and some clinical studies have shown that statin therapy can reduce central sympathetic activity by different mechanisms. The aim of this study was to evaluate the effect of 6 weeks treatment with statins (Lipitor 20mg/day) added renin inhibitors on sympathetic activity in hypertensive stage 2-4 CKD patients.

Methods: In ten CKD patients (8 males, aged 44 ± 11 years, eGFR 59 ± 22 ml/min per 1.73 m$^2$) blood pressure and sympathetic activity (quantified by assessment of muscle sympathetic nerve activity, MSNA) were assessed, while lipitor 20mg/day was added to renin inhibitor (aliskiren 300mg/day), and during 6 weeks only aliskiren 300 mg/day. Total cholesterol and low-density lipoprotein (LDL), high-density lipoprotein (HDL) and triglyceride levels were measured before and after treatment with Lipitor.

Results: Mean arterial blood pressure remained stable throughout the study (93 ± 5 with Lipitor vs 94 ± 5 without Lipitor 20mg/day). MSNA was reduced from 32 ± 8 to 25 ± 6 bursts/minute (P = 0.01) while heart rate remained stable during the study (62 ± 2 with Lipitor vs 61 ± 3 without Lipitor). Total cholesterol and LDL, HDL and triglyceride levels were elevated when patients were off medication however, the difference was not significant. Conclusion: Addition of statin on renine inhibitors has a substantial sympatholytics effect in hypertensive CKD patients, while blood pressure and heart rate remain unchanged.

**Clinical and Pathological Phenotype of Leukocyte Cell-Derived Chemotaxin-2 Amyloidosis (ALECT2)** Julian D. Gillmore,[1] Jennifer H. Pinney,[1,2] Janet Gilbertson,[1] Simon Gibbs,[1] Prayman Sattianayagam,[1] Ashutosh D. Wechalekar,[1] Helen J. Lachmann,[1] Ahmet Dogan,[3] Philip Hawkins.[1] *[1]National Amyloidosis Centre, Division of Medicine, UCL Medical School, London, United Kingdom; [2]Centre for Nephrology, Division of Medicine, UCL Medical School, London, United Kingdom; [3]Departments of Laboratory Medicine and Pathology and Haematology, Mayo Clinic, Rochester, MN.*

LECT2 is a chemokine and growth factor that was recently identified as a novel amyloid fibril protein from renal biopsy specimens. In this study, we report the clinical and pathological features in 7 patients with LECT2-associated amyloidosis (ALECT2).

Diagnosis was confirmed in all patients by histology and mass spectrometry based proteomic analysis of amyloid deposits. Deposition of LECT2 amyloid within kidney biopsy specimens was mainly interstitial and vascular with relative sparing of the glomeruli. The LECT2 gene and promoter region was sequenced in all cases. Although no novel mutations were identified within the coding region, all patients were homozygous for a described non-synonymous SNP.

Median age at presentation was 62 (52-70) years. Five patients were Punjabi and 2 were North African. Six of 7 patients presented with low level proteinuria (median 0.5 g/24hr) and/or renal impairment (median eGFR 32 ml/min). In the remaining patient, LECT2 amyloid deposits were incidentally discovered in a liver biopsy for unrelated liver disease. No patient had amyloid involvement of the heart or nerves, and none had a family history. Amyloid was imaged in the spleen and kidneys by SAP scintigraphy in all 7 patients, and the liver and adrenal glands were also involved in 4 and 6 cases respectively.

Median follow up was 24 (6-49) months during which no patient developed extra-renal amyloidotic organ dysfunction. GFR was stable or declined slowly in all patients (range 0-10 ml/min/yr).

ALECT2 is characterized by renal, splenic, hepatic and adrenal amyloid deposition and a clinical picture of slowly progressive chronic kidney disease with low level proteinuria. The pathogenesis of ALECT2 remain unclear. Accurate recognition of ALECT2 amyloidosis is essential to avoid inappropriate treatment for other types of amyloidosis.

**TH-PO114**

**High Prevalence of CKD May Be Socioeconomically Driven** Rebecca J. Schmidt, Bethany S. Pellegrino. *Nephrology, West Virginia University, Morgantown, WV.*

Chronic kidney disease (CKD) has reached epidemic proportions nationwide, and in 2007, West Virginia led the nation in numbers of patients starting dialysis (434.3 vs 353.8 per million). The state's high prevalence of diabetes (12 vs 7% nationally), along with its older population (15.7% > 65 years) and the geographic distance to specialty care likely contribute to the high prevalence of CKD.

A predominantly rural state of 1.8 million people, West Virginia has a high prevalence of non-Hispanic whites (93.5% vs 65.6% for US) with an African American prevalence of 3.6% (vs 12.8% for US). Compared to national figures, the percent of West Virginians living below the federal poverty level (%<FPL) in 2008 was 17.4% compared to 13.2% nationally. Median household income is $37,528 compared to $52,029 for the US.

Of 5406 patients with CKD Stages 3-5 seen from 54 counties in West Virginia between January 1, 2001 and May 31, 2010, African Americans comprised 3.0% and the prevalence of non-Hispanic whites was 93.4%. These estimates differ significantly ($p<0.0001$) from national CKD data, which report a prevalence of 7.3% for African American and 87.3% for non-Hispanic whites (UDRDS).

Of the 29 counties represented by 4532 patients total, two had a lower %<FPL than the national average and only one county had a median income exceeding the national average of $52,029. Median household income ($35,896) and % <FPL (17.6) for the CKD group was similar to the state overall. No African American patient came from a county where the %<FPL exceeded 16.4%. Only two counties were represented by African American patients; these counties had median household incomes exceeding those of 21 other counties.

No state started more patients on dialysis in 2007 than West Virginia, reflecting the high prevalence of CKD. The proportion of African Americans in our CKD population is lower than that of the nation. More West Virginians than the national average live at levels below the FPL and have lower median household incomes. Socioeconomic factors, irrespective of race, may impact the prevalence of CKD and additional study is warranted to ascertain the strength and independence of this potential risk.

**A Ten-Year Review of Percutaneous Kidney Biopsies in an Adult Afro-Caribbean Population. Specific Place of Lupus Nephritis** Jean-Marc Roger Dueymes-Laporte,[1] Raluca Ples,[2] Christophe Deligny,[4] Alex Ranlin,[1] Maryvonne R. Dueymes,[3] Hawa Traore.[1] *[1]Nephrology Department, Centre Hospitalier, Lamentin, Martinique, Martinique; [2]Anatomo-Pathology Laboratory, Centre Hospitalier Universitaire, Fort de France, Martinique; [3]Immunology Laboratory, Centre Hospitalier Universitaire, Fort de France, Martinique; [4]Internal Medicine Department, Centre Hospitalier Universitaire, Fort de France, Martinique.*

Objectives

A retrospective ten-year study (2000-09) study of histological findings obtained by kidney biopsy (KB) was made in the only Nephrology Dpt of a French West Indies Island (400000 inhabitants).The aim of the study was to review histological aspects of primary and secondary glomerulonephritis (GN), with special attention to Lupus Nephritis(LN).

Methods

Clinical and histological reports were reviewed for KB performed in the Nephrology Department from 2000 to 09. Different Data were collected from the Histology requisition form.

Results

243 biopsies(147female, 96male) were performed. Creatininemia was under 120micromol/l in 51%, over 300micromol/l in 20%, proteinuria over 3gr/24h in 171patients. Post biopsy,10pts had a transient gross hematuria or peri-renal hematoma. The biopsy was usable for histology examination in 93%. Membranous glomerulonephritis (MGN)was observed in 61 pts(27%),Focal Segmental GN (FSGN) in 37pts(16%), MPGN in 33pts, Minimal Change in 27pts. Vascular lesions were observed in 58% and tubulo-interstitial lesions in 77%.GN was primitive in 85pts(38%), secondary to systemic disease in 158pts. 75/158 were LES with Lupus Nephritis LN(47.4%). Histology of LN according to the ISN/RPS 2003 classification showed classIV in 32pts, classV in 23pts, classIII in 12pts,classII in 7pts.LN patients tested positive for antiRNP(58.7 %),antiSSA(47.2 %),antiSm(37.1%). Epidemiological parameters of LN pts were found to be similar to those described in a previous ten-year period in the same population.

Conclusion

In this Afro-Caribbean population, the most common histological findings following KB for Primary GN were MGN, FSGS, MPGN.For LN, diffuse proliferative and Membranous GN were the main types (73.3%).

**Long Term Follow-Up of Overweight and Obese Living Kidney Donors** H. Tent,[1] Mieneke Rook,[1] Hendrik Sijbrand Hofker,[2] Rutger J. Ploeg,[2] Jaap Homan vd Heide,[1] Gerjan Navis.[1] *[1]Internal Medicine Division of Nephrology, University Medical Center Groningen, Netherlands; [2]Surgery, University Medical Center Groningen, Netherlands.*

Due to donor organ shortage, living kidney donor selection has become more liberal with acceptation of overweight and obese donors. We found that early after donation overweight donors have a higher risk for impaired GFR and lower renal reserve. Whether this results in a worse long term outcome is unknown.

We evaluated 5–year outcome in 64 donors who donated at our center. All had GFR ($^{125}$I-iothalamate) and ERPF ($^{131}$I-hippuran) measured 4 months prior, and 2 months and 5.2±1.1 year after donation. Delta GFR from 'single kidney status' was calculated as [GFR long term – (pre-donation GFR/2)].

Results are shown in the table, with a break-up for pre-donation BMI. On regression analysis ΔGFR was associated negatively with pre-donation age ($R^2$ 0.13, $p<0.05$), but not with BMI. Long term blood pressure was positively related to age and BMI ($R^2$ 0.18 and 0.08, $p<0.05$). No proteinuria occurred pre- and post-donation.

In conclusion, in this small population overweight donors have lower ERPF prior and higher blood pressure prior and post-donation. However, long term course of renal function is equal to lean donors and not determined by BMI. We want to emphasize that although these overweight donors perform well, close long term monitoring and adequate blood pressure treatment remains necessary.

| BMI pre-Unx | BMI<25 | BMI 25-28 | BMI≥28 |
|---|---|---|---|
| N (%male) | 28 (40) | 20 (45) | 16 (38) |
| Age at Unx (years) | 44±12 | 48±8 | 53±9* |
| Duration of follow-up (years) | 5.3±1.3 | 5.3±0.8 | 4.9±1.1 |
| BMI pre-Unx | 23±2 | 27±1 | 32±5 |
| BMI early post-Unx | 23±2 | 27±1* | 31±5*$ |
| BMI long term post-Unx | 24±2 | 27±2* | 33±6*$ |
| GFR pre-Unx | 113±13 | 118±19 | 117±24 |
| GFR early post-Unx | 74±11 | 74±10 | 76±12 |
| GFR long term post-Unx | 81±14 | 84±12 | 84±12 |
| ΔGFR to long term | 26±10 | 24±10 | 25±8 |
| ERPF pre-Unx | 435±84 | 449±56 | 397±64$ |
| ERPF early post-Unx | 295±57 | 295±37 | 280±48 |
| ERPF long term post Unx | 300±62 | 292±36 | 290±56 |
| MAP pre-Unx | 87±8 | 93±9* | 97±8* |
| MAP early post-Unx | 92±9 | 93±7 | 98±6*$ |
| MAP long term post-Unx | 92±8 | 92±9 | 99±9*$ |

Unx: donation. *$p<0.05$ vs BMI<25; $p<0.05$ vs BMI 25-28. (Δ)GFR and ERPF in mL/min, MAP in mmHG.

**TH-PO117**

**A Randomized Controlled Trial of Enzyme Replacement Therapy in Fabry Disease: The Canadian Fabry Disease Initiative at Year Three** Michael L. West,[1] Daniel G. Bichet,[2] Sandra Sirrs,[3] Christiane Auray-Blais.[5] *[1]Medicine, Dalhousie University, Halifax, NS, Canada; [2]Medicine, Universite de Montreal, Montreal, NS, Canada; [3]Medicine, University of British Columbia, Vancouver, BC, Canada; [4]Pediatrics, Universite de Sherbrooke, Sherbrooke, QC, Canada.*

Fabry disease is a rare X-linked lysosomal storage disorder which causes cardiomyopathy, renal failure, strokes and death by 60 years if untreated. Enzyme replacement therapy (ERT) with recombinant agalsidase is not reimbursed in Canada by government due to high cost and lack of clinical effectiveness. The Canadian Fabry Disease Initiative (CFDI) study provides ERT (agalsidase alfa 0.2 mg/kg or agalsidase beta 1.0 mg/kg I.V. every 2 wks) to Fabry patients and collects outcomes data (Clinical Trial Registration protocol # NCT 00455104). Fabry patients ages 5 - 85 years in Canada are eligible with cohort 1a those on prior ERT; cohort 1b ERT naïve patients who meet Canadian ERT guidelines; cohort 1c those refusing or not meeting ERT criteria. Patients are randomized In cohort 1b to agalsidase alfa or beta. Data are collected prospectively as to clinical outcomes (eGFR, proteinuria, LVMI, unstable angina, MI, PTCA, ICD, pacemaker, CHF, arrhythmia, hospitalization, stroke, TIA, acute deafness, death), MSSI, quality of life, and pain. Over 36 mos 277 patients were enrolled with data available on 266: cohort 1a 30.2%, cohort 1b 21.5% and cohort 1c 48.9%. Mean duration of follow up was 23.0 mos. In cohort 1b, females predominated (34, 63.0%) over males (20, 37.0%) but were balanced between the agalsidase treatment groups. Clinical features at baseline did not differ in the two treatment arms. Anti-agalsidase antibodies were more prevalent and of higher titre in the agalsidase beta group. Urine globotriaosylceramide was lower with ERT and in females. Outcomes data in cohorts 1a and 1b up to 30 months showed no differences between agalsidase-alfa and agalsidase-beta. Similar results were seen with a composite clinical outcome. In the short term no significant differences in clinical outcomes can be shown between agalsidase alfa and beta for Fabry disease.

**Adverse Renal Outcomes after Nephrectomy for Renal Tumours: A Population-Based Analysis** Scott Klarenbach,[1] Ron Moore,[2] Dave Chapman,[1,2] James Dong,[1] Branko Braam.[1] *[1]Medicine/Nephrology, Univ. of Alberta, Edmonton, Canada; [2]Surgery/Urology, Univ. of Alberta.*

Oncologic outcomes are excellent for early stage renal cell carcinoma (RCC). However, patients may be at risk for chronic kidney disease (CKD) given the shared risk factors of HTN, smoking, and age. We sought to describe adverse renal outcomes in a population-based cohort of subjects undergoing partial (PN) or radical nephrectomy (RN) for renal tumors, and identify baseline risk factors associated with poor renal outcomes.

All subjects undergoing nephrectomy for renal tumors between 2002 and 2009 were identified from inpatient encounters using ICD9/ICD-10 codes. Baseline comorbid conditions (including DM, HTN, CVD, CHF, and Charleson Comorbidity), proteinuria status, and eGFR was determined. Descriptive statistics and Cox proportional hazards were used, and the composite outcome of CKD (eGFR < ml/min/1.73m$^2$), rapid CKD progression (eGFR <60 and delta eGFR ≥4 ml/min/1.73m$^2$/year), or acute or chronic renal replacement therapy was considered.

Over follow-up of 1,151 patients, 23 (2.0%) developed ESRD or required acute dialysis, 114 (9.9%) developed CKD, and 24 (2.1%) developed rapidly progressive CKD. The 132 (11.5%) subjects that developed an adverse renal outcome were older, had lower baseline eGFR, and had more concomitant comorbidity. In adjusted analysis, partial nephrectomy was associated with a HR of 0.56 (95% CI 0.33-0.96) of adverse renal outcomes. In addition to lower baseline eGFR, greater Charlson Comorbity score and presence of proteinuria were also associated with adverse renal outcomes, with HR of 1.12 (1.02-1.23) and 2.44 (1.54-3.87) respectively.

In this large population based cohort of patients undergoing nephrectomy for renal masses, baseline renal function and proteinuria were important predictors of adverse renal outcomes. Renal outcomes were negatively affected by RN versus PN. The study supports routine assessment of eGFR, proteinuria and comorbidity prior to surgery to assist in the decision for RN or PN, and identify high risk patients for follow-up.

**TH-PO119**

**Cost-Effectiveness of Paricalcitol in Type 2 Diabetes, Nephropathy, and Residual Albuminuria** Hiddo Jan Lambers Heerspink,[1] Mark Nuijten,[2] Steven E. Marx,[3] Raimund K. Sterz,[3] Dick De Zeeuw.[1] *[1]University Medical Center, Groningen, Netherlands; [2]Ars Accessus Medica, Erasmus University, Rotterdam, Netherlands; [3]Abbott, Abbott Park, IL.*

**Introduction:** The Selective Vitamin D Receptor Activator for Albuminuria Lowering (VITAL) Study showed that paricalcitol at doses of 2 mcg per day significantly reduced residual albuminuria over 6 months in addition to ACEI and/or ARB therapy. The objective of this analysis is to assess the cost-effectiveness of paricalcitol with ACEI and/or ARB therapy in type 2 diabetic patients with nephropathy.

**Methods:** A Markov model was used to simulate the progression from microalbuminuria to end stage renal disease. We use data from the VITAL study and published literature (Delea JASN 2008) to estimate probabilities of progression of renal disease, utilities and costs. The comparator was ACEI and/or ARB therapy compared to ACEI and/or ARB therapy plus paricalcitol 2 mcg per day. The data was analyzed from a US healthcare payer perspective, using 2007 costs and discounted at 3%. The efficacy outcome, reduction in urinary albumin creatinine ratio, was extrapolated to lifetime life-years gained (LYS) and quality adjusted life-years gained (QALY).

**Results:** Compared to ACEI and/or ARB therapy, the addition of paricalcitol 2 mcg per day leads to additional lifetime healthcare costs of $9,622 (USD). The health benefits of paricalcitol lead to an increase in LYG of 0.411 and a gain in QALYs of 0.498. The use of paricalcitol results in an incremental cost-effectiveness ratio of $19,333/QALY and $23,387/LYS. These values are in a range which is accepted as cost-effective (<$50,000/QALY).

**Conclusion:** This model showed increase in life expectancy and quality-adjusted life years saved. The additional lifetime costs for paricalcitol were offset by the savings associated with delayed in chronic kidney disease progression. The addition of paricalcitol 2mcg per day to ACEI and/or ARB therapy in patients with type 2 diabetes and nephropathy is cost-effective from a US healthcare perspective.

**Temporal Hemoglobin Trends in Erythropoiesis-Stimulating Agent Treated Chronic Kidney Disease Patients Not on Dialysis** Robert A. Bailey,[1] Marie-Helene Lafeuille,[2] Isabelle Raymond,[2] Mekre Senbetta,[1] Patrick Lefebvre.[2] *[1]Health Economics and Outcomes Research, Centocor Ortho Biotech Services, LLC, Horsham, PA; [2]Group d'Analyse, Ltee, Montreal, QC, Canada.*

**Purpose:** To evaluate hemoglobin (Hb) values over time in patients with chronic kidney disease (CKD) not on dialysis treated with erythropoiesis-stimulating agents (ESAs).

**Methods:** Data on CKD patients receiving ESAs in nephrology clinics in the United States collected between November 2001 and December 2009 were analyzed. Visits associated with ESA treatment and a Hb value were selected for analysis. Patients receiving renal dialysis were excluded. Hemoglobin values were reported as either baseline or on ESA treatment and were categorized in this manner for analysis. Mean baseline and on-treatment Hb values were evaluated by semester (S1: Jan-Jun; S2: Jul-Dec) and for two distinct periods: Pre-Kidney Disease Outcomes Quality Initiative (KDOQI) period (visits prior to 04/01/2007), and Post-KDOQI period (visits on 04/01/2007 or after).

**Results:** A total of 10,053 (baseline: 1,109, on-treatment: 8,944) Hb values associated with ESA treatment were analyzed. Mean hemoglobin (SD) was 10.4 (1.3) g/dL at baseline and 11.2 (1.3) g/dL for on-treatment. Semi-annual mean baseline and on-treatment Hb were relatively stable over the study period (across semesters, g/dL: Baseline: mean (SD): 10.4 (0.2), median: 10.3, 25$^{th}$ and 75$^{th}$ percentiles: 10.2 and 10.6; On-treatment: mean (SD): 11.2 (0.3), median: 11.2, 25$^{th}$ and 75$^{th}$ percentiles: 11.0 and 11.5). The proportion of Hb values ≥12 g/dL decreased from 12.0% in the Pre-KDOQI period to 2.9% in the Post-KDOQI period for baseline (*P*<.0001) and from 28.5% to 15.2% for on-treatment visits (*P*<.0001).

**Conclusions:** This study observed a stable trend in Hb values and a reduction in the proportion of hemoglobin readings greater than 12 g/dL over the period from November 2001 to December 2009 in CKD patients not on dialysis receiving ESAs in nephrology clinics.

**TH-PO121**

**Comparative Effectiveness of Incident Oral Antidiabetic Drugs (OADs) on Kidney Function in Veterans with Type 2 Diabetes** Adriana Hung,[1,2] Christianne Roumie,[1,2] Robert Greevy,[1,2] Xulei Liu,[1,2] Carlos Grijalva,[1,2] Harvey J. Murff,[1,2] M. M. Huizinga,[3] Marie Griffin.[1,2] *[1]Medicine, Vanderbilt University, TN; [2]GRECC, VA Tennessee Valley Healthcare System, TN; [3]John Hopkins University, MD.*

OADs are the mainstay of therapy for patients with type 2 diabetes; however, data comparing their effect on kidney function are sparse. Of 18123 veterans who filled an incident OAD prescription at the VA-VISN9 between 1/1/2000-12/31/2007, we identified 10418 who met our inclusion criteria: 1 or more baseline creatinine measures, a GFR> 60 ml/min, and complete covariates. Incident users of sulfonylurea (SU) or combination metformin + sulfonylurea (MET-SU) were compared to metformin (MET) users (reference group), using a time to event analysis. The primary outcome was: a persistent (confirmatory value within 3-12 months) eGFR decline of 30 ml/min (GFR event), confirmed end stage renal disease (ESRD), or death, and the secondary outcome was: GFR event or ESRD, censoring at death. This analysis was performed in all individuals to reflect real clinical practice settings (n=10418) and on the subgroup with available urine protein test during baseline (n=7110). The analysis was performed in patients while on their incident OAD regimen. Exposure ended with: a gap in medication > 90 days, addition or changed to a different OAD or insulin, leave the VA, or end of the study. Covariates included: age, sex, race, blood pressure, history of cardiovascular disease, body mass index, glycosylated hemoglobin, specific medications, marital status, year, healthcare utilization, and, in the n=7110 subset, proteinuria.

For the primary outcome, the SU vs MET group had an adjusted hazard ratio (aHR) of 1.23 (95% CI 1.04, 1.45) for all patients and 1.32 (95% CI 1.07, 1.62) for the proteinuria subgroup and for the secondary outcome an aHR 1.17 (0.97, 1.41) and 1.33 (95%CI 1.07, 1.67) respectively. There was no difference observed between the combination group and metformin in either analysis.

Our findings suggest that patients on sulfonylureas have a higher risk of a clinically significant decline in their kidney function or death, independent of glycemic control.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO122**

**Long-Term Renal Survival Analysis of Patients with IgA Nephropathy: Results from a Cohort of 590 Cases in a Chinese Population** Wei-Bo Le, Kang-Ping Deng, Yang-Lin Hu, Cai-Hong Zeng, Zhi-Hong Liu. *Research Insitute of Nephrology, Jinling Hospital, Nanjing University of Medcine, Nanjing, Jiangsu, China.*

Although numerous long-term renal survival analysis and related risk factors of patients with IgA nephropathy (IgAN) have been published, data from a large cohort of Chinese patients are sparse. We performed a retrospective study of patients with biopsy-proven primary IgAN in the NanJing Glomerulonephritis Registry from January in 1989 to December in 2004. Patients with estimated glomerular filtration rate (eGFR, MDRD formula) less than 30ml/min per 1.73m$^2$, or follow-up less than 12 month, were excluded. Clinical features at the time of renal biopsy were reviewed, and all the follow-up data was updated to May, 2010. There were 590 patients enrolled. Among those patients, 69 (12%) developed ESRD during the follow-up. The 5, 10, 15, and 20-year cumulative renal survival rate were 96%, 84%, 74% and 65% respectively. Univariate analysis indicated that lower initial eGFR, hypertension at presentation, no history of recurrent macroscopic hematuria, higher level of proteinuria, lower serum albumin, and hyperuricaemia, were the risk factors of ESRD. Gender, age, body mass index and microscopic hematuria were irrelevant factors.. Multivariate Cox regression confirmed that eGFR<60 ml/min per 1.73m$^2$ at biopsy(HR 4.0, *P<0.001*), the square root of proteinuria at biopsy (HR, 3.3, *P<0.001*), hypertension at presentation (HR 2.5, *P<0.001*), were the independent risk factors of long-term renal survival, and patients with recurrent macroscopic hematuria (HR 0.23, *P=0.047*) were strongly predictive of a favorable outcome. While the follow-up data were concerned, the median of proteinuria > 1.0g/24h(HR 8.9, P<001), the mean of mean artertial pressure(HR 1.02, *P=0.02*), and the initial eGFR<60 ml/min per 1.73m2 (HR 3.2, *P<0.001*), were the most important risk factors of a unfavorable outcome. In Conclusion, IgAN is a progressive disease. Our data shows that the renal survival was 84% within 10

years, and 65% within 20 years. The major independent risk factors were impaired eGFR, hypertension, and proteinuria, while the recurrent macroscopic hematuria was associated with a favorable outcome.

### TH-PO123

**Renal and Patient Death of Idiopathic Membranous Nephropathy in Japan** Shinji Kitajima,[1] Yasuyuki Shinozaki,[1] Tadashi Toyama,[1] Akinori Hara,[1] Kiyoki Kitagawa,[1] Kengo Furuichi,[1] Hitoshi Yokoyama,[2] Takashi Wada.[1] *[1]Department of Nephrology, Kanazawa University Hospital, Kanazawa, Japan; [2]Department of Nephrology, Kanazawa Medical University Hospital, Kanazawa, Japan.*

BACKGROUND: The 20-year renal survival of Idiopathic membranous nephropathy (IMN) in Japanese adults with nephrotic syndrome was reported around 60%. On the other hand, the long-term patient survival of IMN remains unclear so far. In this study, we evaluated the predisposing clinicopathological factors of IMN patients with renal or patient death.

METHODS: One hundred forty three patients (84 males and 59 females; mean age 46.2 years) with biopsy proven IMN from 1965 to 2006 in Kanazawa Universitiy Hospital were evaluated in this study. Clinicopathological features were evaluated for renal and patient death.

RESULTS: Renal death was observed 14 out of 143 patients (9.8%). The percentage of nephrotic syndrome was higher in renal death group than that in non renal death group (92.9% vs. 69.0%). Based on the electron microscopic findings, the patients were assigned to two distinct groups, homogeneous type and heterogeneous type (synchronous electron dense deposits or various phases of dense deposits in basement membrane, respectively) as we previously published in Kidney International in 2004. The heterogeneous group showed higher renal death rate than that in homogeneous group (25.0% vs. 1.4%). Moreover, the patient group with massive proteinuria (> 3.0g/day) under any treatment had the higher rate of renal death. Patients death was observed 24 four out of 143 patients (16.8%). The major three causes of patients death were cardiovascular disorder (9 patient, 38%), malignant tumors (7 patients, 29%), and infection (5 patient, 21%). Patient death due to infection was observed in early clinical period of IMN. Older age and higher rate of nephrotic syndrome at onset were significant predictive factors for patient death due to infection.

CONCLUSION: Onset with nephrotic syndrome, heterogeneous type, and no response to treatment were predictors of progression to renal death. Infection was one of major cause of death in early clinical period of IMN, and older patients with nephrotic syndrome needs careful treatment.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO124

**Influence of Anti-Agalsidase Antibody on Clinical Outcomes in the Canadian Fabry Disease Initiative Study** Michael L. West,[1] Daniel G. Bichet,[2] Sandra Sirrs,[3] Christiane Auray-Blais.[4] *[1]Medicine, Dalhousie University, Halifax, NS, Canada; [2]Medicine, Universite de Montreal, Montreal, NS, Canada; [3]Medicine, University of British Columbia, Vancouver, BC, Canada; [4]Pediatrics, Universite de Sherbrooke, Sherbrooke, QC, Canada.*

Fabry disease is a rare X-linked lysosomal storage disorder which causes renal failure, cardiomyopathy and premature strokes. Enzyme replacement therapy (ERT) with recombinant agalsidase stabilizes renal function with a sustained fall in urine globotriaosylceramide (Gb3), the glycosphingolipid enzyme substrate that accumulates in the kidney in Fabry disease. Antibodies (Ab) to agalsidase develop in many patients with Fabry disease but the clinical significance of this is unknown. We report the anti-agalsidase antibody status of patients in the Canadian Fabry Disease Initiative study (CFDI) (Clinical Trial Registration protocol # NCT 00455104) receiving ERT (agalsidase alfa 0.2 mg/kg, agalsidase beta 1.0 mg/kg) IV every 2 wks. No difference in clinical outcomes has been seen between the 2 forms of agalsidase so far. Anti-agalsidase antibody ELISA assays done by the drug manufacturers vary in method and in sensitivity. Of the 288 patients in the CFDI study at 42 mos, 149 received ERT: antibody results were done in 121: 89 (73.6%) negative and 32 (26.4%) positive, median titer 1/800, range 1/50-1/25,600. Mean age, time on ERT and clinical parameters did not differ between the two groups at baseline. Ab + was more likely in males (40.8%) and in those on agalsidase beta (81.2%). Urine Gb3 levels fell less at 24 mos in Ab + patients (26.1%) vs Ab – patients (65.1%). A greater number of clinical events (renal, cardiac, stroke, death) occurred in Ab + (25%) vs. Ab – patients (20.2%). Intermediate/high Ab titer (≥ 1/800) was associated with no fall in urine Gb3 but no difference in clinical outcomes vs. low Ab titer. The presence of anti-agalsidase Ab of any titer is associated with lower urine Gb3 and worse clinical outcomes. While this suggests that Ab interferes with ERT action in the kidney in some way, an effect of male gender with more severe disease cannot be excluded in the Ab + group.

**Altered Regulations of Matrix Metalloproteinase (MMP)-2 Are Associated with a Rat Model of CKD-MBD** Neal X. Chen,[1] Kalisha O'Neill,[1] Xianming Chen,[1] Kraiwiporn Kiattisunthorn,[2] Vincent H. Gattone,[1] Sharon M. Moe.[1,3] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Faculty of Siriraj Medical School, Mahidol University, Bangkok, Thailand; [3]Roudebush Veterans Medical Center, Indianapolis, IN.*

MMPs are responsible for extracellular matrix degradation which is critical for bone and arterial remodeling and therefore may play a role in the pathogenesis of CKD-MBD. We have previously demonstrated that the Cy/+ rat is a progressive model of CKD-MBD, with spontaneous hyperphosphatemia, hyperparathyroidism and vascular calcification. The objective of the current study was to determine if altered regulation of MMP-2 may predispose to extracellular matrix degradation, facilitating arterial calcification. Sera were collected from Normal or Cy/+ rats at 20, 29, 34 or 38 weeks and the MMP-2 level and activity determined by ELISA or zymography. The results demonstrated that at each time point, serum total MMP-2 levels are increased in CKD rats compared to that in normal rats, as were levels of tissue inhibitor of metalloproteinases (TIMP)-1. Importantly, MMP-2 activity by zymography was progressively increased in the Cy/+ rats with the development of CKD-MBD (20 week=28507±1101 Odu vs. 38 week 45199±5055 Odu, overall p over time<0.001). MMP-2 expression by real time RT-PCR in aorta tissue from 34 week old animals showed increased expression in Cy/+ rats compared to Normal rats (5.7±1.1 vs. 2.6±0.4, p<0.02). To further investigate the mechanism by which MMPs might be involved, we used the aorta ring culture model which calcifies in the presence of sodium phosphate and alkaline phosphatase. Immunohistochemistry demonstrated an increased expression of MMP-2 in areas of calcification compared to non calcified section. Furthermore, MMP inhibitors, GM6001 and doxycycline, significantly reduced calcification of the aorta rings (95.6±16.6 μmol/g, control; 58.1±11.7 μmol/g, GM6001; 34.3±8.6 μmol/g, doxycycline, p<0.001). In conclusion, MMP-2 activity increases with progressive CKD-MBD in vivo and ex vivo, and blockade of MMP acitivity ex vivo can inhibit arterial calcification. Thus, matrix remodeling may be important contributor to CKD-MBD.

**Development of Klotho-FGFR1/3 Dependent Resistance to FGF-23 in Human Aortic Smooth Muscle Cells Exposed to Calcifying Stress** Kenneth Lim,[1,2] Tzong-Shi Lu,[1] Daniel Zehnder,[2] Li-Li Hsiao.[1] *[1]Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Clinical Sciences Research Institute, Warwick Medical School, Coventry, United Kingdom.*

Vascular calcification (VC) is a significant contributor to cardiovascular mortality in chronic kidney disease (CKD). Osteo/chondrocytic transformation and simultaneous dedifferentiation of smooth muscle cells (SMC) are important in the pathogenesis of VC. FGF-23 is a bone-derived circulating hormone that binds to FGFR1/3-Klotho receptor complex at the kidney to counteract hyperphosphatemia. FGF-23 levels rise in CKD, however there are currently conflicting data on the role of FGF-23 in the inhibition of VC. Our results show for the first time that Klotho and FGFR1/3 are expressed in healthy human arteries, in vivo and normal HA-SMCs, in vitro. Co-expression of Klotho with FGFR1/3 was observed in normal HA-SMCs on immunostaining. We found that Klotho, FGFR1/3 expression were downregulated in HA-SMCs grown in borderline high (2.0mM CaCl2 and 2.7mM β-Glycerolphosphate(GP)) and high (5mM CaCl2 and 5mM β-GP calcification medium, in short-term (3 and 6 hours) and long-term (21 day) cultures, in vitro. These cells exhibited concomitant core binding factor alpha-1-dependent osteo/chondrocytic transformation and loss of serum response factor (SRF)-dependent SMC contractile phenotype. Downregulation of klotho expression was also observed following treatment of HA-SMCs with the SRF inhibitor, CCG-1423 (10μM), suggesting SRF-dependent regulation of Klotho. We next showed that FGF-23 treatment (1ng/ml) of HA-SMCs induced upregulation of P-ERK and P-AKT expression, in vitro. However, FGF-23 failed to induce P-ERK and P-AKT expression in HA-SMCs exhibiting loss of klotho expression. In summary, we show for the first time that Klotho and FGFR1/3 are co-expressed in HA-SMCs; loss of Klotho and FGFR1/3 was associated with the development of VC; regulation of Klotho expression is SRF-dependent; and FGF-23 failed to initiate intracellular signaling in the absence of Klotho. We therefore conclude that downregulation of Klotho-FGFR1/3 expression in arteries exposed to calcifying stress may mediate vascular resistance to FGF-23.

**Antioxidant Ameliorates the Progression of Vascular Calcification in Uremic Rats** Shunsuke Yamada,[1] Masatomo Taniguchi,[1] Masanori Tokumoto,[3] Kazuhiko Tsuruya.[2] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [3]Department of Medicine, Fukuoka Dental College, Fukuoka, Japan.*

(Background) Oxidative stress has been reported to be involved in the pathogenesis of vascular calcification (VC). This study was aimed to elucidate the role of oxidative stress in VC progression by assessing the effect of apocynin, an antioxidant and a specific inhibitor of NADPH oxidase.

(Methods) Ten-week-old SD rats were divided into the three groups (n=12 for each group); 1) control rats (fed normal diet and water)(CNT), 2) CKD rats (fed adenine diet and normal water)(CKD), 3) CKD rats treated with apocynin (fed adenine diet and 1.5 mM apocynin water) (CKD+APO). All rats were killed after 7 weeks. Oxidative stress of the aorta was assessed using immunohistochemistry (IHC) for 8-hydroxydeoxyguanosine(8-OHdG), and urinary 8-OHdG content was assessed as systemic oxidative stress. The calcified area was confirmed by von Kossa staining, and the features of calcified area were assessed by IHC. The aortic calcification was quantitatively determined by Ca content in the aorta.

(Results) CKD and CKD+APO developed progressive renal failure over 7 weeks in contrast with CNT. Von Kossa staining revealed arterial medial calcification in CKD and CKD+TMP. Twenty-four-hour urinary 8-OHdG content and Ca content in the aorta in CKD significantly ($p<0.05$) increased compared to CNT. The urinary 8-OHdG content showed significant ($p<0.05$) positive correlation with Ca content in the aorta. The calcified area of aorta in CKD was positive for Runx2, osteocalcin and 8-OHdG as assessed by IHC, suggestive of the involvement of osteoblast-like cells. The aortic Ca content and the urinary8-OHdG content in CKD+APO were significantly ($p<0.05$) lower than those in CKD.

(Conclusion) Apocynin prevented the progression of VC in uremic rats, signifying that oxidative stress plays pivotal roles in the progression of VC in uremia.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO128

**PA21, a New Iron-Based Phosphate Binder Prevents Arterial Calcification in Chronic Renal Failure Rats?** Olivier Phan,[1] Marc P. Maillard,[1] Christine Perregaux,[1] David Mordasini,[1] Stehle J. C Jean-Christophe,[3] Felix W. Funk,[2] Michel Burnier.[1] *[1]Nephrology, CHUV, Lausanne, Switzerland; [2]Vifor (International) Inc, St Gallen, Switzerland; [3]MPF UNIL, CHUV, Switzerland.*

BACKGROUND: The use of calcium-based phosphate binders to control hyperphosphatemia can induce hypercalcemia and has been associated with progression of vascular calcifications. The purpose of the present study was to evaluate the effects of PA21, a new iron-based non calcium phosphate binder, on the development of vascular calcifications in uremic Wistar rats.

METHODS: Chronic renal failure (CRF) was induced by feeding rats with an adenine-enriched diet for 4 weeks. Then CRF rats were randomized to receive either PA21 5% or calcium carbonate ($CaCO_3$) 3% in the diet or a placebo for another 4 week period. Drugs were added to the food and control non-CRF rats received the same diet (n=6-11/group). Vascular calcifications were assessed blinded on random sections of several vessels (aorta, carotid and femoral arteries). The degree of Von Kossa positivity was scored semi-quantitatively with scores ranging from 0 to 3 depending on the surface of Von Kossa positivity.

RESULTS: At randomization, no statistical difference was observed for serum calcium, phosphate, creatinine and body weight between the CRF groups. At sacrifice, serum phosphate was similarly decreased by $CaCO_3$ 3% and PA21 5% (to 2.02 and 2.21 mmol/l respectively) compared with CRF control rats (2.86 mmol/l, $p <0.005$). Serum calcium, creatinine and weight were similar between the CRF groups. Preliminary results show that despite comparable effects on serum phosphate and calcium, PA21 5% was associated with a significantly lower score of vascular calcifications ($p= 0.043$, chi-square test) when compared with $CaCO_3$ 3%-treated CRF rats and controls.

CONCLUSION: These preliminary results suggest that the new iron-based phosphate binder PA21 reduces the development of vascular calcifications in rats with chronic renal failure beyond the control of phosphatemia and hypercalcemia.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO129

**Serum Glycoprotein Fetuin-A Is Degraded in Renal Proximal Tubular Epithelial Cells** Kazunori Inoue,[#1] Isao Matsui,[#1] Chikako Nakano,[#1] Hiroki Omori,[#1] Jun-Ya Kaimori,[#1] Takayuki Hamano,[#2] Toshiki Moriyama,[#1] Hiromi Rakugi,[#1] Yoshitaka Isaka.[#1] *[1]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Center for Clinical Epidemiology and Biostatistics, University of Pennsylvania, School of Medicine, Philadelphia, PA.*

Serum glycoprotein fetuin-A is synthesized in the liver, secreted into blood and thereby exerts potent inhibition of calcification. Although it has been revealed that hepatic and serum fetuin-A levels are repressed by inflammatory changes or malnutrition, the degrading pathway of fetuin-A is poorly understood. To assess the fetuin-A-degrading pathway, we performed immunohistochemical analysis using normal Wistar rat tissues. In addition to fetuin-A staining in the liver, we found dotted pattern staining of fetuin-A in renal proximal tubular epithelial cells. Because normal rat kidney dose not express mRNA for fetuin-A, this result suggested an uptake of fetuin-A in these cells. For the inhibition of proximal tubular reabsorption, a basic amino acid L-lysine or histidine-tagged soluble receptor-associated protein (His-RAP) was administrated. After the treatment with L-lysine, dotted pattern staining of fetuin-A completely disappeared concomitantly with the excretion of fetuin-A into the urine. Glycine administrated rats, which served as control in L-lysine administrated experiments, did not show such changes. Megalin, a key player of proximal tubular reabsorption, was localized at the base of brush border in glycine administrated rats, whereas L-lysine administration was associated with an intense brush border labeling for megalin to the tip of the microvilli. Similar to the results in L-lysine administrated rats, His-RAP injected rats showed a decreased staining of fetuin-A in the proximal tubular cells. We further analyzed whether lysosomal blockade changes fetuin-A distribution in proximal tubular cells. Immunohistochemistry revealed that intraperitoneal injection of leupeptin accumulated fetuin-A in the proximal tubular cells. Western blot analysis confirmed the lysosomal distribution of fetuin-A in the leupeptin injected rats. Kidney plays a role in fetuin-A metabolism.

### TH-PO130

**Breast Arterial Calcification: A Window into the Prevalence, Pathogenesis, and Significance of Medial Vascular Calcification in Chronic Kidney Disease** W. Charles O'Neill,[1] Valerie S. Duhn,[1] Amy Adams,[2] Ellen M. D'Orsi,[3] Carl J. D'orsi.[3] *[1]Renal Division, Emory University, Atlanta, GA; [2]Department of Pathology, Emory University, Atlanta, GA; [3]Department of Radiology, Emory University, Atlanta, GA.*

Renal failure predisposes to medial vascular calcification but its prevalence and significance are unknown because imaging is not routinely performed, has unknown sensitivity, and cannot distinguish it from intimal calcification. Because of the frequency of mammography and breast excision, breast arterial calcification (BAC) may provide a useful window into medial vascular calcification in CKD. Medial calcification but not intimal calcification was present in all 18 specimens (visible only by von Kossa staining in 5) of breast tissue from patients with ESRD (n=8) or CKD (creatinine 1.0-3.9). Coarse calcifications were present in 5, while 13 cases showed granular staining. Prominent linear staining of the internal elastic lamina (IEL) was noted in 8 cases. There was no staining for osteocalcin, a marker of osteogenesis. Mammograms in 71 patients with ESRD and 66 controls without renal disease (serum creatinine < 1.0 mg/dl) matched for age and diabetes were retrospectively reviewed. The mean age of the patients was $60.4 \pm 2.1$ (range: 35-85), mean ESRD duration was $5.7 \pm 0.9$ yr, and 55 % had diabetes. The prevalence of BAC was 63 % in ESRD patients compared to 15 % in controls ($p<0.001$). Of 16 patients with subsequent mammograms, 8 showed progression of BAC. Peripheral vascular disease (OR = 3.0; $p = 0.028$) but not coronary artery disease (OR = 1.05) was more prevalent in those with BAC. BAC was present in 36 % of mammograms performed prior to ESRD ($5.5 \pm 0.7$ yrs). We conclude that BAC is limited to the media and the internal elastic lamina and does not occur in the intima, and that early medial calcification may be universal in CKD. Our data do not support osteogenic differentiation of smooth muscle as an initial event. The prevalence of BAC on mammography is markedly increased in ESRD and CKD and may correlate with peripheral vascular disease. Breast arterial calcification will be a useful tool to study medial vascular calcification in CKD.

### TH-PO131

**Thiosulfate Inhibits Vascular Calcification In Vitro Independent of Interactions with Calcium or Hydroxyapatite** W. Charles O'Neill,[1] Kenneth Hardcastle,[2] George R. Dubyak.[3] *[1]Renal Division, Emory University, Atlanta, GA; [2]Department of Chemistry, Emory University, Atlanta, GA; [3]Department of Physiology and Biophysics, Case Western Reserve University, Cleveland, OH.*

Thiosulfate has been shown to inhibit vascular calcification in rats and may inhibit calcification in humans but whether this is due to a systemic or local action is unknown. The underlying mechanism is also unclear but complexation of calcium ions has been proposed. In vitro assays were used to determine the effect of thiosulfate on vascular calcification and hydroxyapatite formation. Thiosulfate ($EC_{50}$: 1-2 mM) prevented calcification of cultured aortas induced by injury but not calcification induced by alkaline phosphatase. Similar results were obtained with sulfate, which was more potent. There was no effect on reversal of calcification. Thiosulfate had no effect on the calcification of purified elastin or on the formation of hydroxyapatite from seed crystals. There was no effect on pyrophophosphate metabolism or on the inhibition of hydroxyapatite formation by pyrophosphate. Measurements with an ion-sensitive electrode (corrected for changes in ionic strength) revealed a very weak interaction between thiosulfate and calcium ($K_a = 3.5 \times 10^{-5}$ L/mol). Adjustment of the calcium concentration to account for this did not prevent the inhibition of aortic calcification by thiosulfate.

It is concluded that thiosulfate can directly inhibit vascular calcification but at millimolar concentrations. This effect is not specific for thiosulfate since sulfate has similar properties. Inhibition is dependent on the cause of calcification and cannot be explained by interactions with elastin, pyrophosphate, hydroxyapatite, or calcium. The mechanism by which thiosulfate inhibits vascular calcification remains to be elucidated.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO132

**The Effect of Sodium Thiosulfate (STS) on Measures of MBD** Tracy Jack Mayne, Tasos Constantin, Carey Colson, Mahesh Krishnan. *DaVita Inc., Denver, CO.*

STS has been used to treat calciphylaxis in ESRD. Though the MOA involves mobilization of calcium, the longitudinal effect on markers of MBD has not been explored in a large setting. A retrospective analysis of 203 dialysis patients treated with STS from 01/01/09 to 12/31/09 was completed at a US dialysis organization. Changes in pre/post initiation Ca, P, PTH and IV paracalcitrol dose (IV D) were examined using repeated measures general linear models. Change in % of patients treated with cinacalcet was assessed using Cochran's Q. We examined patients treated for 1 (n=203), 2 (N=68) and 3 (N=42) consecutive months.

Results:

| STS Treatment | Mo. -2 | Mo. -1 | Mo. 0 | Mo. 1 | Mo. 2 | Mo. 3 | p-value |
|---|---|---|---|---|---|---|---|
| **1 Mo.** | | | | | | | |
| | | | | | | | |
| Ca | 8.9±0.9 | 8.8±0.8 | 8.9±0.9 | 8.9±1.0 | | | 0.81 |
| P | 6.2±2.1 | 6.0±2.1 | 5.5±1.8 | 5.5±2.0 | | | <0.01 |
| PTH | 549.5±714.4 | 505.4±585.2 | 422.4±459.5 | 424.0±587.1 | | | <0.01 |
| IV D | 5.7±4.1 | 5.7±4.0 | 5.2±3.6 | 4.7±3.4 | | | 0.55 |
| Cinacalcet | 30.5% | 34.5% | 34.0% | 25.6% | | | 0.05 |
| **2 M.** | | | | | | | |
| | | | | | | | |
| Ca | 9.0±0.7 | 8.9±0.6 | 8.9±0.8 | 8.9±0.8 | 9.0±0.7 | | 0.64 |
| P | 5.7±1.7 | 5.4±1.8 | 5.2±1.8 | 5.1±1.7 | 5.4±2.1 | | 0.11 |
| PTH | 578.0±1035.9 | 485.0±737.1 | 457.9±563.6 | 403.6±672.3 | 575.3±1158.7 | | 0.38 |
| IV D | 5.5±4.6 | 4.9±4.2 | 4.8±3.8 | 4.1±3.1 | 4.1±3.2 | | 0.97 |
| Cinacalcet | 32.4 | 35.3 | 41.2 | 35.3 | 32.3 | | 0.21 |
| **3 M.** | | | | | | | |
| Ca | 8.9±0.7 | 8.9±0.6 | 8.9±0.7 | 8.9±0.8 | 8.9±0.8 | 9.0±0.7 | 0.95 |
| P | 5.7±1.7 | 5.4±1.9 | 5.4±1.8 | 5.2±1.9 | 5.6±2.1 | 5.6±1.7 | 0.21 |
| PTH | 423.4±679.2 | 343.6±353.5 | 302.9±382.2 | 415.0±860.7 | 414.5±619.7 | 478.7± 706.0 | 0.04 |
| IV.D | 5.5±4.8 | 5.3±4.6 | 4.8±4.0 | 3.9±2.7 | 4.3±3.2 | 4.4±3.1 | 0.40 |
| Cinacalcet | 40.5 | 38.1 | 42.9 | 33.5 | 35.7 | 38.5 | 0.50 |

This may be the largest case series of patients receiving STS treatment for clinically diagnosed calciphylaxis. STS treatment was associated with reductions in P, PTH and cinacalcet in the first 2 mo following initial treatment. Serum Ca and IV paricalcitrol dose showed no change. Results suggest STS transiently improves MBD outcomes, but improvements aren't maintained over time. A RCT is needed to determine the benefit of STS on intermediate and terminal outcomes.

## TH-PO133

### Sodium Thiosulfate (STS) Dosing Strategies for Treatment of Calciphylaxis

Edward A. Ross,[1] Hartmut Derendorf,[2] Rajendra P. Singh.[2] *[1]Division of Nephrology, Univ of FL; [2]Dept of Pharmaceutics, Univ of FL, Gainesville, FL.*

**Background:** Calciphylaxis is a poorly understood but life threatening disorder with limited therapeutic options. STS ($Na_2S_2O_3$) has reported efficacy, thought due to it dissolving calcium deposits by producing the calcium salt ($S_2O_3Ca$), which is extremely soluble and cleared by hemodialysis (HD). The exposure to the STS (area under curve, AUC) is thought to be proportional to its ability to dissolve calcifications.

**Aim:** Given that there are successes using an empiric 25 gm IV 3x/wk given after HD, we performed simulations to determine dosing strategies for alternative, more or less intense dialysis regimens so as to produce equivalent AUC drug exposure.

**Methods:** Since a 2 compartment model has described pharmacokinetics of STS in healthy humans, we used it to simulate exposure for HD. The modeled prescriptions varied HD time from 12-40 hrs/week over 3-6 sessions, QB 200-400 ml/min, QD 500 or 800 ml/min, or CVVHD at low flow rates, using F160 high-flux filters, and also accounting for residual renal function. The simulations to calculate the AUC exposure were performed using nonlinear mixed-effect modeling software (NONMEM).

**Results:** Simulations showed a marked variation in STS doses depending upon HD frequency and duration. Blood and dialysate flows have a less prominent effect. Assuming no residual renal function, HD prescription permutations caused the dose to vary from 75-168 gm/week, with examples in the table below.

| Dialyses per week | 3 | 4 | 5 | | 6 | CVVHD |
|---|---|---|---|---|---|---|
| QB (ml/min) | 400 | 400 | 400 | 400 | 400 | 200 |
| QD (ml/min) | 800 | 800 | 800 | 800 | 800 | 33 |
| HD Time (hr) | 4 | 3 | 2.5 | 8 | 2 | continuous |
| Dose post-HD (g) | 25 | 22 | 18 | 24 | 16 | 24, daily |
| Weekly Dose (g) | 75 | 88 | 90 | 120 | 96 | 168 |

**Conclusion:** Based on 1) the success reported for one STS dosing regimen and 2) assuming AUC exposure of STS is proportional to its effect, pharmacokinetic simulations can be used to calculate the dose for alternative, higher or lower intensity dialysis regimens. These strategies are imperative to assure adequate treatment for this mortal disease, as well as to avoid toxicity from excess dosing.

### Response of Calcific Uraemic Arteriopathy to Sodium Thiosulphate; Ten Case Reports

Nicholas J. New, Dougal Stirling Carlisle, Dwarakanathan Ranganathan, Sree Krishna Venuthurupalli. *Nephrology Department, Royal Brisbane Women's Hospital, Brisbane, QLD, Australia.*

**INTRODUCTION:** Calcific uraemic arteriopathy (CUS) is an uncommon but increasingly recognized condition, associated with high morbidity and mortality. Pathogenetic mechanisms of calciphylaxis are incompletely understood, however calcium and phosphate homeostasis are integrally involved. Current multimodality treatment involves aggressive serum calcium and phosphate control with dialysis, non-calcium phosphate binders, cinacalcet and parathyroidectomy, wound care including surgical debridement and infection control. Sodium Thiosulphate and hyperbaric oxygen are emerging as promising agents for the treatment of CUS.

**AIM:** To assess Sodium Thiosulphate therapy for CUS at a tertiary care hospital.

**METHODS:** A retrospective chart review of all patients over the previous 5 years, treated for CUS using Sodium Thiosulphate. Treatment modalities were identified and success of treatment, as determined by survival, reduction in pain and/or size of skin lesions, was examined.

**RESULTS:** Ten patients received sodium thiosulphate for treatment of CUS over the previous 5 years, 9 of whom had End Stage Renal disease (ESRD) on dialysis. Complete resolution of lesions occurred in 1 patient who in addition underwent parathyroidectomy and received hyperbaric oxygen therapy. A further 4 patients demonstrated a reduction in both pain and size of skin lesions, 3 of whom also received hyperbaric oxygen. Only one death was directly attributable to CUS.

**CONCLUSIONS:** The small population size of our study does not permit definitive conclusions. Literature supporting the use of sodium thiosulphate remains limited to case studies. Further prospective research is required in order to fully determine the potential benefits of sodium thiosulphate in the treatment of CUS in ESRD.

## TH-PO135

### Effect of Sodium Thiosulfate on Urinary Lithogenicity in Normal Adults

David S. Goldfarb,[1] Ruchika Batwara,[1] John R. Asplin.[2] *[1]Nephrology, New York VA Medical Center and New York University School of Medicine, New York, NY; [2]Litholink Corp, Chicago, IL.*

**Purpose**: Sodium thiosulfate (STS) has been shown to reduce calcium stone formation in humans (Yatzidis H; Clin Nephrol 1985) and hypercalciuric rats (Asplin et al; J Am Soc Nephrol 2009). We studied the effects of STS on urine chemistry in normal adults.

**Methods**: 5 healthy people with a mean age of 34 years completed the study. Two baseline 24-hour urine collections were done and then repeated after oral intake of STS 10 mmol BID for 7 days. Participants kept a diet diary during baseline urine collections and replicated the diet during the STS urine collections. Results were compared by non parametric Wilcoxon signed rank test.

**Results**:

Effect of STS on 24 Hour Urine Chemistry

| 24 hour excretion: | Calcium (mg) | Oxalate (mg) | Phos (mg) | pH | NH4 (meq) | Citrate (mg) | SO4 (meq) |
|---|---|---|---|---|---|---|---|
| Mean baseline | 111.5 | 37.8 | 805 | 6.67 | 24.8 | 740.6 | 44 |
| SD | 24.9 | 15.1 | 410.2 | 0.39 | 5.9 | 504.7 | 18.8 |
| Mean post STS | 147 | 36.3 | 830 | 6.08 | 43.4 | 713.9 | 85.8 |
| SD | 43.9 | 17.3 | 496.5 | 0.40 | 17.3 | 548.6 | 29.3 |
| p value | 0.08 | 0.9 | 0.5 | <0.05 | <0.05 | 0.5 | 0.08 |

SD: standard deviation

Urine pH decreased while urinary $NH_4$ excretion increased without any significant change in urinary citrate. Urinary Ca excretion rose; $PO_4$ and oxalate excretion did not change. Urinary $SO_4$ excretion increased but urinary thiosulfate concentrations were negligible post STS. Urine volume, creatinine, urea, sodium and other measured analytes remained unchanged, confirming replication of diets during the collections.

**Conclusions**: Increased urinary $Ca^{2+}$ excretion would be counterproductive for prevention of stones. Also, STS may be causing metabolic acidosis, suggested by a fall in urinary pH and increased urinary $NH_4$. Interestingly, a rise in urine $SO_4$ with negligible urine thiosulfate suggests a conversion of thiosulfate to sulfate, hence challenging the previously proposed theory of $Ca^{2+}$ chelation by STS as its mechanism of action. Whether STS reduces stone formation in hypercalciuric stone formers has not been tested in a controlled study.

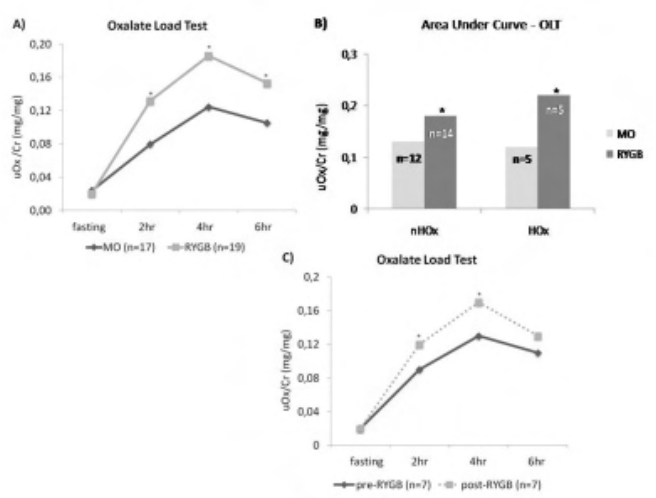
## TH-PO136

### Urinary Response to an Oral Oxalate Load after Roux-en-Y Gastric Bypass

Leila Froeder, Alessandra Calábria Baxmann, Ita Pfeferman Heilberg. *Nephrology Division, Universidade Federal de Sao Paulo, Sao Paulo, Brazil.*

Several studies have reported increased oxalate excretion and risk for stone formation following bariatric surgery but the underlying mechanisms for hyperoxaluria are not fully elucidated yet. We aimed to evaluate the urinary response to an oral oxalate load by patients who had undergone Roux-en-Y gastric bypass (RYGB) for at least 6 months. Methods: A total of 19 RYGB patients and 17 morbidly obese (MO) subjects (controls) collected a 24-hour urine specimen and were classified as Hyperoxalurics (HOx) or non-Hyperoxalurics (nHOx). There have been 5 HOx and 3 stone formers in each group. All patients were further submitted to an oral oxalate loading test (OLT) consisting of two-hour urine samples obtained after an overnight fast, 2, 4 and 6 hours after a 375mg oxalate load (spinach). In addition, a prospective longitudinal analysis of 7 patients who underwent the OLT both before (pre-RYGB) and after 6 months of the procedure (post-RYGB) was performed. Results: Calcium excretion did not differ between the periods of the test. The mean urinary oxalate-to-creatinine (uOx/Cr) ratio in RYGB was significantly higher vs. MO at all periods after the load (figure 1A) and the mean area under the curve (AUC) of RYGB was higher vs. MO ($0.20 \pm 0.05$ vs.$0.13 \pm 0.04$, $p<0.001$). As shown in figure 1B, mean AUC of RYGB was significantly higher vs. MO both among nHOx and HOx but there was a trend for a higher mean AUC value achieved by the RYBG HOx group. Mean uOx/Cr of post-RYGB patients (figure 1C) was significantly higher 2 and 4 hours after the oxalate load vs. pre-RYGB and AUC value was also higher in the former ($0.18 \pm 0.05$ vs.$0.14 \pm 0.04$, $p = 0.02$).



Conclusions: RYGB patients exhibited an exaggerated urinary response to an oral oxalate load suggesting an increased intestinal absorption of dietary oxalate. These patients may benefit from oxalate restriction.

### TH-PO137

**Increased Risk for Calcium Oxalate Nephrolithiasis after Roux-en-Y Gastric Bypass Surgery Starts in the Early Post-Operative Period** Varun Agrawal, Daniel L. Landry, Xiao Jie Liu, Ann Lagoy, Inta Discenza, Thomas Campfield, John Romanelli, J. Enrique Silva, Gregory Lee Braden. *Baystate Medical Center, Springfield MA.*

Hyperoxaluria and nephrolithiasis are known complications of Roux-en-Y gastric bypass surgery (RYGB), but little is known if this stone risk starts in the early post-operative period and whether it changes with time. We prospectively studied 13 morbidly obese adults who underwent RYGB and had urine collections 2 weeks before, 1, 2, 4 and 6 months after surgery. Relative saturation ratio (RSR) with regard to calcium oxalate was computed by EQUIL. Non-parametric analyses were performed and results expressed as median (25th-75th %ile). Eleven subjects were female, median age was 40(36-48)years and none had history of diabetes or nephrolithiasis. Body mass index decreased from 44.6 (41.6-47.6)kg/m² to 34.1 (30.4-36.8)kg/m² in 6 months, p<0.0001. We observed significant decreases in urine volume [2100 (1537-3290) to 1360 (1200-1700)ml, p<0.0001], urine sodium [207.3 (145.6-258.4) to 92.5 (57.8-203.8)mmol/24h, p=0.002], urine potassium [70.1 (39.7-111.4) to 32.1 (22.4-53.8)mmol/24h, p<0.0001], urine magnesium [8.7 (4.2-14.1) to 7.1 (3.3-11.4) mg/24h, p=0.016], urine phosphorus [1.0 (0.7-1.2) to 0.5 (0.4-0.9)g/24h, p=0.01] , urine uric acid [0.6 (0.4-0.8) to 0.4 (0.3-0.6)g/24h, p=0.015] and creatinine clearance [144.0 (117.5-193.1) to 108.5 (90.8-164.8)ml/min, p=0.046]. The increase in urine oxalate approached significance [28.6 (18.7-49.7) to 51.6 (25.2-85.0)mg/24hour, p=0.054]. No change was seen in urine pH, 24 hour urine creatinine or 24 hour urine calcium excretion. Calcium oxalate RSR increased after RYGB [1.7 (1.2-3.6), 4.5 (1.6-9.2), 5.73 (2.1-12.2), 5.27 (2.7-9.1), 6.3 (3.4-13.9) at baseline, 1, 2, 4 and 6 months respectively, p=0.020). One patient had critical supersaturation (RSR=23.7) at 1 month that peaked at 42.3 at 6 months after RYGB. We conclude that calcium oxalate RSR and risk for nephrolithiasis start early and persist in the first 6 months after RYGB due to decreased urine volume, magnesium and increased urine oxalate. Studies of increased fluid intake and oral agents to bind enteric oxalate to reduce this risk are needed.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO138

**Increased Intestinal Oxalate Absorption, Serum Oxalate Concentrations and Urinary Calcium Oxalate Supersaturation in Patients after RYGB Surgery** Rajiv Kumar, John C. Lieske, Maria L. Collazo-Clavell, Ellen Olson, Xujian Li, Eric J. Bergstralh, Zachary C. Ryan. *Mayo Clinic, Rochester, MN.*

Patients frequently develop hyperoxaluria after RYGB surgery for morbid obesity. The mechanism by which hyperoxaluria occurs is unknown. We hypothesized that hyperoxaluria and increased serum oxalate (Ox) concentrations occur as a result of the intestinal hyperabsorption of Ox. We tested 11 RYGB patients for the presence of intestinal Ox hyperabsorption before, 6, and 12 months (m) after surgery. Fasting serum and urine Ox, and urine Ox following oral administration of 120 mg of Ox were measured. Relevant urinary analytes and supersaturations for calcium (Ca) Ox, apatite, brushite, uric acid, and sodium urate were measured in 24-h urines. 72-h fecal fat was measured.

*Results:* The results (**Table)** demonstrate increases in serum Ox levels, urine CaOx supersaturation, and 72 h fecal fat excretion at 6 and 12 m after RYGB surgery. An increase in urine Ox levels following an oral dose of 120 mg of disodium Ox was observed at both 6 and 12 m.

Serum and Urine Values Before and After RYGB

| Serum or urine test | Baseline, 0 m, mean±SD | 6 m, mean±SD | 12 m, mean±SD | P-value, paired t-test, 0-6 m | P-value, paired t-test, 0-12 m |
|---|---|---|---|---|---|
| Serum Ox, mol/L | 1.2±0.36 | 2.2±1.26 | 1.9±0.84 | 0.018 | 0.016 |
| Urine Ox, mg/24h | 26.4±13.26 | 27.2±8.21 | 32.6±11.42 | 0.89 | 0.18 |
| Urine volume, mL/24h | 2091±768 | 1317±540 | 1596±568 | 0.02 | 0.11 |
| CaOx DG SS | 1.0±0.88 | 2.3±0.36 | 1.8±0.54 | 0.003 | 0.009 |
| Urine Ox following oral Ox load, mg/24h | 35.3±8.22 | 64.4±23.1 | 69.7±17.86 | 0.02 | <0.0001 |
| Fecal fat, g/72h | 4.1±3.48 | 9.3±6.93 | 7.7±4.31 | 0.026 | 0.055 |

*Conclusions:* An increase in the proportion of Ox absorbed in the intestine and excreted in the urine following a dose of oral oxalate accounts for the increase in serum oxalate concentrations and urinary CaOx supersaturation values at 6 and 12 m following RYGB surgery. Increases in fecal fat are likely to reduce the amount of free Ca available for binding to oxalate causing absorptive intestinal hyperoxaluria in RYGB patients.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO139

**Sex and Sib Prevalences of Upper Urinary Tract Stone Disease (UUTS): The Effects of Urinary Physicochemical and Inhibitory Activities** Suchai Sritippayawan. *Renal Division, Internal Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand.*

We explored sex and sib prevalences of UUTS and study urinary physicochemical and inhibitory activities(IA) of stone formers(SF), nonstone former sibs(NSFS) and controls(C) in northeastern(NE) Thailand.

**Methods** Prevalence of UUTS in GP was studied by randomly choosing subjects>15 years(y) from the census records of 5 villages(n=344). Prevalence in sib study was hospital-based(n=430). Plain KUB film was done in all subjects. Fasting urine(U)Ca, oxalate(Ox), citrate(Cit), creatinine(Cr) and CaOx supersaturation(SS) were measured in 95 CaOxSF, 158 NSFS and 114 C. Urine was also dialyzed against distilled water using 80 kd cutoff membrane and 1 µg of urine protein was used for CaOx crystal aggregation assay by spectrophotometry. Bad inhibitor was the urine protein having IA less than the IA of 1 µg of control Tamm Horsfall protein.

**Results** UUTS was 3 times more prevalent in sib than in GP. Male(M):Female(F) ratio was 1.3-2.6:1 in subjects<70y, but the ratio reversed to 0.5:1 in subjects≥70y. SF had significantly(p<0.05) higher UCa/Cr(370vs257 mmol/mol), UCa/Cit(15.6vs5.9), UOx/Cr(30.5vs24.6 mmol/mol) and CaOxSS(6.4vs5.2) than C. NSFS had significantly higher CaOxSS(6.4vs5.2) and UCa/Cr(321vs257) than C but had significantly lower UCa/Cit(7.8vs15.6), UOx/Cr(24.6vs30.5) and higher UCit/Cr(1.2vs0.84 mmol/gCr) than SF. Bad inhibitor was significantly higher in SF than NSFS&C(37.5%vs10.9%&9.4% respectively). Males had significantly lower UOx/Cr and UCit/Cr than females in all 3 groups(C,NSFS,SF: UOx/Cr=20.5,21.4,23.5vs27.3:26.5vs35.3; UCit/Cr=0.67,0.85,0.55vs1.08,1.51,1.03 respectively). UCit/Cr and UCa/Cr had negative correlation with age. UCit/Cr was significantly lower in females≥70y than females<70y(0.66vs1.32) and closed to the UCit/Cr in males≥70y(0.54). UOx/Cr decreased in M≥70y but increased in females≥70y(<70vs≥70y, M:21.9vs18.4, F:28.7vs32.9).

**Conclusion** This study demonstrated UCit & genetic influence on the UUTS in NE Thailand. The increase prevalence of UUTS in elderly female may be from the decrease in UCit and increase in UOx. SF had worse urinary promoters and inhibitors than C while NSFS had better inhibitors and UOx than SF.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO140

**Gallstones and the Risk of Nephrolithiasis** Eric N. Taylor,[1,2] Gary C. Curhan.[2,3] *[1]Division of Nephrology and Transplantation, Maine Medical Center, Portland, ME; [2]Channing Laboratory, Brigham and Women's Hospital, Boston, MA; [3]Renal Division, Brigham and Women's Hospital, Boston, MA.*

**Background**. Existing data on the potential association between gallstones and nephrolithiasis are suggestive but limited.

**Methods**. To evaluate the relation between symptomatic radiographically confirmed gallstones and/or cholecystectomy (GS) and prevalent kidney stones (KS), we conducted a cross-sectional study of three large cohorts including over 240,000 participants: the Nurses' Health Study I (older women), the Nurses' Health Study II (younger women), and the Health Professionals Follow-up Study (men). We then prospectively studied the association between history of GS and incident symptomatic KS over a combined 56 years of follow-up. We also prospectively examined the relation between history of KS and incident GS. Multivariate regression models adjusted for age, body size, thiazide diuretic use, fluid intake, diet, and other factors.

**Results.** At baseline, the multivariate odds ratio of prevalent KS in individuals with GS compared to individuals without was 1.67 (95 % CI 1.48 to 1.89) in older women, 1.87 (95% CI 1.67 to 2.10) in younger women, and 1.62 (95% CI 1.41 to 1.85) in men. Prospectively, the multivariate relative risk of incident KS in participants with GS compared to participants without was 1.32 (95 % CI 1.16 to 1.51) in older women, 1.35 (95% CI 1.17 to 1.55) in younger women, and 1.34 (95% CI 1.10 to 1.64) in men. The multivariate relative risk of incident GS in participants with a history of KS compared to participants without was 1.18 (95 % CI 1.07 to 1.30) in older women, 1.29 (95% CI 1.17 to 1.42) in younger women, and 1.48 (95% CI 1.29 to 1.69) in men. Prospective "lag" analyses instituting a delay of 4 years between the diagnoses of GS and KS yielded similar results.

**Conclusion.** Gallstones are associated with kidney stones, independent of diet, body size, and other factors. Additional studies are needed to elucidate potential mechanisms underlying this association.

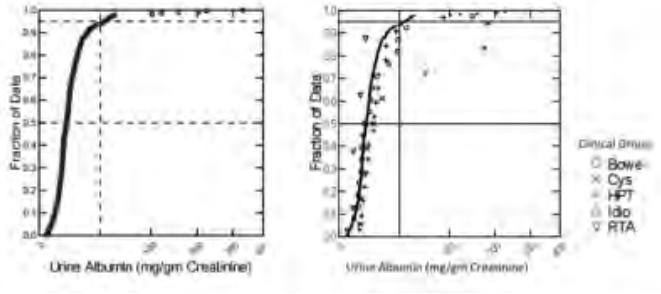
**TH-PO141**

**Prevalence of Albuminuria Is Not Increased in Patients with Idiopathic Calcium Nephrolithiasis** Anna L. Zisman, Kristin J. Bergsland, Elaine M. Worcester, Fredric L. Coe. *Department of Medicine, Section of Nephrology, University of Chicago, Chicago, IL.*

Nephrolithiasis has been associated with decreased renal function in population studies, but those data are limited in that the stone forming population is poorly characterized. Microalbuminuria is associated with kidney injury. We hypothesized that stone formers (SF) would be more likely to show evidence of renal injury in the form of microalbuminuria. We evaluated the clinical and laboratory data for 549 SF who had submitted 24-hour urine collections in the past 2 years. We excluded urine samples with any evidence of hematuria (trace or above) by dipstick (n=134, 24.4%). After exclusion of patients with diabetes (n=46), proteinuria >1g/day (n=6), urine oxalate >100 mg/day (n=4), those with non-idiopathic calcium stones (n=51), and those with missing data (n=19), our sample included 289 SF (36% F) with a mean age of 45.5 ± 13.5 years. There was no relationship between albumin excretion and age, gender, weight, measured creatinine clearance, systolic blood pressure, number of ESWL, or urine pH (p=NS). Only 5% of patients demonstrated urinary albumin/creatinine ratio of >30 mg/g, which is similar to that documented for the general population in NHANES III (Figure, left panel). When we compared the albumin excretion of the idiopathic SF to that of the other stone forming populations (RTA, hyperparathyroidism, bowel disease, and cystinuria), only the cystine SF demonstrated higher albumin excretion (ANOVA, p<0.002). (Figure, right panel). **Conclusions:** Nearly one fourth of patients referred for kidney stone prevention present with at least microscopic hematuria. Idiopathic calcium SF without hematuria show no evidence of increased microalbuminuria. Cystine SF exhibit increased albumin excretion, potentially signifying the presence of greater renal injury.



Disclosure of Financial Relationships: nothing to disclose

**TH-PO142**

**Obesity in Adolescents Induces Insulin Resistance & Increased Risk for Uric Acid & Calcium Oxalate Kidney Stones** Gregory Lee Braden,[2] Rishita Tiwari,[1] Holley F. Allen,[1] Thomas Campfield,[1] Varun Agrawal,[2] Edward O. Reiter.[1] *[1]Dept of Pediatrics, Baystate Medical Ctr/Tufts University School of Medicine, Springfield & Boston, MA; [2]Dept of Medicine, Baystate Medical Ctr/ Tufts University School of Medicine, Springfield & Boston, MA.*

Obese adults are at risk for calcium oxalate(CaOx) & uric acid(UA) kidney stones(KS) from the metabolic syndrome & insulin resistance(IR) which inhibits renal ammoniagenesis leading to a low urine ph and insoluble UA. Whether these same risks occur in obese adolescents(ADs) are unknown. We studied 46 obese ADs, mean age 14.6 years, BMI 36 kg/m2 with no KS history. They formed 2 groups, 26 ADs with IR defined as a HOMA>4.4 (fasting glucose/fasting serum insulin) vs 20 obese AD controls ( HOMA < 4.4). Metabolic syndrome traits were measured: HOMA>4.4, HDL chol<40mg/dL, blood pressure>90th%, or triglycerides>150mg/dL. 24 hour urines were obtained for sodium(Na), magnesium, calcium(Ca), uric acid(UA), potassium, phosphorus, chloride, oxalate(Ox) & 24 hour ph. A fasting urine for all stone forming elements was obatined to calculate the relative CaOx saturation ratio(RSR)by the EQUIL program and urine ph by ion electrode. 24 hour osteopontin was measured by ELISA. There were no differences in mean daily excretion of Na,Ca,Ox,UA or osteopontin in the IR ADs vs Cs. However, the 24 hour urine ph correlated inversely with increasing HOMA value (r=-.31,p=.04). Fasting urine ph correlated inversely with increasing numbers of metabolic syndrome traits (r=-.34,p=.02). There was no relationship of HOMA to UA or Ox excretion but HOMA correlated positively to increasing calcium excretion(r=.34,p=.02) & positively to increasing CaOxRSR (r=.33,p=.03).We conclude: Similar to adults with metabolic syndrome, in obese ADs, IR correlates directly to increased urinary calcium excretion and increased CaOxRSR & lower urinary ph. Metabolic syndrome traits correlate directly to lower urinary ph. Obese ADs with IR & metabolic syndrome traits are at risk for UA & CaOx KS.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO143**

**A Comparison of Metabolic Variables among Obese and Non-Obese Kidney Stone Formers** Nikhil Johri, Stephen B. Walsh, William G. Robertson, Robert J. Unwin. *Centre for Nephrology, Royal Free Hospital NHS Trust and UCL Medical School, London, United Kingdom.*

Kidney stone disease is common worldwide and the incidence is growing. Increasing prevalence of obesity has been linked with this increase. Studies suggest that insulin resistant states may be associated with increased risk of uric acid stones. We studied metabolic differences between obese and non-obese stone formers.

We investigated the kidney stone database created between November 97 and November 09 (N=1654). Patients were divided into two categories – BMI ≤ 25.0 kg/m$^2$ and BMI ≥30.0 kg/m$^2$. Serum (S) and urinary (U) analytes were compared. We also compared the stone composition for these groups. Data were processed using 'GraphPad' software and statistical significance calculated using Mann-Whitney Test. Results are expressed as mean ± S.E .M.

Analysis showed 664 (40.1%) individuals had BMI ≤25 and 336 (20.3%) had BMI ≥30. In BMI≥30 group, S. Creatinine levels were significantly higher (95.6 ± 2.38 vs. 88.6 ± 1.56 umol/L p<0.001) as was S. Urate (371.0 ± 6.0 vs. 301.5 ± 4.0 umol/L p<0.001). S. Bicarbonate levels on the other hand were lower (26.5 ± 0.1 vs. 27.8 ± 0.2 mmol/L p<0.001). Higher levels of U.Oxalate (0.364 ± 0.0 vs. 0.348 ± 0.1 mmol/L p<0.001), U.Citrate (2.7 ± 0.1 vs. 2.4 ± 0.0 mmol/L p= 0.004), U.Urate (3.9 ± 0.07 vs. 3.19 ± 0.04 mmol/L p<0.001), U.Na (188 ± 4.0 vs. 150 ± 2.5 mmol/L p<0.001) and U.K (71 ± 1.3 vs. 68.4 ± 1.09 mmol/L p=0.037) were also seen in those with BMI ≥30. U.pH was significantly lower (5.974 ± 0.072 vs. 6.382 ± 0.023 p<0.001) in those with BMI ≥30. Differences in U.Volume, U.Mg and U.Ca were not significant. Stone composition data (N=468) showed 4% of stones to be composed of uric acid in those with BMI ≤25, whereas the proportion of uric acid stones was 27.8% in those with BMI ≥30.

Increasing BMI not only increases the overall risk of stone formation but also skews the risk factors in favor of uric acid stones. This greater risk is primarily due to raised U.Urate, U.Oxalate, U.Na and lower U.pH. U.Ca was not a significant additional risk factor. High BMI patients also have worse renal function which puts them at a higher risk of prospective renal dysfunction.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO144**

**Beta Thalassemia Major and Urolithiasis** Nikhil Johri, William G. Robertson, Robert J. Unwin, Stephen B. Walsh. *University College London Partners Renal Centre, London, United Kingdom.*

Patients with beta-thalassaemia major (BTM) are prone to urolithiasis, thought to be due to chronic hemolysis leading to uric acid (UA) stones. We interrogated our renal stone database in order to compare patients with BTM and kidney stones with the other stone forming patients.

13 BTM patients were compared with the other 432 stone forming (SF) patients. The probability of stone formation (PSF) was calculated. Significance was calculated using the unpaired t-test. Values expressed are means ± S.E.M.

BTM patients were younger than SF patients (31.4 ± 3 vs. 47.2 ± 1 years p=0.0001). All identified stones in the BTM group were calcium oxalate (CaOx) or mixed calcium oxalate/phosphate (CaOx/P).

Serum bicarbonate was higher in BTM patients (28.6 ± 0.5 vs. 26.4 ± 0.2 mmol/L p=0.01) but there was no difference in urine pH (6.18 ± 0.1 vs. 6.15 ± 0.1, ns).

Serum UA was lower in the BTM group (270 ± 34 vs. 340 ± 5 µmol/L, p=0.01), however the 24-hour urinary uric acid was higher in BTM patients (4.1 ± 0.4 vs. 3.3 ± 0.1 µmol/L, p=0.02).

24-hour urinary calcium was higher in BTM patients (9.5 ± 1.8 vs. 5.4 ± 0.2 mmol/L, p<0.0001), but they had a lower dietary calcium intake than SF patients (23.3 ± 2 vs. 24.6 ± 1 mmol/day, ns).

Serum phosphate was higher in the BTM group (1.2 ± 0.1 vs. 1.02 ± 0 mmol/L, p=0.001), as was 24-hour urinary citrate (3.4 ± 0.4 vs. 2.5 ± 0.1 mmol/L, p=0.03).

The PSF in BTM and SF patients was very low for UA stones (0.7 x $10^{-6}$ ± 0 vs. 0.04 ± 0, ns), and mixed UA and CaOx stones (0.5 x $10^{-4}$ ± 0 vs. 0.04 ± 0, ns).

The PSF was significantly higher in BTM patients for the formation of CaOx (0.57 ± 0.1 vs. 0.3 ± 0.01, p=0.005) and mixed CaOx/P stones (0.6 ± 0.1 vs. 0.3 ± 0.01, p=0.005).

Despite a higher concentration of urinary UA in the BTM group, these data do not support the common view that they are more likely to form UA stones. They are hypercalciuric and have a higher tendency to form CaOx and mixed CaOx/P stones than the other stone forming patients on the database. Resorptive bone disease is prevalent in BTM, which may be related to hypogonadism: we suspect that the consequent hypercalciuria is the cause of urolithiasis, rather than UA stone formation due to chronic haemolysis.

**The Increasing Burden of Pediatric Urolithiasis in the United States** John D. Spencer, Halima S. Janjua, Rose M. Ayoob, John D. Mahan. *Division of Pediatrics, Department of Nephrology, Nationwide Children's Hospital, Columbus, OH.*

**Background**: Recent evidence suggests that the prevalence of urolithiasis is increasing in the USA. The epidemiology of pediatric urolithiasis is not well characterized. A recent NIH report identified pediatric urolithiasis as an insufficiently researched area.

**Objective**: To evaluate the demographics of pediatric urolithiasis admissions and identify trends in their utilization of healthcare resources.

**Design/Methods**: A retrospective analysis was performed on children ≤18 yrs of age, admitted with urolithiasis from 1997-2006, using the Healthcare Cost and Utilization Project Kids' Inpatient Database (KID).

**Results**: *Hospitalizations*: From 1997-2006, the KID captured 6.5 million annual discharges. During this period, 3,799 ± 152 children/yr were hospitalized with urolithiasis. Hospitalizations increased 30% (p<0.001); female admissions increased 36% and male admissions increased 27% (p<0.001). The average hospitalization was 2.2 +/- 0.1 days and did not vary by year, gender, or age group. *Patient Demographics*: Females were 1.5 times more likely to be admitted than males. Children ≤10 yrs of age were more likely to be hospitalized if they were male; patients ≥15 yrs of age were more likely to be hospitalized if they were female (p < 0.001). Children with ureteral calculi were 1.5 times more likely to be admitted than children with renal calculi. *Geographic Location*: Hospitalization rates in the South were 1.7 times more common than hospitalization rates in the Midwest and 2.5 times more common than in the Northeast or West. *Hospital Economics*: In 2000, estimated hospital costs for a urolithiasis admission were $3,384/hospitalization. In 2006, costs rose to $5,115/hospitalization. Mean hospital charges increased from $5,927 to $9,868 per hospitalization – representing a 66% increase.

**Conclusions:** Urolithiasis is common in the American pediatric population. Since 1997, hospitalization rates for urolithiasis rapidly increased. Hospitalization is more common in females, teens, and children from Southern states. Although lengths of hospitalization remain constant, hospital charges continue to rise.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO146

**Kidney Stones and the Risk of End-Stage Renal Disease (ESRD)** Ziad El-Zoghby,[1] John C. Lieske,[1] Robert N. Foley,[1] Eric J. Bergstralh,[2] Xujian Li,[2] Amy E. Krambeck,[3] Andrew D. Rule.[1] *[1]Nephrology and Hypertension, Mayo Clinic; [2]Biomedical Statistics and Informatics, Mayo Clinic; [3]Urology, Mayo Clinic, Rochester, MN.*

**Background:** Kidney stones are a risk factor for chronic kidney disease but it is unclear the extent they contribute to the development of end-stage renal disease (ESRD). To our knowledge, no cohort studies have assessed the ESRD risk among kidney stone formers in the general population.

**Methods:** The study cohort included all stone formers in Olmsted County, Minnesota first diagnosed between 1984 and 2003. Controls were matched 3:1 on age, sex, duration of medical record, and year of a clinic visit date. Incident ESRD cases were identified by querying the United States Renal Data System and Mayo Clinic dialysis and transplant databases validated by chart review through 12/31/2007. Co-morbidities (hypertension, diabetes, obesity, dyslipidemia, gout, alcohol dependence, tobacco use) were determined by diagnostic codes. Subjects were censored at ESRD or death (Minnesota death certificate).

**Results:** Mean follow up was 9.0 years in 4461 stone formers and 9.2 years in 10,638 controls. A total of 92 subjects developed ESRD after the index date. The incidence of ESRD was 1.02 (95% CI: 0.73 to 1.39) events per 1000 person years in stone formers and 0.52 (95% CI: 0.39 to 0.68) events per 1000 person years in controls. The risk of ESRD in stone formers increased with age-sex-adjustment (HR= 1.92, 95% CI: 1.27 to 2.90) and with adjustment for all comorbidities (HR=1.77, 95% CI: 1.16 to 2.68). The reported causes of ESRD among stone formers (n=41) were kidney stones in 3, diabetes in 10, glomerulonephritis/vasculitis in 5, hypertension in 4, multifactorial in 4, polycystic kidney disease in 3 and other/unknown in 12.

**Conclusion:** Kidney stone formers in the general population are at increased risk for ESRD, but kidney stones are usually not the primary cause attributed to the development of ESRD.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO147

**Temporal Trends in the Incidence of Kidney Stone Disease in Iceland: Results of a Nationwide Study** Vidar O. Edvardsson,[1,3] Olafur S. Indridason,[2] Runolfur Palsson.[2,3] *[1]Children´s Medical Center, Landspitali University Hospital, Reykjavik, Iceland; [2]Division of Nephrology, Landspitali University Hospital, Reykjavik, Iceland; [3]Faculty of Medicine, School of Health Sciences, University of Iceland, Reykjavik, Iceland.*

Recent reports have suggested a rising occurrence of kidney stone disease. The aim of the study was to examine the incidence and recent trends of kidney stone disease in the adult Icelandic population.

Computerized databases of all major hospitals and medical imaging centers in Iceland covering the years 1983-2008, were searched for ICD, radiology and surgical procedure codes indicative of kidney stones. Patients diagnosed with kidney stones before 1990 were excluded from the analysis due to incomplete electronic coding. Medical records were reviewed to confirm the diagnosis of kidney stone disease and to determine if the stones were associated with clinical symptoms. Time trends in the incidence of kidney stones were assessed by regression analysis.

During the years 1990 to 2008 the number of incident patients was 5026, of whom 3170 were men. Mean age at diagnosis was 52.8 ± 17.5 years for men and 48.9 ± 18.9 years for women. Symptomatic stones were present in 4202 patients (83.6%), 505 patients (10%) were asymptomatic and the presence of symptoms could not be determined in 319 patients (6.3%). The annual incidence of kidney stones ranged from 149 to 185 per 100,000 in men and remained unchanged over time (P=0.76). In women, the incidence was also similar throughout the study period, ranging from 72 to 123 per 100,000 (P=0.17). The annual incidence of asymptomatic stones increased over time from 10 to 24 per 100,000 in men (P <0.001) and from 6 to 21 per 100,000 in women (P=0.001). Asymptomatic patients were significantly older than symtomatic patients, 65.6 ± 15.0 vs. 49.4 ± 17.8 years, respectively (P <0.001).

The incidence of kidney stones in the Icelandic population has not increased over the past two decades. However, the diagnosis of asymptomatic stones has more than doubled during this period, possibly due to increased use of imaging studies in older patients.

**Incidence of Kidney Stone Disease in Icelandic Children, 1990-2008: A Nationwide Study** Vidar O. Edvardsson,[1,3] Olafur S. Indridason,[2] Runolfur Palsson.[2,3] *[1]Children´s Medical Center, Landspitali University Hospital, Reykjavik, Iceland; [2]Division of Nephrology, Landspitali University Hospital, Reykjavik, Iceland; [3]Faculty of Medicine, School of Health Sciences, University of Iceland, Reykjavik, Iceland.*

The incidence of kidney stone disease in children has been rising according to recent studies. The aim of the study was to examine the incidence and temporal trends of confirmed kidney stone disease in Icelandic children.

Computerized databases of all major hospitals and medical imaging centers in Iceland covering the years 1983 to 2008, were searched for ICD, radiology and surgical procedure codes indicative of kidney stones in children and adolescents less than 18 years of age. Children diagnosed with kidney stones before 1990 were excluded from the analysis due to incomplete electronic coding. Medical records were reviewed to confirm the diagnosis of kidney stone disease and to determine if the stones were associated with clinical symptoms. Age-standardized incidence was calculated and trends in the incidence over time were assessed by regression analysis.

We identified 147 children who were diagnosed with their first kidney stone between 1990 and 2008, 66 males and 81 females. The medan (range) age for males was 13.7 (0.22-17.99) years and 15.1 (0.77-17.76) years for females. All but 6 patients were symptomatic at the time of diagnosis. The mean annual incidence was 9.9 ± 4.5 per 100,000 children. It was 8.7 ± 4.3 and 11.1 ± 7.2 per 100,000 for males and females, respectively (P=0.21). There was a borderline significant (P=0.058) linear increase in the annual incidence over time, that largely resulted from a relatively low annual incidence during the first 5 years of the study period.

The incidence of kidney stones in Icelandic children is high compared to other Western nations. Contrary to recent studies, the incidence of kidney stone disease in children has not increased significantly during the last two decades in Iceland.

### TH-PO149

**Previous Shock Wave Lithotripsy Is Not Associated with Hypertension among Community Stone Formers at Long-Term Follow-Up** Amy E. Krambeck,[1] Andrew D. Rule,[2] Xujian Li,[3] Eric J. Bergstralh,[3] John C. Lieske.[1] *[1]Urology, Mayo Clinic, Rochester, MN; [2]Internal Medicine, Mayo Clinic, Rochester, MN; [3]Biomedical Statistics and Informatics, Mayo Clinic, Rochester, MN.*

Concern exists over the subsequent development of hypertension after use of shock wave lithotripsy (SWL) for the treatment of symptomatic urolithiasis. A referral bias and lack of long-term follow-up has been a limitation of prior studies.

We identified all Olmsted County, Minnesota residents with a diagnosis of urolithiasis from 1985 to 2008. The charts were electronically queried for hypertension and obesity by diagnostic codes and use of SWL by surgical codes. All patients first diagnosed with hypertension before or up to 90 days after their first documented kidney stone were considered to have prevalent hypertension. Cox proportional hazards models were used to assess the association of SWL with a subsequent diagnosis of hypertension.

6,077 incident urolithiasis patients were identified with greater than 90 days follow-up. We excluded 1,295 (21.3%) of the population for prevalent hypertension leaving 4,782 incident urolithiasis patients for analysis. During an average follow-up of 8.7 years, new-onset hypertension was diagnosed in 983 (20.6%) of the cohort at a mean of 6.0 years from index stone date. Only 400 (8.4%) of the cohort received SWL therapy. There was no significant association between SWL treatment and the development of hypertension in univariate (P=0.33) and multivariate modeling controlling for age, gender, and obesity (Hazard ratio [95% CI] =1.03[0.84, 1.27], P=0.77).

Therefore, in a large population-based cohort of kidney stone formers we failed to identify an association between SWL and the subsequent long-term risk of hypertension.

### TH-PO150

**Renal Histology of Living Kidney Donors with and without Radiographic Stones and Past Symptomatic Stone Events** Merfake Semret,[1] John C. Lieske,[1] Lynn D. Cornell,[2] Elizabeth C. Lorenz,[1] Terri J. Vrtiska,[3] Andrew D. Rule.[1] *[1]Nephrology, Mayo Clinic, Rochester, MN; [2]Anatomic Pathology, Mayo Clinic, Rochester, MN; [3]Radiology, Mayo Clinic, Rochester, MN.*

Background: Certain risk factors for kidney stones (age, hypertension, obesity, hyperuricemia) associate with nephrosclerosis or increased nephron size on renal biopsy. Our objective was to determine if kidney stones were associated with changes in renal histology among living kidney donors.

Methods: Kidney donors at the Mayo Clinic from 2001 and 2009 were identified. During donor evaluation, radiographic kidney stones from computed tomography scans and past symptomatic kidney stones from clinic notes were identified. Renal biopsies at the time of transplant were reviewed for the presence of crystals, including using polarizing light microscopy for detection of Ca-Oxalate crystals. Nephrosclerosis was determined from 2 or more of the following: any glomerulosclerosis, any tubular atrophy, interstitial fibrosis >5%, any arteriosclerosis. Cortex per glomerulus (mm2), a measure of nephron size, was calculated [sectioned width x length x % cortex/number of glomeruli].

Results: There were 1143 kidney donors (58% female, mean age 44 years) of which 107 (9.4%) had radiographic stones and 21 (1.8%) had past symptomatic stones. Between persons with and without radiographic stones, there was no difference in the prevalence of crystals (3 vs 2%, p=0.54), nephrosclerosis (28% vs 28%, p=0.93), or nephron size (mean 0.48 vs 0.49 mm2, p=0.80). Between persons with and without past symptomatic stones, there was a difference in the prevalence of crystals (10 vs 2%, p=0.013), and possibly nephrosclerosis (43% vs 27%, p=0.12), but not nephron size (mean 0.48 vs 0.48, p=0.98). However, with age adjustment there is no association between past symptomatic stones and nephrosclerosis (p=0.52). Of the 23 donors with renal crystals, 21 had Ca-Phosphate, 3 had Ca-oxalate and 15 were in cortex.

Conclusion: There is no evidence that radiographic or past symptomatic kidney stones associate with nephrosclerosis or nephron size. Crystals in the cortex may contribute to kidney stones particularly in persons with past symptomatic stone passage.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO151

**Gender Differences in Urinary Osteopontin among Incident Stone Formers**

Michael P. Linnes,[1] Amy E. Krambeck,[2] Andrew D. Rule,[1] John C. Lieske.[1] *[1]Internal Medicine, Mayo Clinic, Rochester, MN; [2]Urology, Mayo Clinic, Rochester, MN.*

Proteins have been identified in urine that inhibit crystal growth, and this activity appears reduced in certain stone formers. Osteopontin (OPN) is one urinary protein with crystal growth inhibition (CGI) activity.

Urine samples from a community-based cohort of recent first-time stone formers (n=81) and controls without a stone history (n=304) were collected. A seeded calcium oxalate crystal assay was used to measure total urinary protein CGI activity. For this study samples were selected from male and female stone formers and controls with CGI in the lower and upper quartile (n=10 each). OPN was quantitated by ELISA and creatinine (Cr) by enzymatic creatinase assay.

Stone formers and controls were matched by age at 43.3 ± 12.5 years and 41.6 ± 12.9 years respectively. OPN/Cr was higher in stone formers vs. controls, 246 ± 21 pg/mg and 141 ± 64 pg/mg respectively. When stratified by gender, OPN/Cr was higher in female stone formers (400 ± 119.6 pg/mg) compared to female controls (161 ± 34 pg/mg) and both male stone formers (134 ± 34 pg/mg) and controls (121 ± 25 pg/mg) (p=0.01). Furthermore, female stone formers with inhibition levels in the upper quartile had significantly higher OPN/Cr (599± 215 pg/mg, n=10) than stone forming females in the lower quartile (200 ±72 pg/mg, n=10) and all other groups (p<0.05). OPN/Cr positively correlated with urinary CGI in the female stone formers and controls but inversely correlated in the male stone formers and controls.

OPN appears to correlate with CGI in women but not men, and levels are higher in female stone formers than female controls, male stone formers, or male controls. These results suggests than OPN may increase in response to stone formation, perhaps in a compensatory manner, or be involved in stone generation. However, the role of OPN in stone pathogenesis may differ between men and women.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO152

**Timing Relative to Stone Events Determines Patient-Reported Outcomes (PRO) of Health-Related Quality of Life (HRQoL) Assessment in Kidney Stone Formers (SF)**

Frank Modersitzki,[1] Laura T. Pizzi,[2] David S. Goldfarb.[1] *[1]Nephrology Section, New York VAMC and NYU School of Medicine, New York, NY; [2]Health Economics and Outcomes Research, Jefferson School of Population Health, Philadelphia, PA.*

Kidney stones are perceived as causing only transient effects on HRQoL. Studies assessing HRQoL of SF are few. We measured HRQoL in SF and compared it to normative values of the US population. We used an online version of SF-36 v2 administered to cystine and non-cystine stone formers. Patients were recruited through an active stone and urology practice and via online solicitation. We surveyed 295 SF. In a secondary data analysis, we determined the effect of the length of the interval between administering the HRQoL instrument and the last reported kidney stone event.

**Results:** For the complete sample, SF had worse HRQoL than the normative US data in all 8 domains composing the Physical Summary Score (PCS) and Mental Summary Score (MCS). In the secondary data analysis, we divided the complete sample into 3 subgroups based on the time since the last reported kidney stone event: within 30 days; > 1 to 6 months; 6 months – 1 year. Our results showed an improvement in all SF-36 domains with increasing time since the last kidney stone event (ANOVA P<0.05).

Effect of time since last stone episode on summary domain scores

| Summary Score | | N | Mean | SD |
|---|---|---|---|---|
| Physical | within 30 days | 91 | 40.53 | 9.34 |
| | 1 - 6 months | 60 | 47.93 | 8.80 |
| | 6 mo - 1 year | 99 | 51.26 | 9.18 |
| Mental | within 30 days | 91 | 35.81 | 13.44 |
| | 1 - 6 months | 60 | 47.53 | 10.70 |
| | 6 mo - 1 year | 99 | 48.03 | 12.25 |

**Conclusions:** SF have worse HRQoL than US normative population. Currently there is no disease specific HRQoL instrument available for kidney stones. When using a generic non-disease specific instrument like the SF-36, the appropriate timing of the assessment of HRQoL is important. The SF-36 is designed so that the majority of the questions elicit patient-reported HRQoL of the past 30 days (22 questions). While applying the SF-36, the time interval since the last stone episode has a major effect on HRQoL PRO.

## TH-PO153

**Once Daily Extended Release Niacin (Niaspan®) Lowers Serum Phosphorus in Patients with the Metabolic Syndrome**

Susie L. Hu,[1] Gregory C. Shearer,[3] Michael Steffes,[2] Andrew G. Bostom.[1] *[1]Medicine, Division of Kidney Disease and Hypertension, Rhode Island Hospital, Warren Alpert School of Medicine at Brown University, Providence, RI; [2]Laboratory Medicine and Pathology, University of Minnesota Medical School, Minneapolis, MN; [3]Sanford Health-USD Biomed Research, Sioux Falls, SD.*

**Introduction:** Hyperphosphatemia has been shown to be independently associated with cardiovascular disease and all-cause mortality among end-stage renal disease and chronic kidney disease patients. The hypophosphatemic effect of niacin compounds appears to be mediated via their direct inhibition of the small intestinal active transporter for phosphorus.

**Methods and Results:** We examined the phosphorous lowering effect of extended-release niacin (ERN, Niaspan®) among 59 subjects with metabolic syndrome during an 8-week randomized, placebo-controlled 2X2 factorial intervention trial assessing the effect of extended release niacin (ERN; Niaspan®) and Omega-3 Fatty acids (OMFA) on lipid and lipoprotein concentrations. Subjects were randomized into 8 weeks duration of dual placebo, OMFA (4 g/day), ER niacin (2 g/day), or both after a 6-week placebo run-in period. Baseline creatinine, and baseline as well as 8-week phosphorus, calcium, and albumin levels were determined. Estimated glomerular filtrations rates for the entire study group ranged from 58 to 122 ml/min/1.73 $m^2$. There was no evidence for ERN-OMFA treatment interaction (test for interaction by ANOVA, p=0.31) with regard to effects on serum phosphorus. After 8 weeks of treatment, ERN (n=29) lowered mean (± SD) baseline phosphorus levels (3.22 ± 0.51) by an average of -0.48 ± 0.48 mg/dl. Placebo ERN treatment (n=30) did not reduce serum mean phosphorus levels from baseline (3.01 ± 0.64 mg/dl; change= -0.03 ± 0.65; unpaired t-test comparison of between group changes, p=0.004). ERN effect on serum phosphorus persisted (at -0.40, SD ± 0.43 mg/dl, p=0.01) upon analysis of covariance adjustment for baseline concentrations of phosphorus.

**Conclusion**: Once daily ERN reduces phosphorus levels by ~12 % among subjects with metabolic syndrome free of advanced CKD.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO154

**PA21, a Novel Oral Iron Based Phosphate Binder (PB), Significantly Reduces Hyperphosphatemia in Hemodialysis (HD) Patients**

James A. Tumlin,[1] Michel B. Chonchol,[2] Edward M. F. Chong,[3] Sylvain Gaillard.[3] *[1]Dept of Nephrology, Univ of Tennessee, Chattanooga, TN; [2]Dept of Nephrology, Univ of Colorado Health Sciences Center, Denver, CO; [3]Vifor Pharma, Glattbrugg, Switzerland.*

**Introduction:** This study's purpose was to determine the ability of escalating doses of PA21 to effectively and safely lower serum phosphate (P) levels in HD patients.

**Methods:** This was a multicenter, randomized, open-label, active-controlled, parallel-group study. Major inclusion criteria were: ≥ 18 years old, on a P restricted diet, & on HD 3 times/wk for ≥ 3 months. After washout of the previous PB, subjects whose P levels increased to ≥ 5.5 mg/dL were randomized equally to 5 PA21 arms (1.25, 5.0, 7.5, 10.0, or 12.5g/day) or the control arm of sevelamer HCl (SEV) 4.8 g/day for 6 wks of treatment. The primary efficacy endpoint was the change in P from Baseline to End of Treatment. Secondary efficacy endpoints included time to reach the first controlled P level and the % of subjects achieving controlled P levels (≥3.5 to ≤5.5 mg/dL).

**Results:** Overall, 154 subjects were randomized. For the primary efficacy endpoint, the intent-to-treat group (n=147) showed a statistically significant (p≤ 0.006) decrease from baseline in all but the lowest PA21 dose (decrease of 1.3, 1.3, 1.6 and 1.8 mg/dL for the 4 higher PA21 doses respectively). SEV showed a decrease of 1.3 mg/dL. Median time to first controlled P level was 1 wk in the 4 higher PA21 groups and 2 wks in the SEV group. During treatment, the % of subjects with controlled P levels in the PA21 5.0 to 12.5g/day groups ranged from 68% to 91% and 83% in the SEV group. Apart from hypophosphatemia, adverse events reported with PA21 were not dose dependent, were mainly GI related & occurred with similar frequency to SEV group. There were no discontinuations due to GI events with PA21, but 2 with SEV (diarrhea).

**Conclusions:** PA21 exerted a significant dose dependent P lowering effect between 5.0 - 12.5g/day. The results for 5.0 and 7.5g/day appeared to be comparable to SEV 4.8g/day; 10.0 and 12.5 g/day achieved a greater lowering of P than the SEV dose. These results demonstrate that PA21 is an efficacious and well tolerated new PB.

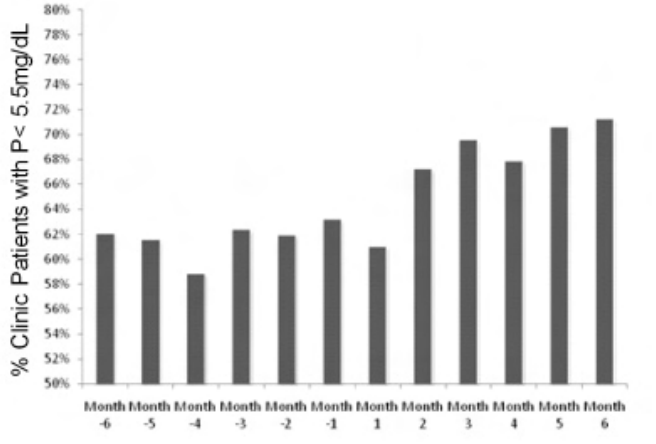
**TH-PO155**

**Focused Phosphorus Management Program Decreases Hyperphosphataemia in End Stage Renal Disease Patients** Tracy Jack Mayne,[1] Steven M. Wilson,[1] Carey Colson,[1] Kathy E. Ricketts.[2] *[1]DaVita Inc., Denver, CO; [2]Shire Pharmaceuticals, Chesterbrook, PA.*

Background End stage renal disease (ESRD) causes disregulation of bone and mineral metabolism, including an increase in serum phosphorus. KDOQI guidelines recommend maintaining phosphorus levels between 3.5 and 5.5 mg/dL. A focused phosphorus management program was designed to support patients with proper diet and phosphorus management through in-center phosphorus educational materials, as well as direct-to-patient adherence communications. It also includes education and access support specific to adherence to lanthanum carbonate.

Method This was an evaluation of 8 dialysis centers before and after initiation of the focused phosphorus management program; the level of analysis was the facility. Mean center size was 88+23 patients (range: 68-141). Centers were geographically diverse (CA, FL, GA, IL, NC, NJ, PA,TX). A repeated measures general linear model was performed.

Results There was a significant increase in the percent of center patients achieving KDOQI phosphorus goals (mean increase from month -6 to month 6=9.2%+6.5%; p<0.01). The percent of patients receiving lanthanum carbonate increased from 18.2% to 24.7% over 12 months. The correlation between change in percent of patients on lanthanum carbonate and change in percent achieving phosphorus < 5.5mg/dL from month -6 to month 6 was r=0.78 (p < 0.01).



Conclusion The focused phosphorus management program improved serum phosphorus goal attainment compared to baseline. Increased lanthanum carbonate use was associated with increased achievement of phosphorus target levels. A larger randomized controlled study is planned.

Disclosure of Financial Relationships: Employer: DaVita, Inc.; Honoraria: Sanofi-Aventis.

**TH-PO156**

**Associations between Serum Phosphorus and Anemia in Kidney Transplant Recipients** Csaba P. Kovesdy,[1,2] Maria Eszter Czira,[3] Anna Rudas,[3] Akos Ujszaszi,[3] Laszlo Rosivall,[3] Myles S. Wolf,[4] Marta Novak,[3] Istvan Mucsi,[3] Miklos Z. Molnar.[3,5] *[1]Salem VA Medical Center, Salem, VA; [2]University of Virginia, Charlottesville, VA; [3]Semmelweis University, Budapest, Hungary; [4]University of Miami, Miami, FL; [5]Harbor-UCLA, Torrance, CA.*

Post-transplant anemia is a common complication in kidney transplant (KT) recipients and is associated with increase in mortality and morbidity. Abnormalities of mineral and bone metabolism have been associated with anemia in patients with CKD and ESRD, but such a link has not been examined in KT recipients.

We examined associations of serum phosphorus (PO4) with blood hemoglobin (Hgb) level and with the prevalence of anemia in 992 KT recipients. Associations were examined in regression models adjusted for age, sex, diabetes, smoking, transplant vintage, acute rejections, medication use, the malnutrition-inflammation score, estimated GFR and serum calcium, PTH, 25OH vitamin D, fibroblast growth factor-23, iron, erythropoetin, percent hypochromic reticulocytes, soluble transferrin receptor, ferritin, C-reactive protein and interleukin-6.

Higher PO4 was associated with significantly lower Hgb and higher risk of anemia (Figure). A 1 mg/dl higher PO4 was associated with 0.29 g/dl lower Hgb (95%CI: 0.42-0.16, p<0.001) and with an odds ratio of anemia of 2.1 (95%CI: 1.4-3.0, p<0.001) after adjustments. The results were consistent in subgroups of patients with different levels of kidney function and various markers of inflammation and mineral-bone disorder.

Higher serum PO4 is associated with anemia in KT recipients even within the normal range of serum phosphorus. This association is independent of kidney function, inflammation, PTH, vitamin D and FGF23. Future studies are needed to assess possible mechanisms of action (such as the effect of PO4 on uremic toxin metabolism), and to determine if lowering serum PO4 can improve Hgb levels.

**TH-PO157**

**Sevelamer Therapy and Mortality in Pre-Dialysis Chronic Kidney Disease Patients** Ana Cabrita, Anabela Malho, Ana Pinho, Elsa Morgado, Ana Paula Silva, Pedro Neves. *Serviço de Nefrologia, Hospital de Faro, EPE, Faro, Portugal.*

Cardiovascular disease (CVD) is the main cause of morbidity and mortality in chronic kidney disease (CKD) patients. Vascular calcification was described as one of the risk factors of CVD, and recently, sevelamer hydrochloride (SH) therapy has been associated in some studies with a decreased calcification and mortality. The aim of this study was to evaluate the influence of SH on the survival of pre-dialysis patients.

We included 95 patients of our "low-clearance" outpatient clinic (f=41 m=54, mean age=69.4 years, mean eGFR = 16.1 ml/ min, mean follow-up=24.1 months). Our population was divided in 2 groups: G I (n = 76) – no phosphate binder therapy or calcium carbonate as the phosphate binder, G II (n = 19) – sevelamer as the phosphate binder. The groups were compared regarding the parameters analyzed and the survival at 24 months. We also looked for risk factors of mortality of our patients.

In the statistical analysis we performed descriptive statistics and used the student´s t-test and chi-square test and the Kaplan-Meier method and the Cox proportional hazard model.

We found at baseline, that G II were younger (59.0 vs 71.9 years, p= 0.001) and showed higher levels of phosphate (5.8 vs 4.5 mg/dl, p = 0.001), PTH (471 vs 304 pg/ml, p=0.036) and Ca x P (58 vs 44 $mg^2/dl^2$, p = 0.001). There were no differences regarding sex distribution, proportion of diabetes or presence of cardiovascular disease and eGFR, calcium, albumin and IL-6 levels. Using the Kaplan-Meier method the survival of G II at 2 years was significantly better (0.947 vs 0.690, logrank = 4.6, p = 0.032). Using the Cox proportional method we found that cardiovascular disease (p = 0.004) and IL-6 (p=0.049) were independent risk factors of death. The absence of phosphate binder therapy / use of calcium carbonate was associated with a higher trend (p=0.08) of increased mortality rate.

In conclusion, our observational study, with a mean 24 months of follow-up and a small number of patients, showed that sevelamer can have a beneficial effect on the survival of pre-dialysis patients. Further studies with more patients are needed to confirm our results

Disclosure of Financial Relationships: nothing to disclose

**TH-PO158**

**Non Calcium Containing Phosphate Binders May Excert Different Effects on Gastrointestinal Calcium Absorption** Geert J. Behets, Marc E. De Broe, Patrick C. D'Haese. *Laboratory of Pathophysiology, University of Antwerp, Antwerp, Belgium.*

Both Ca- and non Ca-containing phosphate binders (PBs) can increase gastrointestinal Ca absorption, which in subjects with chronic renal failure (CRF) may lead to increased serum Ca levels, low bone formation rate and increased risk for vascular calcifications, particularly in combination with vit D therapy. We observed in rats that administration of $La_2(CO_3)_3$ does not give rise to increased calciuria. In CRF patients, $La_2(CO_3)_3$ treatment is associated with a less pronounced decrease in serum PTH, compared to other PBs.

In the current study, Male Wistar rats (normal renal function (NRF) or CRF) received $La_2(CO_3)_3$, sevelamer, $CaCO_3$ or cellulose (2% in diet) for 8 days, followed by a 6-day washout.

Animals with NRF, treated with sevelamer showed increased serum iCa ($p < 0.05$), from 2 days after start, returning to normal within 1 day of washout. $CaCO_3$ treated animals showed a smaller increase. $La_2(CO_3)_3$treated animals did not show differences in serum iCa vs control.

In CRF animals, no significant differences in iCa were found between sevelamer, $CaCO_3$ or control groups. In the $La_2(CO_3)_3$ group, lower serum iCa ($p < 0.05$) were seen after 2 days of treatment which persisted during treatment. During washout, serum iCa returned to normal within 24h.

In a short-term experiment in which CRF animals received a single dose of any of the PBs under study showed that $CaCO_3$ induced a rapid increase in serum iCa already after 2h, whilst in the sevelamer group an increase was seen after 6 to 8 h. In contrast in the $La_2(CO_3)_3$ group a decrease in serum iCa was observed 2h after dosing. In all groups, serum iCa returned to normal within 24h.

In these experiments a concomitant inverse relationship between serum iCa and PTH was noted.

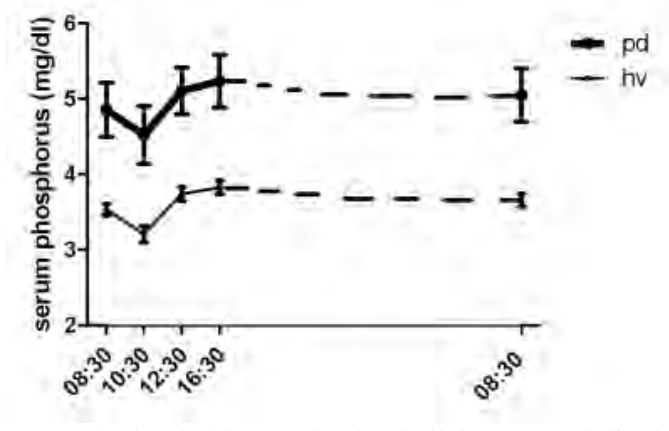
Our results show that Ca-containing as well as non Ca-containing PBs show a differential effect on serum iCa levels, likely due to the well-documented Ca-channel blocking of La at high concentrations. Our findings indicate that $La_2(CO_3)_3$ treatment may be of particular interest for CRF patients with increased risk of hypercalcemia and/or patients with low bone turnover and may facilitate the combined use of vit D.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO159

**Daytime Rhythm in Phosphorus Concentration in Healthy Volunteers and Peritoneal Dialysis Patients** Liesbeth Viaene,[1] Bjorn K. I. Meijers,[1] Bert Vermeiren,[1] Vanrenterghem Yves,[1] Dirk Vanderschueren,[2] Pieter Evenepoel.[1] *[1]Nephrology, University Hospital Leuven, Leuven, Belgium; [2]Endocrinology, University Hospital Leuven, Leuven, Belgium.*

Introduction: Serum phosphorus concentrations reflect a dynamic balance between dietary phosphorus absorption, urinary excretion and exchanges between intra- and extracellular stores. Methods: To elucidate the role of renal function, we compared the daytime rhythm in phosphorus concentration in 9 stable peritoneal dialysis (PD) patients and 10 healthy volunteers (HV). Patients were studied during a 24-hour period with standardized meals at 08:30 and 13:00 and blood sampling at 08:30, 09:30, 10:30, 12:30, 16:30 and 08:30 (day 2). Phosphate binder therapy was stopped two days in advance. All PD patients received the same dialysis regimen. Individual daytime nadir and absolute amplitude was determined. In addition, serum phosphorus levels were analyzed according to blood sample timing (07:30 to 09:30 vs 09:30 to 11:30 vs 11:30 to 13:00) in 152 unselected chronic kidney disease (CKD) patients stage 3 (eGFR 40.8±8.4 ml/min). Results: The daytime rhythm was similar in HV and PD patients: nadir: 09:42±00:40 vs 09:20±01:00; amplitude 1.14±0.33 vs 0.92±0.92 (Mean ± SD, p>0.05, all).



Serum phosphorus levels in CKD patients determined before 09:30 were significantly higher than those determined later in the morning (3.6±0.6 vs 3.1±0.6 + 3.2±0.6; p=0.02), independent of eGFR and fasted/non-fasted condition. Conclusion: The daytime rhythm in phosphorus concentration is similar in PD patients and healthy volunteers. Our data support the thesis that the daytime periodicity in serum phosphorus concentration reflects an endogenous rhythm, caused by a shift between the cellular and extracellular compartment. Blood sample timing should be accounted for when comparing serum phosphorus concentrations between groups.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO160

**Hormonal and Dietary Determinants of Urinary Calcium Excretion in Healthy Volunteers and Patients with Chronic Kidney Disease Stage 1-4** Liesbeth Viaene,[1] Bjorn K. I. Meijers,[1] Vanrenterghem Yves,[1] Dirk Vanderschueren,[2] Pieter Evenepoel.[1] *[1]Nephrology, University Hospital Gasthuisberg, Leuven, Belgium; [2]Endocrinology, University Hospital Gasthuisberg, Leuven, Belgium.*

Introduction: Calcium balance and homeostasis are disturbed in chronic kidney disease (CKD). In steady-state, 24-hour urinary calcium excretion (24h-$Ur_{Ca}$) corresponds to net daily gastrointestinal calcium absorption. We aimed to identify hormonal and dietary determinants of 24h-$Ur_{Ca}$ and 24 hour fractional ($FE_{ca}$) urinary calcium excretion. Methods: 20 healthy volunteers (HV) (8 male; age 34±10 year) and 170 stable CKD stage 1-4 patients (108 male; age 59±15 year) were studied. Fasting blood and 24-hour urine samples were analyzed for parameters of mineral metabolism including calcitriol and PTH. Dietary data were available in all HV and in 72 CKD patients. Results: Consistent with literature data, we observed decreasing calcitriol, increasing PTH and stable calcium levels along CKD progression. Dietary data and urinary indices are summarised in table1.

| | HV | >60 ml/min/m² | 30-60 ml/min/m² | 15-30 ml/min/m² | p-value |
|---|---|---|---|---|---|
| 24h-UrCa (mg/day) | 220 | 92 | 42 | 21 | <0.0001 |
| FEca (%) | 1.4 | 0.7 | 0.6 | 0.5 | 0.0003 |
| Calcium intake (mg/day) | 977 | 819 | 774 | 627 | 0.006 |

Median values are shown.

In univariate analysis high 24h-$Ur_{Ca}$ was significantly associated with male gender, younger age, high dietary calcium intake, high calcitriol, high eGFR and low PTH. In multivariate analysis calcitriol, dietary calcium intake and age were found to be independently associated with 24h-$Ur_{Ca}$ ($R^2$=0.32, p<0.0001). $FE_{ca}$ decreased along CKD progression. Remarkably, only 24h-$Ur_{Ca}$ was independently associated with $FE_{ca}$, explaining 78% of its variability (p<0.0001). Conclusions: Our data confirm and extend previous clinical and experimental observations. Urinary calcium retention seems to compensate for suppressed net intestinal calcium absorption along the progression of CKD. Low calcitriol levels contribute to this decreased absorption. Our data support the notion of a tenuous calcium balance in CKD patients stage1-4 and strengthen the need for formal calcium balance studies.

**The Calcimimetic R568 Increases Serum Phosphate (P) Via Decreased Urinary P Excretion** Sean Morony, Jei-In Young, Edward Shatzen, Paul Harrington, Christopher Fotsch, Charles M. Henley III. *Amgen Inc.*

The calcimimetic (CaM) Cinacalcet lowers PTH, Ca, and P levels in dialysis patients; however in CKD 3-4 patients treatment induces hyperphosphatemia. This suggests a role for the kidney in the effect of CaM on serum P. We tested this hypothesis by treating 5/6Nx rats with research CaM that were either orally (R568) or not orally bioavailable (CpdA). Male SD rats (250g, 3wks post 5/6Nx, N=7) were dosed PO with R568 (30mg/kg, $t_{1/2}$=2.9h, F=6%), CpdA (30mg/kg, $t_{1/2}$=BQL, F=BQL), or vehicle. Urine and serum were collected 4 and 24h post-dose for PTH, Ca and P determination. Additionally, kidney and duodenum were analyzed for NaPi cotransporter mRNA expression.

| | 4h | | | 24th | | |
|---|---|---|---|---|---|---|
| Serum | Vehicle | R568 | CpdA | Vehicle | R568 | CpdA |
| Ca (mg/dL) | 11.6±0.1 | 9.2±0.2* | 11.6±0.1 | 11.3±0.1 | 10.5±0.2* | 11.1±0.1 |
| P (mg/dL) | 9.4±0.2 | 10.5±0.3* | 9.5±0.2 | 8.5±0.2 | 8.6±0.2 | 8.6±0.2 |
| PTH (pg/mL) | 1388±276 | 492±56* | 1318±174 | 999±126 | 1297±103 | 890±53 |
| Urine | | | | | | |
| FE Ca (%) | 1.7±0.2 | 5.1±0.5* | 2.8±0.7 | 0.4±0.1 | 1.7±0.3* | 0.7 ± 0.2 |
| FE P (%) | 15.1±3.0 | 2.8±0.9* | 13.2±1.4 | 22.0±1.6 | 23.6±2.3 | 20.1±2.2 |

Mean±SEM, N=7, *P<0.05 compared to vehicle

R568 decreased serum PTH and Ca while elevating P, compared to vehicle treated rats. Serum changes reflected urine Ca and P levels; as R568 increased $FE_{Ca}$ and decreased $FE_P$ compared to vehicle treated rats. In contrast, the non-orally bioavailable compound, CpdA, had no effect on serum PTH, Ca, P, or urine $FE_{Ca}$ and $FE_P$ compared to vehicle treated rats. Together these data suggest that decreased urinary P excretion mediates the elevated serum P noted in CaM treated animals with residual kidney function. To further evaluate the mechanism of CaM-induced hyperphosphatemia we determined NaPi cotransporter mRNA levels in kidney and duodenum and found no change in expression; however, post-translational modification of these transporters cannot be ruled out. Additionally, reduced kidney-mediated phosphaturic effects of PTH and FGF23 may explain the decreased urinary P excretion seen with R568 since CaM decrease both of these phosphaturic hormones.

## TH-PO162

**Positive Calcium Balance in CKD** David M. Spiegel, Rebecca H. Moore. *Division of Renal Diseases and HTN, University of Colorado Denver, Denver, CO.*

Vascular calcification (VC) is common at dialysis initiation. Children starting dialysis have increased blood vessel calcium content. The pathophysiology of VC is complex but calcium loading has not been felt to play a role as it is assumed that non-dialysis CKD patients are in calcium balance. We investigated calcium balance in 6 late stage 3 or stage 4 CKD patients on 2 calcium diets (800 mg/day and 2000 mg/day). Both diets contained 1600 mg of phosphorus and all foods were prepared by the GCRC for each 9 day (7 outpt, 2 inpt) period. Following each 7 day outpatient diet period patients were admitted to the GCRC. Urine was collected over 48 hrs and blood was drawn each morning. Methylene blue was used to label the stool and all stool stained blue was collected during and after the GCRC stay. Calcium balance was calculated as (24 hour ca intake) - (24 hr stool ca) - (24 hr urine ca). Stool calcium was normalized to 24 hrs by assuming patients were in neutral phosphorus balance. The eGFR was 28.6±4.2 ml/min/1.73m². Serum ca and phos were not different on the 2 diets (low vs high: ca 8.8±0.4 vs 8.8±0.4, phos 4.2±0.5 vs 4.1±0.5). On the 800 mg/day ca diet patients were in slightly negative ca balance (mean± SD)(-91±113 mg/d). On the 2000 mg/day diet patients were in markedly positive ca balance (759±121 mg/d) p<0.0001 (non-paired t-test) (Fig). Furthermore, patients in late stage 3 and stage 4 CKD were unable to increase their urinary ca excretion despite increased net ca intake (low vs high ca diets; urinary ca: 82±48 vs 99±72 mg/d, p=0.65). This study suggests that positive calcium balance can occur in late stage 3 or stage 4 CKD if dietary calcium intake exceeds 1200 to 1300 mg/day and patients are in marked positive balance when intake is 2000 mg/day. This study suggests that calcium loading in late stage 3 and 4 CKD may contribute to tissue deposition including vascular calcification.

### TH-PO163

**Ionized Calcium in Hemodialysis-Patients** Jean-Christophe Szelag, Myriam Pastural, Alejandra Lenz, Ignace Mpio, Nouredine Boumendjel, Carlos Cardozo, Elias Abdullah, Walid Arkouche. *AURAL Villon, AURAL, Lyon, France.*

**Background**: The last KDIGO guideline for the evaluation of Chronic Kidney Disease-Mineral and Bone Disorder (CKD-BMD) do not recommend the use of ionized calcium measurement in haemodialysis-patients. However, ionized calcium is the physiologically active part of serum calcium and his measurement may be useful in case of major acid-base disorders or hypoalbuminemia.

**Methods**: We analyzed the bone and mineral metabolism of 164 HD-patients (68 women, 96 men, 61,8 yr) (total calcium, corrected calcium, phosphorus, PTH, 25-hydroxyvitamin D). Ionized calcium was simultaneously measured in optimal technical conditions.

**Results:** mean values were: total calcium 2,21+/-0,17 mmol/L, corrected calcium 2,23+/-0,19mmol/L, ionized calcium 1,14+/-0,11 mmol/L, phosphorus 1,55+/-0,49 mmol/L, PTH 385+/-319 ng/L, 25-hydroxyvitamin D 27,2+/-16,4 ng/mL. Hypocalcemia frequency was significantly higher by using total calcium (59%, threshold 2,2mmol/L, p<0,0001) or corrected calcium (53%, threshold 2,25mmol/L) that ionized calcium (34%, threshold 1,12mmol/L) (chi2 analysis). Low ionized calcium subjects have a lower 25-hydroxyvitamin D concentration (21,4 +/-9,4 *vs* 30,2 +/-18,4 ng/mL, p<0,01) and an higher phosphorus (1,68+/-0,51 *vs* 1,49+/-0,46 mmol/L, p<0,01, Mann Wythney analysis) than other patients.

In contrast, there was no significant difference on 25-OHvitamin D or phosphorus by using total or corrected calcium. 25OH-vitaminD under 20ng/mL was associated with a higher PTH (460+/-373 *vs* 328+/-261 ng/mL; p<0,05) and a lower ionized calcium (1,12+/-0,11 *vs* 1,16+/-0,10 mmol/L; p<0,05) without significant modification of total calcium. The rate of vitamin D was especially correlated to the ionized calcium (p<0,0005) and the PTH (p<0,005) (simple regression analysis).

**Conclusion:** Although the ionized calcium measurement cannot be routinely used because of technical difficulties and of its cost, it represents the most reliable parameter to analyze the BMD disturbances of low calcium HD-patients.

Disclosure of Financial Relationships: nothing to disclose

**Differential Actions of Calcium Acetate (CaAc) in the Early CKD-MBD: Stage 2 Compared to Stage 3 CKD** Yifu Fang, Suresh Mathew, Keith A. Hruska. *Pediatric Nephrology, Washington University School of Medicine, St. Louis, MO.*

CKD induces the CKD-MBD associated with increased mortality by stage 2. We have shown the loss of bone anabolism and vascular smooth muscle cell phenotype before abnormalities of mineral metabolism are detected. The CKD-MBD in stage 2 CKD consists of an increase in vascular calcification (VC), a decrease in bone formation, and an increase in FGF23 levels. In stage 3 CKD, the onset of hyperphosphatemia increases VC, and Pi binders such as CaCO3 are protective against VC (Davies et al, JASN: 2005). However, calcium salt phosphate binders have been associated with calcium absorption and body burden contributing to VC. CaAc is commonly prescribed, and the CARE trial (Qunibi et al, Kid. Int., 2004) demonstrated that CaAc was more effective than others in controlling serum phosphorus and Ca X P product in ESKD. Therefore, we examined the role of CaAc in the treatment of early phase CKD-MBD. Ldlr deficient mice fed high fat diets were subjected to partial kidney ablation at 14 weeks of age to create an early CKD-MBD mouse model. At 22 weeks of age, treatment was begun with Vehicle, CaAc 1%, and CaAc 3% or 3% CaCO3 from 22 to 28 weeks. A relatively mild reduction in the GFR measured by inulin clearance was produced (76 % of normal, stage 2 CKD) at 22 weeks of age after renal cortical electrocautery and contralateral nephrectomy. Aortic Ca levels were increased at 28 weeks of age, while the serum levels of BUN, Ca, Pi and PTH were normal. Skeletal osteoblast surfaces and bone formation rates were diminished. FGF23 levels were elevated. Treatment with CaAc (both doses) increased the serum Ca from 8.8±1.4 to 9.88±2.2 or 9.65±2 respectively, decreased PTH levels and did not decrease the serum Pi. Neither CaAc nor CaCO3 decreased aortic Ca or FGF23 levels in the stage 2 CKD-MBD, but they reduced, aortic Ca, corrected hyperphosphatemia, and decreased serum FGF-23 levels, in stage 3 CKD (vehicle vs. treated CKD, P<0.05 for each parameter). In conclusion, CaAc controls aortic Ca levels and serum FGF-23 levels in hyperphosphatemic stage 3 CKD, but causes increased serum Ca but no effect on aortic Ca in stage 2 CKD-MBD.

### TH-PO165

**Lowering Dietary Phosphate Intake Reduces Fibroblast Growth Factor 23 (FGF-23) in Chronic Kidney Disease Stages 3 and 4** Mhairi K. Sigrist, Monica C. Beaulieu, Adeera Levin. *Dept of Nephrology, University of British Columbia.*

FGF-23 is thought to play a critical role in the hormonal regulation of urinary phosphate. In the later stages of CKD both phosphate and FGF-23 are highly deranged and associated with both vascular calcification and mortality. This study describes the physiological response of altered dietary phosphate on circulating FGF-23 and associated biochemical parameters of mineral metabolism in early stages of CKD.

20 stage 3 and 4 CKD Subjects and 12 healthy controls with serum phosphate in the normal range were included in this study. Subjects followed 7-days of the following three diets; high phosphate (HP) (2500mg), low phosphate (LP) (750mg) and low phosphate plus an aluminum based phosphate binder (LP+B). Dietary compliance was encouraged with the provision of a daily eating plan including specified quantities and portion sizes and a grocery basket of appropriate foods. Fasting serum Calcium, phosphate ($PO_4$), intact PTH, intact FGF-23, 1,25 and 25 vitamin D and 24hr urinary excretion of Calcium and $PO_4$ were assessed at the end of each week. FGF-23 was assessed using the Kainos assay.

Baseline FGF-23 was 100pg/ml in the CKD group and 32 pg/ml in the control group (P<0.0001). Baseline phosphate was 3.3±0.5 mg/dl in the CKD group and 3.4±0.5 mg/dl in the control group (NS). In CKD FGF-23 was significantly higher with a HP diet (121± 7pg/ml) than with a LP+B diet (82±60 pg/ml) (P<0.01). Concurrently there were significant falls in urinary $PO_4$, PTH & 25 Vit D on the LP+B diet, although1,25 vit D rose while $PO_4$ stayed relatively stable. Results followed similar trends in the control group. FGF-23 significantly correlated with eGFR (r=-0.78, P<0.0001), intact PTH (r=0.51, P=0.002) and 1,25(OH)D (r=-0.68, P<0.0001).

Reductions in dietary phosphate result in reductions in FGF-23, even when serum phosphate levels are normal. These results demonstrate that a phosphate lowering diet could be beneficial for CKD patients well before their serum phosphate starts to rise late in the progression of CKD.

### TH-PO166

**Results of a Targeted Phosphorus Management Quality Improvement Program ($PO_4$-QIP); Significant Benefits of the $PO_4$-QIP of ESRD Network of Texas (NW-14) during Year One** Donald A. Molony,[1] Glenda Harbert.[2] *[1]Internal Medicine / Renal Dis & Htn, University of Texas Houston Medical Sch, Houston, TX; [2]ESRD Network of Texas, Dallas, TX.*

Successful management of hyperphosphatemia amongst dialysis patients remains an important but incompletely achieved goal. The degree of successful management can vary widely amongst comparable dialysis facilities within a single region. In order to improve overall management of $PO_4$, NW-14 developed and implemented the $PO_4$-QIP to foster quality improvement on a facility level. All facilities in Texas were notified that $PO_4$ would be a special focus for 2009 and invited to participate in an educational activity. Hemodialysis (HD) and peritoneal-dialysis (PD) facilities reporting less than 40% of their patients within the KDOQI range for $PO_4$ of 3.5 to 5.5 mEq/L were enrolled in a focused intervention (focused facilities) whereby NW-14 provided technical assistance and education and additionally required reporting of facility quality improvement processes and outcomes. We report here the changes in successful $PO_4$ management amongst the focused facilities compared to all other facilities in Texas during year 1 of the QIP.

Improvements in Mineral Metabolism in Focused Facilities 12/08 to 12/09

| Facility Type | n | % of patients with PO4 >3.5 - <5.5, 12/08 | Change in absolute % (12/09) ± 95% CI | P | % facilities improved / deteriorated |
|---|---|---|---|---|---|
| HD, non-focused | n = 364 | 52.6 | 53.2 ± 0.9 | 0.211 | 52.7 / 45.9 |
| HD, focused | n = 38 | 36.1 | 49.3 ± 4.3 | 0.00001 | 94.7 / 5.3 |
| PD, non-focused | n = 79 | 58.8 | 57.4 ± 4.4 | 0.592 | 51.9 / 44.3 |
| PD, focused | n = 22 | 31.7 | 55.6 ± 6.8 | 0.00003 | 86.4 / 4.6 |

These findings from a large region, demonstrate that interventions from NW-14 as part of a QIP focused on improving quality on a facility level can result in significant sustained improvement in $PO_4$ management. Similar improvements did not occur with education alone. Such interventions may provide additional tools for achieving optimal patient-centered outcomes.

**Sevelamer Based $PO_4$ Binders Result in Reduced Mortality Compared to Calcium-Based $PO_4$ Binders; a Meta-Analysis of Long-Term Randomized Controlled Trials** Donald A. Molony. *Internal Medicine / Renal Diseases and Htn, University of Texas Houston Medical Sch, Houston, TX.*

Animal and epidemiologic studies have supported the hypothesis that excess oral intake of calcium can result in vascular calcification and increased cardiovascular morbidity and mortality. Conversely, by reducing calcium and $PO_4$ burdens in ESRD patients, sevelamer-based binders may have the potential to improve survival. Demonstrating a by meta-analysis a survival advantage with sevelamer has been difficult, in part, because of the small sample size, short duration, or incomplete follow-up in studies conducted to date.

The purpose of the current study, was to re-examine the RCT literature in order to perform a meta-analysis (MA) which included only those studies in which some subjects were followed for a minimum of 1 year and to consider a subject as contributing to the estimate of risk for death from an exposure only as long as they were followed in the study. A systematic review of the literature was performed by searching PubMed, EmBase, the Cochrane trials registry and the gray literature through 5/31/10. Authors were contacted if they did not report deaths by group allocation. Seven RCTs reporting on unique populations were included in the final analysis. For these studies the combined odds ratio (OR) was 0.676, 95% CI 0.0438 – 0.998, heterogeneity p = 0.1623. The DCOR trial had the largest impact on the overall estimate of effect. The OR favoring a survival benefit with use of sevelamer was no-longer seen when RCTs of a duration of less than 1 year were included in the analysis. There was an insufficient number of RCTs to interrogate by MA whether older patients or incident dialysis patients might demonstrate a higher magnitude of risk reduction.

Thus, the meta-analysis reported here differs from others reported recently. The current meta-analysis shows a survival advantage with sevelamer. Meta-analysis is a particularly powerful tool when combining similar studies of inadequate power on populations of similar baseline risk but may soimetimes obscure potential benefits. Comparison of this MA with those published recently, illustrate the power and the limitation of this analytical framework.

**TH-PO168**

**Association between CCR7 and Vitamin D Deficiency in Patients with CKD Stages 3 & 4** Chun Khai Chong,[1] Kalisha O'Neill,[1] Braca Benizry,[1] Edward F. Srour,[1] Sharon M. Moe.[1,2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Roudebush VAMC, Indianapolis, IN.*

**Background:** In vitro and in vivo animal studies have demonstrated that vitamin D modulates immune function. In patients with CKD, there is a high prevalence of vitamin D (25-hydroxyvitaminD (25D)) deficiency and high morbidity secondary to infection. We therefore tested the hypothesis that vitamin D insufficiency/deficiency (levels < 30 ng/ml) altered T-cell function.

**Methods:** We performed a cross-sectional study of 100 subjects with CKD 3 or 4. We measured blood levels of biochemistries, 25D, and intact PTH levels. Immune function was assessed by flow cytometry, analyzing CD4/CD8 lymphocyte ratio, and CD27 (TNF receptor), CD25 (Regulatory T-cell), CD197 (Chemokine Receptor 7 (CCR7)) and CD45RO (Memory T-cell) on both CD4 and CD8 subpopulations.

**Results:** One hundred subjects were recruited. The mean 25D level was 22±13 ng/ml, 75 subjects were 25D insufficient/deficient (DefD, levels < 30 ng/ml) and 19 subjects were 25D sufficient (SufD, levels ≥ 30 ng/ml). Levels of 25D correlated with iPTH (r=0.37, p<0.001). Mean flow cytometry values demonstrated 68% lymphocytes; 50% $CD4^+$, and 20% $CD8^+$ T-cells with a CD4/CD8 ratio of 3±1.5. However, there was no difference between the DefD and SufD groups. The comparison of specific receptors on CD4 or CD8 lymphocytes demonstrated that the $CD4^+CD27^+$ lymphocytes were 85±9 vs 92±5% in DefD vs SufD (p=0.001) and the $CD4^+CD197^+$ lymphocytes were 48±18 vs 63±10% in DefD vs SufD (p<0.001). There were no differences between both groups for any other markers. The 25D levels correlated with the percentage of $CD4^+CD27^+$ (r=0.35) and $CD4^+CD197^+$ (r=0.37) lymphocytes, both p<0.001.

**Conclusions:** Vitamin D insufficiency or deficiency in subjects with CKD 3 or 4 is associated with significantly lower percentage of $CD4^+CD197^+$ (CCR7) lymphocytes when compared to those who are vitamin D sufficient. CCR7 is critical for the generation of T-cell responses. Previous studies have shown that CCR7 deficiency leads to increased susceptibility of infections and therefore CCR7 might be the link between vitamin D deficiency and increased infection in CKD 3 or 4 patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO169**

**African-American Race Is an Independent Predictor of Increased PTH but Not Calcium and Phosphorus in Chronic Kidney Disease** Jennifer L. Ennis,[1] Susan E. Donahue,[1] John R. Asplin,[1] Elaine M. Worcester,[2] Fredric L. Coe.[2] *[1]Litholink Corporation, Chicago, IL; [2]Department of Medicine, Section of Nephrology, University of Chicago, Chicago, IL.*

**Purpose:** African-Americans (AA) comprise a significant and growing portion of the chronic kidney disease (CKD) population, but few studies have focused on bone and mineral abnormalities in this patient group. One prior study demonstrated higher rates of vitamin D (vit D) deficiency and increased serum calcium (Ca), phosphorus (P), and parathyroid hormone (PTH) levels in AAs compared to non-AAs with pre-dialysis CKD.[1] We sought to test whether these results would hold in a larger cohort of CKD patients from unselected US practices.

**Methods:** We performed a cross-sectional analysis of initial laboratory data collected on AA (n=817) and non-AA (n= 2162) stage 1-5 US CKD patients enrolled in the Litholink CKD program. Serum Ca, P, 25-hydroxy vitamin D (25 Vit D) and plasma PTH levels were compared between the two groups.

**Results:** Mean plasma PTH values were higher and mean 25 Vit D values were lower in AAs versus non-AAs across all CKD stages. Differences reached statistical significance in stages 2-5 for PTH and in stages 1-3 for 25 Vit D. Unlike Gutierrez et al, mean Ca and P did not differ between groups at any stage. In a general linear model with PTH as the dependent variable, and Ca, P, 25-Vit D, CKD stage, and AA race as the independent variables, AA race remained a significant predictor of PTH along with Ca, 25 vit D, and CKD stage (p<0.001). Serum P did not enter the model.

**Conclusions:** To our knowledge, this is the largest analysis of mineral metabolism in AA CKD patients. AAs have more severe vit D deficiency and elevations in PTH across all stages of CKD compared to other races. However, we could not confirm differences in serum Ca and P. We confirm that AA race is a novel and unexplained risk factor for elevated PTH in CKD patients independent of other established factors.

**TH-PO170**

**The Effect of Combining an ACE Inhibitor and a VDR Activator on Glomerulosclerosis, Proteinuria and Renal Oxidative Stress in Uremic Rats** Eduardo Slatopolsky,[1] Edu Suarez,[3] Kazim Husain,[2] Leon F. Ferder,[2] Michell Cruz,[3] Denis J. Glenn,[3] David Gardner,[3] Helen Liapis,[1] Jane L. Finch.[1] *[1]Washington University School of Medicine, St. Louis, MO; [2]Physiology and Pharmacology, Ponce School of Medicine, Ponce, PR; [3]Medicine, Diabetes Center, University of California, San Francisco, San Francisco, CA.*

ACE inhibitors can suppress the progression of renal disease. In combination with vitamin D receptor activators, they provide additional benefits. Previously, we showed suppression of renal TGFβ and Smad2 in uremic rats treated with a combination of enalapril and paricalcitol. In these studies, uremic (U) rats were treated as follows: U+vehicle (UC), U+enalapril (UE) (25mg/L in drinking water), U+paricalcitol (UP) (0.8ug/Kg, IP/3 x week), and U+Enalapril+ paricalcitol (UEP). Blood pressure (BP) was significantly elevated in the UC and UP rats versus normal animals (NC), while BP in enalapril-treated rats was well controlled. Despite hypertension in UP rats, proteinuria decreased by 32% versus UC rats. Addition of enalapril caused a further decrease (71%). Glomerulosclerosis increased from 5% (NC) to 22% in UC rats. Paricalcitol prevented this (7%). Interstitial infiltration increased from 4% (NC) to 42% in UC rats. Paricalcitol reduced it to 29% and co-treatment with enalapril to15%. Renal oxidative stress (OS) plays a critical role in inflammation and the progression of sclerosis. The antioxidant glutathione reductase was increased in all treatments groups (UE=44% and UP=67% compared to the UC group (p<0.001). In addition, expression of super oxide dismutase increased significantly in all treatment groups. NADPH oxidase and pro-inflammatory inducible nitric oxide synthase (iNOS) decreased in the treated groups. Also, peroxidase activity, a marker of OS, was increased in UC animals (550 vs. 410 nmol/min/ml (NC)). Paricalcitol alone prevented this increase which was further inhibited by addition of enalapril. In conclusion, paricalcitol can suppress progression of renal failure via TGFβ, Smad2, proteinuria, glomerulosclerosis, interstitial infiltration and OS reduction. These effects are amplified when an ACE inhibitor is added.

**Vitamin D Deficiency and Its Association with Physical Activity and Quality of Life: The Comprehensive Dialysis Study** Shuchi Anand,[1] George A. Kaysen,[2] Kirsten L. Johansen,[3] Glenn M. Chertow,[1] Barbara A. Grimes,[3] Manjula Kurella Tamura.[1] *[1]Nephrology, Stanford University School of Medicine, Palo Alto, CA; [2]Nephrology, University of California, Davis, Davis, CA; [3]Nephrology, University of California, San Francisco, San Francisco, CA.*

As research has identified a wide array of biological functions of vitamin D, the consequences of vitamin D deficiency in persons with and without CKD has attracted increased attention. The objective of this study was to determine the extent of 25-hydroxyvitamin D (25D) deficiency and its associations with self-reported physical activity and health-related quality of life (HRQoL) among participants of the Comprehensive Dialysis Study (CDS). The nutrition substudy of the CDS collected data on patients new to dialysis recruited from 68 units throughout the U.S. 25D concentration was measured using the Immunodiagnostic Systems Inc. Direct EIA assay. Physical activity was measured with the Human Activity Profile (HAP) Adjusted Activity Score (AAS) and Maximum Activity Score (MAS). HRQoL was measured with the SF-12 Physical Component Score (PCS) and Mental Component Scores (MCS). Mean age of the participants in the analytic cohort (n=192) was 62 years. There were 124 participants (65%) with 25D < 15ng/mL, indicating deficiency. After adjusting for age, sex, race/ethnicity, diabetes status, season and center, lower 25D levels were independently associated with lower scores on the HAP and a lower score on the MCS of the SF-12.

Association of 25OHD level with physical activity and quality of life.

| Dependent variable | Adjusted ß coefficient (p value) |
|---|---|
| HAP, AAS | 0.72 (0.03) |
| HAP, MAS | 0.55 (0.03) |
| SF-12, PCS | 0.25 (0.15) |

In a well-characterized cohort of incident dialysis patients, lower 25D concentrations are associated with lower self-reported physical activity and poorer self-reported mental health. Further research is required to determine whether hypovitaminosis D is causally linked to reduced activity, and whether supplementation can improve physical activity and HRQoL in the dialysis population.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO172

**Ethnic Differences in Response to Ergocalciferol Therapy in Chronic Kidney Disease** Iris Sanchez,[1] Roberto Mangoo-Karim,[1] Jason R. Stubbs,[2] George P. Yanev,[3] James B. Wetmore.[2] *[1]South Texas Kidney Specialists, PA, McAllen, TX; [2]Medicine, Division of Nephrology, University of Kansas Medical Center, Kansas City, KS; [3]Mathematics, University of Texas - Pan American, Edinburg, TX.*

Nutritional vitamin D deficiency is common in patients with chronic kidney disease (CKD). Previous investigations have suggested racial differences in prevalence of this disorder, but no studies have specifically examined differences between ethnic groups in response to vitamin D2 repletion.

We performed a retrospective analysis evaluating the effectiveness of D2 repletion in 261 Hispanic and Caucasian CKD patients from a solar-rich environment treated with the ergocalciferol replacement as recommended by KDOQI. We measured baseline and end-of-study 25(OH)D levels and compared responses to therapy. We stratified individuals by the presence of proteinuria to assess its effects on response to therapy.

Low 25(OH)D levels (<30 ng/mL) were found in 89.5% of Hispanics versus 53.1% of Caucasians with similar degrees of CKD. Treatment with ergocalciferol per KDOQI guidelines was clinically ineffective in restoring 25(OH)D levels to the normal range, with 86.1% of Hispanics and 50.0% of Caucasians remaining insufficient following therapy. Caucasians had a two-fold greater increase in 25(OH)D levels (2.2 +/- 0.5 ng/ml per 100,000 IU ergocalciferol) compared to Hispanics (0.9 +/- 0.2 ng/ml per 100,000 IU; between-group $p < 0.001$). Patients with proteinuria >300 mg/d demonstrated a poor response to therapy (-0.2 +/- 0.4 ng/ml per 100,000 IU) compared to individuals with lower levels of proteinuria (increase of 1.1 +/- 0.4 ng/ml per 100,000 IU; between-group $p = 0.03$).

25(OH)D deficiency is common in Hispanics, a growing population with high rates of CKD. Hispanics demonstrated less robust response to therapy than did non-Hispanics. The presence of proteinuria > 300 mg/d was associated with a poorer response to ergocalciferol therapy. Overall, use of the KDOQI protocol demonstrated suboptimal effectiveness. Future research should focus on establishing a more effective repletion strategy in patients with CKD, especially among Hispanics and in patients with proteinuria.

**Seasonal Variation in 25-Hydroxyvitamin D in the Cardiovascular Health Study** Abigail B. Shoben, Bryan R. Kestenbaum, David Siscovick, Ian H. de Boer. *University of Washington, Seattle, WA.*

Low serum concentrations of 25-hydroxyvitamin D (25OHD) are associated with adverse health outcomes in diverse populations. However, serum 25OHD levels are expected to fluctuate seasonally with sun exposure, such that a single measurement may not accurately capture the vitamin D status of an individual. We investigated sinusoidal trends in population average levels of serum 25OHD among 2298 individuals enrolled in the Cardiovascular Health Study, a community-based study of adults aged 65 years and older. A sinusoidal model fit observed 25OHD levels significantly better than a mean model, which assumes no seasonal variation ($p<0.0001$). Peak 25OHD levels occurred in September with trough in March. From the sinusoidal model, the mean peak-trough difference in 25OHD levels was 9.6 ng/mL (95% CI: 9.5 to 9.7; see Figure). A greater peak-trough difference was associated with younger age, male sex, more northern study sites, and greater physical activity ($p<0.05$ for all). Neither overall mean 25OHD nor 25OHD peak-trough difference varied by estimated GFR. Serum levels of intact parathyroid hormone (PTH) and bone-specific alkaline phosphatase (BAP) also varied by season in a sinusoidal fashion ($p<0.0001$) reciprocal to 25OHD. Participants with estimated GFR < 60 mL/min/1.73m2 (N=406, 18%) had higher overall levels of PTH and BAP with no difference in seasonal variation. In conclusion, serum 25OHD varies in a sinusoidal manner throughout the year, with reciprocal changes in PTH and BAP. Single 25OHD measurements may not capture overall vitamin D exposure, and extent of misclassification may vary by key demographic and behavioral factors. Findings have implications for the interpretations of 25OHD levels clinically and in the research setting.

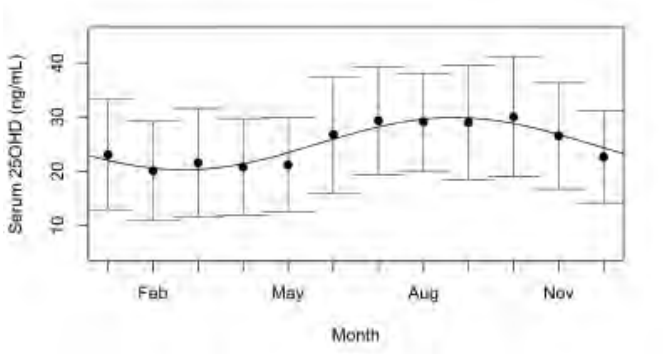

**Figure.** Sinusoidal model fit for observed 25OHD levels superimposed on plot of observed mean (+/- sd) 25OHD level by month.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO174

**Antiproteinuric Treatment Reduces Urinary Excretion of Vitamin D Binding Protein in Patients with Chronic Kidney Disease but Does Not Improve Serum Vitamin D Levels** Carolina R. C. Doorenbos,[1] Milton M. de Cuba,[1] Maartje C. J. Slagman,[1] Jacob Van den Born,[1] Reinold O. B. Gans,[2] Gerjan Navis,[1] Martin H. De Borst.[1] *[1]Internal Medicine, Nephrology, University Medical Center Groningen, Netherlands; [2]Internal Medicine, University Medical Center Groningen, Netherlands.*

Vitamin D deficiency is common in chronic kidney disease (CKD) and associated with its progression. Proteinuria (UP) is associated with urinary loss of vitamin D binding protein (VDBP), the main vitamin D transport protein. Urinary VDBP loss has been postulated to contribute to vitamin D deficiency in CKD.

Urine and plasma VDBP levels were measured in a randomized double-blind crossover study (n=13, clearance median 60(range 25-177) ml/min), at 3 timepoints: after a 4-wk washout period without treatment, or after 4-wk treatment with lisinopril 40 mg QD (LIS), or indomethacin 75 mg BID (IND), respectively. Age and sex matched individuals screened for donation (n=10) were included as controls. Patients with more marked UP (3.9(1.7-7.5) g/24h, n=10) treated with valsartan + lisinopril were studied separately.

UP decreased from 2.9(1.3-13.1) on placebo to 1.5(0.2-6.6) on LIS and 1.2(0.3-12.5) g/24h on IND. Urinary VDBP was increased during placebo (5413(155-211027) µg/24h) compared to controls (50(41-68) µg/24h, $p<0.001$). Treatment reduced VDBP excretion: LIS 4276(50-35800) IND 1653(97-129854) µg/24h ($p<0.05$). UP and urine VDBP were correlated. Plasma VDBP was normal and unaffected by intervention: controls 41(29-51), placebo 37(18-50), LIS 34(28-61), IND 34(22-49) mg/dl, just like plasma 25(OH) vitamin D: controls 43(16-80), placebo 80(33-110), LIS 48(21-78), IND 54(27-193) nmol/l. Fractional VDBP excretion was <1% in all samples. Patients with more marked UP (n=10) showed similar results.

Urinary VDBP loss is markedly increased in proteinuric CKD, and responds to antiproteinuric treatment in proportion to UP reduction irrespective of the mode of intervention. Urinary VDBP loss was not associated with plasma levels of VDBP or 25(OH) vitamin D. Fractional VDBP excretion remains low even in nephrotic range UP. These data suggest that urinary loss of VDBP does not contribute to vitamin D deficiency in proteinuric patients.

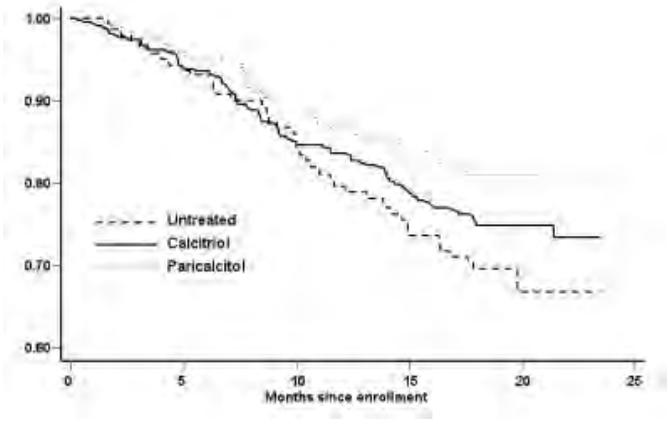
### TH-PO175

**VDRA Therapy Is Associated with Improved Survival in Dialysis Patients Even When Serum PTH Is Lower Than 150 pg/ml – Results of the Italian FARO Survey** Mario Cozzolino, Diego Brancaccio, Piergiorgio Messa, Giuseppe Cannella, Sandro Mazzaferro. *Renal Division, San Paolo Hospital, Milan, Italy.*

Chronic kidney disease (CKD) patients affected by MBD (Mineral Bone Disorders) have been shown to have higher rates for both all-cause and cardiovascular-related mortality. Surprisingly, most of hemodialysis (HD) patients have low serum PTH levels, but it has not been yet fully elucidated the reason why they have higher mortality compared to patients with serum PTH levels in the normal range. Using data from the FARO, a two year longitudinal study on 2378 Italian HD patients from 28 centers that collected data with standardized forms every 6 months, we have investigated the time-to-death (any cause) cumulative probability in patients with serum PTH ≤ 150 pg/ml.and in particular we investiagted the effect of vitamin D receptor activator (VDRA) therapy. Kaplan-Meier curves and proportional hazards regression models (including time-dependent covariates) were used, observing cumulative probability of time to death and adjusted hazard ratios for demographic, clinical, and/or CKD-MBD treatment characteristics. The cumulative probability of death for any cause was higher for patients with serum PTH levels ≤ 150 pg/ml., compared to HD with serum PTH > 150 pg(ml. In a model with time dependent covariates restricted to time-periods when patients had PTH ≤ 150 pg/ml, we observed a lower mortality in VDRA-treated compared to untreated patients ($P<0.001$). VDRA

treatment was associated with lower all-cause mortality hazard ratios regardless of all measured variables. Furthermore, patients who received intravenously (iv) paricalcitol, compared with either oral or iv calcitriol, showed a reduced mortality ($p<0.001$).



In conclusion, our results suggest that VDRA therapy was associated with improved survival in HD patients, even with lower serum PTH levels.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO176**

**Associations of 25 Hydroxyvitamin D Levels with Mortality Are Independent of Physical Activity and Physical Functioning in CKD: NHANES III** Vidya M. Raj Krishnamurthy,[1,2] Bradley C. Baird,[1] Guo Wei,[1] Tom H. Greene,[1,2] Srinivasan Beddhu.[1,2] *[1]Univ of Utah; [2]VA, SLC, UT.*

Vitamin D deficiency as well as poor physical functioning and lower physical activity are common in the CKD population. However, it is unclear whether the associations of low serum vitamin D levels with mortality are independent of the levels of physical activity and physical functioning. Therefore, we examined these in the National Health And Nutrition Examination Survey (NHANES III) data (n=1207). Physical activity was obtained based on the frequency and intensity of leisure time physical activity obtained by a questionnaire. Physical function was assessed by timed rising 5 times from a chair and timed walking on a 8 foot course. Mortality data were obtained by NCHS by linkage of NHANES III and National Death Index records through December 31, 2006.

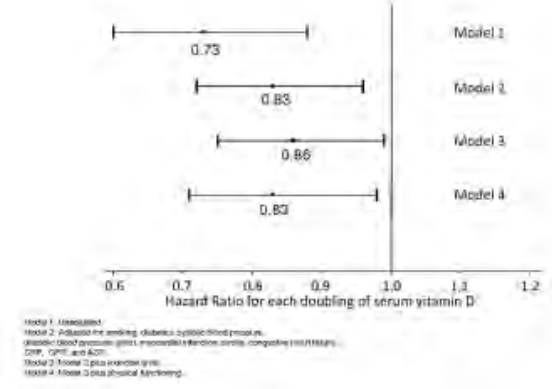
Baseline characteristics by serum vitamin D groups are summarized in Table 1.

Baseline Characteristics by Vitamin D Levels

| | < 15 ng/mL (10%) | 15-30ng/mL (52%) | > 30 ng/mL (38%) |
|---|---|---|---|
| Vitamin D (ng/mL) | 11.8±0.2 | 22.6±0.3 | 38.8±0.5 |
| Age (yrs) | 69±2 | 70±1 | 68±1 |
| Male (%)** | 24 | 30 | 48 |
| AA Race (%)** | 23 | 7 | 3 |
| MI (%) | 16 | 15 | 16 |
| CHF (%) | 13 | 13 | 12 |
| DM (%)** | 33 | 25 | 12 |
| Smoking (%) | 17 | 14 | 11 |
| Inactivity (%)* | 44 | 31 | 20 |
| Time to 5 stands (sec)** | 16.3±0.7 | 14.6±0.4 | 13.1±0.3 |
| Time to 8-foot Walk (sec)* | 5.3±0.5 | 4.2±0.1 | 3.8±0.1 |
| eGFR (ml/min/1.73m²)* | 45.5±1.3 | 49.1±0.5 | 50.4±0.5 |
| Waist (inch)* | 39.1±0.8 | 38.6±0.3 | 37.6±0.4 |

* $0.001<p\leq0.05$, ** $p\leq0.001$.

The associations of vitamin D with mortality are summarized in Figure 1.



We conclude that higher serum vitamin D levels are associated with better physical activity and functioning levels but the associations of higher vitamin D levels with lower hazard of death were independent of physical activity and functioning in CKD.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO177**

**1,25-Dihydroxyvitamin D Inhibits Hyperglycemia-Induced Podocyte Apoptosis** Youli Wang, Dilip K. Deb, Yan Chun Li. *Medicine, The University of Chicago, Chicago, IL.*

Podocytes are a key component of the glomerular filtration barrier and podocyte loss is a major pathogenic factor in diabetic nephropathy. Our previous studies demonstrated that vitamin D inhibits diabetic nephropathy by reducing proteinuria and podocyte loss in diabetic mice, and the aim of this study is to explore the molecular mechanism whereby vitamin D blocks podocyte apoptosis. Chromatin condensation and DNA fragmentation assays demonstrated that exposure of podocyte cultures to high glucose (HG, 30 mM) caused apoptosis, and apoptosis was blocked by 1,25-dihydroxyvitamin D (1,25-VD) treatment. Podocytes exposed to HG showed up-regulation of angiotensinogen, renin and AT1 receptor, and the elevation of these proteins was attenuated by 1,25-VD. Treatment of podocytes cultured in low glucose (LG, 5 mM) condition with Ang II also induced apoptosis, which could be blocked by AT1 blocker losartan, but not by 1,25-VD. These observations suggest that activation of the local renin-angiotensin system (RAS) by HG plays a key role in podocyte apoptosis, and 1,25-VD blocks apoptosis by targeting the upstream components of Ang II, namely renin and angiotensinogen. HG stimulated Bak but had little effects on Bcl-2, Bcl-xL and Bax, and 1,25-VD stimulated Bcl-2 and down-regulated Bax and Bak expression. Moreover, 1,25-VD also blocked active caspase-3 in podocyte cultures. Studies are undergoing to assess whether 1,25-VD affects the increase in p38 phosphorylation and Erk induced by HG. Taken together, 1,25-VD appears to block HG-induced podocyte apoptosis by targeting the local RAS and the mitochondrial outer membrane permeabilization in hyperglycemia.

**TH-PO178**

**Inhibition of Monocyte ADAM17 by Paricalcitol May Provide Renal and Cardiovascular Protection in Human Kidney Disease** Adriana S. Dusso,[1] M. Vittoria Arcidiacono,[2] Karla Giles,[1] Kathy Norwood,[1] Daniel W. Coyne,[1] Christine Pham.[3] *[1]Renal, Washington University, St. Louis, MO; [2]Experimental Nephrology, IRB Lleida, Lleida, Spain; [3]Rheumatology, Washington University, St. Louis, MO.*

Activation of the renin-angiotensin II system (RAS) and systemic inflammation are key determinants of renal and cardiovascular damage in chronic kidney disease (CKD). Whereas RAS activation-driven increases in renal ADAM17 cause renal lesions in mice and human CKD, elevated monocyte ADAM17 activation drives systemic inflammation and increases the risk of cardiovascular death in normal individuals. This work examined the role of ADAM17 inhibition in paricalcitol suppression of RAS activation and inflammation in 30 hemodialysis (HD) patients. Cell surface expression of ADAM17 on monocytes obtained from peripheral blood was assessed by flow cytometry and showed levels 15-fold higher in HD than in 18 age-matched normal individuals. ADAM 17 activity was measured by the release to the blood of the soluble forms of tumor necrosis factor α (TNFα), transforming growth factor α (TGFα), and vascular cell adhesion molecule 1 (VCAM-1). Serum levels of these markers of pro-inflammatory renal, endothelial, and cardiovascular lesions were 3.2-, 1.6- and 2.8-fold higher, respectively, in HD patients compared to normal controls ($p<0.05$). Furthermore, monocyte ADAM17 expression strongly correlated with serum VCAM-1, a known marker of endothelial dysfunction ($r=0.44$, $p<0.01$). More importantly, in a subpopulation of 16 HD patients receiving nutritional vitamin D and anti-RAS therapy, paricalcitol doses of 4 ug or higher reduced monocyte ADAM17 expression by 39.1% ($p<0.05$) and serum levels of intercellular cell adhesion molecule 1 (ICAM-1), a marker of pro-fibrotic lesions released by ADAM17 from epithelial cells, by 41.2% ($p<0.01$). These reductions were unrelated to changes in serum calcium, phosphate, or PTH. Thus, the active vitamin D analog, paricalcitol, synergizes with anti-RAS therapy in renal and cardiovascular protection through a pathway unrelated to PTH suppression that involves inhibition of ADAM17 to moderate renal and systemic inflammation.

**TH-PO179**

**A Novel Organ Culture Model To Demonstrate That Direct Suppression of PTH by the Vitamin D Prohormones, Doxercalciferol and 25-Hydroxyvitamin $D_3$, Requires the Vitamin D Receptor** Cynthia S. Ritter, Alex J. Brown. *Renal Division, Washington University School of Medicine, St. Louis, MO.*

Vitamin D compounds regulate PTH at the transcriptional level, presumably via binding to the vitamin D receptor (VDR). We recently reported that the several vitamin D prohormones that have low VDR affinity suppressed PTH, even when their activation was inhibited. To test whether prohormone efficacy is associated with a VDR-dependent mechanism, we developed a novel organ culture that allowed the assessment of activities of the prohormones on PTH release from wild-type and VDR null thyroparathyroid explants. The cultures remained viable with respect to PTH release for at least two weeks. Full suppression of PTH by the native vitamin D hormone, 1,25-dihydroxyvitamin $D_3$,[$1,25(OH)_2D_3$] required two days, consistent with a transcriptional mechanism, and was reversible, indicating that reduced PTH was not attributable to cell death. Inhibition of PTH release by $1,25(OH)_2D_3$ and two prohormones, 25-hydroxyvitamin $D_3$ and 1α-hydroxyvitamin $D_2$ was observed in explants from wild-type mice but not in those from VDR null mice. These findings 1) are the first direct demonstration of the role of

the VDR in regulation of PTH by $1,25(OH)_2D_3$, 2) confirm that the suppressive actions of the vitamin D prohormones are mediated by the VDR, and 3) introduce a novel organ culture model that allows the *ex vivo* study of the function of parathyroid glands from transgenic animals.

**A Vitamin D Analog Inhibits VSMC Mineralization Induced by TNF-α and Phosphate** Yumie Aoshima,[1] Masahide Mizobuchi,[1] Chiaki Kumata,[1] Fumiko Kondo,[1] Naoko Ono,[1] Ai Nakazawa,[1] Hiroaki Ogata,[2] Eriko Kinugasa,[2] Tadao Akizawa.[1] *[1]Division of Nephrology, Department of Medicine, Showa University School of Medicine; [2]Internal Medicine, Showa University Northern Yokohama Hospital.*

**Background:** Inflammatory cytokines such as tumor necrosis factor-α (TNF-α) have been shown to accelerate the highly regulated osteogenic process in vascular smooth muscle cells (VSMCs). On the other hand, vitamin D has been demonstrated to decrease the mortality in patients with CKD, which may be partly due to protective actions on the cardiovascular system. In the present study, we examined whether maxacalcitol (Maxa), a vitamin D analog, has a suppressive effect on VSMC mineralization induced by TNF-α and phosphate.

**Methods:** Human VSMCs were treated with either vehicle (ethanol) or Maxa ($10^{-9}$ M to $10^{-7}$ M) in 2.5 mM of phosphate media with TNF-α (1 ng/ml) for 9 days. VSMC mineralization was determined by von Kossa staining and quantitated by total calcium measurement. Expression of genes associated with the osteogenic process was examined by real-time RT-PCR. Gene expression of matrix metalloproteinase-2 (MMP-2) and MMP-2 concentration in media was also analyzed.

**Results:** Vehicle treated VSMCs showed massive mineralization (30.6±7.9 μg/mg protein) while Maxa inhibited the mineralization in a concentration-dependent manner (14.0±4.4 μg/mg protein at $10^{-7}$ M $p<0.05$, 26.7±3.1 μg/mg protein at $10^{-8}$ M, and 28.3±5.0 μg/mg protein at $10^{-9}$ M). While vehicle treated VSMCs increased mRNAs associated with the osteogenic process (Runx2, osteocalcin, and collagen type I) compared with VSMCs with a regular media without TNF-α (control), Maxa had a suppressive effect on this increase in mRNAs, suggesting that Maxa inhibits VSMC mineralization with the blockade of the osteogenic process. Furthermore, vehicle treated VSMCs increased both mRNA levels and concentrations in the media of MMP-2 while Maxa suppressed both levels.

**Conclusions:** Maxacalcitol, a vitamin D analog, has a potency to inhibit VSMC mineralization induced by TNF-α and phosphate with the blockade of the osteogenic process. Anti-inflammatory properties of maxacalcitol may contribute to this inhibitory effect.

### TH-PO181

**Acute Hyperuricemia Reduces 1,25 Dihydroxy-Vitamin D in Rats** Diana I. Jalal,[1] Carlos Alberto Roncal-Jimenez,[1] Miguel A. Lanaspa,[1] Wei Chen,[1,2] Michel B. Chonchol,[1] Richard J. Johnson.[1,3] *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Department of Nephrology, The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China; [3]Division of Nephrology, Hypertension, and Transplantation, University of Florida, Gainesville, FL.*

Patients with gout are reported to have lower 1,25 dihydroxy-vitamin D ($1,25(OH)_2D$) levels, that improve with treatment of hyperuricemia, suggesting that uric acid inhibits 1- α hydroxylase activity. We hypothesized that acute hyperuricemia would lead to lower $1,25(OH)_2D$ levels in rats. Sprague Dawley rats were randomized to 4 groups: control, the uricase inhibitor, allantoxanamide (150 mg/kg intraperitoneally), the xanthine oxidase inhibitor, febuxostat (30 mg/kg by gavage), or allantoxanamide and febuxostat. All rats were sacrificed after 24 hours, and serum and tissue samples were collected. $1,25(OH)_2D$ and 25 hydroxy- vitamin D (25(OH)D) were measured by Elisa assay, and the ratio of $1,25(OH)_2D$/ 25(OH)D was calculated for each animal as an indicator of 1- α hydroxylase activity. 1- α hydroxylase expression was evaluated by western blot of whole kidney lysates. Allantoxanamide administration resulted in significantly higher serum uric acid levels (3.3± 1.4 mg/dL) when compared to control (1.9± 0.1 mg/dL), and uric acid levels were lower (1.2± 0.3 mg/dL) in the rats treated with allantoxanamide and febuxostat (P value for trend 0.0002). When compared to the control group, the allantoxanamide group had significantly lower $1,25(OH)_2D$ levels while 25(OH)D levels did not differ significantly between groups. Consistently, the $1,25(OH)_2D$/25(OH)D ratio was significantly lower in the allantoxanamide group. Febuxostat prevented the allantoxanamide-induced drop in $1,25(OH)_2D$ levels and the reduction in the $1,25(OH)_2D$/25(OH)D ratio. In addition, 1- α hydroxylase protein expression in the kidney was reduced in the allantoxanamide group compared to the control animals and was restored in the group that received febuxostat and allantoxanamide. Our results suggest that uric acid suppresses 1- α hydroxylase activity and that treatment of hyperuricemia may improve vitamin D metabolism.

### TH-PO182

**Vida-5: A Novel VDR Modulator with Expanded Therapeutic Index and Cardio-Renal Protective Effects** J. Ruth Wu-Wong, Megumi Kawai, Yung-Wu Chen, Masaki Nakane. *Vidasym, Chicago, IL.*

VDR modulators (VDRMs) such as calcitriol, paricalcitol and doxercalciferol are commonly used to manage hyperparathyroidism secondary to chronic kidney disease (CKD). Clinical observations demonstrate that VDRM therapy may provide cardio-renal protective and survival benefit for CKD patients. However, hypercalcemia remains a serious concern for current VDRMs due to narrow TI (therapeutic index: a ratio estimated from the minimum toxic hypercalcemic dose and minimum PTH suppressing dose) at 1-4-fold, which leads to the need for frequent dose titration and serum calcium monitoring. Significant clinical benefit can be derived from a VDRM with expanded TI and cardio-renal protective benefits. We have identified a series of novel VDRMs with significantly less hypercalcemic potential. Treatment (3x/week over a period of two weeks ) by Vida-5 (0.004-0.64 μg/kg, i.p.) of 5/6 nephrectomized (NX) male Sprague–Dawley rats with established uremia at Week 6 after surgery suppressed serum PTH in a dose-dependent manner without raising serum calcium or phosphate, demonstrating a >50-fold TI. Untreated NX rats exhibited compromised endothelial function and increased left ventricular (LV) weight. When the NX uremic rats with established LV hypertrophy were treated with Vida-5 for two weeks, Vida-5 at 0.004-0.16 μg/kg improved endothelium-dependent aortic relaxation and attenuated LV abnormalities in a dose-dependent manner without affecting serum calcium. Treatment with Vida-5 significantly reduced proteinuria in the NX rats. Similar results were obtained when Vida-5 was given to NX rats by oral gavage, once daily, for two weeks. Real-Time PCR and Western blotting results showed that Vida-5 induced CYP24A1 and CD14 expression in HL-60 cells with $EC_{50}$ values at 7 and 4 nM, respectively, and suppressed thrombospondin-1 expression in human coronary artery smooth muscle cells. These studies demonstrate that Vida-5 is a VDRM with greatly expanded TI and an overall therapeutic product profile that support expanded use in pre-dialysis CKD to realize the cardio-renal protective effects of VDR activation.

**Restoration of Physiological Concentrations of 25-OH-Vitamin D (25-OH-D) Enables Calcitriol (1,25-OH2-D) Production in Hemodialysis (HD) Patients: Evidence from a Multicentre Randomized Controlled Trial** Annick Massart,[1] Michel Dhaene,[3] Joelle L. Nortier,[1] Frederic D. Debelle.[3] *[1]Nephrology, Erasme Academic Hospital, Brussels, Belgium; [2]Nephrology, Universitair Ziekenhuis Brussel, Brussels, Belgium; [3]Nephrology, RHMS Baudour, Baudour, Belgium.*

AIM OF THE STUDY: To investigate the impact of correcting cholecalciferol deficiency on mineral and bone disorder (MBD) parameters in HD patients.

METHODS: Adult HD patients with 25-OH-D level <30 ng/ml from 2 Belgian centres were included. Participants were randomly allocated 1:1 in double-blinded manner to receive an oral dose of 25,000 IU 25-OH-D or placebo once a week for 13 weeks. Based on preliminary data, we estimated that 15 case subjects and 15 controls would provide >95% power to detect a standardized difference of 15 ng/ml in 25-OH-D levels, assuming a two-sided type 1 error rate of 5%.

RESULTS: 54 patients were randomized and data were analysed according to intention to treat. Baseline serum 25-OH-D and 1,25-OH2-D levels were similar in both groups (13.8 +/-5,51 vs 16.1 +/-7.96 ng/ml and 18 +/- 9.8 vs 16.1 +/-7.14 pg/ml, respectively p=NS). After 13 weeks, serum 25-OH-D, 1,25-OH2-D and calcium levels significantly increased in the treated group compared to the placebo group (31.3 +/- 12.6 vs 15.7 +/- 8.13 ng/ml, p <.0001; 26.1 +/- 12.2 vs 12.4 +/-5.36, p <.0001 and 8.80 +/- 0.57 vs 8.26 +/- 1.20 mg/dl, p=.029). No statistical difference was found for serum intact parathormone (376 +/-278 vs 463 +/- 288 pg/ml), phosphorus (4.56 +/-1.60 vs 5.02 +/-1.82), C-telopeptide (2257 +/-1261 vs 2393 +/-1085.4), and bone specific alkaline phosphatase (34.4 +/-25.3 vs 31.6 +/- 31.9) levels.

CONCLUSIONS: Weekly oral administration of 25.000 IU cholecalciferol for 3 months is safe and efficient to correct 25-0H-D as well as 1,25-OH2-D deficiencies in HD patients. Long term studies are required to hypothesize the impact of cholecalciferol therapy on MBD.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO184

**The Vitamin D Analog, Eldecalcitol [1α,25-Dihydroxy-2β-(3-Hydroxypropyloxy)Vitamin $D_3$], Is a Potent Regulator of Calcium and Phosphate Metabolism** Alex J. Brown, Jane L. Finch, Eduardo Slatopolsky, Cynthia S. Ritter. *Renal Division, Washington University School of Medicine, St. Louis, MO.*

The vitamin D analog eldecalcitol has been shown to increase bone mineral density in ovariectomized rats and in post-menopausal women. Here, we compared the effects of eldecalcitol and 1,25-dihydroxyvitamin $D_3$ [calcitriol] on calcium and phosphate metabolism in normal rats. In the 1st protocol, eldecalcitol and calcitriol (0. 7.5, 20 or 50 pmol) were given orally every other day for two wks. The highest dose of eldecalcitol elevated ionized Ca, enhanced intestinal Ca absorption and increased urinary Ca; calcitriol had no significant effects at these doses. The high dose eldecalcitol stimulated both intestinal Pi absorption and urinary Pi, but not serum Pi. The phosphaturia was attributable, in part, to an increase in serum FGF-23. In a 2nd protocol, the effects of the high dose eldecalcitol on Ca and

Pi absorption and urinary excretion, and the increased FGF-23, persisted for several days following cessation of treatment, likely due to its higher DBP affinity and slower clearance than calcitriol. Because vitamin D compounds can modulate mineral metabolism indirectly by altering PTH levels, a 3rd protocol examined the effects of eldecalcitol and calcitriol in PTX'd rats that were infused with PTH to normalize Ca levels. Eldecalcitol (50 pmol) had greater effects than calcitriol on serum Ca and urinary Ca. In this model, eldecalcitol and, to a lesser extent, calcitriol (50 pmol) increased intestinal Pi absorption, but decreased serum Pi. This was due to a greater increase in urinary P, secondary to elevations in FGF-23. These studies indicated that with chronic oral administration, eldecalcitol is more potent than calcitriol in stimulating intestinal Ca and Pi absorption and renal excretion of Ca and P. The higher urinary Pi with eldecalcitol is due to a greater stimulation of FGF-23. The greater effects of eldecalcitol on mineral metabolism are not due to VDR affinity, which is lower, but likely to its higher DBP affinity and resistance to metabolism. The role of DBP binding in the beneficial effects of eldecalcitol on bone is under investigation.

**Pharmacodynamic and Pharmacokinetic Profiles of CTAP101 Capsules and Intravenous Calcifediol for Secondary Hyperparathyroidism in Stage 3 or 4 CKD** Joel Z. Melnick,[1] John R. Sedor,[2] Navindra J. Ramjit,[1] Samir P. Tabash,[1] Peg Pepping,[1] Nancy L. Samberg,[1] Susan C. Cronin,[1] Mojtaba Noursalehi,[1] Gerald Schulman.[3] *[1]Cytochroma Inc., Markham, ON, Canada; [2]Case Western Reserve University, Cleveland, OH; [3]Vanderbilt University Medical Center, Nashville, TN.*

Most CKD patients develop vitamin D insufficiency leading to secondary hyperparathyroidism (SHPT), bone and cardiovascular disease. Current therapies are poorly effective in normalizing serum total 25D and intact parathyroid hormone (iPTH). CTAP101 Capsules is a modified-release formulation of calcifediol being developed to treat SHPT associated with vitamin D insufficiency in Stages 3 and 4 CKD.

In this randomized open label single-dose study, 27 subjects with baseline serum total 25D between 16 and 29 ng/mL and serum iPTH above K/DOQI targets were dosed with CTAP101 (450 or 900 mcg) or IV calcifediol (450 mcg) to evaluate bioavailability, pharmacokinetics, pharmacodynamics, safety and tolerability. Serum calcium (Ca), phosphorus (P), iPTH, $25D_3$ and total 1,25D were monitored for 6 weeks. Mean (±SD) baseline $25D_3$ and iPTH were 20±10 ng/mL and 197±146 pg/mL, respectively. IV calcifediol rapidly raised mean $25D_3$ to 134±19 ng/mL. CTAP101 produced gradual increases in $25D_3$ to a mean of 25±10 (450 mcg) and 32±16 ng/mL (900 mcg). The bioavailability was ~10%. No confirmed hypercalcemia (>10.3 mg/dL) was observed in any treatment group. No SAEs were reported. Serum total 1,25D reached an increase of 13 pg/mL at 4 hrs after IV calcifediol, and of 3 and 7 pg/mL at 24 hrs after 450 and 900 mcg of CTAP101, respectively. IV calcifediol and 450 mcg of CTAP101 had no clinically meaningful effect on mean iPTH. CTAP101 dosed at 900 mcg reduced iPTH from baseline by a mean of 19% at 24 hrs. The rapid increase in serum total 1,25D after IV calcifediol may have triggered excessive expression of the vitamin D catabolic enzyme, CYP24, in the parathyroid glands, leading to local hormone resistance and limited iPTH suppression.

These findings demonstrate that CTAP101 Capsules gradually normalized $25D_3$ levels and suppressed elevated iPTH, and that the mechanism to lower iPTH may be more complex than simply boosting serum total 25D.

## TH-PO186

**Suppression of PTH by the Vitamin D Analog, Eldecalcitol [1α,25-Dihydroxy-2β-(3-Hydroxypropyloxy)Vitamin $D_3$], Is Modulated by Its High Affinity to the Serum Vitamin D Binding Protein and Resistance to Metabolism** Cynthia S. Ritter, Alex J. Brown. *Renal Division, Washington University School of Medicine, St. Louis, MO.*

The vitamin D analog, eldecalcitol [1α,25-dihydroxy-2β-(3-hydroxypropyloxy)vitamin $D_3$], has a greater efficacy than alfacalcidol (1α-hydroxyvitamin $D_3$) for the treatment of osteoporosis. The explanation for the greater stimulatory effects on bone formation and inhibitory actions on bone resorption is not clear. Eldecalcitol has been found to be less potent than 1,25-dihydroxyvitamin $D_3$ (calcitriol) in suppressing PTH in vivo. To define the mechanism for the latter observation, we compared the effects of eldecalcitol and calcitriol on PTH secretion by bovine parathyroid cells (bPTC). Dispersed bPTC were cultured in the presence of 15% calf serum. After 72 h, the cells were treated daily with eldecalcitol or calcitriol (0, 0.1, 1, 10 or 100 nM) for 3 d, and the rate of PTH release measured. Eldecalcitol was equipotent with calcitriol in regulating PTH under these conditions. Since eldecalcitol has a higher affinity for the serum vitamin D binding protein (DBP), we repeated the experiment in the absence of serum and found eldecalcitol to be ~100 times more potent than calcitriol in suppressing PTH release. Therefore, DBP appears to limit the uptake and activity of eldecalcitol in bPTC, providing an explanation for the lower PTH suppressing activity in vivo (100% serum). However, the 100-fold higher activity of eldecalcitol in the absence of serum was unexpected since the VDR affinity of eldecalcitol is half that of calcitriol. Preferential uptake was ruled out since $^3$H-eldecalcitol was taken up more slowly than $^3$H-calcitriol. The explanation for the potency of eldecalcitol was found to be its resistance to metabolism. While $^3$H-calcitriol was completely degraded within 24 h, $^3$H-eldecalcitol was not metabolized, despite the induction of the vitamin D catabolic enzyme, 24-hydroxylase (CYP24A). Thus, the unique properties of eldecalcitol in vivo can be attributed, in part, to its high DBP affinity which increases the half-life, but limits uptake, of eldecalcitol, and to its reduced metabolism, which prolongs the activity of this analog in target tissues.

## TH-PO187

**Novel Synthetic Prohormonal Forms of Vitamin D for Use in the Treatment of Secondary Hyperparathyroidism Associated with CKD** Christian Helvig,[1] Christopher Hosfield,[1] Rina Glozman,[1] Dominic Cuerrier,[1] Gary H. Posner,[2] Aza Kharebov,[1] Martin P. Petkovich.[1] *[1]Research and Development, Cytochroma Inc., Markham, ON, Canada; [2]Department of Chemistry, The Johns Hopkins University, Baltimore, MD.*

The vitamin D prohormone, 25-hydroxyvitamin $D_3$ ($25D_3$), is hydroxylated at C-1 by the cytochrome P450, 1α-hydroxylase (CYP27B1), to form the active hormone, 1,25-dihydroxyvitamin $D_3$ ($1,25D_3$). In healthy individuals, CYP27B1 is most abundantly expressed in the kidney where its expression is regulated -positively by PTH and negatively by $1,25D_3$ and FGF23 - to tightly control blood levels of $1,25D_3$. CYP27B1 is also expressed at lower levels in essentially all other (extra-renal) tissues. While extra-renal CYP27B1 allows for local generation of $1,25D_3$ from circulating $25D_3$, total hormone production becomes insufficient to correct secondary hyperparathyroidism (SHPT) in late-stage CKD.

We have designed CTA192, a novel synthetic vitamin D prohormone which, when activated by CYP27B1, resists inactivation by CYP24, the cytochrome P450 24-hydroxylase specifically responsible for vitamin D catabolism. In HPK1a-*ras* cells expressing CYP27B1, CTA192 induced transcriptional activity approximately 5 -10% of that observed with the C-1 hydroxylated parent compound. Comparatively, the prohormone $25D_3$ exhibited approximately 10% of the activity of $1,25D_3$ in this cell line. Further *in vitro* studies demonstrated that CTA192 did not bind to the vitamin D receptor and was inactive when compared to its parent compound in U937 cells expressing low levels of CYP27B1. CTA192, when administered over a 2-week period (6 doses) to rats rendered uremic by exposure to adenine, was equally effective in lowering blood PTH levels as its parent compound at doses only 5-6 fold higher. In contrast to its parent, CTA192 did not raise serum calcium or FGF23 levels. These studies indicate that synthetic prohormones requiring CYP27B1 for activation, such as CTA192, may offer safety advantages over current hormone replacement therapies which frequently cause hypercalcemia.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO188

**Relationships of IV Vitamin D (IVVD) Use with Mortality and Hospitalization in Hemodialysis (HD) Patients Are Not Modified by Race/Ethnicity (R/E)** K. Servilla,[1] B. Horowitz,[1] W. Hunt,[1,2] P. Zager.[1,2] *[1]UNM, Abq, NM; [2]DCI, Abq, NM.*

R/E impacts outcomes of HD patients. Black & Hispanic HD patients have lower mortality than non-Hispanic whites (NHW). Wolf observed an interaction between R/E and IVVD use in FMC-NA HD patients (JASN 2008). Specifically in patients not receiving IVVD mortality was higher in blacks vs. NHW. The opposite was true in those receiving IVVD. We tested for effect modification by R/E on the association of IVVD with mortality and hospitalization in DCI HD patients. We studied an incident cohort (n=14,661; black, n=5,301; Hispanic n=633; NHW, n=8,727). Mean PTH (pg/ml) was highest in blacks (334), intermediate in Hispanics (253) & lowest in NHW (209). Blacks (80%) & Hispanics (67%) were more likely than whites (48%) to receive IVVD. IVVD doses were higher in blacks vs. Hispanics and NHW. We constructed proportional hazards (PHM) and marginal structural models (MSM) to test for associations of IVVD with mortality and hospitalization. Three-year mortality was lower in blacks & Hispanics vs. NHW, regardless of IVVD exposure (table).

HR for Mortality by R/E and IVVD (computed) in PHM

| | Black vs. NHW | Hispanic vs. NHW | Hispanic vs. Black |
|---|---|---|---|
| IVVD | 0.71 (0.65, 0.78) | 0.70 (0.56, 0.87) | 0.98 (0.79, 1.23) |
| No IVVD | 0.75 (0.67, 0.84) | 0.68 (0.52, 0.88) | 0.90 (0.68, 1.18) |
| All | 0.73 (0.68, 0.78) | 0.69 (0.58, 0.82) | 0.95 (0.80, 1.13) |

In aggregate, the HR (95% CI) for mortality with IVVD were 0.93 (0.87, 0.99) in PHM and 0.89 (0.80, 0.90) MSM. In an analysis stratified by R/E mortality tended to be lower in each group of IVVD treated patients, but these differences reached statistical significance only in the MSM for NHW (0.88 (0.78,0.99). There were no interactions between R/E & IVVD in either the PHM (p=0.72) or MSM (p=0.68). There was no significant relationship between IVVD & hospitalization. Summary: IVVD use was associated with decreased mortality. This relationship was not modified by R/E. Conclusion: The greater use of IVVD among blacks & Hispanics vs. NHW suggests that it may be prudent to add R/E as a variable in the expanded bundle.

**TH-PO189**

**Safety of Rapid, High-Dose Vitamin D Repletion in ESRD Patients: A Pilot Study** M. S. Singapuri, Monnie Wasse. *Renal Division, Emory University School of Medicine, Atlanta, GA.*

Background: 25-hydroxyvitamin D (25-OHD) is an essential nutrient frequently deficient in up to 90% of ESRD patients due to impaired renal conversion of 25-OHD to 1,25-dihydroxyvitamin D, insufficient sunlight exposure, and low dietary intake. This pilot study evaluated the safety and efficacy of a novel vitamin D repletion regimen in ESRD patients.

Methods: We conducted a double-blind randomized controlled pilot study to evaluate the safety and efficacy of rapid, high-dose nutritional vitamin D repletion in ESRD patients deficient in 25-OHD. 22 ESRD patients were randomly assigned to receive placebo or Vitamin D3 (cholecalciferol), which were taken orally and were identical in shape and color. Subjects were directly observed taking vitamin D3 200,000 IU once weekly for 3 weeks (total 600,000 IU). Blood samples were collected at baseline and within two weeks following completion of medication dosing. Serum levels of parathyroid hormone, 25-OHD, phosphorus and calcium were compared before and after treatment with cholecalcifierol.

Results: In the overall cohort, mean 25-OHD concentration was 17.8 ng/dL, mean age was 54 years, and 95% of patients were Black. No differences in baseline characteristics were observed between placebo (n=12) vs. vitamin D3 (n=10) treated patients. Within the treatment arm, 25(OH) D levels increased from 15.8 ng/dL to 57.6 ng/dL (p=0.0002), and 1,25 (OH)D levels rose (10.5 ng/dL to 25 ng/dL {p=0.02}), while no significant change in 25-OHD or 1,25-OHD was observed within the placebo-treated arm. 100% of patients in the treatment arm achieved 25-OHD sufficiency without vitamin D toxicity. Changes in serum phosphorus (p=0.30), calcium (p=0.38) and PTH (p=0.28) were no different between treatment arms , although PTH trended downward in vitamin D-treated patients (488 pg/ml pre-treatment to 404 pg/ml post-treatment (p=0.26}.

Conclusion: Our regimen of 600,000 IU of cholecalcifierol given over 21 days achieved vitamin D sufficiency in 100% of cases, without vitamin D toxicity. Initial results of our rapid, high-dose vitamin D repletion regimen to correct vitamin D status in ESRD patients show that it is safe and effective in achieving vitamin D sufficiency.

**Heritability and Seasonal Variability of Vitamin D Levels in Male Twins** Cristina Karohl,[1] Shaoyong Su,[2] Meena Kumari,[3] Vin Tangpricha,[3] Emir Veledar,[4] Viola Vaccarino,[2] Paolo Raggi.[4] *[1]Department of Nephrology, Hospital de Clinicas de Porto Alegre, Porto Alegre, RS, Brazil; [2]Department of Epidemiology, Rollins School of Public Health; [3]Department of Endocrinology; [4]Department of Cardiology, Emory University, Atlanta, GA.*

**Objective:** It is not clear to what extent genetic influences play a role in determining vitamin D status. We estimated the heritability of vitamin D levels and the impact of season on heritability estimates.

**Method:** We measured serum 25-hydroxyvitamin D (25(OH)D) in 510 middle-age male twins selected from the Vietnam Era Twin Registry [310 monozygotic (MZ) and 200 dizygotic (DZ) twins]. Generalized estimating equations were used to test the association between 25(OH)D and other study factors. Structural equation modeling was used to estimate the heritability of 25(OH)D. Winter was defined as November to March, and summer was defined as April to October.

**Results:** The mean age was 55±2.8 years. The mean 25(OH)D level was 38.4±23.3 ng/mL, with a substantial seasonal variation (6.1 ng/mL lower values during the winter compared to summer, P=0.003). About 70% of the variation in 25(OH)D levels during the winter was explained by genetic factors. However, in the summer, the levels of 25(OH)D did not show a heritable trait. During the summer, 53% of the variation in 25(OH)D levels was due to shared environmental factors and 47% to unique environmental factors.

Variance components in vitamin D explained by additive genetic factors (A), common (C) and unique (E) environmental factors during winter and summer seasons

| Season | A | C | E |
|---|---|---|---|
| Winter | 70 (31-80) | 0 (0-34) | 30 (20-46) |
| Summer | 0 (0-35) | 53 (21-64) | 47 (36-59) |

Data: parameter estimates (95% CI)

**Conclusion:** Serum 25(OH)D levels are highly heritable during the winter season. In the summer, environmental conditions (such as sun exposure) prevail over genetic background in determining serum 25(OH)D levels.

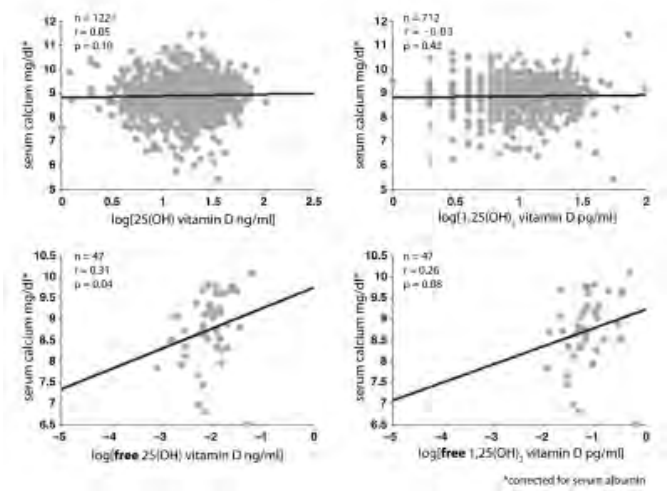
**TH-PO191**

**Vitamin D Binding Protein Modifies Relationship between Vitamin D and Calcium in Dialysis** Camille Elise Powe,[1] S. Ananth Karumanchi,[2] Julien L. Pham,[1] Jun Ye,[1] Catherine E. Ricciardi,[1] Elizabeth D. Ankers,[1] Ravi I. Thadhani,[1] Ishir Bhan.[1] *[1]Division of Nephrology, Massachusetts General Hospital, Boston, MA; [2]Division of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: The free hormone hypothesis stipulates that only unbound hormones are biologically active. Over 85% of circulating 25-hydroxyvitamin D 25(OH)D and 1,25-hydroxyvitamin D (1,25$(OH)_2$D) is bound to vitamin D binding protein (DBP). Few, if any, studies have examined free Vitamin D levels in subjects with end-stage renal disease (ESRD) and assessed their biological significance.

Methods: We measured levels of DBP, total 25(OH)D, total 1,25$(OH)_2$D, calcium, and albumin levels in incident dialysis patients from the Accelerated MOrtality on Renal Replacement (ArMORR) cohort. Using vitamin D, albumin, and DBP levels, we calculated free 25(OH)D and 1,25$(OH)_2$D levels using previously published formulae. We explored associations between vitamin D levels and levels of serum calcium, which are biologically linked to vitamin D action .

Results: Calcium levels (corrected for albumin) were correlated with free levels of 25(OH)D (r=0.31, p=0.04), but not total 25(OH)D (r=0.05, p=0.10). Corrected calcium levels appeared to be more strongly correlated with free 1,25$(OH)_2$D (r=0.26, p=0.08) than total 1,25$(OH)_2$D levels (r=-0.03, p=0.42). Figure 1 shows the relationship of corrected calcium with total and free vitamin D levels.



Conclusion: In ESRD, free levels of 25(OH)D and 1,25(OH)D are more strongly associated with serum calcium levels than total vitamin D levels. Future studies should explore the link between free vitamin D levels and outcomes in ESRD.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO192**

**Vitamin D Supplementation in Chronic Kidney Disease: A Systematic Review and Meta-Analysis** Praveen Kandula,[1] Mirela A. Dobre,[2] Jesse D. Schold,[3] Rajnish Mehrotra,[4] Sankar D. Navaneethan.[3] *[1]Internal Medicine, Southern Illinois University School of Medicine, Springfield, IL; [2]Internal Medicine, Huron Hospital; [3]Nephrology, Cleveland Clinic, Cleveland, OH; [4]Nephrology, UCLA Medical Center, Torrence, CA.*

Vitamin D deficiency is highly prevalent among patients with CKD. We assessed the benefits and harms of vitamin D supplementation (ergocalciferol or cholecalciferol) in patients with CKD.

MEDLINE (1966-September 2009), SCOPUS (September 2009), and nephrology conference proceedings were searched for relevant observational and randomized controlled trials (RCTs). Treatment effects were summarized as relative risk (RR) or mean differences (MD) with 95% confidence intervals (CI) using a random effects model. Separate analyses were conducted for observational studies and RCTs.

Twenty-two studies (17 observational and 5 RCTs) were included. There was a significant improvement in 25-hydroxyvitamin D (25D)(24.1 ng/ml, 95% CI 19.6 to 28.6) as well as 1, 25 D levels and an associated decline in PTH levels (-41.7 pg/ml, 95% CI -55.8 to -27.7) among observational studies. PTH reduction was higher in dialysis patients. Among RCTs, there was a significant improvement in 25 D (14 ng/ml, 95% CI 5.6 to 22.4) and an associated decline in PTH levels (-31.5 pg/ml, 95% CI -57 to -6.1) but no significant change in 1, 25 D levels. A low incidence of hypercalcemia and hyperphosphatemia was reported with vitamin D supplementation. Effects of vitamin D supplementation on outcomes related to cardiovascular and bone disease have not been studied.

Available evidence from low to moderate quality observational studies and few RCTs suggests that vitamin D supplementation improves biochemical endpoints. However, whether such improvements translate into clinically significant outcomes is yet to be determined.

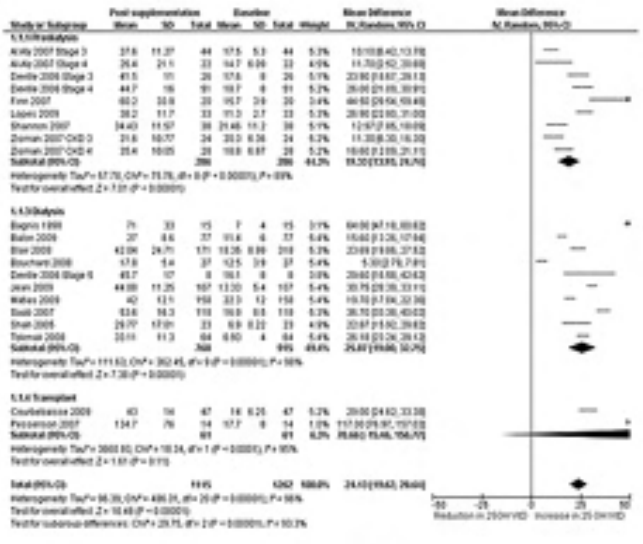


**Figure 1** Effect of vitamin D supplementation on the end of treatment 25(OH)D levels among observational studies in people with chronic kidney disease

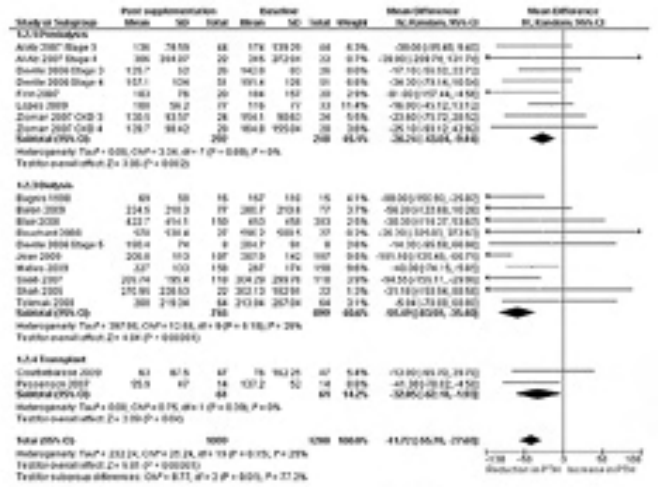

**Figure 2** Effect of vitamin D supplementation on the end of treatment PTH levels in observational studies in people with chronic kidney disease

**Relationships between Diasorin LIAISON 1-84PTH, Intact PTH, Bone ALP, and 25(OH)Vitamin D in a CKD Cohort from the CanPREDDICT Study** Daniel T. Holmes, Ognjenka Djurdjev, Adeera Levin. *U. of British Columbia.*

We desired to investigate relationships between a new automated 1-84PTH assay, intact PTH (iPTH), and other bone markers in a CKD cohort. Specimens from 2374 pts from the CanPREDDICT study were analyzed for 1-84PTH, bone ALP (BAP),and 25(OH)VitaminD (VitD) on the Diasorin LIAISON analyzer. Recruiting sites performed iPTH,Ca,PO4,and Cre using local methods. Large biases exist between iPTH and 1-84PTH. After method-specific iPTH correction, correlations between iPTH, 1-84PTH and bone markers were similar. Difference plots show large scatter. Nonlinear regression shows little decrease in 1-84PTH or BAP for VitD>75 nM. VitD status is difficult to predict from PTH or BAP. 1-84PTH and iPTH assays are not directly comparable. Discrepancy can be modeled as a fn. of eGFR.

Descriptive Statistics and Correlations

| **Analyte** | **1-84PTH (pM)** | **BAP (ug/L)** | **VitD (nM)** | **Ca (mM)** | **PO4 (mM)** | **Cre (μM)** | **% in CKD Stages 3,4 & 5** |

## TH-PO194

**Effective Management of Hyperparathyroidism, Vitamin D and Mineral Metabolism Following Roux-en-Y Gastric Bypass Surgery** Rajiv Kumar, John C. Lieske, Ellen Olson, Xujian Li, Zachary C. Ryan, Eric J. Bergstralh, Maria L. Collazo-Clavell. *Nephrology Research, Mayo Clinic, Rochester, MN.*

Patients with morbid obesity frequently undergo RYGB surgery for weight loss. Patients often develop secondary hyperparathyroidism and elevated alkaline phosphatase concentrations, placing them at risk for bone loss. We examined the effects of aggressive vitamin $D_3$ and calcium (Ca) citrate supplementation on parameters of mineral metabolism in 11 patients at 6 and 12 months (m) post RYGB surgery. The patients received an average of 5000 IU of vitamin $D_3$/per day and 1600 mg of elemental calcium/day immediately following surgery.

*Results:* The results immediately prior to surgery, and at 6 m and 12 m following surgery (**Table)**, demonstrate stable serum Ca, phosphorus, total and bone alkaline phosphatase, and intact PTH concentrations. Total 25(OH)D increased to 38.5 ng/mL at 12 months from a baseline level of 26.5 ng/mL. Serum $1,25(OH)_2D$ and urine Ca did not change.

Serum and Urine Values Prior To and Following RYGB Surgery

| **Serum or urine test** | **Baseline, 0 m, mean±SD** | **6 m, mean±SD** | **12 m, mean±SD** | **P-value, paired t-test, 0-6 m** | **P-value, paired t-test, 0-12 m** |
|---|---|---|---|---|---|
| Serum Ca, mg/dL | 9.4±0.35 | 9.5±0.33 | 9.3±0.27 | 1.0 | 0.38 |
| Ionized serum Ca, mg/dL | 4.9±0.13 | 5.0±0.17 | 5.0±0.15 | 0.18 | 0.1 |
| Serum phosphorus, mg/dL | 3.8±0.65 | 3.8±0.43 | 4.2±0.39 | 0.77 | 0.051 |
| Serum PTH, pg/mL | 55.5±12.7 | 48.1±14.48 | 48.9±20.0 | 0.22 | 0.27 |
| 25(OH)D, ng/mL | 26.5±8.4 | 36.8±10.4 | 38.5±12.3 | 0.036 | 0.017 |
| $1,25(OH)_2D$, pg/mL | 41.1±7.22 | 51.4±20.57 | 52.1±20.0 | 0.11 | 0.07 |
| Total serum alkaline phosphatase, U/L | 86.3±20.4 | 100.8±32.6 | 92.0±24.8 | 0.20 | 0.53 |
| Bone serum alkaline phosphatase, U/L | 27.1±9.9 | 33.3±10.66 | 30.6±11.5 | 0.82 | 0.64 |
| Urinary Ca, mg/24h | 120.1±76.6 | 141.1±60.85 | 111.4±52.1 | 0.82 | 0.58 |

*Conclusions:* Following RYGB surgery secondary hyperparathyroidism and reductions in 25(OH)D can be effectively prevented by a regimen that contains 5000 IU vitamin $D_3$ and 1600 mg of elemental Ca/day in the form of Ca citrate.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO195

**Impact of Hypovitaminosis D and Alfacalcidol Therapy on Survival of Haemodialysis Patients: Results from the French ARNOS Study** Guillaume Jean,[1] X. Moreau-Gaudry,[3] Denis Fouque.[2] *[1]Hemodialyse, Centre de Rein Artificiel, Tassin, France; [2]Néphrologie Hemodialyse, Hopital Edouard Herriot, Lyon, France; [3]Hemodialyse, AGDUC, Montelimar, France.*

**Background:** In chronic kidney disease (CKD) and dialysis patients, vitamin D deficiency is associated with mortality. In some observational studies, calcitriol analogues therapy was associated with a better survival rate in haemodialysis (HD) patients. The aim of this study was to determine the relationship between serum 25-hydroxyvitamin D (25-OHD) levels and alfacalcidol therapy with the HD patients' outcomes.

**Methods**: We measured baseline 25-OHD levels using a cross-sectional analysis in 648 HD prevalent patients from the regional ARNOS French cohort. A 42-month survival analysis was applied according to serum 25-OHD level and CA therapy.

**Results**: The prevalence of 25-OHD insufficiency < 30 ng/ml was high (73%) with only 22% taking native vitamin D supplementation. A baseline 25-OHD level above the median value (18 ng/ml) was associated with lower all-cause mortality (hazard ratio [HR], 0.73[0.5–0.96]; $P$ = 0.02) after adjustment for age, gender, dialysis vintage, calcaemia, phosphataemia, cardiovascular disease, and diabetes. Only in monovariate analysis, low doses oral alfacalcidol therapy, was associated with a better survival rate in patients with and without 25-OHD deficiency (HR, 0.7 [0.5–0.92]; $P$ = 0.05).

**Conclusions:** Our study shows that, among prevalent HD patients, low 25-OHD levels affects mortality. Alfacalcidol therapy, especially in small doses, may provide compensation, but this needs to be further confirmed using prospective controlled studies comparing native and active vitamin D compounds.

## TH-PO196

**Vitamin D Deficiency (Vit D Def) Is Highly Prevalent in Pediatric (ped) Patients (pts) Receiving Chronic Dialysis** Poyyapakkam Srivaths,[1] Eileen D. Brewer,[1] Stuart Goldstein,[3] Douglas M. Silverstein.[2] *[1]Pediatrics, Renal Section, Baylor College of Medicine, Houston, TX; [2]Pediatric Nephrology, Children's National Medical Center, Washington, DC; [3]Pediatric Nephrology, Cincinnati Children's Hospital, Cincinnati, OH.*

**Background**: Vit D def is widespread in adults receiving chronic dialysis. Prevalence and risk factors associated with vit D def are not well known in ped pts.

**Aim**: Assess prevalence and potential demographic risk factors for vit D def in ped pts receiving chronic dialysis.

**Method**: Cross-sectional study of 25-hydroxy vit D (25OHD) levels in 101 ped pts (median age 15y; range 0.4-26y; 42 Black,39 Hispanic,16 Caucasian,4 other); 53 hemodialysis (HD)/48 peritoneal dialysis (PD) pts at 2 centers (Houston TX & Washington DC). 66 pts also had 1,25-dihydroxy vit D (1,25D) levels assessed; among those 56/66 pts (85%) were taking calcitriol.

**Results**: 94/101 pts (93%) had vit D def (25OHD<30ng/ml); 29% had severe deficiency (25OHD<7ng/ml). Black & Hispanic pts had lower 25OHD (Black 13.3±7.9, Hispanic 13.1±7.7 vs Caucasian 21.6±9.7, p=0.01). 1,25D levels were 31.3±21.6pg/mL (range 6-86; normal 15-75). Vit D def was negatively correlated with age and positively correlated with 1,25D levels, even after controlling for calcitriol therapy and anephric state (10/66), but was not correlated with serum Ca, P or PTH levels (Table 1).

25OHD Correlation with Variables

| | Age | 1,25D | Ca | P | PTH |
|---|---|---|---|---|---|
| Pearson R | -0.43 | 0.39 | -0.11 | -0.09 | -0.14 |
| p value | 0.0001 | 0.001 | 0.23 | 0.32 | 0.16 |

25OHD levels did not differ by modality (HD vs. PD) or center (Houston vs DC).

**Conclusions:** Our data show 1) vit D def is highly prevalent in ped dialysis pts, 2) race, ethnicity and older age are significant risk factors, 3) low 25OHD levels are associated with low 1,25D levels, even in the presence of calcitriol therapy, and 4) residing in more southern latitude does not seem to offer protection from vit D def. We conclude that since vit D def is highly prevalent, calciferol supplementation may be desirable for overall health and improvement of 1,25D levels in ped pts receiving chronic dialysis.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO197

**Urinary and Dialysate Losses of Vitamin D Binding Protein May Contribute to Vitamin D Deficiency in Children with CKD and on Dialysis** Agnieszka Prytula,[1 and 2] David R. Wells,[1] Timothy I. Mclean,[3] Filipa Rola Balona,[1] Ambrose M. Gullett,[1] Kimberly Rita Hassen,[1] Sarah Ledermann,[1] Lesley Rees,[1] Rukshana C. Shroff.[1] *[1]Renal Unit, Great Ormond Street Hospital for Children, NHS Trust, London, United Kingdom; [2]Department of Pediatric Nephrology, Erasmus Medical Center- Sophia Children's Hospital, Rotterdam, Netherlands; [3]North West London Hospitals NHS Trust, Harrow, United Kingdom.*

Vitamin D deficiency is widely prevalent in CKD and dialysis patients. We hypothesise that low circulating levels of vitamin D metabolites 25-hydroxyvitamin D (25OHD) and 1,25-dihydroxyvitamin D ($1,25(OH)_2D$) are due to a loss of vitamin D binding protein (VDBP) in urine and dialysate.

We studied serum, urine and dialysate VDBP levels and compared these with circulating 25OHD and $1,25(OH)_2D$ levels in 16 children on automated PD, 14 on HD and 10 in pre-dialysis CKD stage 4-5. The mean age of the study population was 9.7± 5.6 years and the median time on dialysis 8.5 (1-33) months.

Serum VDBP and 25OHD levels were significantly lower in children on HD than on PD or pre-dialysis patients ($p = 0.03$ and $p = 0.023$ respectively). There were no significant differences in $1,25(OH)_2D$ serum levels, but all except 3 children received daily oral 1-alfahydroxycholecalciferol (alfacalcidol). In the pre-dialysis group urine VDBP losses strongly correlated with urinary albumin losses ($p = 0.0008$, $r = 0.91$). Serum VDBP levels decreased with increasing time on dialysis ($p = 0.0004$, $r = -0.77$) in PD children, but not in HD. In PD children there was a correlation between serum VDBP levels and total dialysate and urine losses ($p = 0.03$, $r = -0.53$). VDBP losses in the long daytime dwell were higher than in the overnight drain ($p = 0.04$), but did not correlate with the type of dialysis fluid used. Patients with high VDBP losses in dialysate also had higher dialysate and urinary albumin losses.

61% of children were 25OHD deficient and 42.5% $1,25(OH)_2D$ deficient despite alfacalcidol supplementation, possibly as a result of high VDBP losses. VDBP losses are higher in patients with high albumin losses and increase with peritoneal membrane changes over time.

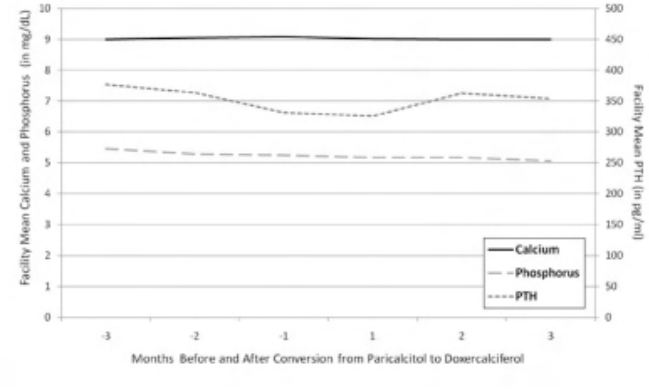
## TH-PO198

**Conversion from Paricalcitol to Doxercalciferol Does Not Affect Bone and Mineral Outcomes** Tracy Jack Mayne,[1] Heather Ashbaugh,[2] Gilbert Marlowe,[1] Mahesh Krishnan.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita Inc., Seattle, WA.*

Background: The issue of comparative effectiveness of drugs has become a national healthcare priority, but with the impending Medicare payment changes, its importance in dialysis is immediate. While a variety of research can be conducted, prospective studies are recognized to be of a higher evidentiary standard. In order to assess the comparative effectiveness of intravenous vitamin D agents used in dialysis, we conducted a prospective conversion from paricalcitol to doxercalciferol and monitored bone and mineral outcomes at the clinic level before and after conversion.

Methods: We conducted a single arm, prospective study of 7 dialysis centers in which patients were initially exclusively prescribed paricalcitol. Patients were converted over a 2-month period to doxercalciferol. Calcium, phosphorus and parathyroid hormone (PTH) were monitored monthly. Clinic level means were computed for each outcome. General Linear Models were used to test for changes in outcomes.

Results: All 7 clinics were located in the Southwest (AZ and NV). Clinics ranged in size from 36 to 247 patients (mean=129±52.4). Utilization at the clinics went from 100% paricalcitol three months before conversion to 100% doxercalciferol three months after. Average paricalcitol clinic dose pre-conversion was 10.7±1.8 mcg. Average doxercalciferol clinic dose post-conversion was 5.7±1.2 mcg. As shown, though there was a numerical trend towards better phosphorus and PTH measures post-conversion, the effects were not statistically significant.



Conclusions: In this small prospective study, clinics successfully converted from paricalcitol to doxercalciferol with non-significant improvements in bone and mineral measures. In this time period, dose conversion was 1.9 mcg paricalcitol to 1.0 mcg doxercalciferol. There was no evidence of the superiority of either agent.

## TH-PO199

**Active Vitamin D Therapy Is Associated with Lower Mortality, Especially in Low 25(OH)D Levels** Masatomo Taniguchi,[1] Shunsuke Yamada,[1] Masanori Tokumoto,[3] Kazuhiko Tsuruya,[2] Hideki N. Hirakata.[4] *[1]Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University; [2]Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University; [3]Medicine, Fukuoka Dental College; [4]Fukuoka Red Cross Hospital.*

**Background.** Vitamin D therapy contributes to mortality or development of cardiovascular disease (CVD) in hemodialysis patients. Low 25(OH)D levels have recently been shown to be associated with all-cause mortality. The present study described the 25(OH)D levels in hemodialysis patients, and the influence of vitamin D treatment on morality or CVD.

**Methods.** In December 2007, we measured serum 25(OH)D levels in a prospective cohort of 2,854 hemodialysis patients, and investigated two-year mortality, onset of CVD, infection- or cancer-related death. Analysis was mainly done using multivariate Cox regression models, adjusted for patient demographics, serum albumin, corrected calcium, phosphate, intact PTH, CRP, urea nitrogen, Kt/V, nPCR, history of CVD and dialysate calcium.

**Results.** Of these patients, 78% were considered 25(OH)D insufficient (<25ng/ml) with 39% considered severely deficient (<15ng/ml). In Cox analysis, the correlation between lower 25(OH)D levels and mortality was not significant. While, injective or oral vitamin D therapy was closely correlated with lower risk of mortality [Hazard ratio (HR) 0.54, 95%CI: 0.51-0.71]. Patients with vitamin D therapy had a significant lower risk of CVD [HR 0.75 (0.58-0.98)], but not that of infection- or cancer-related death. In 25(OH)D insufficient state (<25ng/ml), vitamin D treatment was associated with lower risk of mortality [HR 0.55 (0.40-0.74)], compared with untreated patients. This association was not significant in 25(OH)D levels with more than 25ng/ml [HR 0.53 (0.25-1.12)].

**Conclusions.** The present study suggests that vitamin D therapy contributes to a lower risk of death, especially in 25(OH)D insufficient state.

Disclosure of Financial Relationships: nothing to disclose

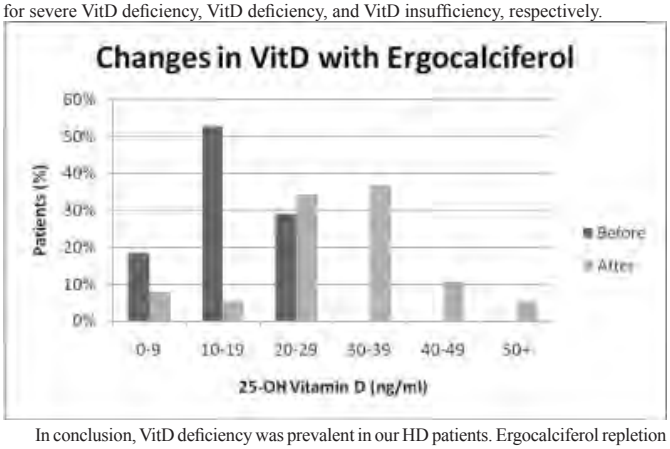
### TH-PO200

**Prevalence of 25-OH Vitamin D Deficiency and Efficacy of Ergocalciferol Supplementation on Hemodialysis Patients** Anna C. Porter,[1] Cheryl L. Gilmartin,[2] Sanjeev Akkina.[1] *[1]Medicine, U. IL, Chicago, IL; [2]Pharmacy, U. IL, Chicago, IL.*

Studies suggest a high prevalence of 25-OH vitamin D (VitD) deficiency among hemodialysis (HD) patients, but the optimal replacement regimen is unknown. This study aimed to investigate the prevalence of VitD deficiency in HD patients in Chicago, IL (latitude 41), and to determine the efficacy of an oral ergocalciferol repletion regimen.

Patients received ergocalciferol replacement according to KDOQI guidelines for CKD stages III-IV based on initial VitD levels (ng/ml) for 6 months. For serum levels <5, 50,000 units (U) weekly were given for 12 weeks, then monthly; for levels 5-15, 50,000 U weekly were given for 4 weeks, then monthly; and for levels 16-30, 50,000 U were given monthly. VitD levels were rechecked after 6 months.

There were 111 HD patients in the study. African-Americans comprised 68% of patients, 29% were Hispanic, and 3% were Caucasian. At baseline, 8% had normal VitD levels (>30 ng/ml), 41% had VitD insufficiency (16-30), and 51% had VitD deficiency (<15). Age, race, history of renal transplant, dialysis vintage, activated vitamin D use, and binder use/type were not associated with baseline VitD levels. Seventy-three patients received repletion according to protocol. Of these, 27% had normal VitD levels after 6 months. Thirty-eight of the 73 patients were treatment-compliant (by pharmacy records) and the results after 6 months are shown in Figure 1. The 3 treatment regimens were 50%, 44%, and 44% effective for severe VitD deficiency, VitD deficiency, and VitD insufficiency, respectively.



In conclusion, VitD deficiency was prevalent in our HD patients. Ergocalciferol repletion resulted in improved VitD levels in compliant patients. However, these regimens were less than 50% effective in normalizing VitD levels in 6 months. The optimal ergocalciferol replacement regimen in HD patients must be determined with further studies.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO201

**Relationship of 25(OH)D Testing on MBD Outcomes and Medication Utilization in Hemodialysis (HD) Patients** Joe Weldon, Mary B. Burgess, Deborah A. Benner, Karen M. Spach, Mahesh Krishnan. *DaVita Inc., Denver, CO.*

**Background:** KDIGO recommends evaluation of 25-hydroxyvitamin D [25(OH)D] in patients with stage 5D CKD and repletion with nutritional vitamin D given the low serum 25(OH)D levels in this population. Small studies have shown nutritional vitamin D use may improve mineral and bone disease (MBD) outcomes and decrease active vitamin D and erythropoietin stimulating agents (ESAs) requirements. We evaluated 25(OH)D testing at a dialysis facility level and correlated the percent of patients being tested with MBD outcomes. **Methods:** We assessed the 25(OH)D testing patterns of 1393 HD facilities. All patients treated more than 13 times in 2009 and at a single facility throughout 2009 were included. Of those, the 730 that tested for 25(OH)D deficiency in their patients were grouped by percent of patients in the facility tested in 2009 at any one point in time. This was correlated with MBD outcomes (phosphorus ≤ 5.5 mg/dL; corrected calcium < 9.5 mg/dL and PTH 150-300 ng/ml) and medication utilization for December 2009. **Results:** Percent of patients meeting the MBD outcome parameters between facilities stratified by percent of patients being tested did not differ. Utilization patterns of medication use are displayed below.

| % of Patients in Facility with 25(OH)D Tested | Facilities | Mean Paricalcitol per tx (mcg) | Mean ESA per tx (U) |
|---|---|---|---|
| None | 663 | Reference | Reference |
| 1-24% | 518 | -0.1 | -128 |
| 25-49% | 44 | -0.5 | -753 |
| 50-74% | 48 | -0.5 | -560 |
| 75-100% | 120 | -0.6 | -472 |

**Conclusions:** Patients in facilities that selectively test 25(OH)D show lower paricalcitol and ESA doses than those that do not test, despite comparable MBD outcomes. If testing is a surrogate for detection and treatment of Vitamin D deficiency with cholecalciferol or ergocalciferol, then our findings are consistent with those of smaller clinical trials regarding the potential benefits of testing and treatment of 25(OH)D deficiency in ESRD patients.

Disclosure of Financial Relationships: Employer: DaVita Inc.

### TH-PO202

**A Phase IV, Randomized, Blinded Single-Center Study of the Effects of Calcitriol and Paricalcitol on Vascular Calcification in Chronic Kidney Disease: Vitamin D and Coronary Calcification Study (VCOR)** Sylvia E. Rosas, Philip T. Cochetti. *Medicine, University of Pennsylvania, Philadelphia, PA.*

Coronary artery calcification (CAC) has been found to predict cardiovascular events and mortality. In animal models, calcitriol significantly increased the serum calcium-phosphate product and aortic calcium content, while paricalcitol had no effect. The objective of this phase IV, randomized, blinded single-center study is to determine the differential effect of calcitriol and paracalcitol on vascular calcification in chronic kidney disease (CKD)patients . The primary endpoint will be percent change in coronary artery (CAC) score at week 48. Inclusion criteria included CKD stage 3-4 and secondary hyperparathyroidism (SHPT) with any CAC. The recruitment goal is 50 participants. Aorto-femoral pulse wave velocity (PWV) and pulse wave analysis were performed to assess aortic stiffness.We present clinical and physiologic parameters on the first 19 participants and compare them with individuals with SHPT that had a baseline research visit but were not eligible to participate due to lack of CAC. There were no differences in measures of mineral metabolism or measures of central pressures (not shown). However, PWV was significantly elevated in those with CAC compared to those without CAC.

| Variable | | No CAC (n=11) | CAC (n=19) | p-value |
|---|---|---|---|---|
| Age (years) | | 57.6 (3.9) | 63.5 (4.3) | 0.11 |
| Gender | Male | 5 (38.5%) | 8 (61.5%) | |
| | Female | 6 (35.3%) | 11 (64.7%) | 0.58 |
| Race | AA | 8 (33.3%) | 16 (66.7%) | |
| | Non-AA | 3 (50.0%) | 3 (50.0%) | 0.38 |
| Diabetes | | 4 (44.4%) | 7 (58.3%) | 0.51 |
| eGFR | | 28.5 (4.9) | 27.2 (2.2) | 0.78 |
| cCalcium* (mg/dL) | | 9.34 (0.08) | 9.47 (0.09) | 0.36 |
| Phosphate (mg/dL) | | 3.85 (0.20) | 4.20 (0.16) | 0.20 |
| iPTH (pmol/L) | | 18.7 (3.5) | 19.2 (3.3) | 0.91 |
| 25(OH)D (ng/mL) | | 20.8 (3.6) | 20.4 (2.1) | 0.91 |
| CAC | | 0 | 261.1 (94.6) | <0.01 |
| PWV | | 9.40 (.73) | 12.00 (.55) | 0.02 |

*cCalc = corrected calcium for serum albumin

Conclusion: Aorto-femoral PWV is significantly higher in patients with CKD and SHPT with CAC compared to those without CAC. CKD patients with SHPT but no CAC have normal PWV.

Disclosure of Financial Relationships: Research Funding: Abbott Laboratories; Scientific Advisor: American Heart Association.

### TH-PO203

**Role of Statin on Vitamin D Usage among Maintenance Hemodialysis Patients** Osama W. Amro,[1] Malik Ladha,[1] Gita Verma,[1] Mahboob Rahman,[2] Saima Iqbal,[1] Salman Rasheed Mallick,[1] Charity Kankam.[1] *[1]Internal Medicine, Saint Vincent Charity Medical Centre, Cleveland, OH; [2]Division of Nephrology, University Hospitals of Cleveland, Case Western Reserve University, Cleveland, OH.*

Statin has been recently proposed to be a vitamin D analogue. Our aim is to test the potential clinical benefit of statin treatment on mineral metabolism in patients with end stage renal disease, favorable outcome will support of the postulated theory that statin indeed might be a vitamin D analogue and its use will be of particular importance in patient with ESRD. Study design was retrospective in fifteen centers in north east Ohio, patients who were on paricalcitol treatment were followed for up to two years. The outcome measure was weekly usage of paricalcitol and intact PTH (iPTH) between patients who were on statin therapy versus those who were not. Final sample had 1685 patients, where 735 were in statin group and 950 were in non-statin group, iPTH was 397.5 ± 333.7 versus 475.9 ± 465.7 (p=<0.001) , weekly dose of paricalcitol was 10.82 ± 6.01 versus 11.46 ± 7.13 (p=0.05), serum calcium was 9.07 ± 0.52 versus 9.0 ± 0.56 (p=0.01), calcium phosphate product was 47.1 +- 8.57 versus 48.64 ± 9.1 (p=0.001), alkaline phosphatase was 112.9 ± 8.6 versus 48.6 ± 9.1 (p=0.01) in the statin group versus non-statin group respectively. When patients were divided in four groups on basis of weekly paricalcitol usage group 1- up to 10 microgram per week, group 2 -10 to 20 microgram per week, group 3- 20 to 30 microgram per week and group - 4 more than 30 microgram per week. Patients percentage on further sub-grouping on basis of statin use versus no statin use , group1; 51.5% versus 48.7%, group 2; 42% versus 41%, group3; 5.2% versus 7.9%, group4; 1.4% versus 2.4% respectively. This data suggest that there may beneficial effects of statin use on iPTH and other markers. Further stronger prospective controlled trials would be needed to test the hypothesis.

**TH-PO204**

**Prevalence and Densitometric Characteristics of Incomplete Renal Tubular Acidosis in Men with Recurrent Nephrolithiasis** Spyridon Arampatzis, Barbara Rieben, Kurt Lippuner. *Osteoporosis Policlinic, University of Bern, Bern, Switzerland.*

Background: The prevalence and skeletal effects of incomplete distal renal tubular acidosis (iRTA) in recurrent nephrolithiasis patients are insufficiently documented.

Methods: 150 male patients with idiopathic nephrolithiasis were evaluated at a tertiary care hospital for iRTA. The diagnosis of iRTA (urinary pH > 5.32, measured from 2 h fasting urine) was confirmed by an additional acid-loading test. Serum and urinary biochemistry were obtained from 10 iRTA and 50 BMI- and age-matched non iRTA recurrent stone formers (nonRTA). Bone mineral density (BMD) of lumbar spine (LS) and femoral neck (FN) was measured by DXA in both groups.

Results: Prevalence of primary iRTA was 6.7% (10/150) in recurrent stone formers. Patients with iRTA had significantly higher urinary pH levels (mean: 5.8 ± 0.3 SD vs 5.1 ± 0.3, p=<0.001) and urinary calcium excretion (8 ± 4 vs 6 ± 2 mmol/day, p=0.013) but significantly lower urinary citrate levels (2 ± 1 vs 3 ± 1 mmol/day, p=0.021) compared to nonRTA patients. No significant difference in skeletal status was found between iRTA and nonRTA patients at the lumbar spine (LS-BMD: 1.046 ± 0.245 vs. 1.004 ± 0.117 g/cm2, LS-Z-score: -0.4 ± 1.8 SD vs. -0.7 ± 0.8 SD, LS-T-score: 0.3 ± 1.8 SD vs. -0.1 ± 0.9 SD) and femoral neck (FN-BMD: 0.829 ± 0.135 vs. 0.852 ± 0.127 g/cm2, FN-Z-score: -0.9 ± 1.1 SD vs.- 0.7 ± 1.0 SD, FN-T-score: 0.3 ± 1.2 SD vs. 0.2 ± 1.5 SD).

Conclusion: This study suggests that iRTA is a prevalent condition in male patients with recurrent urolithiasis. Moderate metabolic acidosis of iRTA did not significantly affect bone mineral density of lumbar spine and femoral neck.

**TH-PO205**

**Maxacalcitol Ameliorates Kidney Injury in Dahl Salt-Sensitive Rats in a Renin-Independent Manner** Kazunori Inoue,[1] Isao Matsui,[1] Chikako Nakano,[1] Tomonori Kimura,[1] Yoshitsugu Takabatake,[1] Takayuki Hamano,[2] Masaru Horio,[1] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Center for Clinical Epidemiology and Biostatistics, University of Pennsylvania School of Medicine, PA.*

Recent studies have revealed vitamin D receptor activators (active vitamin D) exert renoprotective roles by repressing renin mRNA transcription. It remains uncertain whether vitamin D protects kidney in a renin-independent manner.

Male Dahl salt-sensitive (DS) rats were randomly divided into four groups; 0.3% NaCl + vehicle or maxacalcitol (LS+V, LS+M), 8% NaCl + vehicle or maxacalcitol (HS+V, HS+M) at age 4 weeks. Vehicle or 0.2 μg/kgBW of maxacalcitol was intraperitoneally injected every day for 6 weeks. To investigate the mechanisms for renoprotection by maxacalcitol, in vitro experiments were performed using normal rat kidney epithelial (NRK52E) cells.

Maxacalcitol therapy did not affect the development of hypertension in HS rats. HS+V group rats showed a marked elevation in urinary protein excretion and serum creatinine levels at age 10 weeks compared to rats fed with LS. Maxacalcitol significantly attenuated proteinuria and renal interstitial fibrosis, and hence blunted serum creatinine increase in HS rats. Renal renin mRNA expression levels in two HS groups were significantly lower than those of LS groups. Maxacalcitol did not affect renal renin mRNA expression levels in HS groups. In NRK52E cell, maxacalcitol inhibited TGFβ1-induced epithelial mesenchymal transition along with the decrease in collagen and fibronectin mRNA expression levels.

Renin-angiotensin-aldosterone system (RAAS) plays an important role in the progression of chronic kidney disease (CKD). Despite rigorous therapeutic interventions for RAAS, CKD remains a major public-health problem. Our findings indicated that maxacalcitol protects kidney independent of its renin repressive effect. Maxacalcitol may serve as a new additional therapy for CKD even concomitantly with RAAS inhibitors including direct renin inhibitor.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO206**

**Low Vitamin 25(OH)D Levels in Peritoneal Dialysis and Hemodialysis: Comparative Analysis and Risk Factors** Gianpaolo Amici, Adriana Caberlotto, Piergianni Calzavara, Carmelo Cascone. *Nephrology and Dialysis, Regional Hospital, Treviso, Italy.*

KDIGO guidelines on CKD-MBD suggest vitamin 25(OH)D monitoring to identify and treat deficiency status. Many papers report vitamin 25(OH)D deficiency in peritoneal dialysis (PD) due to chronic loss of vitamin D binding protein in PD fluids, but this issue is not considered in guidelines. Serum vitamin 25(OH)D has been assayed by LIAISON DiaSorin method in 29 PD patients (APD 18, CAPD 11) and 40 hemodialysis (HD) patients (standard 28, hemodialfiltration 12), matching was controlled for body weight (PD 70.8±12.2 vs HD 67.2±13.2 kg, p=ns), age (PD 65.9±16.6 vs HD 65.1±13.9 years, p=ns), sex (M/F PD 20/9 vs HD 23/17, p=ns) and diabetes (PD 7/22 vs HD 15/25, p=ns). Statistical analysis was performed by JMP SAS software. PD and HD groups showed differences for: serum 25(OH)D PD 16.0±8.6 vs HD 51.8±31.3 nmol/L (p<0.001), APD 15.8±8.9, CAPD 16.4±8.4, HD 54.5±31.5, HDF 45.6±31.5, (p<0.001), median time on dialysis PD 2.6 (0.2-8.0) vs HD 4.3 (0.3-50.6) years (p=0.0023), vitamin D therapy, 59 treated: PD 28/1 vs HD 31/9 (p=0.0369), albumin PD 3.7±0.4 vs HD 3.9±0.4 g/dL (p=0.0409). There were no differences for antihypertensive medication calculated as median Defined Daily Dose (ATC-WHO) overall 1.75 (0-14): PD 1.75 vs HD 1.75 (p=ns), patients were treated with paricalcitol: PD 2/27 vs HD 6/34 (p=ns), phosphate binding therapy (sevelamer, lantanium, aluminum, calcium) PD vs HD p=ns, cinacalcet treatment: PD 4/25 vs HD 1/39 (p=ns), serum Ca PD 9.2±0.8 vs HD 9.2±0.7 mg/dL (p=ns), serum Pi PD 5.1±1.4 vs HD 5.1±1.1 mg/dL (p=ns), serum ALP PD 85.5±36.9 vs HD 86.6±40.6 U/L (p=ns), iPTH PD 240±183 vs HD 251±213 ng/mL (p=ns). Applying a multiple linear regression model, 25(OH)D serum level (Rsq=0.652) results dependent to: dialysis type (F=38.4, p<0.001), time on dialysis (F=7.5, p=0.008), diabetes (F=7.1, p=0.010), non significant variables in the model: sex, age and vitamin D therapy. PD and HD showed a markedly different circulating pool of vitamin 25(OH)D and this finding, together with other reports as corroborative evidence, should be considered in treatment; other risk factors of vitamin D deficiency can be time on dialysis and diabetes.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO207**

**Phosphate Management with Reduced Calcium Load Increases Administration of Vitamin D** Naomi Sasaki, Nobuo Hashimoto. *HN Medic, Sapporo, Japan.*

**Background** Phosphate management is particularly important for chronic kidney disease mineral and bone disorder (CKD-MBD).Even at the same apparent serum phosphorus level, VD administration sometimes varies depending on which phosphate binder is used. Specifically, when calcium carbonate (CC) or calcium acetate is used as a phosphate binder, it becomes a calcium load and may prevent the administration of VD. **Methods** The subjects were 116 chronic dialysis patients at our facility who were being orally administered CC. We discontinued or drastically decreased the dosage of CC.We compared the effect of VD administration and the levels of serum albumin-corrected calcium (Ca (Alb)), phosphorus (P), and intact parathyroid hormone (iPTH) before, immediately after, and 1 year after the change in CC dosage.**Results** The number of patients receiving CC was reduced to 30, and the mean dosage was reduced from 1.82±0.72 to1.53±0.37 g/day(p<0.05). Before the change, the serum Ca (Alb), P, and iPTH had been 9.21±0.48mg/dl, 5.12±0.73mg/dl, and 127±81pg/ml respectively. Immediately after the change, the serum Ca (Alb) decreased to 8.96±0.53(p<0.001). The serum P and iPTH increased to 5.48±0.67, and 177±87(p<0.001). One year after the change, the serum Ca (Alb) and P were 9.17±0.63 and 5.19±0.61; both levels were no longer significantly different from the levels before the change. The serum iPTH decreased to149±70. We compared the effect of VD administration before and one year after the change.

VD administration

| | Before(%) | One year after(%) |
|---|---|---|
| non VD | 11.2 | 1.0 |
| 1α(OH)$D_3$ ,oral / mean dosage(μg/day) | 51.8 / 0.12±0.11 | 25.2 / 0.24±0.06* |
| 1α25(OH)$_2$$D_3$,oral/ mean dosage(μg/day) | 37.0 / 0.12±0.14 | 63.5 / 0.36±0.13* |
| 22-oxacalcitol | – | 10.3 |

*p<0.001 vs before

The percentage of patients who were not administered VD decreased dramatically from 11.2% to 1.0%, which was only one patient. The mean dosage of VD increased significantly. **Conclusion** It was clear that when CC was administered, VD administration decreased because of increase in serum calcium and inhibition of PTH secretion. Phosphate management with reduced calcium load increased the administration and dosage of VD.

**TH-PO208**

**Dose Comparison Study of CTAP201 Injection and Doxercalciferol (Hectorol®) Injection in Hemodialysis Patients with Secondary Hyperparathyroidism** Joel Z. Melnick,[1] Navindra J. Ramjit,[1] Donna Radjenovich,[1] Nancy L. Samberg,[1] Susan C. Cronin,[1] Samir P. Tabash,[1] Mojtaba Noursalehi,[1] Kotagal Shashi Kant,[2] Mariliza Bernardo.[3] *[1]Cytochroma Inc., Markham, ON, Canada; [2]University of Cincinnati, Cincinnati, OH; [3]Southwest Houston Research, Houston, TX.*

Secondary hyperparathyroidism (SHPT) is a serious condition developing in chronic kidney disease (CKD) as vitamin D levels decline. Left untreated, SHPT causes bone and cardiovascular disease. CTAP201 (1,25-$(OH)_2D_2$) Injection is being developed to treat SHPT in hemodialysis (HD) patients.

In this open label pharmacokinetic (PK) cross-over study, CTAP201 Injection was compared to doxercalciferol (DOX) injection in 24 HD patients. Subjects were enrolled sequentially into 2 dose groups and were randomized to receive single doses of CTAP201 and DOX, separated by a 2-week wash-out. One dose group received 1 mcg of CTAP201 and 4 mcg of DOX while the other received 3 mcg of CTAP201 and 6 mcg of DOX. PK, serum calcium (Ca), phosphorus (P) and intact parathyroid hormone (iPTH) were assessed over 68 hrs. Ca, P and iPTH were compared across dose group, sequence, period, time and treatment using mixed effect model.

Subject demographics, baseline clinical labs, and medical history were comparable between dose groups and treatment sequences. Mean total exposures ($AUC_{0-t}$ and $AUC_{0-last}$) to 1,25-$(OH)_2D_2$ from CTAP201 at the 3 mcg dose were comparable to those from the 6 mcg dose of DOX, while exposures at the 1 mcg dose were approximately 50% lower than those from the 4 mcg dose of DOX. Despite comparable % changes in iPTH after CTAP201 and DOX, significantly lower Ca (8.93±0.15 vs. 9.12±0.15) and a trend toward lower P (4.08±0.17 vs. 4.28±0.17) were observed with CTAP201.

CTAP201 Injection was safe and well tolerated in HD patients. Treatment with CTAP201 Injection may result in lower serum Ca and P than with DOX when similar control of iPTH is achieved.

## TH-PO209

**Development of Vitamin D, iPTH, Calcium, Phosphate and BAP in Hemodialysis Patients over 8 Years** Frans A. Zantvoort. *Renal Transplant Center, Central Hospital, Bremen, Germany.*

We analyzed, retrospectively the development of 25-OH-D3 levels over the years in combination with other related parameters, per year in the timeperiod 2002 - 2009. In our renal transplant center, all recipients have blood taken immediately before transplantation before any drugs have been given. This reflects the status in patients on renal replacement in the north-western part of Germany. For this abstract we took serum Ca (normal range 2.20-2.70 mmol/l), serum Ph (0.81-1.62 mmol/l), iPTH (1.6-6.9 pmol/l), 1,25-diOH-D3 (20-65 pg/l) and bone specific alkaline phosphatase (BAP). For 25-OH-D3 there are no normal values, as 'normal' values tend to be sub-optimal. Values < 20 nmol/l are regarded as a sign of severe deficiency, values > 70 nmol/l are regarded as sufficient. Results are shown in table 1:

Labvalues over the years

| Year | N | Ca (mmol/l) | Ph (mmol/l | 25-D (nmol/l) | 1,25-D (pg/ml) | iPTH (pmol/l) | BAP (µg/l |
|---|---|---|---|---|---|---|---|
| 2002 | 42 | 2.58 ± 0.21 | 1.87 ± 0.59 | 14.0 ± 17.3 | 27.1 ± 20.6 | 18.8 ± 23.0 | 15.4 ± 2.8 |
| 2003 | 36 | 2.49 ± 0.28 | 1.78 ± 0.53 | 11.9 ± 8.1 | 24.5 ± 16.8 | 27.9 ± 28.0 | 12.5 ± 7.2 |
| 2004 | 43 | 2.46 ± 0.24 | 1.69 ± 0.49 | 12.1 ± 8.9 | 22.3 ± 13.8 | 26.5 ± 26.3 | 12.7 ± 9.4 |
| 2005 | 34 | 2.43 ± 0.26 | 1.80 ± 0.61 | 13.0 ± 14.0 | 30.6 ± 18.1 | 43.1 ± 70.4 | 16.4 ± 17.4 |
| 2006 | 50 | 2.37 ± 0.29 | 1.71 ± 0.46 | 37.8 ± 28.8 | 19.3 ± 12.0 | 33.1 ± 37.9 | 18.6 ± 21.3 |
| 2007 | 42 | 2.44 ± 0.21 | 1.68 ± 0.41 | 61.7 ± 38.8 | 17.3 ± 10.5 | 24.9 ± 24.4 | 15.7 ± 10.2 |
| 2008 | 33 | 2.40 ± 0.29 | 1.76 ± 0.55 | 52.3 ± 36.5 | 25.6 ± 18.9 | 23.8 ± 30.9 | 14.1 ± 11.7 |
| 2009 | 31 | 2.39 ± 0.21 | 1.74 ± 0.55 | 75.6 ± 51.0 | 24.5 ± 15.9 | 34.0 ± 33.6 | 18.4 ± 10.7 |

In the period < 2006 123 P. (79.4%) had a severe 25-OH-D3 deficiency, only 2 patients (1.3%) had a level regarded as sufficient. After 2006 the numbers were respectively 10 (9.4%) and 35 (33%). None of the other parameters given changed over time.

In conclusion, nephrologists in the north-western part of Germany are apparently well informed and react rapidly to new insights and information. For 25-OH-D3 this change happened in 2006.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO210

**Use and Outcomes for Oral Vitamin D Preparations Used in Peritoneal Dialysis Patients** Carey Colson, Joe Weldon, Mahesh Krishnan. *DaVita, Denver, CO.*

**Background:** Oral vitamin D agents used for patients on peritoneal dialysis (PD) varies by prescriber preference. However, little is known about the relative differences between achieved outcomes for those patients between agents. We utilized an electronic health record to understand the comparative effectiveness between products in a PD population.

**Methods:** Patients were included in the analysis if they were on continuous ambulatory PD (CAPD), continuously cycling PD (CCPD), or intermittent PD in March of 2010 with the following criteria: > age 18 as of the end of the month, at least one treatment in the month, on dialysis for ≥ 90 days, ≥ 1 of the lab tests below within the last 90 days, and an open order for one (and only one) oral vitamin D preparation during the month. Oral medication records were reviewed and the predominantly prescribed oral vitamin D was used to categorize patients into calcitriol, doxercalciferol, and paricalcitol groupings. Demographic characteristics of each group were generated. Propensity score matching was then performed for the three different agents. Relevant bone and mineral outcomes for March 2010 for each oral agent were generated for each group and compared.

**Results:** Demographic characteristics for patients using the various preparations were not significantly different. 1,372 patients were included in each group following the propensity score analysis. In those patients, lab outcomes for each oral agent are listed below.

| Vitamin D preparations (oral) | Albumin ≥ 3.5 g/dL | PTH 150-600 pg/ml | Ca 8.5-10.2 mg/dL | Ca >10.2 mg/dL | Phos ≤5.5 mg/dL |
|---|---|---|---|---|---|
| Calcitriol | 68.1% | 70.0% | 80.9% | 3.5% | 66.4% |
| Doercalciferol | 67.4% | 70.3% | 80.7% | 3.6% | 66.5% |
| Paricalcitol | 70.0% | 71.8% | 83.4% | 3.9% | 64.5% |
| p-value | NS | NS | NS | NS | NS |

**Discussion:** Baseline demographic characteristics did not differ between the groups. MBD-related outcomes, including albumin, PTH, calcium and phosphate levels showed no between-group differences.

**Conclusion:** In propensity-matched groups of PD patients, use of either of three predominant oral vitamin D preparations produces no clinically significant differences in key MBD outcomes.

## TH-PO211

**Has the Control of Mineral Metabolism Disorders Improved in the Past Three Years? Data Analysis of the OSERCE I and OSERCE II Studies** Jose L. Gorriz,[2] Celestino Pinera,[3] Alberto M. Martinez-Castelao,[4] Javier Nieto,[5] Guillermina Barril.[6] *[1]Servicio de Nefrologia, Fundacio Puigvert, Barcelona, Spain; [2]Servicio de Nefrologia, Hospital Univ Dr Peset, Valencia, Spain; [3]Servicio de Nefrologia, Hospital M Valdecilla, Santander, Spain; [4]Servicio de Nefrologia, Hospital Bellvitge, Barcelona, Spain; [5]Servicio de Nefrologia, Hosp Ciudad Real, Spain; [6]Servicio de Nefrologia, Hosp La Princesa, Madrid, Spain.*

**Objective:** To analyze the degree of compliance with the K/DOQI guidelines in chronic kidney disease (CKD) patients with GFR < 60 mL/min/1.73m2 (stages 3, 4, and 5 not on dialysis) by comparing the results of the OSERCE I and OSERCE II studies.

**Patients and methods**: The OSERCE I study is a multicenter, cross-sectional study that collected consecutive data in April and May 2006 in 634 patients from the outpatient clinics of 32 sites. The OSERCE II study also intends to analyze the degree of compliance in mineral and bone disorders in CKD patients, in addition to other primary objectives including 742 patients from 39 sites, with the same inclusion criteria (April and May 2009).

The degree of compliance with the K/DOQI guidelines parameters is showed in table 1.

Compliance with K/DOQI guidelines

| Compliance with K/DOQI guidelines | inadequate (%) | higher (%) | lower (%) |
|---|---|---|---|
| i-PTH (pg/mL) OSERCE I | 68.4 | 50.7 | 17.7 |
| i-PTH (pg/mL) OSERCE II | 70 | 50.2 | 19.8 |
| Corrected calcium (mg/dL) OSERCE I | 44 | 40 | 4 |
| Corrected Ca (mg/dL) OSERCE II | 64.4 | 61 | 4.4 |
| Phosphorus (mg/dL) OSERCE I | 25.1 | 18.8 | 6.3 |
| Phosphorus (mg/dL) OSERCE II | 23.5 | 5.7 | 17.7 |
| Ca x P (mg2/dL2) OSERCE I | 3 | 3 | - |
| Ca x P (mg2/dL2) OSERCE II | 1 | 1 | - |
| 25-(OH)-Vit D (ng/mL) OSERCE I | 81.5 | - | 81.5 |
| 25-(OH)-Vit D (ng/mL) OSERCE II | 84 | | 84 |

i-PTH was measured with Immulite 2000 (chemiluminescece) .

**Conclusions**: It is still very difficult to achieve the objectives established by the K/DOQI guidelines for mineral and bone metabolism disorders in stage 3, 4, and 5 CKD patients not on dialysis; no improvement was seen in the past three years. The main compliance difficulty is with the PTH-i goals. The levels of 25-(OH)-Vit D are inadequate in a high percentage of patients in both studies.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO212

**Effect of Ergocalciferol Supplements on Bone Metabolism Parameters and ESA Use in Hemodialysis Patients** Anna C. Porter,[1] Cheryl L. Gilmartin,[2] Sanjeev Akkina.[1] *[1]Medicine, U. Illinois, Chicago, IL; [2]Pharmacy, U. IL, Chicago, IL.*

There has been growing interest in the role of 25-OH vitamin D (VitD) supplements in patients with ESRD. Previous studies suggested that VitD repletion results in improved bone metabolism parameters, reduced erythropoiesis-stimulating agent (ESA) doses, and improved albumin levels. This retrospective study evaluated the effects of oral VitD supplements on these parameters in a group of hemodialysis (HD) patients in Chicago.

Baseline VitD, PTH, hemoglobin, phosphorus, and calcium levels were obtained. Based on initial VitD levels, participants received ergocalciferol repletion according to KDOQI guidelines for CKD. These parameters were reassessed after 6 months of treatment.

We examined data for 111 HD patients with VitD levels in Oct. 2009. At baseline, 8% had normal VitD levels (>30 ng/ml), 41% had insufficiency (16-30), and 51% had deficiency (≤15). Seventy-three patients received ergocalciferol, 38 of whom were compliant with treatment, the remainder noncompliant. Only phosphorus levels improved in the compliant group while sevelamer dose increased in both groups.

| | Compliant (change) | p | Non-compliant (change) | p |
|---|---|---|---|---|
| VitD (ng/ml) | 13.7 | <0.001 | -1.1 | 0.21 |
| PTH (pg/ml) | -13.6 | 0.79 | -108 | 0.28 |
| Calcium (mg/dl) | 0.07 | 0.45 | -.03 | 0.81 |
| Albumin (g/dl) | 0.08 | 0.14 | 0 | 0.97 |
| Corrected Ca (mg/dl) | 0.02 | 0.83 | -0.03 | 0.82 |
| Phos. (mg/dl) | -0.98 | 0.0002 | -0.2 | 0.56 |
| Doxercalciferol dose (mcg/treatment) | -0.4 | 0.23 | -0.04 | 0.93 |
| Sevelamer dose (caps/day) | 0.97 | 0.009 | 0.8 | 0.02 |
| Cinacalcet dose (mg/day) | 0.8 | 0.74 | -6.9 | 0.25 |
| Hgb (g/dl) | -0.1 | 0.65 | -0.2 | 0.53 |
| Darbepoetin dose (mcg/week) | +1.6 | 0.75 | -6.5 | 0.35 |

Ergocalciferol replacement resulted in improved phosphorus levels in compliant patients, though sevelamer use also increased. In contrast to findings of previous studies, other bone parameters and reduced ESA dose did not occur. Further studies should determine the effects of ergocalciferol repletion on other clinical outcomes in HD patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO213**

**Fibroblast Growth Factor 23 in Long-Term Kidney Transplantation** Sinee Disthabanchong, Supinda Sirilak, Vasant Sumethkul. *Division of Nephrology, Department of Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Phayathai, Bangkok, Thailand.*

Fibroblast growth factor 23 (FGF-23) is synthesized by bone cells whose function is regulation of calcium-phosphate metabolism. In CKD, as GFR declines, FGF-23 increases in concert with PTH resulting in phosphaturia alleviating phosphate retention. Recent evidence added the role of FGF-23 in direct suppression of PTH and FGF-23 may be released in response to high PTH. In early post-transplantation, despite significant phosphate wasting, FGF-23 accumulates accentuating hypophosphatemia. The relationship between FGF-23 and phosphate as well as allograft function in long-term kidney transplantation is largely unexplored. Phosphate retention is less of a problem in these patients and the role of FGF-23 may be different than that in CKD. The present study investigates FGF-23 in 229 kidney allograft recipients at least 1-year post transplantation and its relationship to other mineral parameters. A comparison was made to CKD with equivalent GFR. The average GFR was 56±19 mL/min/1.73m$^2$. Serum phosphate was normal in 93%, low in 6% and high in 1%. Inverse correlations were observed between phosphate, FGF-23 and PTH with GFR ($p<0.001$). Serum phosphate correlated modestly with FGF-23 ($p=0.045$). Urinary phosphate excretion increased as GFR declined and correlated well to the increase in PTH ($p<0.001$) and FGF-23 ($p=0.006$). In multiple regression analysis, the only independent predictors for FGF-23 levels were increased PTH and decreased GFR. The relationships between FGF-23 with serum and urinary phosphate were lost after adjustment suggesting closer relationship between FGF-23 and PTH than phosphate. Comparison to CKD patients with equivalent GFR, PTH and serum calcium were higher and serum phosphate was lower in the transplant group ($p<0.001$) confirming the existence of persistent hyperparathyroidism that may promote FGF-23 secretion. Using ROC analysis, AUC of FGF-23 for predicting PTH>100 pg/mL was the highest among other parameters (AUC= 0.653). In conclusion, the increase in FGF-23 appeared to associate with the severity of hyperparathyroidism rather than phosphate retention in long-term kidney transplantation.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO214**

**Functional Analysis of a Novel Klotho Mutation Identified in a Patient with End-Stage Renal Disease** David De Brauwere,[1] Pablo A. Urena,[1,3] Caroline Kannengiesser,[4] Christine Leroy,[1,2] Bernard Grandchamp,[4] Dominique Prie,[1,2] Laurent Beck,[1,2] Gerard Friedlander.[1,2] *[1]INSERM U845, Paris, France; [2]Universite Paris Descartes, Paris, France; [3]Clinique du Landy, Saint-Ouen, France; [4]Hopital Bichat, Paris, France.*

Klotho is implicated in the regulation of phosphate (Pi) homeostasis by modulating the phosphaturic action of fibroblast growth factor 23 (FGF23) and parathyroid hormone (PTH). In a previous clinical study, comparing normophosphatemic to hyperphosphatemic hemodialysis patients, we found that, in a significant proportion of patients, the hyperphosphatemia was independent from serum levels of PTH, vitamin D, circulating bone markers, the effectiveness of dialysis, dietary Pi intake and Pi lowering therapies, suggesting that a genetic background could predispose to hyperphosphatemia. We hypothesized that alteration in the klotho gene could be responsible for the hyperphosphatemia. We identified a novel klotho mutation (c.1041delT) in a patient belonging to the hyperphosphatemic group. The aim of this study was to elucidate whether this mutation could account for the observed phenotype. We first asked whether soluble klotho (1-980 aa) through its beta-glucuronidase activity could have a direct effect on intestinal Pi transport. To test this hypothesis, Pi uptake was assessed in intestinal CaCo-2 cells transfected with NPT2b following treatment by beta-glucuronidase, klotho and/or FGF23. We found that Pi uptake was not modified by beta-glucuronidase nor by recombinant Klotho (Kl) or conditioned media from Kl-transfected HEK cells. Similarly, the addition of FGF23 to Kl or Kl-conditioned media did not affect Pi uptake. We then asked whether soluble klotho could modulate systemic Pi uptake in fibroblastic NIH-3T3 cultured cells. We found that recombinant Klotho (Kl) or Kl-conditioned media only in combination with FGF23 increased PiT-2 mRNA expression and Pi uptake by 2 fold, while mutated klotho did not have any effect. In conclusion, for the first time, we demonstrate that klotho plus FGF23 up-regulated PiT-2 mRNA expression and increased Pi uptake in NIH-3T3 cells and that a novel klotho mutation completely lacks this effect, which might explain the patient phenotype

Disclosure of Financial Relationships: nothing to disclose

**TH-PO215**

**Purification of Intestinal Phosphatonin from Porcine Intestine** Zachary C. Ryan, Rajiv Kumar. *Dept of Medicine, Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

The proximal intestine releases a factor(s) that inhibits renal phosphate (P) transport upon exposure to a high P meal. Previous experiments have demonstrated that the factor is present in the intestinal mucosa and in the liver. Further experiments have shown that rat intestinal cells maintained in culture also express and secrete a factor that inhibits sodium-dependent P transport in opossum kidney (OK) cells. To identify a readily available and abundant source of this factor, we isolated porcine intestinal mucosa and tested purified fractions for the presence of an inhibitor of renal P transport.

*Results:* Porcine intestinal mucosa was scraped and homogenized in isotonic saline at 4 °C. The homogenate was treated with trichloroacetic acid (to a final concentration of 3%). The acidified homogenate was centrifuged at 27,000 x g in an SS34 rotor at 4 °C for 60 minutes. The pellet was discarded and the supernatant was neutralized with 1M NaOH and dialyzed extensively against water at 4 °C. The dialyzed material was lyophilized and resuspended in 25mM HEPES, 100mM NaCl, pH 7.2 (Buffer A). This material was chromatographed on a 26/60 Superdex 75 column in Buffer A at a flow rate of 0.5 mL/min. Fractions were collected, dialyzed against water, lyophilized, resuspended in P-free DMEM, and tested for P uptake inhibitory activity in OK cells. The **Table** demonstrates the presence of P uptake inhibitory activity in different fractions.

OK Cell P Uptake Inhibitory Activity in Fractions of Porcine Intestine

| *Purified fractions from porcine intestine* | *Percent inhibition (mean ± SEM) of sodium dependent phosphate uptake in OK cells* |
|---|---|
| Original homogenate | 12.58±2.2 |
| Supernatant following TCA treatment | 11.8±2.1 |
| ***Fractions from Superdex column*** | |
| • >67 kDa | 21.8±1.8 |
| • 67-16.7 kDa | 39.6±1.3 |
| • 16.7-5.7 kDa | 4.4±2.2 |
| • 5.7-0.2kDa | 10.2±3.6 |
| • <0.2kDa | 3.9±2.9 |

*Conclusions:* Porcine intestinal mucosa contains a factor that inhibits renal phosphate transport. Purification of the inhibitor by trichloroacetic acid precipitation, and size exclusion chromatography effects a substantial purification of the inhibitor. Further characterization of the inhibitor should be possible using porcine intestine as the source of material.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO216**

**Intracellular Angiotensin II Induces the Expression of $Na^+/HCO_3^-$ Co-Transporter in Mouse Proximal Tubule Cells Via MAPK- and NF-κB-Dependent Signaling** Xiao C. Li,[1] Julia Cook,[2] Ulrich Hopfer,[3] Jia L. Zhuo.[1] *[1]Division of Hypertension and Vascular Research, Department of Internal Medicine, Henry Ford Hospital, Detroit, MI; [2]Department of Medical Genetics, Ochsner Clinic Foundation, New Orleans, LA; [3]Department of Physiology and Biophysics, Case Western Reserve University, Cleveland, OH.*

Extracellular angiotensin II (ANG II) stimulates sodium and bicarbonate reabsorption in proximal tubules (PT) via activation of cell surface ANG II receptor-induced expression/activity of $Na^+/HCO_3^-$ co-transporters. However, whether intracellular ANG II plays a physiological role is unknown. The present study tested the hypothesis that intracellular ANG II stimulates $Na^+/HCO_3^-$ cotransporter expression in mouse PT cells via MAPK- and NF-κB-dependent signaling. Expression of a cyan fluorescent fusion of ANG II chimera (ECFP/ANG II) in PT cells induced time-dependent increases in intracellular ANG II levels with a peak response at 48 h after transfection (control: 191.9 ± 17.6 *vs.* ECFP/ANG II: 484.0 ± 31.8 pg/mg protein, $p<0.01$). However, ECFP/ANG II was not released into the medium. ECFP/ANG II increased $Na^+/HCO_3^-$ cotransporter expression by >2-fold (control: 0.18 ± 0.03 *vs.* ECFP/ANG II: 0.46 ± 0.06 $Na^+/HCO_3^-$/actin ratio, $p<0.01$), which was associated with 2.7-fold increases in MAP kinases p-ERK1/2 (control: 0.18 ± 0.04 *vs.* ECFP/ANG II: 0.49 ± 0.14 p-ERK1/2/t-ERK1/2 ratio, $p<0.01$) and >10-fold increases in the p65 subunit of NF-κB proteins (control: 0.16 ± 0.02 *vs.* ECFP/ANG II: 1.96 ± 0.31 NF-κB/actin ratio, $p<0.01$). ECFP/ANG II-induced activation of p-ERK1/2 and NF-κB/p65 and expression of $Na^+/HCO_3^-$ cotransporter were blocked by the $AT_1$ receptor antagonist losartan (10 μM; $p<0.01$), the MEK1 & MEK2 inhibitor UO126 (10 μM; $p<0.01$), or by the NF-κB inhibitor, Ro 106-9920 (10 μM; $p<0.01$). By contrast, ECFP/ANG II had no specific effects on p-ERK1/2, NF-κB/p65 or $Na^+/HCO_3^-$ cotransporter protein expression in PT cells of $AT_{1a}$-KO mice. These results suggest that intracellular ANG II induces $Na^+/HCO_3^-$ cotransporter expression in PT cells via $AT_{1a}$ receptor-mediated activation of MAP kinases and NF-κB signaling mechanisms.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO217**

**Angiotensin II Stimulates Heterogenous Nuclear Ribonucleoprotein F and K Expression in Renal Proximal Tubular Cells Via Reactive Oxygen Species Generation** Chao-Sheng Lo,[1] Shiao-Ying Chang,[1] Isabelle Chenier,[1] Shao-Ling Zhang,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] John S. D. Chan.[1] *[1]Res. Ctr., CHUM-Hotel Dieu Hosp, Montreal, QC, Canada; [2]Res. Ctr., Maisonneuve-Rosemont Hosp, Montreal, QC, Canada; [3]Pediatr Nephrol Unit, Mass Gen Hosp, Boston, MA.*

Heterogeneous nuclear ribonucleoprotein F (hnRNP F) and hnRNP K (hnRNP F/K) bind to the rat angiotensinogen (Agt) gene promoter and inhibit Agt gene transcription in vitro (JBC, 2006). The present study investigated whether angiotensin II (Ang II) stimulates hnRNP F/K expression, thereby exerting 'negative feedback' on Agt gene expression in renal proximal tubular cells (RPTCs) and subsequently attenuates the Ang II-effect on RPTC injury. Adult male transgenic (Tg) mice specifically overexpressing rat Agt in their RPTCs (10 weeks of age) were given ± RAS blockers (losartan (30 mg/kg/day) plus perindopril (4 mg/kg/day)) and euthanized at week 20 while untreated non-Tg littermates served as controls. Kidneys were processed for histology and immunostaining for hnRNP F/K expression. Renal proximal tubular hnRNP F/K mRNA and protein expression were quantified by respective real time qPCR assay and Western blotting. Rat RPTCs stably transfected with the plasmid containing Agt cDNA were cultured in 5 mM D-glucose DMEM ± losartan or DPI (an inhibitor of NADPH oxidase). RPTC reactive oxygen species (ROS) generation was determined by lucigenin assay. HnRNP F/K expression were significantly increased in RPTCs of Agt-Tg mice as compared to non-Tg littermates and normalized by RAS blockers in vivo. Furthermore, Tg mice overexpressing both Agt and catalase in their RPTCs normalized hnRNP F/K expression. Finally, hnRNP F/K mRNA expression and ROS generation were significantly increased (2-fold increase) in Agt-stable transformants,

and these parameters were reversed by losartan and DPI in vitro. These data demonstrate that Ang II stimulates both hnRNP F/K expression via Ang II type 1 receptor and ROS generation in RPTCs. HnRNP F/K expression might play an important 'negative feedback' role in attenuating Agt gene expression and subsequently attenuating hypertension and kidney injury induced by intrarenal RAS activation in vivo.

**Epithelial Sodium Channel Regulation by Cell Surface Sgk1** Sheela V. Thomas, Madhumitha Rajagopal, Carol Charlton, Alan C. Pao. *Medicine/ Nephrology, Stanford University, Stanford, CA.*

Serum and glucocorticoid regulated kinase 1 (Sgk1) participates in diverse biologic processes including cell growth, osmoregulation, and sodium homeostasis. In the kidney, Sgk1 mediates aldosterone-regulated sodium transport in the distal nephron by stimulating surface expression of the epithelial sodium channel (ENaC). Recent studies have suggested that subcellular localization of Sgk1 may represent a mechanism for modulating Sgk1 function. We used a mammalian kidney cell ($mpkCCD_{c14}$) line to examine the subcellular localization of the aldosterone-regulated isoform of Sgk1. By cell fractionation studies, we identified aldosterone-stimulated Sgk1 to be mostly localized to the membrane and the cytosol rather than to the nuclear fraction. To determine if membrane-associated Sgk1 is at the plasma membrane, we used surface biotinylation assays and immunocytochemistry to confirm that the aldosterone-regulated isoform of Sgk1 is present at the apical surface of kidney collecting duct cells. Cell surface Sgk1 expression in $mpkCCD_{c14}$ cells was attenuated with pre-treatment with methyl-b-cyclodextrin (MβCD), a compound that depletes membrane cholesterol, suggesting that Sgk1 requires intact lipid raft formation to associate with the cell surface. Furthermore, in HEK293T cells, Sgk1 associated with the cell surface only when ENaC was co-transfected, suggesting that Sgk1 associates with ENaC at the cell surface. This Sgk1-ENaC association was also confirmed by co-immunoprecipitation assays. To evaluate the functional significance of cell surface Sgk1, we treated $mpkCCD_{c14}$ cells with MβCD (or vehicle) and used an Ussing chamber to measure aldosterone-stimulated short-circuit currents that are sensitive to the Sgk1 inhibitor GSK650394. MβCD treatment attenuated baseline amiloride-sensitive currents modestly but it significantly diminished aldosterone-stimulated amiloride-sensitive currents and aldosterone-stimulated GSK650394-inhibitable currents. We propose that Sgk1 associates with ENaC and lipid raft microdomains at the cell surface, where an assembly platform may exist for the regulation of ENaC by Sgk1.

**Uninephrectomy (UNX) Reduces 11beta-Hydroxysteroid Dehydrogenase Type 1 (11beta-HSD1) and Type 2 (11-beta-HSD2) in Rats** Meret Lauterburg, Brigitte Frey, Bernhard Dick, Geneviève Escher, Felix J. Frey. *Department of Nephrology and Hypertension, University Hospital of Bern, Switzerland.*

RATIONALE. Renal allograft donors are at risk to develop hypertension and a metabolic syndrome by an unknown mechanism. We hypothesized that this risk is at least in part explained by an enhanced intracellular availability of glucocorticoids due to an increased 11beta-HSD1, an intracellular prereceptor activator of corticosteroids in glucocorticoid target tissues (Escher G, J Exp Med.1997:189-98) and/or a diminished 11beta-HSD2, an inactivator of corticosteroids in mineralocorticoid target tissues (Frey FJ, Curr Opin Nephrol Hypertens. 2004 :451-8).

METHODS. Uninephrectomized or sham operated rats (n=7 per group) were investigated four weeks after UNX.

The mRNA of 11beta-HSD1 and 11beta-HSD2 were assessed by RT-PCR in liver and kidney tissue, respectively and the enzyme activities were directly quantified in the corresponding tissues by determining the ratios of (THB+5alpha-THB)/THA ((tetrahydrocorticosterone+5alpha-tetrahydrocorticosterone)/ tetrahydrodehydrocorticosterone) and the B/A (corticosterone/dehydrocorticosterone) by gas chromatography-mass spectrometry. The apparent total body activities of 11beta-HSD1 and 11beta-HSD2 were estimated by the urinary ratios of (THB+5alpha-THB)/THA and B/A, respectively.

RESULTS. The hepatic mRNA content and the hepatic and urinary ratios of (THB+5alpha-THB)/THA were decreased after UNX, indicating diminished access of glucocorticoids to glucocorticoid receptors. In renal tissue 11beta-HSD2 mRNA and measures of activity were diminished and, as a corollary, the renal and urinary ratios of B/A were increased, indicating enhanced access of glucocorticoids to mineralocorticoid receptors ($p < 0.01$ for all parameters analyzed).

CONCLUSION. Both 11beta-HSD1 and 11beta-HSD2 are down-regulated after UNX in rats, a constellation known to induce salt-sensitive hypertension but not insulin-resistance.

**Angiotensin II Type 2 Receptor Binding and Signaling in Mesothelial Cells** Michael E. Ullian,[1,2] Thomas Morinelli.[1,2] *[1]Medicine/Nephrology, Medical University of South Carolina, Charleston, SC; [2]Medicine, Ralph H. Johnson VA Medical Center, Charleston, SC.*

The process of thickening and inflammation of the peritoneal mesothelium is a major problem in patients undergoing chronic peritoneal dialysis. We have been exploring the role of angiotensin II (AngII) receptor subtypes (AT1 and AT2) in this phenomenon, using MET5A mesothelial cells as a model system. Monolayers of these cells display typical mesothelial cell cobblestone appearance. Radioligand binding competition studies with 125I-AngII or 125I-CGP42112 (a specific AT2 receptor agonist) and 100-fold excesses of unlabeled AngII or unlabeled losartan (a specific AT1 receptor antagonist) or unlabeled PD123319 (a specific AT2 receptor antagonist) in crude membrane suspensions revealed specific binding to AT2 receptors but not AT1 receptors; 125I-AngII was displaced by 19% by PD123319 but only by 7% by losartan, and 125I-CGP42112 was displaced by 32% by PD123319 and only 4% by losartan ($N = 5$, both $p < 0.05$). In intact cells, the absence of AngII-stimulated (1 nM - 100 nM) increases in intracellular calcium concentration, an AT1 receptor-coupled signaling event, as measured with the fluorescent probe Fluo-3 and a fluorescence imaging plate reader, confirmed the absence of AT1 receptors ($N = 1$). Next, we investigated signaling [phosphorylation of extracellular-regulated kinase (p42/44 ERK) by immunoblotting] through AT2 receptors in intact cells. Uniform protein loading was verified by immunoblotting of total p42/44 ERK. AngII-stimulated (100 nM for 5 minutes) increases in p42/44 ERK phosphorylation were decreased by 27% by a 100-fold excess of PD123319 ($p < 0.05$) but not by losartan ($N = 3$). These preliminary results suggest that AngII might contribute to mesothelial membrane thickening and inflammation through AT2 receptors during the course of peritoneal dialysis. Studies of the effects of AngII, losartan, and PD123319 on p42/44 ERK phosphorylation in primary cultures of rat peritoneal mesothelial cells and on peritoneal membrane thickening and inflammation in rats models of peritoneal dialysis are ongoing.

**TH-PO221**

**Angiotensin II (AII)-Induced AT1A Receptor (AT1AR) Internalization and Subsequent Increased Cyclooxygenase 2 (COX-2) Protein Expression in Rat Aortic Vascular Smooth Muscle Cells (RASMC) Are Mediated by NF-κB Activation** Thomas Morinelli,[1,2] Michael E. Ullian.[1,2] *[1]Medicine Division of Nephrology, Medical University of South Carolina, Charleston, SC; [2]Research Services Ralph H. Johnson VA Medical Center, Department of Veteran's Affairs, Charleston, SC.*

Previously, we showed that AII activation of COX-2 transcription and protein expression is dependent upon AII AT1AR internalization and nuclear localization (Morinelli, et al, 2007; 2008; 2009). Others have shown that the transcription factor NF-κB mediates AII-induced COX-2 expression (Hu et al 2002;Ohnaka et al, 200). Activation of the NF-κB protein complex is initiated by phosphorylation and degradation of its IκB component and nuclear localization and DNA binding of the p65 component. The present study examines the involvement of NF-κB complex activation in AII AT1AR internalization and subsequent COX-2 protein expression in RASMC. The NF-κB inhibitor Ro-1069920 blocked AII-induced COX-2 expression in a concentration-dependent manner as determined by COX-2 immunoblots ($5.7 \pm 2.2$ fold increase for AII, 100 nM, 3 hrs. vs. $0.75 \pm 0.6$ fold with 10 μM Ro-1069920 pre-treatment, $n=3$, $p<0.05$). AII-induced NF-κB nuclear localization (immunofluorescence) and AII-induced AT1AR internalization as measured by radioligand binding assays ($57.3\% \pm 11\%$ internalization after 5' for Control vs. $28.2 \pm 6\%$ for Ro-1069920 pre-treatment, $n=4$; $p < 0.05$) were also inhibited. Additional inhibitors of the NF-κB pathway were tested. Both parthenolide, like Ro-1069920 inhibits degradation of IκB, and curcumin an inhibitor of NF-κB/DNA complex formation and subsequent transcription also blocked AII-induced COX-2 expression (80% and 76% inhibition, respectively, n=3). In contrast, betulinic acid, an inhibitor of NF-κB phosphorylation, had no effect on COX-2 protein expression induced by AII. These data suggest that inhibition of IκB degradation inhibits AII-induced AT1AR internalization and subsequent COX-2 protein expression, possibly linking internalization of the AT1AR with activation of the NF-κB pathway. Supported by Dialysis Clinic Incorporated and the U.S. Department of Veteran's Affairs.

**AGTR1 and AGTR2 Modulation by Ang II and Cytokines in Human Monocytes, Granulocytes and Lymphocytes** Branko Braam, Wenqing Zhuang. *Medicine/Nephrology, Univ. of Alberta, Edmonton, AB, Canada.*

**Introduction**: Angiotensin II (Ang II) is a key player in hypertension, inflammation and oxidative stress, all associated with atherosclerosis. Although several circulating cells reportedly express AT1 receptors (AGTR1), its regulation has not been studied. Angiotensin AT2 receptor (AGTR2) expression in circulating cells is largely unknown. We measured cell surface expression of AGTR1 and AGTR2 in human leukocytes and modulation by Ang II itself and the cytokines IFNg, IL6 and TNFa.

**Methods and results**Monocytes (MONO), granulocytes (GRAN) and B-cells (B), but not T-cells, expressed AGTR1 and AGTR2 assessed by FACS on fresh whole blood (n=5 healthy humans). MONO showed the strongest expression. Western blotting revealed AGTR1 protein expression in all cell types including T-cells. Next, whole blood was stimulated with Ang II (100 nM), a combination of IL6 (20 IU/ml), IFNγ (4 ng/ml) and

TNFa (20 ng/ml) (CytMix), or CytMix+Ang II for 4h ex vivo at 37C under gentle automated movement. Ang II by itself tended to depress MONO AGTR1 (81±10%) and AGTR2 (87±14%) expression assessed by FACS on whole blood. GRAN and B AGTR1 and -2 were not affected by Ang II. CytMix and CytMix+Ang II increased MONO AGTR1 (to 133±34 and 126±27%, resp.) and AGTR2 (to 137±26 and 126±15%,resp.) to levels exceeding Ang II alone (both $P<0.05$). When tested in U937 human MONO cell line, these results were reproduced for AGTR1. IFNγ seemed responsible for AGTR1 induction by CytMix.

**Conclusion**These data demonstrate that AGTR1 and -2 are present on cell surface of freshly isolated MONO, GRAN and B cells. Ang II by itself did not significantly modulate AGTR1 or AGTR2 expression. However, cytokines (presumably IFNg) cell-specifically stimulate AGTR1 and -2 expression in MONO. This absence of ligand repression of AGTR1 and -2 would indicate continued receptor stimulation in the presence of Ang II, which could induce a vicious circle leading to more inflammation and oxidative stress. These observations prompt exploration of aberrant AGTR expression in pro-atherosclerotic disease states such as CKD and HTN.

**Roles of NO/sGC/cGMP/PKG Pathway in the Regulation of NBCe1 Activity by Angiotensin II** Ayumi Shirai, Osamu Yamazaki, Motonobu Nakamura, Hideomi Yamada, Masashi Suzuki, Shoko Horita, George Seki, Toshiro Fujita. *Internal Medicine, Tokyo University, Tokyo, Japan.*

Although nitric oxide (NO) has been known to affect renal proximal tubule transport, whether NO signaling is stimulatory or inhibitory in this segment has been controversial. Moreover, the roles of NO in the regulation of proximal transport by angiotensin (Ang) II have not been clarified. In the present study we investigated the roles of NO in the regulation of renal Na-$HCO_3$ cotransporter (NBCe1) activity by Ang II. Cell pH in isolated mouse renal proximal tubules was monitored by the pH sensitive dye BCECF, and the NBCe1 activity was determined by the rates of cell pH reduction in response to bath bicarbonate concentrations. As previously reported, Ang II had a biphasic effect on NBCe1 activity via AT1 receptor: 26% stimulation by $10^{-10}$ M AngII, no effect by $10^{-8}$ M Ang II, and 31% inhibition by $10^{-6}$ M Ang II. In the presence of nitric oxide synthetase (NOS) inhibitor L-NAME, however, all the concentrations of Ang II stimulated the NBCe1 activity by approximately 30%. In the presence of soluble guanylyl cyclase (sGC) inhibitor ODQ, $10^{-6}$ M Ang II stimulated the NBCe1 activity by 32%. In the presence of protein kinase G (PKG) inhibitor KT5823, $10^{-6}$ M Ang II also stimulated the NBCe1 activity by 42%. On the other hand, the addition of NO donor sodium nitroprusside dose-dependently inhibited the NBCe1 activity: 17%, 32%, and 40% inhibition by $10^{-5}$ M, $10^{-4}$ M, and $10^{-3}$ M SNP, respectively. Moreover, the addition of membrane permeable cGMP analog 8Br-cGMP (2 x $10^{-5}$ M) significantly reduced the NBCe1 activity by 24%. SNP also reduced the NBCe1 activity in the presence of cytosolic phospholipase A2 (cPLA2) inhibitor AACOCF3. By contrast, the addition of arachidonic acid significantly inhibited the NBCe1 activity, but failed to inhibit the NBCe1 activity in the presence of L-NAME. These results indicate that NOS/NO/sGC/cGMP/PKG pathway mediates the inhibitory action of Ang II in this segment. Furthermore, this pathway may lie downstream of cPLA2/arachidonic acid pathway, which was previously identified as another mediator of Ang II inhibitory action.

## TH-PO224

**Role of Rho-Kinase (ROCK) and Epidermal Growth Factor Receptor (EGFR) Activation in Glomerular Injuries Induced by Angiotensin II (AngII)-Dependent Hypertension** Hiroyuki Suzuki,[1] Tatsuo Yamamoto,[2] Yoshihide Fujigaki,[1] Akira Hishida.[1] *[1]First Department of Medicine, Hamamatsu University School of Medicine, Japan; [2]Department of Health and Nutritional Sciences, Hamamatsu University, Japan.*

Among many kinases that are activated by AngII, role of ROCK and EGFR in the glomerular injuries are not well known. Therefore, we investigated the effect of fasudil (ROCK inhibitor) and gefitinib (EGFR inhibitor) on the progression of glomerular injuries using AngII-dependent hypertension model of rats.

Male Wistar rats were infused with AngII at a rate of 400ng/kg/min for 14 days. Fasudil (20mg/kg) and gefitinib (3mg/kg) were administered once every day intraperitoneally and orally, respectively.

We found that staining intensity of phosphorylation of myosin light chain at Ser19, downstream target of ROCK, and phosphorylation of EGFR at Tyr1068 were increased in kidneys at day 14, suggesting ROCK and EGFR in the kidney were activated by AngII. AngII infusion increased blood pressure (BP) (220.3±18.7mmHg: $p<0.05$) as well as urinary protein excretion (118.0±19.0mg/day: $p<0.05$) and the number of proliferating cells in glomeruli judged by Ki67 and PCNA staining by day 14. Also, p27 expressions in the glomeruli were reduced, suggesting AngII-induced cell proliferation is partly dependent on p27. AngII infusion induced dissociation of immunostaining patterns of nephrin and podocin, suggesting that proteinuria in this model might be related with slit diaphragm dysfunction. Fasudil significantly reduced proteinuria (57.2±17.5mg/day: $p<0.05$), completely inhibited cell proliferation and reduction of p27. On the other hand, gefitinib also completely inhibited glomerular cell proliferation and reduction of p27 in glomeruli. However, proteinuria was not reduced by treatment with gefitinib (133.3±30.9mg/day) at all. In agreement with the result of reduced proteinuria, dissociation of expression patterns of podocin and nephrin was ameliorated by fasudil but not by gefitinib.

In conclusions, AngII activates ROCK and mediates both proteinuria and glomerular cell proliferation. Although AngII also activates EGFR, it may induce glomerular cell proliferation but not proteinuria.

## TH-PO225

**Adiponectin Attenuates Angiotensin II-Induced NADPH Oxidase Activity in Human Kidney Cells** Fei Fang, George Chu Liu, Xiaohua Zhou, James W. Scholey. *Medicine, University of Toronto, Toronto, ON, Canada.*

Although the mechanism(s) responsible for the progression of chronic kidney disease (CKD) to end-stage renal disease have not been fully elucidated, two important determinants of CKD are activation of the renin-angiotensin system (RAS) and obesity. The generation of angiotensin II (AngII) contributes to kidney injury, at least in part, by leading to NADPH oxidase activation and superoxide generation. Obesity is associated with reduced levels of adiponectin, and adiponectin attenuates high glucose-induced superoxide generation in endothelial cells. However the effect of adiponectin on Ang II-induced NADPH oxidase activation has not been studied. Accordingly, we sought to determine if there was an interaction between adiponectin and AngII in cultured human renal epithelial (HRE) cells. Primary cultured HRE cells expressed the adiponectin receptors, AdipoR1 and AdipoR2, and exhibited a robust increase in NADPH oxidase activity and superoxide production after incubation with AngII (0.1μM). Pre-treatment with adiponectin decreased the AngII-induced NADPH oxidase in a dose dependent manner. The effect of adiponectin on AngII-induced NADPH oxidase activity was mimicked by treatment with stable cAMP analogues (pCTP cAMP, 20μM; db cAMP, 25μM,) and was blocked by both the adenylyl cyclase inhibitor (SQ22536, 0.1mM) and the protein kinase A (PKA) inhibitor (H89, 1μM). In addition, incubation with an AMP activated kinase (AMPK) agonist, AICAR (1mM), normalized AngII-induced superoxide generation, and incubation with an AMPK antagonist, compound C (1μM), reversed the effect of adiponectin on AngII-induced NADPH oxidase activity. In conclusion, adiponectin attenuates AngII-induced superoxide production in human kidney cells, and this effect is mediated by both cAMP-PKA and AMPK signal transduction pathways. This finding suggests that declining levels of adiponectin may contribute to the deleterious effect of obesity on progression of CKD.

**Local Balance of Angiopoietins (Ang) Is Essential To Protect the Glomerulus in Diabetes** Marie Jeansson,[1] Chengjin Li,[1] Susan E. Quaggin.[2] *[1]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; [2]Division of Nephrology, St Michael's Hospital/University of Toronto, Toronto, ON, Canada.*

Endothelial dysfunction is central to complications of diabetes, sepsis, and malaria. An elevated ratio of Ang2:Ang1 has been associated with increased morbidity and mortality in these conditions. Ang1 and Ang2 are ligands for the tyrosine kinase receptor, Tie2, found on endothelial cells. Ang1, produced by endothelial support cells (pericytes, podocytes), is an agonist and promotes endothelial cell stabilization and quiescence. Ang2, produced by endothelial cells, is an antagonist and causes endothelial activation, destabilization, and inflammation. We hypothesize that imbalance between Ang1 and Ang2 is a critical factor in pathogenesis of endothelial dysfunction, particularly in diabetes.

Standard KO of Ang1 is embryonic lethal so to test this hypothesis, we generated a conditional allele for Ang1. Timed whole body KO of Ang1 was accomplished using a doxycycline sensitive ROSArtTA/tetOcre system. Deletion of Ang1 at E10.5 resulted in lethality at E17.5, with abnormal vascular remodeling. In the kidney, glomeruli had dilated Bowman's capsules and markedly enlarged capillary loop structures. Interestingly, when Ang1 was deleted at E16.5 or later the mice appear NORMAL.

Mice lacking Ang1 from E16.5 or later were then challenged with diabetes (STZ). Diabetic Ang1 KO mice had decreased survival (80%) and significantly higher urinary albumin/creatinine ratios. Histology showed increased glomerulosclerosis and mesangial matrix expansion. To study local Ang2 regulation, glomerular endothelial cells were isolated from diabetic mice and found to have an increased expression of Ang2. Also, cultured glomerular endothelial cells demonstrate marked increase in release of Ang2 when exposed to D-glucose, AngII or TGFb, known mediators of progression of diabetic nephropathy.

Taken together, the data shows that Ang1 is not required in the fully developed quiescent glomerulus, but is essential to prevent glomerular injury in the presence of enhanced Ang2 release, and demonstrates for the first time that local balance of Ang1:Ang2 plays a pathogenic role in diabetic nephropathy.

## TH-PO227

**Parathyroid Hormone Induces ICAM-1 Protein Expression and Oxidative Stress in Human Aortic Endothelial Cells** Wei Chen,[1,2] Miguel A. Lanaspa,[1] Diana I. Jalal.[1] *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Department of Nephrology, The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China.*

Parathyroid hormone (PTH), inflammation, and oxidative stress are all associated with the development of cardiovascular disease in patients with chronic kidney disease (CKD). Although PTH has been shown to induce proatherosclerotic mediators such as interleukin 6 in endothelial cells, the effect of PTH on other inflammatory mediators such as intracellular adhesion molecule-1 (ICAM-1) or on oxidative stress has not been explored. We hypothesized that PTH induces ICAM-1 and oxidative stress in human aortic endothelial cells (HAECs). HAECs were purchased from Lonza, and grown at 37°C with 5% $CO_2$, then treated with PTH at various dosages (1 $X10^{-12}$, 1 $X10^{-11}$, $1X10^{-10}$ nmol/mL ). ICAM-1 protein expression was determined in whole cell lysates by western blot. Western blots were normalized by detection of GAPDH expression. Reactive oxygen species (ROS) were measured by Image-iT™ LIVE Green Reactive Oxygen Species Detection Kit and

imaged by confocal fluorescence microscopy. In addition, time course experiments were conducted at the following time points: 0, 1, 3, 6, and 24 hours, and PTH- mediated activation of Nuclear Factor κ-B (NFκ-B) was evaluated by western blot for NFκ-B-p65 expression in nuclear extracts. PTH significantly increased ICAM-1 protein expression compared to the negative control in a dose- and time- dependent manner. ROS increased progressively in response to increasing PTH dosages peaking at a dose of $1X10^{-10}$ nmol/mL. NFκB -p65 expression increased in the nuclear extracts in response to PTH treatment in a time dependent manner. In conclusion, the present study demonstrates that PTH induces ICAM-1 and oxidative stress in HAECs. These findings support a direct role for PTH in inflammation and oxidative stress in CKD patients.

**VEGF-Induced Glomerular Endothelial Cells Hyperpermeability Via PI3K/Akt-Mediated Rac1 Activation** Zengchun Ye, Hui Peng, Cheng Wang, Canming Li, Tan-Qi Lou. *Division of Nephrology, Department of Nephrology, The Third Affiliated Hospital of Sun Yet-Sun University, Guangzhou, Guangdong, China.*

Purpose: To investigate the roles of PI3K/Akt and Rac1 in vascular endothelial growth factor (VEGF) -induced hyperpermeability in glomerular endothelial cells (GEnCs). Methods: The GEnCs permeability was detected by measuring the transendothelial electrical resistance and flux of FITC-BSA across the GEnCs monolayers. Rac1 activity was detected by pull-down assay, and Akt phospholylation was measured by western blotting. ZO-1 and Occludin were detected by immunofluorescence. Membranous and cytoplasmic proteins were separated and western blotting was performed to analyze the re-distribution of ZO-1 and Occludin. Results: Rac1 is activated within 15 min of VEGF treatment, and this activation was reduced by the PI3K antagonist, suggesting Rac1 activation required PI3K activity. Additionally, treatment with VEGF caused Akt phospholylation in wild type Rac1 GEnCs, dominant negative Rac1 mutant GEnCs and constitutively active Rac1 mutant GEnCs within 15 min, while PI3K inhibitor, wortmannin, can completely block these effects, suggesting that Akt is the upstream of Rac1. VEGF-stimulated induction of ZO-1 and occludin disassembly was diminished by inhibiting PI3K activity in wild type GEnCs and was increased by a constitutively active Rac1 mutant, which cannot be inhibited by wortmannin. Whereas dominant negative Rac1 mutant cells dramatically attenuated the effect of VEGF on ZO-1 and occludin. Furthermore, VEGF increases paracellular permeability of wild type Rac1 GEnCs and constitutively active Rac1 mutant GEnCs. The PI3K antagonist can inhibit the effect of VEGF on wild type Rac1 GEnCs permeability and have no effect on constitutively active Rac1 mutant GEnCs. Conversely, VEGF has no effect on dominant negative Rac1 GEnCs permeability. Conclusion: Collectively, these data suggest that VEGF leads to a PI3K/Akt-mediated generation of Rac1, which induce disassembly of ZO-1 and occludin in GEnCs, ultimately regulating tight junction integrity and endothelial cells permeability.

**Chronic Celebrex Promotes Early Glomerular Changes of Diabetic Nephropathy in OVE26 Mice** Rania Nasrallah,[1] Susan J. Robertson,[2] Richard L. Hebert.[1] *[1]Cellular and Molecular Medicine, Kidney Research Centre, University of Ottawa, Ottawa, ON, Canada; [2]Pathology, Ottawa Hospital, Ottawa, ON, Canada.*

Cyclooxygenases (COX-1 and -2) contribute to renal prostaglandin synthesis, and are implicated in the regulation of many kidney processes. Given the controversies concerning the role of COX-2 in the development of renal pathologies, we compared the effect of COX inhibition by non-steroidal anti-inflammatory drugs (NSAIDs; non-selective: Ibuprofen, COX-2 selective: Celebrex) on the onset of diabetic change in type I diabetic OVE26 mice. FVB (control) and OVE26 (diabetic) mice received 15 or 50 mg/kg/day of NSAIDs in standard chow from 8 to 20 weeks of age. All OVE26 mice developed sustained hyperglycaemia (>600mg/dL) prior to 5 wks of age. Systolic blood pressures were monitored bi-weekly by tail-cuff from 8wks, and levels were comparable between OVE26 and FVB mice up to 20 wks (125-140 mmHg), but increased gradually in response to Celebrex in diabetics (155 mmHg at 20 wks). By 20 wks, OVE26 mice had increased kidney/body weights (2-fold) and urinary albumin/creatinine was increased 5-fold, but these were unaltered by NSAIDs. Enzyme immunoassays of urinary prostaglandins showed elevated levels of $PGE_2$ (3-fold), PGEM (4.2-fold), $TXB_2$ (3.2-fold), and 6-keto-PGF1α (3.3-fold) in diabetics, but $PGE_2$ and 6-keto-PGF1α were reduced 50% and 30% respectively by high dose Celebrex. Cortical fibronectin levels as assessed by Western blotting were increased 2.3-fold in diabetics but unaltered by NSAIDs. Glomerular structure was examined by electron microscopy. Glomerular diameters were increased by 17% but were unaltered by NSAIDs. Although no difference was noted between untreated OVE26 and FVB mice, diabetics receiving Celebrex had diminished glomerular basement membrane thickness (22%) and slit pore diameters (17%). Foot process densities were reduced by 27% in OVE26 mice compared to FVB, and further reduced by 15% in Celebrex treated diabetic mice. In summary, our study indicates that chronic Celebrex may promote the development of early glomerular changes characteristic of diabetic nephropathy.

**Effects of Paricalcitol on Endothelial Cells Stimulated with Advanced Glycation End Products** Eliezer Golan,[1,2,3] Sydney Benchetrit,[1,2,3] Jacques Bernheim,[1,2,3] Janice Green,[1] Tali Zitman-Gal.[1] *[1]Renal Laboratory, Meir Medical Center, Kfar Saba, Israel; [2]Nephrology & Hypertension, Meir Medical Center, Kfar-Saba, Israel; [3]Sackler Faculty of Medicine, Tel Aviv University, Tel-Aviv, Israel.*

**Background**: Increased formation of advanced glycation end products (AGEs) play a role in the development of vascular complications in kidney failure, aging, and diabetes. Paricalcitol, a vitamin D receptor activator, is a synthetic analogue of calcitriol. It has already been demonstrated that calcitriol may inhibit endothelial proliferation, blunt angiogenesis, and be a cardioprotective agent.

**Objectives**: To investigate the possible impact of various concentrations of paricalcitol on gene and protein expression in human umbilical vein cord endothelial cells (HUVEC) stimulated with AGEs.

**Methods:** Cultured HUVEC were treated with paricalcitol at $10^{-9}$, $10^{-10}$, and $10^{-11}$ mol/L, and human serum albumin (HSA) or AGE-HSA for 6 and 24 hours. Pro-inflammatory markers such as the receptor of AGEs (RAGE), interleukin-6 (IL6), interleukin-8 (IL8), NFKB-p65, and endothelial nitric oxide synthase (eNOS) were tested at the mRNA and/or protein levels.

**Results:** Our results demonstrate that after 6 hours of stimulation with AGE-HSA, paricalcitol significantly decreased RAGE mRNA and protein expression and significantly increased eNOS mRNA, while p65, IL6, and IL8 mRNA levels were not changed. However, after 24 hours of stimulation p65, IL6, and IL8 mRNA levels were significantly down regulated. At the level of protein expression, after 24 hours, paricalcitol significantly decreased RAGE protein expression, while eNOS showed no significant change.

**Discussion**: Paricalcitol seems to have a beneficial effect on the expression of genes that are involved in the inflammatory processes that take place following the stimulation of HUVEC with AGEs. We observed that RAGE and eNOS, which are located upstream in the inflammatory signal pathway started to change at 6 hours, while changes in genes that are downstream in the inflammatory pathway such as p65, IL6 , IL8 were modified only after 24 hours. These findings indicate that paricalcitol may act as a vascular protective agent starting as early as 6 hours after induction.

**The Effect of Silibinin on the Expression of Vascular Endothelial Growth Factor (VEGF) and the Type IV Collagen in Human Podocytes Induced by High Glucose** Changying Xing, Jia Liu. *Dept of Nephrolgy, First Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China.*

To explore the effects of silibinin on the expression of vascular endothelial growth factor (VEGF) and the secretion of type IV collagen in normal immortalized human podocytes induced by high glucose (HG). The normal immortalized human podocytes were cultured at 33° and allowed to differentiate at 37° for 2 weeks. The differentiated podocytes were incubated with medium (1%FBS and 5.5mmol/L D-glucose) for 24 hours to synchronize cell growth. Podocytes were divided into several groups: 1. High glucose (30mmol/L D-glucose) was given on different time course (0h, 24h, 48h, and 72h). 2. The podocytes were divided into seven groups of normal medium (NG, 5.5mmol/L D-glucose), mannitol (MN, 24.5mmol/L mannitol plus 5.5mmol/L D-glucose), high glucose (HG, 30mmol/L D-glucose), HG plus low concentration of silibinin (HG+LS, silibinin5μg/ml), HG plus medium concentration of silibinin(HG+MS, silibinin 10μg/ml),HG plus high concentration of silibinin(HG+HS, silibinin 20μg/ml), and HG plus DMSO (HG+D, DMSO1mg/ml). These groups were incubated for 48h. The expressions of VEGF mRNA and protein in podocytes were detected by semiquantitative reverse transcription-PCR and Western blot analysis respectively. The concentrations of collagen IV in culture supernatant secreted by the podocytes were determined by ELISA. Results: 1. Compared with 0h group, high concentration of glucose increased the expressions of VEGF and collagen IV in podocytes in a time-dependent manner ($P<0.05$ or $P<0.01$). 2. Compared with NG group, the levels of VEGF and collagen IV expression were increased markedly after HG treatment for 48 hours ($P<0.01$). Compared with HG group, the different concentrations of 5, 10, 20μg/ml silibinin effectively suppressed HG-induced expressions of VEGF mRNA, VEGF protein and the secreted collagen IV in a dose-dependent manner ($P<0.05$).

High concentration of glucose increases the expressions of VEGF and collagen IV by podocyte. Silibinin may exert a protective effect on podocyte and the effects of prevention and treatment on diabetic nephropathy via reducing the over-expressions of VEGF and collagen IV induced by HG.

**Effects of Apelin on Hemodynamic Function in the Rat Kidney** Annette Hus-Citharel,[1] Nadine Bouby,[2] Laurence Bodineau,[1] Alain Frugière,[1] Jean-Marie Gasc,[3] Catherine Llorens-Cortes.[1] *[1]INSERM U691, Paris, France; [2]INSERM U872, Paris, France; [3]INSERM U833, Paris, France.*

Apelin, a recently discovered peptide, and its receptor have a wide tissue distribution not only in the brain but also in the periphery, especially in the kidney. Central injection of apelin inhibits the electrical activity of vasopressin neurons, reduces plasma vasopressin levels and increases aqueous diuresis, thus showing a central role in the control of body fluid homeostasis. We recently reported that apelin receptor mRNA is expressed in the four renal zones with the highest density in the inner stripe of the outer medulla. Along the nephron,

the highest apelin receptor mRNA expression is found in glomeruli and to a lesser extent in the nephron segments, including outer and inner medullary collecting ducts that express $V_{1a}$ and $V_2$ vasopressin receptors. Apelin receptor mRNA is also found in endothelial cells and vascular smooth muscle cells of glomerular arterioles. These observations led us to investigate the functional role of apelin in the kidney. Apelin 17 induced vasorelaxation of AngII-preconstricted juxtamedullary afferent (AA) and efferent (EA) arterioles as shown by an increase in arteriolar diameter (from 18.6±0.5 to 21.8±0.7 μm, *p<0.01*). This vasorelaxation observed in AA and EA was NO-dependent and directly linked to the inhibition by apelin 17 of AngII-elicited $[Ca^{2+}]_i$ increase (43±5 and 44±7%, respectively). In glomeruli, apelin 17 significantly inhibited forskolin-induced cAMP production by 46% (*p<0.05*). This effect may increase glomerular filtration. Consistent with the distribution of apelin receptors in collecting ducts, intravenous injection of increasing doses of apelin 17 in lactating female rats caused a dose-dependent increase in diuresis. Taken together, these data showed that apelin exerts a complex and fine regulation on renal hemodynamic functions through actions on glomeruli and pre- and post-glomerular microvasculature. Moreover, in addition to its central action, apelin may directly counteract antidiuretic effects of vasopressin at the tubular level.

**Hematide™/Peginesatide Binds to the Human Erythropoietin Receptor with High Affinity and Favorable Thermodynamics** Jennifer M. Green,[1] Yijun Pan,[1] Rishi Arora,[2] Robert K. Suto,[2] Peter R. Young,[1] Christopher P. Holmes.[1] *[1]Affymax, Inc., Palo Alto, CA; [2]Xtal BioStructures, Inc., Natick, MA.*

Peginesatide is a PEGylated, investigational, peptide-based erythropoiesis-stimulating agent that was designed and engineered to stimulate specifically the erythropoietin receptor (EPOR) dimer that governs erythropoiesis. Peginesatide is currently being developed for the treatment of anemia of chronic kidney disease. Peginesatide stimulates erythropoiesis by binding to the EPOR at a site cross-competitive with EPO. Methods: Isothermal titration calorimetry (ITC) was used to compare peginesatide with EPO by assessing the thermodynamic parameters that are associated with binding to the extracellular domain of the EPOR. ITC measures the binding equilibrium directly by determining the heat gained or lost when 2 molecules interact in solution. The thermodynamics of binding are characterized by free energy (ΔG), enthalpy (ΔH), entropy (ΔS), heat capacity of binding (ΔCp), and the stoichiometry of the interaction. Results: Calorimetric titrations at 25 °C of both peginesatide and EPO into a solution containing the soluble extracellular domain of the EPOR show strong, high affinity binding events characterized by equilibrium dissociation constants (Kd) of 631 and 172 pM, respectively. The large negative overall free energy associated with peginesatide binding (ΔG = -12.6 kcal/mol), comprised of favorable enthalpic (ΔH = -24.4 kcal/mol) and unfavorable entropic (ΔS = -11.9 kcal/mol/K) components, was greater in magnitude than it was for EPO binding (ΔG = -9.22 kcal/mol). The large negative heat capacities calculated for both peginesatide and EPO binding (ΔCp = -1.047 and -1.230 kcal/mol/K, respectively) suggest that a large amount of the water-accessible surface area on the EPOR is occupied and buried upon ligand binding. As expected, 1 peginesatide molecule was found to bind to 2 EPOR chains, similar to the known 1:2 interaction between EPO and the EPOR. Conclusions: The thermodynamic parameters of binding indicate a favorable and high affinity interaction between peginesatide and the EPOR that may contribute to the prolonged in vivo activity of peginesatide.

## TH-PO234

**Prostaglandin Transporter PGT Regulates PGE2 Signaling** Yuling Chi, Victor L. Schuster. *Medicine, Albert Einstein College of Medicine, Bronx, NY.*

Prostaglandin E2 (PGE2) triggers cellular events by binding to EP1, EP2, EP3, or EP4 receptors. The EPs 1-3 reside stably on the cell surface, whereas EP4 undergoes ligand-induced internalization. Net signaling has typically been considered to be a function of the number of cell-surface receptors and cell-surface [PGE2]. However, plasma membrane PGT (Km for PGE2 = 50 nM) could remove cell-surface PGE2 and thus locally regulate PGE2 access to its receptors. To test this hypothesis directly, we established two experimental systems: 1) an "EP1 system" consisting of wild type HEK 293 cells ± EP1 ± PGT; and 2) an "EP4 system" consisting of MDCK cells ± EP4 ± PGT. In the EP1-HEK system, exogenous PGE2 (0.1 nM – 10 μM) induced a dose-dependent Ca2+ spike. When EP1-HEK also expressed plasma membrane PGT, the PGE2 dose-response curve was right-shifted. A potent PGT inhibitor, T26A, reversed this shift. Moreover, when bradykinin was used to induce endogenous PGE2 release and autocrine EP1 signaling, expression of PGT also induced a (T26A-inhibitable) reduction in the Ca2+ spike. In the EP4-MDCK system, bradykinin induced autocrine signaling as judged by acutely raised cellular cAMP levels. Expression of plasma membrane PGT induced a (T26A-inhibitable) reduction in this acute cAMP accumulation. Finally, we assayed the ability of pharmacological exogenous PGE2 to induce EP4 internalization, as judged by cell-surface ligand binding, immunocytochemical EP4 receptor localization, and cAMP accumulation. PGT reduced PGE2-induced EP4 receptor internalization in a T26A-inhibitable fashion. Summary: as judged by EP1 signaling (Ca2+), acute EP4 signaling (early cAMP), and longer-term EP4 internalization (binding, labeling, delayed cAMP), PGT at the plasma membrane reduces PGE2's ability to interact with its receptors. Conclusion: Plasma membrane PGT regulates EP signaling by internalizing cell-surface PGE2, making it unavailable for EP receptor activation.

## TH-PO235

**Novel Transcription Regulation of Endothelin-1 in the Collecting Duct** Donald E. Kohan, Kevin A. Strait, Peter K. Stricklett. *Division of Nephrology, University of Utah, Salt Lake City, UT.*

Collecting duct (CD) endothelin-1 (ET-1) is an important autocrine inhibitor of CD Na reabsorption. Salt loading increases CD ET-1 production, however the cellular mechanisms involved are poorly understood. Herein, we studied factors modulating ET-1 gene transcription in cultured rat inner medullary CD (IMCD). Transiently transfected rat ET-1 promoter-reporter constructs revealed enhancer activity in the 500 bp region between 1.2-1.7 kb 5' to the transcription start site. This 500 bp region is sufficient to drive reporter expression from a heterologous promoter. Activity of the proximal 1.7 kb ET-1 or the 500 bp heterologous promoter was almost abolished by calmodulin inhibition. Sequence analysis revealed two NFAT consensus binding sites in the 1.2-1.7 kb region which could potentially be regulated by calmodulin. Mutation of either NFAT site (at -1563 and -1263) reduced activity of the 1.7 kb ET-1 promoter by over 80%. Electrophoretic mobility shift confirmed nuclear protein binding to these NFAT sites. Supershift analysis showed NFATc3 binding to the -1563 site and NFATc1 binding to the -1263 site. INCA-6, an NFAT inhibitor, markedly reduced ET-1 secretion and promoter activity. Several AP-1 sites were also identified in the 1.7 kb ET-1 promoter. PKC inhibition (calphostin C) reduced (35-40%) ET-1 secretion, mRNA and 1.7 kb promoter activity. PMA rapidly increased ET-1 mRNA and promoter activity, but was inhibitory after 1 hr of exposure. PKC inhibition reduced ET-1 promoter activity by about 35% in all constructs from -366 to -3048 bp. Mutation of the AP-1 consensus binding site at -186, but not at -1219 or -1394, inhibited .36 kb and 1.7 kb ET-1 promoter activity by over 60%. In summary, Ca/calmodulin-sensitive NFAT isoforms and PKC stimulate IMCD ET-1 promoter activity through interaction with unique cis-acting domains. This suggests that changes in intracellular calcium (as can occur with altered tubule fluid flow), via NFAT and PKC, may regulate IMCD ET-1 production, thereby providing a novel mechanism coupling salt intake to tubule Na reabsorption.

## TH-PO236

**Endogenous PPAR-gamma Ligand,15-Deoxy-(Delta)12,14-Prostagalndin $J_2$ (15d-$PGJ_2$) Has a Protective Effect on $H_2O_2$ Induced Cell Damage in MDCK Cells** Tomoya Makihara, Masaru Horio. *Osaka University, Suita, Japan.*

**Background:** Oxidative stress in renal tubular cell is a possible factor inducing the cell damage and the tubulointerstitial fibrosis. 15-d-$PGJ_2$ is a prostaglandin and an endogenous ligand of PPAR-gamma. 15-d-$PGJ_2$ was reported to increase cellular glutathione (GSH) content in some cultured cells. We examined the effect of 15-d-$PGJ_2$ on GSH content and protective effect on $H_2O_2$-induced cell damage in MDCK cells.

**Methods:** Cell damage was assessed by MTT assay and LDH activity in culture medium. GSH content, activity of glutamate-cysteine ligase (GCL), the rate-limiting enzyme of GSH synthesis, and activity of NADPH oxidase, one of the primary sources of superoxide, were measured.

**Results:** $H_2O_2$ induced cell damage in MDCK cells in dose dependent manner. Pre-incubation and simultaneous addition of 0.5, 1 and 2μM 15-d-$PGJ_2$ protected the $H_2O_2$-induced cell damage assessed by LDH activity in culture medium. 15-d-$PGJ_2$ significantly increased GSH content up to 2 fold the value of control cells after 8h. But, higher concentration (5 and 10 μM) of 15-d-$PGJ_2$ did not show further increase of GSH, but induced cell death after 24h. Simultaneously addition of 10μM GW9662, an inhibitor of PPAR-gamma, did not inhibit the induction of the GSH content by 1μM 15-d-$PGJ_2$. Ciglitazone (1, 2 and 10μM), a PPAR-gamma agonist, did not change GSH content significantly, indicating that the increase of GSH by 15-d-$PGJ_2$ was PPAR-gamma independent mechanism. GCL activity were not increased but significantly decreased after the addition of 15d-$PGJ_2$. GW9662 did not have significant effect on the decrease of GCL. Ciglitazone did not have any significant effect on GCL activities. Change of GCL activity by 15-d-$PGJ_2$ seems to be the result of negative feedback of the induction of GSH contents. NADPH activity was not changed significantly after addition of 15d-PGJ2. The mechanism of inducing GSH content by 15-d-PGJ2 in MDCK cells needs further investigation. **Conclusion:** 15d-$PGJ_2$ has a protective effect on $H_2O_2$ induced cell damage in MDCK cells, suggesting the possibility of a participation against renal cell damage by oxidative stress.

## TH-PO237

**Retinoic Acid Activity in Collecting Duct: Potential Target Gene and Anti-Fibrotic Potential** Yuen Fei Wong,[1] Jeffrey B. Kopp,[2] Bruce M. Hendry,[1] Qihe Xu.[1] *[1]Renal Medicine, King's College London, London, United Kingdom; [2]Kidney Disease Section, National Institute of Diabetes, Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD.*

Retinoic acid (RA), the primary bioactive derivative of vitamin A, plays an essential role in nephrogenesis by promoting ureteric bud branching via retinoic acid receptor (RAR) activation. We hypothesized that RA-RAR response system remained active in kidneys after birth, and may serve as an inbuilt defence mechanism against kidney injury or enhance wound repair by regulating the expression of certain genes. By employing a retinoic acid response element (RARE)-*hsp68-lacZ* transgenic mouse model, we found that RA activity is present specifically in the renal collecting ducts of neonatal, young and adult mice. A well-established mouse inner medullary collecting duct cell line (mIMCD-3) was used as an *in vitro* model to identify potential target genes of RA. Transient transfection

of RARE-luciferase reporter plasmid to mIMCD-3 revealed presence of endogenous RA; exogenous RA treatment increases luciferase activity in a dose-dependent manner, which was blocked by AGN193109, a pan-antagonist of RAR, suggesting an intact RA-RAR-RARE response system. Wnt7b, Pax2 and Bmp7 genes were selected as these genes are expressed in collecting duct and are reported to mediate repair mechanisms during renal injury. Effects of RA on mRNA expression of these genes were examined with quantitative PCR. Of these candidate genes, basal expression of Bmp7 was blocked by AGN193109. Furthermore, Bmp7 expression was induced by RA in a dose dependent manner and blocked by AGN193109. As Bmp7 is best known for its anti-fibrotic property, fibrogenesis was induced in mIMCD-3 by transforming growth factor-β1 (TGF-β1) to examine the role of RA in this context. RA did not prevent TGF-β1-induced loss of epithelial marker (E-cadherin) and *de novo* gain of mesenchymal marker (α-smooth muscle actin) but suppressed the induction of fibronectin, a main fibrogenic matrix protein. The mechanism of Bmp7 induction by RA and its role in regulating fibrogenesis in mIMCD-3 are currently being investigated.

**Hormonal Status Influences mTOR Signaling Pathway in Adaptive and Maladaptive Myocardial Hypertrophy** Angelika Kusch, Maria Schmidt, Rusan Catar, Bjoern Hegner, Duska Dragun. *Department of Nephrology and Intensive Care Medicine/Center for Cardiovascular Research, Charité, Berlin, Germany.*

Background

Activation of PI3K/Akt/mTOR pathway is a hallmark of both, adaptive and maladaptive myocardial hypertrophy (MH). Hormonally induced differences in regulation of this pathway might influence clinical outcome in a sex-specific manner. Aim of our study was to investigate how beta-estradiol (E2) modulates PI3K/Akt signaling in response to hypertrophic stimuli and determine consequences of mTOR inhibition in the context of female cardiomyocyte.

Methods

Female HL-1 cardiomyocytes were treated with physiologic (IGF-1) and pathologic (ET-1) stimuli in the presence or absence of estradiol or mTOR inhibitor rapamycin. Cell size was determined by immunocytochemistry and FACS-analysis. Signal transduction was assessed by immunoprecipitation with anti-mTOR polyclonal antibodies and westernblotting using polyclonal antibodies against raptor/ rictor, phospho-specific antibodies against Erk, Akt to monitor TORC2-activity, p70S6K to monitor TORC1-activity, polyclonal antibodies against respective non-phosphorylated forms of proteins and SERCA2A. Taqman was applied to investigate genomic changes.

Results

E2, IGF-1 and ET-1 induced phosphorylation of Akt and p70S6K in a time-dependent manner. E2 reversed the increase in p70S6K-phosphorylation upon ET-1-stimulation, whereas co-treatment of E2 with IGF-1 increased p70S6K-phosphorylation. Estradiol increased both, mTOR-complex formation with raptor and rictor. SERCA2A protein expression was upregulated by E2. ANP-mRNA-expression increased significantly with E2-cotreatment and most markedly with additional ET-1. Rapamycin inhibited cardiomyocyte hypertrophy and p70S6K-phosphorylation by IGF-1 and ET-1 irrespective of E2-cotreatment, whereas positive feedback loop towards Akt-phosphorylation was differentially regulated by rapamycin dependent on the presence or absence of E2.

Conclusions

mTOR inhibition effectively inhibits female cardiomyocyte hypertrophy irrespective of the presence or absence of E2. However, E2 differentially modulates TORC1 and TORC2 activities dependent on the nature of hypertrophic stimulus and rapamycin treatment.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO239

**Cardiac Fibrosis Is Modulated by Endogenous PAI-1** Jianyong Zhong,[1] Haichun Yang,[2] Agnes B. Fogo,[2] Valentina Kon,[1] Iekuni Ichikawa,[1] Ji Ma.[1] *[1]Pediatrics, Vanderbilt University, Nashville, TN; [2]Pathology, Vanderbilt University, Nashville, TN.*

The profibrotic effects of plasminogen activator inhibitor-1 (PAI-1) are postulated to reflect decreased extracellular matrix degradation due to decreased plasmin activity and increased inflammation due to PAI-1 binding to vitronectin (Vn). However, recent findings suggest that, depending on the tissue, increased plasmin activity can also promote fibrosis. This study was designed to determine the importance of plasmin *vs.* vitronectin pathways in angiotensin II (Ang II)-induced cardiac fibrosis.

Uninephrectomized (UNx) mice were fed a high salt diet and infused with Ang II for 8 weeks. Different human stable PAI-1 variants, including PAI-1AK (retaining protease inhibitory effects of native PAI-1 but not binding to Vn), or PAI-1RR (competitive blocker of Vn), or CPAI (control PAI-1, retaining all known functions of native PAI-1), or PBS was injected daily.

Increased systolic blood pressure and albuminuria were found in all mice with Ang II infusion. In the heart, PAI-1AK-injected mice showed significantly more extensive myocardial and interstitial fibrosis compared with the other Ang II-infused mice (PAI-1AK 1.79±0.26%, PAI-1RR 0.91±0.18%, CAPI 0.81±0.12%, PBS 1.15±0.26% and UNx/salt 0.24±0.04%; n= 9 for PAI-1AK, 11 for PAI-1RR, 11 for CAPI, 7 for PBS and 4 for UNx/salt). Active plasmin was increased in kidneys of PAI-1AK-injected mice, but it was not changed by Ang II and was not different among the groups treated with PAI-1 variants. However, although Ang II increased the level of endogenous total mouse PAI-1 in heart tissue, this was further elevated by PAI-1AK (1.40±0.23 *vs.* 0.93±0.09 in CPAI, $P<0.05$).

Our study suggests that the severity of cardiac fibrosis induced by high circulating Ang II is dependent on endogenous tissue PAI-1, which is influenced by the balance between the two main PAI-1 pathways.

**Fusion of Activated Omentum with Kidney Attenuates Progression of Chronic Kidney Disease** Nishit Pancholi,[2] Jilpa Patel,[2] Krishnamurthy P. Gudehithlu,[1,2] George Dunea,[1,2,3] Jose A. L. Arruda,[3,1,2] Ashok K. Singh.[1,2] *[1]Nephrology, John H. Stroger Hospital of Cook County, Chicago, IL; [2]Nephrology, Hektoen Institute of Medicine, Chicago, IL; [3]Nephrology, University of Illinois at Chicago, Chicago, IL.*

In previous work we showed that fusion of activated omentum, a tissue rich in stem cells and growth factors, to the injured liver facilitated repair and regeneration of the liver. Here we tested whether fusion of activated omentum to the kidney could ameliorate chronic kidney disease (CKD) in rats. CKD was induced in rats by renal mass reduction (5/6 nephrectomy by removal of right kidney and excision of the two poles of the left kidney). After inducing the injury, the rats were divided into two groups. Group 1 rats (N = 22; treated) received one intraperitoneal injection of polydextran gel particles to activate the omentum and promote its fusion to the wounded edges of the kidney, while Group 2 rats (N = 22; control) underwent total omentectomy. Following surgery, both groups showed a gradual rise in plasma creatinine and urea over baseline (baseline plasma creatinine 0.8 ± 0.02 mg/dL, plasma urea 56 ± 1.9 mg/dL, creatinine clearance 0.31 ± 0.017 mL/min/100g). However at weeks 6 and 12, as compared to control rats, the treated rats had significantly lower plasma creatinine and urea levels and higher creatinine clearance.

Table 1.

| | Week 6 | | Week 12 | |
|---|---|---|---|---|
| | TREATED | CONTROL | TREATED | CONTROL |
| **Creatinine (mg/dL)** | 1.5 ± 0.00* | 1.9 ± 0.02 | 1.6 ± 0.02* | 2.2 ± 0.03 |
| **Urea (mg/dL)** | 103 ± 0.5* | 155 ± 3.6 | 105 ± 2.0* | 197 ± 8.5 |
| **Creatinine Clearance (mL/min/100g)** | 0.22 ± 0.007* | 0.16 ± 0.011 | 0.18 ± 0.012* | 0.10 ± 0.012 |

*(p <0.05 versus respective control)

Weight gain in treated rats was higher than in controls. Histologically, the treated rats had a lower kidney injury score, with less glomerulosclerosis, tubular dilatation, and interstitial fibrosis, as well as lower immunoreactivity for α-SMA in the tubulo-interstitial areas. These results show that fusion of activated omentum to the kidney slows the progression of CKD in rats.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO241

**Smad Anchor for Receptor Activation (SARA) Regulates High Glucose Induced EMT Via Modulation of Smad2 and Smad3 Activities in Renal Tubular Epithelial Cells** Guanghui Ling,[1] Wenbin Tang,[1] Yuncheng Xia,[1] Lin Sun,[1,2] Yinghong Liu,[1] Youming Peng,[1] Yashpal S. Kanwar,[2] Fu-You Liu.[1] *[1]Department of Nephrology, Second Xiangya Hospital, Center of Kidney Disease and Dialysis in Hunan Province, Central South University, Changsha, Hunan, China; [2]Department of Pathology and Medicine, Northwestern University Medical School, Chicago, lL.*

Recent studies demonstrated that SARA is an essential adaptor protein in TGF-β1 signaling, and it is also involved in the process of epithelial-mesenchymal transition (EMT) and fibrosis. We investigated the effect of SARA on high glucose (HG) induced EMT and extracellular matrix (ECM) synthesis in renal tubular epithelial cells, HK-2 cells. The cells were transfected with the following plasmids: wild-type SARA (SARA-WT), SARA mutant (SARA with Smad binding domain deletion, SARA-dSBD) and SARA-WT + SARA-dSBD, and then subjected to high glucose ambience (HG, 30mM). The expression levels were assessed by QPCR, Western-blot analysis, and Immunofluorescence and Confocal microscopy. The HG induced EMT phenotype with increased expression of ECM genes in HK-2 cells. This was associated with the decreased expression of SARA and Smad2. In comparison with HG group, over-expression of SARA in HK-2 cells, a relatively high up-regulation of mRNA and protein expression of ZO-1 was seen; while that of vimentin, fibronectin and collagen I was decreased. No change in the expression of EMT profile was observed in cells doubly transfected with SARA-WT and SARA-dSBD. The Smad2 protein expression was increased in HK-2 cells after transfection with SARA WT plasmid. Interestingly, the over-expression of SARA prolonged the activity period of Smad2 and shortened that of Smad3, which seemed consistent with the change of EMT phenotype and ECM changes in HK-2 cell induced by HG. In conclusion, SARA regulates HG induced EMT and ECM accumulation and modulation via the activation of Smad2 and Smad3 in renal tubular epithelial cells. In view of these findings it is conceivable that SARA may serve as a potential novel target in pre-EMT states for the amelioration renal fibrosis seen in chronic kidney diseases.

**TH-PO242**

**Dysfunctional Regulation of PGC-1α in Skeletal Muscle during CKD and Diabetes: A Potential Mechanism for Sustaining Atrophy** Russ Price, Haiyan Li, Bin Zheng, Myra Woodworth-Hobbs. *Renal Division, Emory University, Atlanta, GA.*

PGC-1α is a transcription coactivator protein that plays an integrative role in energy and protein metabolism in skeletal muscle. It also regulates muscle fiber-type specification and is less abundant in MHC II fibers than MHC I fibers. In CKD or diabetes (DM), MHC II fibers preferentially undergo atrophy and fiber-type switching from MHC I to MHC II has been noted; PGC-1α expression is also reduced. To elucidate the mechanism for the reduction in PGC-1α, we studied the signaling process that controls its transcription. The cAMP signaling pathway controls fiber type by regulating PGC-1α gene expression via CREB. Paradoxically, phosphorylated CREB (i.e, activated) was >7-fold higher in muscle of DM rats or dexamethasone-treated L6 muscle cells vs controls (P<0.03 in each model). Under the same conditions, PGC-1α was suppressed >50% (P<0.05 in each model). This led us to hypothesize that dysfunctional cAMP/CREB signaling contributes to the reduction in PGC-1α during muscle atrophy. To study the regulation of PGC-1α transcription by CREB, we transfected L6 muscle cells with a PGC-1α-luciferase (Luc) plasmid or with PGC-1αΔCRE-Luc which contains PGC-1α-Luc without the CRE binding site. PGC-1αΔCRE-Luc activity was reduced 72% vs PGC-1α-Luc (P<0.01). Treatment of transfected cells with forskolin (FSK) to raise cAMP did not increase luciferase activity from either PGC-1α reporter plasmid whereas FSK increased luciferase activity >9-fold (P<0.001) in cells transfected with a generic CRE-Luc reporter gene. These results suggested that CREB regulates PGC-1α transcription but that cAMP alone is insufficient to drive PGC-1α expression. To explore potential defects in cAMP/CREB signaling, we examined TORC1, a CREB coactivator that participates in PGC-1α transcription, in DM and control rat muscle. TORC1 protein was reduced 31% in DM muscle (P<0.005). Thus, defective cAMP/CREB signaling contributes to the abnormal transcriptional regulation of PGC-1α during skeletal muscle atrophy. Reduced PGC-1α and the concurrent fiber-type switching could serve as a mechanism to sustain atrophy in CKD and DM.

**Determination of Optimal Time Point of Conversion from Cyclosporine to Sirolimus Using Experimental Model of Chronic Cyclosporine** Jungyeon Ghee,[1] Ji-Hyun Song,[1] ShangGuo Piao,[1] Sol Kim,[2] Chul Woo Yang.[1] *[1]Department of Internal medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea; [2]Department of Bioengineering, University of Pennsylvania, Philadelphia.*

**BACKGROUND:** Sirolimus (SRL) is a promising drug for replacing calcineurin inhibitors, but the conversion point is still undetermined. We performed this study to determine optimal time point of conversion of SRL in cyclosporine (CsA)-induced nephrotoxicity.

**METHODS:** Three separate studies were performed in rats. First, CsA was treated with or without SRL for 28 days. Second, CsA (15mg/kg per day) was switched to SRL (0.3mg/kg per day) at day 7 (early conversion). Third, CsA was switched to SRL or withdrawn at day 28 and followed for 4 weeks (late conversion). The conversion effect from CsA to SRL was evaluated by renal function, histopathology (interstitial inflammation and fibrosis), inflammatory and fibrotic markers (osteopontin and beta-igh3), and apoptotic cell death (TUNEL-positive cells and caspase 3).

**RESULTS:** Combined treatment of CsA and SRL further deteriorated renal function, increased interstitial fibrosis and beta-igh3 and apoptotic cell death. CsA treatment for one week did not decrease renal function and increase interstitial fibrosis compared with the control group, and early conversion to SRL did not affect these parameters. CsA treatment for four weeks significantly deteriorated renal function and increased interstitial inflammation and fibrosis. But, withdrawal of CsA after four weeks CsA treatment improved renal function and decreased interstitial fibrosis and inflammation. Late conversion to SRL aggravated both parameters compared with the CsA withdrawal group.

**CONCLUSION:** Early conversion of from CSA to SRL is effective in preventing CsA-induced renal injury, but later conversion aggravates CsA-induced renal injury.

**Functional Research of CD2-Associated Protein Gene Mutation in Podocytes** Nan Chen, Xiaoxia Pan, Caixia Zhao, Xiaobei Feng, Weiming Wang, Zhaohui Wang, Qi Long. *Ruijin Hospital.*

**Objective:** To investigate the influence of CD2-associated protein (CD2AP) gene mutation on other podocyte associated proteins and cytoskeletal structures in mouse podocytes.

**Methods:** CD2AP heterozygous mutation V54I in exon 2, which was found in one Chinese patients with sporadic focal segmental glomerular sclerosis (FSGS) in our department, was selected. Wild-type and V54I mutant CD2AP plasmid were constructed and transfected into mouse podocytes using lipofectamin 2000. The mRNA level and protein expression of CD2AP and other podocyte associated proteins such as nephrin, podocin and synaptopodin were detected by realtime PCR and flow cytometry respectively. The distribution of nephrin, podocin and cytoskeletal structures in podocytes were observed by immunofluorescent technique.

**Results:** Mutant CD2AP had no obvious effects on the protein expression of nephrin, podocin and synaptopodin in podocytes. There was no significant difference of mRNA level of nephrin and podocin between mutant and wild-type CD2AP expression group. However the mRNA level of synaptopodin in mutant group significantly decreased, comparing to the wild-type group. No significant differences on the distribution of nephrin and podocin were observed between the wild-type and mutant groups. In interphase of cell division, stress fibers destructed in cytoplasm, and appeared thick, short dot-like structures mainly around the nuclei in podocytes expressing wild-type CD2AP, while in podocytes expressing mutant CD2AP, stress fibers mainly expressed along the cytoplasm membrane. In the metaphase of cell division, F-actin filaments aggregated encircling podocyte in wild-type group, however the F-actin in the mutant group did not show similar changes, but simply an increase in cytoplasm with some regional aggregation.**Conclusion:** The V54I mutant CD2AP has no obvious effects on genetic transcription and protein translation of podocin and nephrin. However the mRNA level of synaptopodin significantly decreased in mutant podocytes, comparing to the wildtype podocytes. It might affect podocyte skeletal construction of F-actin.

**Cigarette Smoking Affects Unfavorably the Renal Function of Hypercholesterolemic Rats** Barbara Costa,[1] Gloria E. Mendes,[1] Monique Martinez,[1] Leandro Pires,[1] Marcos Luz,[1] Emmanuel A. Burdmann.[1,2] *[1]Sao Jose do Rio Preto Medical School; [2]University of Sao Paulo Medical School, Brazil.*

The aim of this study was to assess the effects of the association of cigarette smoking (CS) and hypercholesterolemia on the renal function of rats. Male adult rats were exposed to CS (smoking chamber) or sham procedure (smoking chamber without CS) for 10 min, twice a day for 18 weeks (w). From the 14 to the 18th w rats received low salt diet (0.06%) and half of them received diet supplemented with 2% of cholesterol (CO) and 0.5% of cholic acid. Final groups (5 to 8 rats/group) were: normal CO+No-CS, normal CO+CS, high CO+No-CS, and high CO+CS. On day 126, GFR (inulin clearance, ml/min/100g), RBF (Doppler ultrasound, ml/min), RVR (mmHg/ml/min), CO serum level (mg/dl), urinary osmolality (UO, mOsm/Kg), hematocrit (Ht, %) and tubulointerstitial fibrosis (TIF, score 0 to 4) were assessed. Data (mean±SE) were analyzed by one-way ANOVA with post-test.

| | Normal cholesterol | | High cholesterol | |
|---|---|---|---|---|
| | No-CS | CS | No-CS | CS |
| GFR | 0.72±0.05 | 0.69±0.03 | 0.40±0.06 * | 0.20±0.03 **, ♦ |
| RBF | 4.0±0.4 | 3.5±0.2 | 4.0±0.5 | 2.2±0.3 **, ♦ |
| RVR | 33±6 | 30±2 | 24±2 | 43±5 **, ♦ |
| UOsm | 382±45 | 235±13 ♣ | 199±20 * | 169±7 |
| TC | 63±2 | 60±1 | 85±5 * | 83±2 ** |
| Ht | 55±2 | 53±1 | 52±2 | 49±1 |
| TIF | 0.03±0.005 | 0.05±0.007 | 0.13±0.02 * | 0.17±0.02 ** |

*p<0.05 vs. NLCO No-CS; **p<0.05 vs. NLCO CS; ♦ p<0.05 vs. HCO No-CS; ♣ p<0.05 vs NLCO NoCS

The obtained results demonstrated the efficacy of the supplemented cholesterol diet in promoting hypercholesterolemia. High cholesterol diet induced GFR decrease, impaired UOsm and TIF. Cigarette smoking associated to hypercholesterolemia worsened GFR decreased and caused RBF decrease and RVR increase.

In conclusion, these data suggest that cigarette smoking can enhance the negative impact of hypercholesterolemia on renal function.

**Mechano-Growth Factor Regulation by Diabetes and GLUT1 in Glomeruli** Minghui Xiang,[1] Kathleen O. Heilig,[1] N. Stanley Nahman,[2,1] Charles W. Heilig.[1] *[1]Medicine, University of Florida COM Jacksonville, Jacksonville, FL; [2]Medicine, Charlie Norwood VA Medical Center & Medical College of Georgia, Augusta, GA.*

Mechano-growth factor (MGF) is a stretch- and hypoxia-induced splice variant of IGF1. It is involved in tissue repair, has anti-apoptotic properties, induces cell hypertrophy, and in skeletal muscle recruits satellite cells to proliferate in response to cell stretch. It is expressed in many cell types, including vascular smooth muscle. However, it has not been investigated in the kidney where its expression potentially could modulate diabetic glomerular disease. We hypothesized it would be expressed in glomeruli where it could be induced by stretch or hyperglycemic stress with diabetes. **Methods**: All mice had the C57BL6 background. Diabetic (db/db, glucose > 250 mg/dl) and non diabetic (db/m) mice, transgenic mice with overexpression of GLUT1 (GT1S), and diabetic mice deficient in mesangial GLUT1 (db/db/antisense-GLUT1) were sacrificed at 8 or 26 weeks of age. Kidneys were harvested, fixed and embedded in paraffin for immunolabeling with antibodies against MGF. Whole kidney and glomeruli were assessed and scored by 2 observers. Primary cultured mouse mesangial cells (MC) were also labeled with the MGF antibodies. **Results**: Glomeruli and some cortical tubular segments exhibited MGF expression. Glomerular MGF was found in the mesangium and capillaries. In the diabetic and GT1S kidneys, glomerular MGF was particularly high. Specifically, glomerular MGF increased 144% (p< 0.0001) in response to diabetes and increased 33% (p< 0.001) in GT1S mice without diabetes. In contrast, GT1AS mice with 50% reduced MC GLUT1 demonstrated protection against diabetes-induced glomerular MGF expression, with 55% (p<0.0001) reduction in MGF. Primary cultured MC's from normal mice expressed MGF in both the nuclei and cytoplasm. **Conclusions**: MGF is expressed in the kidney, particularly in glomeruli where it was detected in the

mesangium and capillaries. Glomerular MGF increased in response to both diabetes and GLUT1-overexpression. This suggests that GLUT1 may contribute to the MGF response in diabetes, where glomerular GLUT1also is increased.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO247

**Resistance to Leucine Stimulated Anabolic Signaling in Work-Overloaded Skeletal Muscle of CKD Rats** Yu Chen,[1,2] Sumita Sood,[1,2] Kevin L. Mcintire,[1,2] Ralph Rabkin.[1,2] *[1]Nephrology, Stanford University School of Medicine, Palo Alto, CA; [2]Nephrology, Veterans Affairs Palo Alto Healthcare System, Palo Alto, CA.*

Muscle wasting is a common and significant complication of advanced CKD caused partly by insensitivity to insulin/IGF-1 induced signal transduction and low serum and tissue levels of branched chain amino acids (BCAA). In an earlier study of CKD rats we reported that resistance exercise fully activates the depressed IRS1/PI3kinase/AKT pathway and induces an increase in muscle mass (Kidney Int.2006). In humans undergoing resistance exercise, ingestion of the BCAA leucine (LEU) enhances exercise induced signaling through the downstream mTOR pathway. This pathway involves phosphorylation of p70 ribosomal S6 kinase-1 ($p70^{S6K}$) and S6 ribosomal protein (rpS6) and increases exercise induced protein synthesis. To test whether in the setting of uremia, administration of LEU can enhance exercise induced mTOR anabolic signaling, we studied the response to LEU in a model of unilateral plantaris work overload (WO) in CKD and control (Con) rats. WO was created by partially ablating the gastrocnemius muscle and tendon which causes significant plantaris muscle hypertrophy. After 7 days of WO the animals were gavaged with LEU or saline (S) and sacrificed 30 mins later. Western blot analysis showed that as anticipated, LEU loading did not affect AKT phosphorylation since it acts downstream of AKT. Nonetheless LEU did activate and normalize the depressed mTOR phosphorylation in CKD muscle. Also phosphorylation of $p70^{S6K}$ increased 3 fold in response to LEU in CKD ($p<0.05$), but this response was significantly less than occurred in Con muscle (5 fold increase). Furthermore LEU failed to stimulate the phosphorylation of the downstream protein rpS6 in CKD while significantly increasing rpS6 phosphorylation in Con muscle. Thus it appears that the uremic state induces resistance to LEU induced anabolic signaling in skeletal muscle undergoing hypertrophy due to sustained work overload. This differs from our findings in unexercised uremic muscle which is sensitive to leucine loading.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO248

**Transforming Growth Factor-β3 Expression and Obesity-Linked Renal Disease** David A. Maddox,[1,2,3] Karen A. Munger.[1,2,3] *[1]VA Medical Center, Sioux Falls, SD; [2]Avera Research Institute, Sioux Falls, SD; [3]Sanford School of Medicine of the University of South Dakota, Sioux Falls, SD.*

**Background:** Obesity closely associated with hypertension, Type II diabetes mellitus, and hypercholesterolemia, which are among the leading causes of end-stage kidney disease. Obese Zucker rats develop these symptoms and die of kidney disease. This is prevented by food limitation to lean animal levels. In this study we examined gene expression of TGF-β2 and TGF-β3 to gain insight into the matrix synthesis cascade in obesity-linked renal disease.

**Methods:** Obese Zucker rats six weeks of age were fed either *ad libitum* or restricted in food intake to that consumed by lean Zucker, then tested at 6, 12, and 18 weeks for each condition and compared to lean animal values. Kidneys were perfusion-fixed with RNA*Later*™, tissue RNA was extracted from kidney cortex, and single stranded cDNA prepared for the study of the two genes of interest, TGF-β2 and TGF-β3. Housekeeping genes (RpL19 and Cyclophilin A) served as reference genes.

**Results:** TGF- β3 gene expression was significantly increased in the 6, 12, and 18 week-old obese ad lib animals compared to lean. Limiting food intake at 6 weeks of age in the obese animals to that consumed by lean rats lowered TGF-β3 expression to lean animal levels by 12 weeks of age and maintained these levels at 18 weeks. Proteinuria did not increase until 12 weeks of age in the obese rats fed ad libitum and food restriction in obese animals beginning at 6 weeks of age completely prevented the development of proteinuria. The TGF- β2 isoform had no elevated expression levels in any of the animals.

**Discussion:** Gene expression of TGF- β3 in the obese rat was already elevated at 6 weeks of age, prior to the development of proteinuria. This is earlier than we previously observed for TGF-β1. Data suggest that elevations in the expression of TGF-β3 is one of the initiating events leading to kidney damage in these animals and that one of the primary benficial effects of food limitation at 6 weeks of age that leads to the prevention of kidney disease is to restore TGF-β3 expression to normal.

### TH-PO249

**Systemic Depletion of $CD4^+$ T Cells Does Not Alter Susceptibility or Resistance to Development of Chronic Kidney Disease (CKD) in Mice after Reversible Unilateral Ureteral Obstruction (rUUO)** Mohammed I. Shakaib, Richard J. Quigg, Tipu S. Puri. *Medicine/Nephrology, The University of Chicago, Chicago, IL.*

Using a rUUO model, we have determined that C57BL/6 mice are susceptible to development of CKD after obstruction-mediated kidney injury while BALB/c mice are resistant. Histological studies demonstrated a significant difference between strains in the extent and resolution of tubulointerstitial inflammation during obstruction and after release of obstruction. The C57BL/6 and BALB/c strains are known to favor different subtypes of helper T-lymphocytes ($T_h$) in their immunologic responses. C57BL/6 mice favor the $T_h1$ subtype which promotes cell-mediated immune responses whereas BALB/c mice favor the $T_h2$ subtype which promotes humoral immune responses. To investigate whether differential extent or type of $T_h$ cell responses might contribute to the differences in susceptibility to development of CKD after rUUO, we used an anti-CD4 antibody (GK1.5) to systemically deplete $CD4^+$ T cells prior to and throughout the rUUO protocol. Flow cytometry confirmed complete depletion of CD4+ T lymphocytes from peripheral blood in both C57BL/6 and BALB/c mice 24 hours after intraperitoneal administration of the GK1.5 antibody that was maintained by re-administration of the antibody every 4 days. Blood urea nitrogen (BUN) levels at 14 days after release of a 6 day obstruction in C57BL/6 mice treated with the GK1.5 antibody were 78.9 ± 5.0 mg/dl as compared to 67.8 ± 6.0 mg/dl in vehicle treated mice. BALB/c mice treated with either the GK1.5 antibody or vehicle remained resistant to development of CKD with BUN levels similar to baseline pre-rUUO levels in both groups. Quantitative assays of the $T_h1/T_h2$ relevant cytokines IL-4, -5, -10, -12, and IFN-g from whole kidney protein preparations also showed no significant differences in these cytokines between strains. Cytokine analysis supported that the immunologic response to obstruction-mediated injury does not involve a $T_h1$ response in C57BL6 mice or a $T_h2$ response in BALB/c mice. Together, our results confirm that differences in $T_h$ lymphocyte responses do not contribute to susceptibility or resistance to development of CKD after rUUO.

### TH-PO250

**TNF-alpha and TGF-beta 1 Exert Synergistic Effect on the Induction of EMT Via Blocking VDR Expression** Xiaoyue Tan,[1] Youhua Liu.[2] *[1]Pathology, Medical School of Nankai University, Tianjin, China; [2]Pathology, Medical Centre, University of Pittsburgh, Pittsburgh, PA.*

Our previous experiments have showed that vitamin D can abrogate both inflammation and EMT, thus alleviate the renal fibrosis. Herein, we performed the study to further explore the mechanism underlying the renal beneficial effect of vitamin D.

In vivo, Immunohistological stain and western blot were used to reveal the expression of VDR. The results showed VDR expression was largely inhibited after UUO, even from the very early stage (1st day after operation. Administration of vitamin D can protect VDR expression compared with control. Immunohistological stain revealed that VDR expression was down-regulated in the patients with chronic renal diseases; moreover, the level of inflammation seemed negative related with VDR expression.

In vitro, we treated cultured HK-2 cells with different dosage of TNF-a (1, 2, 5 and 10 ng/ml). The results suggested TNF-a can inhibit the expression of VDR. Then, we treated cultured HK-2 cells by 5ng/ml TNF-a, relative low dose of TGF-b1 (0.1ng/ml, 0.2ng/ml and 0.5ng/ml) or their combination separately. We used western blot to access the expression of VDR and EMT related protein (E-cadherin, a-SMA, Fibronetin and PAI). The results suggested that TNF-a and TGF-b has synergistic effect on the induction of EMT. Further, VDR RNAi and VDR over express plasmid were used to knock down and high regulate the expression of VDR. The results showed that knocking down VDR gene expression through siRNA could mimic the affect of TNF-a while over expression of VDR through VDR plasmid could abolish it. parallel experiments with different dosage ($10^{-9}$, $10^{-8}$, $10^{-7}$, $10^{-6}$M) of vitamin D showed [/bold]Vitamin D can rescue the VDR expression inhibited by TNF-a and also the effect of VDR knock-down on EMT.

These data demonstrate that inflammation factor TNF-a has synergistic effect on EMT induced by TGF-b1 and this effect might be mediated by blocking the expression of VDR. Our study sheds new light on the mechanism underlying the renal beneficial role of vitamin D.

### TH-PO251

**The Effect of Low Protein Diet with Keto-Acid Supplement on Local RAS Activation in Rats with Subtotal Renal Ablation** Chuan-Ming Hao. *Huashan Hospital, Fudan university.*

**Objective** To investigate whether low protein plus keto-acid diet ameliorates progression of CKD by influence local RAS.**Methods** 30 male SD rats received subtotal renal ablation(Nx) and were placed on 18% normal protein diet (NPD), 6% low protein diet (LPD) or 5% low protein plus 1%keto-acid diet (LK) for 12 weeks (n=10 in each). 10 male SD sham-operated rats fed with NPD were used as control. Mesangial cells(MsC) were cultured in plasmas (10%) collected from animals with or without losartan ($10^{-7}$M) for 48hs. **Results** Nutritional indices were comparable among the four groups. The urinary protein excretion in Nx-rats markedly increased vs. control. Reducing dietary protein intake was associated with less proteinuria. Serum creatinine in Nx-rats increased significantly vs. sham group, but did not show statistical difference among Nx rats. Plasma and kidney AngII levels in NPD rats were 4.89 and 3.37 times higher vs. control. Renal AT1 mRNA and protein levels also markedly increased in NPD rats vs. sham group, but no changes of renin expression were observed. LPD diet greatly reduced renal cortical AngII, $AT_1$ and renin protein expression, accounting for only 56%, 73.7% and 61.8% of those in NPD group respectively. LK diet further decreased these parameters. In cultured MsC, NPD plasma induced higher levels of FN, LN, TGF-β and AngII in the supernatant vs. those in control group. The mRNA expression of these parameters as well as renin and AT1 receptor in cells were increased to 2.5, 1.72, 5.22, 1.57, 5.45 and 2.64 folds vs. control respectively. LPD plasma significantly decreased the production of ECM and RAS expression in MsC, while LK plasma showed stronger inhibitory effects. Application losartan to block the activity of RAS further reduced the expression of FN, LN and TGF-β in different plasma treated group, all of them were less than 1/5 vs. corresponding losartan negative groups.**Conclusion** Low

protein diet and keto-acid supplement was associated with reduced local RAS activation, which may contribute to its beneficial effect on the kidney in CKD patients.

### TH-PO252

**TWEAK in Renal Fibrosis** Alvaro C. Ucero,[1] Alberto Benito Martin,[1] Isabel Fuentes-Calvo,[2] Beatriz Santamaria Pérez,[1] Carlos Martinez-Salgado,[2] Jose M. Lopez-Novoa,[2] Marta Ruiz-Ortega,[1] Jesus Egido,[1] Alberto Ortiz.[1] *[1]Experimental Nephrology Laboratory, Instituto de Investigación Sanitaria - FJD, Madrid, Spain; [2]Unidad de Fisiopatología Renal y Vascular, Universidad de Salamanca, Salamanca, Castilla y Leon, Spain.*

Renal fibroblasts are key players in renal fibrosis. TNF-related weak inducer of apoptosis (TWEAK) is a TNF superfamily member involved in different processes like angiogenesis, proliferation, differentiation and apoptosis. Other members of this family, TNF-α and Fas, induce apoptosis in murine renal interstitial fibroblasts. However, there is no information on the role of TWEAK in renal fibrosis.

In cultured murine renal interstitial fibroblasts addition of TWEAK increased viability at 24, 48 and 72 h. Flow cytometry of DNA content showed that this was the result of both decreased apoptosis and increased proliferation, which were dose-dependent. TWEAK also increased cyclin D1 protein expression which is necessary for the cell cycle G1/S phase transition. TWEAK promoted an early activation of extracellular-regulated kinase (ERK) pathway and pretreatment with an ERK inhibitor (PD98059) reversed both proliferation and cyclin D1 overexpression induced by TWEAK. We also studied the effect of TWEAK in mice embryonary fibroblasts (MEF) observing the same effects, but cell viability of MEFs lacking N- and H-Ras isoforms was not increased after TWEAK treatment. In addition, TWEAK also activated ERK in MEFs in a N- and H-Ras-dependent manner, suggesting the involvement of Ras/ERK pathway.

Renal interstitial fibroblasts play an active role in the recruitment of inflammatory cells into the interstitium. In TFBs TWEAK upregulates mRNA expression of inflammatory cells chemoattractants (MCP-1 and RANTES), adhesion molecules (ICAM-1) and inflammatory cytokines (IL-6 and CXCL16) in an NFκB-dependent way. This effect was inhibited by parthenolide. Immunofluorescence and EMSA showed that NFκB translocated to the nucleus and bound a DNA NFκB consensus sequence after TWEAK treatment. In conclusion, TWEAK increases fibroblast number and promotes a pro-inflammatory phenotype through the ERK and NFκB pathways. These results suggest that TWEAK may contribute to renal fibrosis.

### TH-PO253

**HSP47 Mediate ECM Accumulation Induced by TGF-beta1 in Proximal Tubular Cells** Hong-Bo Xiao, Li Xiao, Lin Sun, Yuncheng Xia, Guanghui Ling, Fu-You Liu, Rui-Hong Liu. *Department of Nephrology, The 2nd XiangYa Hospital, Kidney Institute of Central South University, ChangSha, Hunan, China.*

To demonstrate the role of Heat shock protein (HSP)47 in TGF-beta1 induced ECM accumulation in proximal tubular cells and the possible mechanism in it. HSP47 expression and ECM related protein collagen (Col) IV and fibronectin (FN) were detected by immunohistochemistry method in UUO rat models. In vitro study, HSP47, Col IV, FN and PAI-1 expressions were evaluated with the treatment of TGF-beta1 in HK-2 cells (a proximal tubular cell line). The results showed that there was obvious up-regulation expression of HSP47 both in UUO rat model and HK-2 cells with the stimulation of TGF-beta1, which was correlated with ECM protein and PAI-1 expression. However, these effects were dramaticaly reversed with pre-treatment of HSP47-siRNA. In addition, the pathway involved in HSP47 induced by TGF-beta1 was explored, HSP47 expression was also observed in HK-2 cells pretreated with ERK1/2 inhibitor(PD98059) or JNK inhibitor(SP600125) under TGF-beta1 condition. Intertestingly, the effect of TGF-beta1 on HSP47 expression was obviously inhibited with ERK1/2 or JNK inhibitor. These data suggests that HSP47 plays an important role in ECM accumulation induced by TGF-beta1 in HK-2 cells, both in ECM production and degradation. ERK1/2 and JNK pathway maybe involved in the regulation of TGF-beta1 on HSP47 production. HSP47 will be served as a vital target to prevent tubular-interstitial fibrosis.

### TH-PO254

**Predictive Factors for Chronic Kidney Disease Following AKI Post Cardiac Surgery** Henrique Palomba,[1] Isac Castro,[3] Luis Yu.[2] *[1]Nephrology, University of São Paulo Medical School, São Paulo, São Paulo, Brazil; [2]Nephrology, University of São Paulo Medical School, São Paulo, São Paulo, Brazil; [3]Nephrology, University of São Paulo Medical School, São Paulo, São Paulo, Brazil.*

Introduction: Acute Kidney Injury (AKI) following cardiac surgery is strongly associated with perioperative morbidity and mortality, but its impact on long term development of renal dysfunction is uncertain.

Patients and Methods: A total of 350 patients (pts) submitted to cardiac surgery between July/2005 and July/2006 were evaluated for AKI, defined according to AKIN Stage I (serum creatinine (SCr) > 0,3 mg/dL over baseline value). Univariate and multivariate analysis were utilized for evaluation of pre, intra and post-operative parameters associated with occurrence of chronic kidney disease (CKD), defined as creatinine clearance < 60 mL/min, after 12 months of follow-up.

Results: AKI incidence was 41% (n=102). The incidence of CKD after 12 mo. of follow-up was 37% (n=130) and it was greater in patients with AKI and previous CKD (88%, n=38), compared with AKI patients without previous CKD (25%, n=15). CKD incidence was lower in non-AKI patients without previous CKD (9%, n=14). In the multivariate logistic regression model, adjusted by previous CKD, the following factors were determined as predictors of long-term renal dysfunction development: AKI (OR 4.74, 95% CI 1.75-12.79), intra-aortic balloon pump use (OR 8.91, 95% CI 1.07-81.99), age > 68 y/o (OR 4.07, 95% CI 1.52-10.91), serum bicarbonate < 24 mEq/L at ICU admission (OR 11.29, 95% CI 1.8-71.06) and pre-operative serum albumin < 3.5 mg/dL (OR 3.49, 95% CI 1.26-9.70).

Conclusions: AKI is frequent following cardiac surgery and presents an important impact on the long-term renal function outcome.

### TH-PO255

**Sunitinib (SU), a VEGFR Blocker, Aggravates Glomerular but Not Interstitial Injury without Reducing Capillary Density in the 5/6 Renal Ablation (Nx) Model** Flavia G. Machado, Patricia Semedo Kuriki, Clarice K. Fujihara, Camilla Fanelli, Simone R. Costa, Claudia R. Sena, Denise M. Malheiros, Marcos Dall'oglio, Niels Olsen Saraiva Camara, Roberto Zatz. *Univ of Sao Paulo, Brazil.*

The role of angiogenesis (ANG) in CKD is unclear. New capillaries may be needed to oppose hypoxia and mitigate capillary rarefaction (CR). Conversely, ANG may worsen injury by favoring influx of inflammatory cells. VEGF, a major growth factor in ANG, has also autocrine/paracrine effects on podocytes and endothelial cells. We investigated the effect of SU on CKD. One day after ablation, Nx rats were assigned to Groups Nx+V (vehicle) or Nx+SU (SU, 4 mg/Kg/d). One week later, serum creatinine ($S_{Cr}$), glomerulosclerosis index (GSI), % cortical interstitium (%INT), % glomerular endothelial area (%GE), interstitial capillary density (ICD) and glomerular volume ($V_G$) were measured in 7 NX+V and 7 Nx+SU rats. The remaining 19 rats were followed until 45 days after Nx. Twelve sham-operated rats given vehicle (S+V) or SU (S+SU) were also studied at this time.

| | $S_{Cr}$ | GSI | %INT | %EG | ICD | $V_G$ | Hct |
|---|---|---|---|---|---|---|---|
| $Nx+V_{7d}$ | 1.2±0.1[b] | 0.2±0.2 | 0.3±0.1[b] | 88±1 | 621±17 | 0.7±0.1 | 47±1 |
| $Nx+SU_{7d}$ | 1.2±0.1[b] | 1.5±0.6[ab] | 0.2±0.1 | 87±1 | 592±21 | 0.6±0.1[b] | 48±1 |
| $Nx+V_{45d}$ | 1.1±0.1[b] | 19.9±5.9 | 2.3±0.4[bc] | 77±3[c] | 359±40[bc] | 1.3±0.1[bc] | 45±1 |
| $Nx+SU_{45d}$ | 1.3±0.1[b] | 57.7±13.2[abc] | 2.2±0.4[bc] | 72±4[c] | 288±33[bc] | 1.1±0.1[abc] | 41±1[abc] |
| $S+V_{45d}$ | 0.6±0.1 | 0.1±0.1 | 0.1±0.1 | 87±1 | 595±49 | 0.7±0.1 | 49±1 |
| $S+SU_{45d}$ | 0.6±0.1 | 0.1±0.1 | 0.1±0.1 | 82±2 | 531±78 | 0.8±0.1 | 49±1 |

Mean±SE, [a]p<0.05 vs. respective untreated, [b]p<0.05 vs. S receiving same treatment, [c]p<0.05 vs. 7 days.

SU had no effect on %EG, ICD or any other parameter in S. At day 7, no CR was seen in Nx. SU had no effect on %EG or ICD in Nx, but worsened GSI. On day 45, CR was evident in Nx. SU caused anemia, a numerical decrease in ICD and a marked increase in GSI vs. Nx+V. Renal injury seems unrelated to impaired ANG. Rather, these preliminary data suggest that VEGF may be necessary for glomerular cell viability in the context of tuft hypertrophy such as observed in Nx.

**Renin Angiotensin Aldosterone Blockade (RAS) Reverses Experimental Cyclosporine Nephropathy** Fernanda Cristina Mazali,[1] Jose B. Lopes de Faria,[1] Richard J. Johnson,[2] Marilda Mazzali.[1] *[1]Division of Nephrology, State University of Campinas, Campinas, SP, Brazil; [2]Division of Renal Diseases and Hypertension, University of Colorado, Denver, CO.*

Chronic cyclosporine nephropathy (CsAN) is associated with renin-angiotensin system activation that aggravates arteriolar vasoconstriction and progressive fibrosis. Aim: Analyze the effect of RAS blockade in the established CsAN model. Methods: Male SD rats, 200 to 250g, received daily injections of cyclosporine (15 mg/kg SC) in presence of low salt diet. After 5 weeks, control group [CsA5] was sacrificed. Remaining animals were divided in 5 groups: CsA withdrawal [CsAWT], CSA for 9 weeks [CsALOS]with losartan 12,5mg/dL[CsA9LOS], enalapril 10 mg/dL[CsA9ENL] or espironolactone 20 mg/dL[CsA9ESP] in drinking water. At sacrifice, renal function and morphology were analyzed. Results: Control animals [CsA5] developed CsAN, with tubular atrophy and stripped interstitial fibrosis, comparable to CSAWT (p=ns). In CsA9 group, CsAN was progressive and more severe (p<0.05 vs CsA5).In treatment groups [CsA9LOS, CsA9ENL and CsAE9SP],despite CsA therapy, RAS blockade was associated with recovery of renal function and reduction of arteriolar and interstitial lesions, with lower interstitial inflammation and fibrosis, independently of oxidative stress regulation.

| | CsA5 | CsAWT | CsA9 | CsAENL | CsALOS | CsAESP |
|---|---|---|---|---|---|---|
| creatinine (mg/dl) | 0.6±0.1 | 0.6±0.1 b | 1.1±0.2 a | 0.6 ±0.2b | 0.6±0.1 a,b | 0.5 ±0.05 b |

| 8-OHdG (cel/mm3) | 96.3±13.2 | 55.2±13 | 130.3±22.5 a,c | 89.78±8 b,c | 100.0±6.7 b,c | 89.7±9.3 b,c |

a-p<0,05 vs CSA 5, b-p<0,05 vs CSA9, c p<0.05 vs.CSAWT

Conclusion: RAS blockade improved renal function and reduced interstitial and vascular lesions in the established CsAN model, suggesting that angiotensin II and aldosterone have a negative impact in the progression of chronic CsAN.

**Correction Factor for e-GFR Calculated with Schwartz Formula To Match with MDRD and CDK – EPE in Adolescents** Licia Peruzzi, Roberta Camilla, Caterina Grillo, Giovanni Conti, Giovanni Montini, Teresa Papalia, A. Amore, Guglielmo Bracco, Rosanna Coppo. *For the Study Group Adult and Child of the Italian Society of Nephrology.*

Estimated glomerular filtration rate (e-GFR) in children and adults is calculated with Schwartz, MDRD and CKD-EPI formulas with frequent discrepancies. Enzymatic creatinine (isotope dilution traceable international standard (IDMS) calibration) does not solve the problem. We aimed at comparing e-GFR obtained by Schwartz (k of 0.413), MDRD and CKD-EPI in young Caucasian subjects, aged 15-19 y. We analyzed 644 subjects 354 males (M) and 290 females (F); e-GFR was calculated with the 3 formulas.

The 3 formulas correlate (r2= 0.77; p<0.0001): MDRD and CKD-EPI give higher results than Schwartz (M +31±18% and +37±16% respectively; F: +13%±10 and +21±11%). To overcome discrepancies we calculated with a linear mathematic model new K for Schwartz in subjects aged 15-19 to match with e-GFR obtained with MDRD and CKD-EPI.

| | a) e-GFR-Schwartz(k=0.413) | b) e-GFR-MDRD | c) e-GFR-CKD-EPI | Wilcoxon test a vs b vs c vs a |
|---|---|---|---|---|
| M Median (IQR) | 75.9 (53.6-90.1) | 104.5 (74.7-131.0) | 117.0 (81.9-140.6) | P<0.0001 |
| F Median (IQR) | 81.4 (68.8-98.0) | 94.0 (76.5-115.7) | 108.2 (87.4-129.6) | P<0.0001 |
| | | | | |
| | | | | |
| K*L/Scr | k to match with MDRD | k to match with CKD-EPI | Mean k to match either with MDRD or CKD-EPI | |
| M Bland Altman | 0.58 ± 0.08 | 0.62 ± 0.09 | 0.60 ± 0.08 | |
| F Bland Altman | 0.47 ± 0.04 | 0.52 ± 0.09 | 0.50 ± 0.05 | |

In M the conversion factor to compare e-GFR-Schwartz$_{(k=0.413)}$ to MDRD was 1.415 and to CKD-EPI was 1.506; in F 1.146 to MDRD and 1.268 to CKD-EPI. Mean conversion factors of 1.46 for M and 1.207 for F can be adopted to convert e-GFR-Schwartz$_{(k=0.413)}$ to both formulas, with analogous accuracy.

We showed a significant difference in e-GFR obtained by different formulas: to allow comparison of data in adolescents from 15 y we propose the adoption of a new k for Schwartz formula of 0.6 in M and 0.5 in F and the conversion factor of 1,506 in M and 1.207 in F for e-GFR-Schwartz to be matched to MDRD or CKD-EPI.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO258**

**Changes in the TRPC6 Expression in Podocytes and Effect of Calcinurin-Inhibitor on the Glomerular Damages in 5/6 Nephrectomized Rats** Hajime Hasegawa, Takatsugu Iwashita, Kaori Takayanagi, Taisuke Shimizu, Yosuke Tayama, Juko Asakura. *Nephrol & Hypertens, Saitama Med Center, Saitama Med Univ, Kawagoe, Saitama, Japan.*

Glomerular hyperfiltration (GHF) is a major factor leading to podocyte injury and subsequent glomerular sclerosis. Recent works reveal that TRPC6 may function as a mechanosensor for intra-glomerular pressure load, and calcinurin-NFAT cascade may involve in the TRPC6 signaling. In this work, changes in the TRPC6 expression in the glomerular hyperfiltration and the possible effect of calcinurin-inhibitor on the TRPC6-related glomerular damages.

5/6 nephrectomy (Nx) or sham operation (S) was applied to male SD rats who were sacrificed 2 weeks after the operation. Tacrolimus (Tac; 0.08 mg/kg, s.c.) was administered to some rats in Nx group until sacrifice (Nx+Tac). Gene expressions were studied by real-time PCR in the isolated glomerulus by magnetic beads method. Glomerular damages and expressions were studied by histology and immunohistochemistry. Existence of TRPC6 in podocytes was confirmed by double immunostaining with WT-1 or synaptopodin.

In results, Nx showed an increase in the glomerular volume, urine protein excretion and desmin expression score which were partially recovered by Tac (glomerular vol: 1449±30 in S, 2257±55 in Nx, 1966±45 in Nx+Tac, urine protein: 215.4±67.3 in S, 619.4±412.4 in Nx, 106.1±17.6 mg/mgCr in Nx+Tac, desmin score: 0.98±0.05 in S, 1.92±0.06 in Nx, 1.75±0.07 in Nx+Tac). Gene expression of TRPC6 was up-regulated in Nx group and partially recovered by Tac (108.5±30.7 in S, 146.3±22.6 in Nx, 134.7±23.3% in Nx+Tac), although expression of NFATc3 was not significantly changed. Immunostaining studies demonstrated the increased TRPC6 expression in podocytes in Nx group, which was partially recovered by Tac.

Present study might suggest that the TRPC6 was up-regulated by glomerular pressure load, indicating that the TRPC6 might be involved in the development of hyperfiltration-related glomerular damages. Inhibition of calcinurin might provide clinical advantages in the hyperfiltration-associated glomerular damages.

**TH-PO259**

**Treatment with an Antioxidant Inflammation Modulator (AIM) Increases Glomerular Filtration Rate Monitored by Inulin Clearance in Rats** Christian Wigley,[1] Ron Bumeister,[1] Rhesa D. Stidham,[1] Yanfeng Ding,[2] Marc L. Sprouse,[2] Colin Meyer,[1] Deborah A. Ferguson,[1] Rong Ma.[2] *[1]Reata Pharmaceuticals, Inc., Irving, TX; [2]UNT Health Sciences Center, Ft. Worth, TX.*

Chronic hyperglycemia and activation of the renin-angiotensin system result in production of reactive oxygen species, which stimulate pro-inflammatory pathways and lead to the development of chronic kidney disease (CKD). Activation of the Keap1-Nrf2 pathway suppresses oxidative stress and inhibits inflammatory signaling in various tissues. Bardoxolone methyl (BARD), the lead AIM, potently induces the activity of Nrf2, a transcription factor that regulates expression of many antioxidant and detoxification genes. AIMs exhibit significant protective effects in models of renal injury and, in a Phase 2 clinical study in CKD patients, BARD significantly improved several parameters of renal function including estimated glomerular filtration rate (eGFR). To test whether the increased eGFR observed in patients upon treatment with BARD reflects a *bona fide* increase in GFR, inulin clearance was monitored to directly measure GFR in rats treated with RTA 405, a BARD analog. To explore the underlying mechanism, the effect of AIMs on Angiotensin II (Ang II)-induced contraction of cultured mesangial cells and isolated rat glomeruli and on Nrf2 and NF-κB activity in cultured mesangial cells were evaluated. Consistent with the clinical trial results, RTA 405 inhibited Ang II-induced decrease in GFR and significantly increased the renal filtration fraction relative to controls. BARD induced expression of various Nrf2 target genes and substantially inhibited NF-κB signaling. A statistically significant inhibitory effect on Ang II-induced mesangial cell contraction was also observed. In addition, the Ang II-induced reduction in total glomerular volume was significantly attenuated. Results from this study demonstrate that AIMs inhibit reduction in GFR and also provide support for the evaluation of BARD in CKD, in which RAS activation, oxidative stress, and inflammation contribute to the pathology. A 12-month Phase 2b pivotal study in CKD patients is currently underway.

**Indoxyl Sulfate Stimulates Reactive Oxygen Species Leakage from Rat Kidney Mitochondria and AST-120 Inhibits This Process in Experimental Acute Kidney Injury** Shigeru Owada,[#1] Sumie Goto,[#2] Shunsuke Ito,[#2] Hideyuki Yamato,[#2] Fuyuhiko Nishijima,[#2] Aki Hirayama.[#3] *[1]Dialysis Center, Asao Clinic, Kawasaki, Kanagawa, Japan; [2]Biomedical Research Laboratories, Kureha Co., Ltd., Tokyo, Japan; [3]Internal Medicine, Tsukuba University of Technology, Tsukuba, Ibaragi, Japan.*

Aim: Free radicals both initiate and contribute to the progress of AKI but there is no direct evidence of free radical production in the injured cells. We have succeeded to identifying free radical leakage (O2- and OH radicals; ROS) from mitochondria (Mito) directly using an EPR spin trapping technique. To clarify the role of Mito stress on development of AKI, we have investigated leakage of ROS from Mito and immunostaining of survivin in the kidney using AKI model rats.

Methods: Ischemic AKI was induced in 29 SD male rats and divided into the following two groups; AKI control ( C ) and AST-120 ( A ). Sham operated rats were used as a normal group (N; n=28). 1-2 days after induction, kidneys were isolated and Mito fractions were prepared by fractional centrifugation. Serum and intra cellular IS levels were measured. Free radicals were detected by the EPR spin trapping method using CYPMPO as a spin trapping agent. ROS adducts were recorded every 1 min for 20 min. Peak height (PH) of ROS were accumulated and expressed as percentage compared to values of sham rats. SOD activities (U/mg protein) in the Mito and survivin expression in the kidney were measured. Results: Levels of serum Cr and IS were significantly lower in the A group compared to the C group. ROS leakage rates (%) were significantly higher in the C group and lower in the A group (N=100±13, C=112±18, A=95±16). Mito SOD activities were lower in the C group (N=9.7±2.4, C=3.1±0.6, A=6.0±28). Intracellular IS levels (n mol/mg protein) and survivin area (%) were higher in the C group (IS;N= 16.2±2.0, C=36.8±6.8,A=12.0±9.3, Survivin; N=5.45±1.17, C=6.44±1.48, A=5.03±0.49). There were significant correlations found between ROS leakage, intracellular IS levels and survivin.

Conclusions: AST-120 protected renal function in Ischemic AKI. It is speculated that one mechanisms of this effect of AST-120 was based on inhibition of Mito ROS leakage and apoptosis.

Disclosure of Financial Relationships: nothing to disclose

**Distinct Roles of mPGES-1 in Mediating Renal Injury and Stimulating Renal Erythropoietin Expression in the 5/6 Nephrectomy Mouse Model** Zhanjun Jia,[1,2] Haiping Wang,[1,2] Tianxin Yang.[1,2] *[1]Internal Medicine, University of Utah, Salt Lake City, UT; [2]Veteran Affairs Medical Center, Salt Lake City, UT.*

COX-2 activity has been shown to contribute to the pathogenesis of chronic kidney disease with a poorly characterized mechanism. In present study, we investigated the role of microsomal prostaglandin E synthase-1 (mPGES-1), in the progression of chronic renal failure in a mouse model of 5/6 nephrectomy (5/6NX). After 4 weeks of 5/6NX, wild-type mice exhibited increases in plasma BUN, Cr, and blood phosphorus, all of which were attenuated in mPGES-1 KO mice (BUN: 41.86 ± 2.8 vs. 55.2 ± 4.8 mg/dl;

Cr: 0.485±0.017 vs. 0.61±0.02 mg/dl; blood phosphorus: 7.27 ± 0.4 vs. 9.2 ± 0.88 mg/dl, p<0.05, respectively). 5/6NX induced a 2.6-fold increase in urinary albumin excretion in WT mice, which was completely abolished by mPGES-1 deletion. Urine concentrating defect was less in 5/6NX KO mice than in 5/6NX WT mice (urine volume: 1.9 ± 0.23 vs. 2.8 ± 0.4 ml/24 h, p<0.05; water intake: 5.26 ± 0.41 vs. 7.01 ± 0.83 ml/24 h, p<0.05; urine osmolality: 1289 ± 76.2 vs. 1021.1 ± 51.6 mOsm/kg $H_2O$, p<0.05). In the remnant kidney, COX-2 and mPGES-1 mRNAs elevated 2.76-fold and 2.73-fold, respectively, contrasting to unchanged mRNA expression of COX-1. Despite the significant reduction of kidney mass, 24-h urinary PGE2 excretion in 5/6NX WT mice was comparable to that in sham animals (940.95 ± 146.5 vs. 855.5 ± 317.9 pg/24 h, p>0.05), evidence of increased PGE2 production in the remnant kidney. Paradoxically, 5/6NX induced more severe anemia in mPGES-1 KO mice than WT controls as assessed by hematocrit and splenomegaly (Hct: 40.1% vs. 46.3%, p<0.05; spleen weight: 159.3 ± 30.8 vs. 103.1 ± 8.4 mg, p<0.05). Erythropoietin (EPO) mRNA in the remnant kidney of WT mice elevated 19-fold, which was reduced by 50% the KO group. Remnant kidney TNF-α protein increase by 85% in the 5/6NX WT mice, which was entirely abolished in KO mice. We conclude that: (1) mPGES-1 deletion ameliorates chronic renal failure in the mouse model of 5/6 nephrectomy, and (2) mPGES-1 deletion paradoxically exacerbates anemia in this model likely via suppression of EPO.

Disclosure of Financial Relationships: nothing to disclose

**Bone Morphogenetic Protein 2 Gene Polymorphisms Contribute to the Development of Childhood IgA Nephropathy (IgAN)** Jin-Soon Suh, Won-Ho Hahn, Byoung-Soo Cho. *Department of Pediatrics, Kyung Hee University Hospital, Seoul, Korea.*

**Background :** Bone morphogenetic proteins (BMPs) are multi-functional growth factors belonging to the TGF-ß superfamily and have been shown to be important in both preservation of kidney function and resistance to injury. BMP2 is highly regulated in the kidney and high affinity binding sites for BMP2 has been identified in kidney epithelial cells. And it has been demonstrated to play various roles in the pathogenesis of renal diseases. However, the role of BMP2 gene in glomerulonephritis is not investigated yet. We aimed to evaluate the association of BMP2 polymorphisms with immunoglobulin A nephropathy (IgAN) in Korean children.

**Methods :** We evaluated 187 pediatric patients with biopsy-proven IgAN and 262 healthy controls. Two single nucleotide polymorphisms in the coding region of BMP2 gene (rs235768 [missense, Arg190Ser] and rs1049007 [synonymous, Ser87Ser]) were selected and genotyped by direct sequencing methods.

**Results :** The genotypes of rs235768 ($p$= 0.0023, OR (95% CI) = 6.39 (1.46-28.03) in the recessive model) and rs1049007 ($p$= 0.0002, OR (95% CI) = 13.67 (1.81-103.42) in the recessive model) were associated with childhood IgAN. And in haplotype analysis, haplotype TG ($p$= 0.011, OR (95% CI) = 6.76 (1.55-29.50) in the dominant model) and haplotype AA ($p$= 0.0137, OR (95% CI)= 0.08 (0.01-0.59) in the recessive model) showed association with IgAN.

**Conclusion :** Polymorphisms in BMP2 gene may contribute the susceptibility to IgAN in Korean children.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO263**

**Aldosterone Receptor Blocker Attenuates Glomerulosclerosis but Not Proteinuria** Nobuaki Takagi, Ji Ma, Valentina Kon, Iekuni Ichikawa. *Division of Pediatric Nephrology, Vanderbilt University Medical Center, Nashville, TN.*

We previously showed that inhibition of angiotensin type 1 receptor (AT1) attenuates podocyte damage and glomerulosclerosis in the NEP25 transgenic mouse model of podocyte-specific injury-induced glomerulosclerosis. However, our studies in NEP25 mice genetically deficient in podocyte AT1 revealed that the protective effect of AT1 blocker (ARB) is not through the podocyte AT1. Therefore, we now test the possibility that the protective effect of ARB on podocytes is systemic, and involves mineralocorticoid inhibition. For this purpose, we compared the ability of ARB, mineralocorticoid receptor blocker (MRB) or both to protect against podocyte injury and subsequent glomerulosclerosis.

NEP25 mice treated with the MRB, spironolactone (25 mg/kg/day, N=10), the ARB, losartan (250 mg/kg/day, N=11), combination of the two (Comb, N=8) or vehicle (Veh, N=9) in drinking water starting from day -7 until sacrifice at day 9. LMB2 was injected to induce podocyte injury at day 0. Proteinuria and systolic blood pressure were followed, and glomerular sclerosis and podocyte population were assessed at sacrifice.

Although MRB treatment did not reduce systolic blood pressure or proteinuria, it significantly decreased collagen type IV deposition and preserved WT-1-positive podocytes compared with glomeruli of untreated controls (Collagen IV: MRB 29.9±1.7% *vs.* Veh 38.9±1.2%; WT-1: MRB 10.2±0.4 *vs.* Veh 8.4±0.3 cells per glomerulus; both $P$<0.05). These benefits were comparable to those observed in ARB-treated mice (33.1±1.6% for Collagen IV, and 10.7±0.4 cells per glomerulus for WT-1). Further, addition of non-BP lowering MRB to the already large dose of ARB significantly attenuated sclerosis (glomerular sclerosis index: Comb 1.67±0.19 *vs.* ARB 2.35±0.19, $P$<0.05) and deposition of collagen type IV (Comb 23.7±1.4% *vs.* ARB 33.1±1.6%, $P$<0.05).

Taken together these data suggest that, mineralocorticoid receptor participates in the later stages of glomerulosclerosis but not in the early events of podocyte injury manifest as proteinuria, an effect that is independent of systemic blood pressure.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO264**

**Renal Arginase (A) Activity in Kidney Cortex (KC) of Rats with Chronic Kidney Disease (CKD)** Sergey Zharikov,[1] Gin-Fu Chen,[1] Natasha C. Moningka,[1] Sidney M. Morris, Jr.,[3] Christine Baylis.[1,2] *[1]Physiol., University of Florida; [2]Med., University of Florida, Gainesville, FL; [3]Biochem., University of Pittsburgh, Pittsburgh, PA.*

Kidney is the major site of synthesis of circulating arginine (Arg) but also contains A (A-II), which consumes some Arg. Moradi et al (2006) report increased urea inhibits A (in liver), which may limit the importance of A as a competitor for Arg, in CKD. In this study we investigated the impact of CKD on KC urea content, A abundance and activity using puromycin aminonucleoside (PAN; Pcreat = 1.09±0.24, sham = 0.22±0.01mg/dl) and 5/6 ablation/infarction of renal mass (5/6AI; Pcreat =0.62±0.07) CKD models. KC urea content was > 50% above sham control values after both 11 weeks PAN and 4-5 weeks 5/6AI. In PAN vs sham there was no difference in abundance of A-II but A activity (using physiologic Arg = 1.8mM and measuring urea accumulation) was low, ~30% of sham. In contrast, in 5/6AI, A-II abundance was low, ~ 40% of sham, but A activity was ~25% higher. We investigated the effect of different concentrations of exogenous urea on arginase activity in normal KC homogenates (1.8mM Arg; measuring ornithine production). Baseline KC urea concentration was 37±3mM and A activity was 2.50±0.01 (µmoles of ornithine/mg/h); with addition of exogenous urea inhibition of A activity occurred to 2.35±0.03 + 10mM, 2.30±0.08 + 25 mM, 2.20±0.04 +50 mM and 2.10±0.02 + 100mM. Of note, the inhibitory effect of urea was mild and declined with increasing concentration. Kinetic analysis of A activity in control KC (± 50mM urea) showed that urea-induced inhibition is due to a decrease in A affinity for Arg. Although baseline A activity was much lower in PAN rats (baseline urea 58±6mM; A activity 0.73±0.01), addition of urea led to increased A activity, to 0.74±0.03 + 10mM, 0.83±0.02 + 25 mM, 0.91±0.00 +50 mM and 0.97±0.08 + 100mM. Thus, the A activity in KC is not predictably related to KC urea content in CKD but varies with injury/model. Further, there are variable post-translational modifications of A having profound effects on activity in different models. Therefore, A activity may contribute to local Arg (and hence NO) deficiency in some types/stages of CKD.

Disclosure of Financial Relationships: nothing to disclose

**Deletion of Scavenger Receptor A I/II Protects Kidney from a High Fat Diet-Induced Superoxide Production, Macrophage Infiltration and Tubulointerstitial Fibrosis** Zhaoyong Hu,[1] Wenjian Wang,[2] William E. Mitch.[1] *[1]Internal Medicine, Baylor College of Medicine, Houston, TX; [2]Internal Medicine, Guangdong General Hospital, Guangzhou, Guangdong, China.*

Tubulointerstitial fibrosis is common in kidney diseases, the degree of fibrosis pathologically is associated with the severity of progressive renal insufficiency. In unilaterally nephrectomized mice fed a high fat died (HFD) for 4 months, we found there was extensive deposition of lipids in tubular cells and cells of the renal interstitium compare to unilateral nephrectomy fed with normal chow. The deposition of lipids in tubular cells was accompanied by progressive tubulointerstitial fibrosis, including increased deposition of fibronectin plus collagens I & III. Because the scavenger receptor AI/II (SRAI/II) is known to mediate lipid uptake into tubular cells, we hypothesized that these receptors are involved in the production of tubulointerstital fibrosis. To address this possibility, we studied mice with global KO of the SRAI/II. Despite the stimulus of hight fat diet, there was a substantial decrease in lipids accumulation in kidney cells. SRAI/II KO also inhibited fibrosis and the deposition of fibronectin and collagens I & III. Using DHE staining and measurements of kidney MDA production, we found that SRAI/II KO caused a dramatic decrease in superoxide production. Moreover, both resident (CD68+) and bone marroe derived (CD68+/CD11c+) macrophages were decreased in kidney of SRAI/II KO mice fed the HFD. In the cultured HK-2 cells, silencing SRAI/II (siRNA interference technique) causes an inhibition of ox-LDL uptake and reduced TGF-beta1 expression and the phosporylation of Smad2/3, providing a mechanism for the suppression of fibrosis. The mechanism underlying the decrease in macrophage infiltration into the tubulointerstitium involved suppression of MCP-1 expression. We conclude that tubulointerstial fibrosis evolves from HFD to uptake ox-LDL by tubular cells leading to stimulation of superoxide formation. This results in increased production of MCP-1, macrophages infiltraion and stimulation of TGF-beta1/Smad signaling. These responses are blocked by inactivating the SRAI/II in tubular cells.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO266**

**Simvastatin Ameliorates Renal Ephithelial-Mesenchymal Transition by Modulating Uterine Sensitization-Associated Gene-1 (USAG-1)** Yoshifumi Hamasaki, Kent Doi, Koji Okamoto, Eisei Noiri, Toshiro Fujita. *Department of Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan.*

[Background & Purpose] BMP-7 suppresses renal fibrosis by counteracting with TGF-β-induced epithelial-mesenchymal transition (EMT). Uterine sensitization-associated gene-1 (USAG-1), the dominant BMP-7 antagonist expressing in distal tubular epithelial cells, promotes renal fibrosis. Although a number of clinical studies have reported the protective effect of statins on chronic kidney disease progression, the mechanism is not fully revealed. In this study, we investigated whether simvastatin (SIM) attenuates renal fibrosis by modulating USAG-1 mediated pathway.

[Method & Results] C57/BL6 mice fed by adenine-containing diet for 4 weeks showed significant increase of BUN accompanied with severe tubulointerstitial fibrosis. SIM treatment (50mg/kg/day) for two weeks significantly reduced BUN compared with

the control group. In pathological analysis, the area of fibrosis evaluated by Masson's trichrome staining and the expression of α-smooth muscle actin were significantly attenuated by SIM. On quantitative PCR, USGA-1 expression was significantly reduced in the SIM group without affecting BMP-7 expression. Immunoblotting analysis showed that SIM increased pSmad1/5/8 expression.

In vitro experiments, MDCK cells incubated with TGF-β (5ng/ml) for 72 hours showed increased expression of USAG-1, but SIM significantly reduced USAG-1 expression without affecting BMP-7 expression.

It has been reported that USAG-1 gene expression is regulated by a transcriptional factor HOXA13 in organ development. In MDCK, suppression of USAG-1 by SIM was not observed when HOXA13 gene was knocked down by RNA interference.

[Conclusion] Our data showed that SIM ameliorated EMT by suppressing USAG-1 expression, not up-regulating BMP-7 expression. Decreased USAG-1 levels may enhance the effect of BMP-7 relatively. We also demonstrated that a new mechanism of action of statins that regulates USAG-1 by modulating HOXA13.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO267

**Clinical Causes of Acute Kidney Injury and Outcome of ICU Patients** Helmut Schiffl. *Medizinische Klinik Innenstadt, University of Munich, Munich, Germany.*

Background: Acute kidney injury (AKI) secondary to acute tubular necrosis (ATN) is common in critically ill patients. The underlying pathophysiology of ICU AKI can be divided into pure ischemic, pure nephrotoxic, and mixed causes. This posthoc analysis of a prospective single-cohort 7 year study aimed to test the hypothesis whether the cause (pure versus mixed) of renal insults resulting in AKI affects the outcome of survivors of AKI.

Methods: A total of 425 critically ill patients with AKI secondary to clinically diagnosed ATN were divided in three groups according to the cause of ATN. Of these patients, 215 had mixed ATN, 203 had pure ischemic ATN, and 7 had pure nephrotoxic ATN. All patients had one episode of AKI. No patient had pre-insult chronic kidney disease. Patients were followed throughout their hospital stay (mortality rate, recovery of renal function at discharge) and up to 7 years after initiation of RRT.

Results: The three patient groups differed in their demographic and renal characteristics at iniation of RRT. The in-hospital mortality rate( 47 % for the cohort ) was 55% for the mixed ATN group, 39% for the pure ischemic group, and 29% for the pure nephrotoxic group. Complete renal recovery at discharge was documented in all 5 surviving patients with pure nephrotoxic ATN and in 92 out of 124 survivors with pure ischemic ATN, but only in 29 out of 97 surviving patients with mixed ATN. All patients discharged alive from the hospital completed the 7-year follow-up. At the end of the observation period, 60% of the survivors of pure ATN, compared with 22% of the survivors of mixed ATN, were alive. At 7 years, 6% of the living patients with pure ATN had early stage chronic kidney disease, but 38% of the mixed group patients had severely decreased eGFR or end-stage renal disease.

Conclusions: The cause of ATN has an impact on short- as well as long-term outcomes. The challenge for intensivists is to prevent further insults to the acutely injured kidneys.

**Periostin: Novel Tissue and Urinary Biomarker of Progressive Renal Injury Induces a Coordinated Mesenchymal Phenotype in Tubular Cells** Bancha Satirapoj,[1,4] Ying Wang,[1] Cynthia C. Nast,[1,2] Mina Patel-Chamberlin,[1] Janine A. La Page,[1] Hans-Henrik Parving, Tiane Dai,[1] Xiwei Wu,[3] Rama Natarajan,[3] Sharon G. Adler,[1] Denis Ouimet.[5] *[1]Harbor-UCLA Los Angeles Biomedical Research Institute; [2]Cedars-Sinai Medical Center; [3]City of Hope National Medical Center, CA; [4]Phramongkutklao Hospital, Bangkok, Thailand; [5]Service de Nephrologie, Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Periostin is involved in cell survival, differentiation and migration, but data concerning periostin expression in kidney injury is scanty. Periostin was identified by microarray and confirmed by real-time PCR in renal tissue after 5/6 nephrectomy (5/6Nx), and streptozotocin-induced diabetes demonstrating generalizability of the periostin increment in renal injury. Periostin was expressed predominantly in distal nephron tubular cells and in tubule cells shed into the lumen. In affected distal nephron tubule cells after 5/6Nx, periostin expression appeared de novo, the epithelial cell adhesion molecule E-cadherin became undetectable, and tubule cells displayed the mesenchymal marker proteins fibroblast specific protein-1 (FSP1) and matrix metalloproteinase-9 (MMP9). To assess whether periostin plays a direct role in mediating the loss of the tubular differentiation marker E-cadherin and the gain of mesenchymal markers, we overexpressed periostin in cultured distal convoluted tubule cells. Tubules overexpressing periostin dramatically increased MMP9 and FSP1 protein, and decreased E-cadherin protein expression. Urine periostin excretion increased over time after 5/6Nx, and it was also excreted in the urine of CKD patients. Urine periostin ELISA at a cutoff value of 32.66 pg/mg creatinine demonstrated sensitivity and specificity for distinguishing patients with proteinuric and non-proteinuric CKD from healthy people (92.3%, and 95.0%, respectively). These values were similar to urine NGAL ELISA by ROC analysis. These data demonstrate that: 1) Periostin is a mediator and marker of mesenchymal phenotype; 2) Tubule cells that are shed into the tubular lumen express periostin-associated mesenchymal phenotype; and 3) Periostin is a promising tissue and urine biomarker for kidney injury in experimental models and in clinical renal disease.

**The Balance of Beneficial and Deleterious Effects of Hypoxia-Inducible Factor Activation by Hydroxylase Inhibitor in Rat Remnant Kidney Depends on the Timing of the Stimulus** Xiaofang Yu, Xiaoqiang Ding, Yi Fang, Jiaming Zhu, Xialian Xu, Suhua Jiang. *Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

**Background.** The purpose of the present study was to characterize HIF expression during the course CKD development, and to investigate the effects of HIF activation on CKD by using prolyl hydroxylase (PHD) inhibitor L-mimosine (L-Min) at different stages of CKD. **Methods.** Rats with remnant kidneys (RK) were sacrificed at wk 1, 2, 4, 6, 8, 12 after subtotal nephrectomy. Then additional groups of RK rats were treated with L-mimosine at different stages of RK basing on the expression pattern of HIF-a . **Results.** The nuclear expression of HIF-1α and -2α, as well as typical HIF target genes VEGF, HO-1, GLUT-1 and EPO, were all up-regulated in the early stage of RK when renal function was stable, and returned to the basal level later, accompanied by impaired renal function and interstitial fibrosis. RK rats were then divided into early treatment group (L-Min administration at week2-12), advanced treatment group (L-Min administration at week4-12) and end stage treatment group (L-Min administration at week8-12). Early L-Min treatment in RK aggravated renal function, tubulointerstitial fibrosis and peritubular capillary loss. Advanced L-Min treatment improved renal function, decreased renal fibrosis and protect peritubular capillary networks. End stage L-Min treatment had no influence on these parameters. Furthermore, compared with the control group, nuclear accumulation of HIF-1a as well as CTGF in the early treatment group was increased soon after the administration and kept increasing during the treatment, while expression of HIF-2a and VEGF were only increased a little in the last 4 weeks; in the advanced administration group, only HIF-2a and VEGF expression kept increasing during the continued L-Min treatment.

**Conclusions.** There was a transient HIF-a activation in the remnant kidney of rats at the early stage following subtotal nephrectomy. HIF-a activation by PHD inhibitor L-Min has dual roles in the development of RK, depending on the timing of administration and, differential activation of HIF-a isoforms and their target genes might be the course.

### TH-PO270

**The Anti-Oxidant Effect of Paricalcitol Improves Chronic Cyclosporine A Nephropathy** ShangGuo Piao,[1] Joonchang Song,[1] Ji-Hyun Song,[1] Jungyeon Ghee,[1] Sol Kim,[2] Chul Woo Yang.[1] *[1]Department of Internal Medicine, The Catholic University of Korea, Seoul, Republic of Korea; [2]Department of Bioengineering, University of Pennsylvania, Philadelphia.*

Oxidative stress is one of main mechanisms in cyclosporine(CsA)-induced renal injury. Vitamin D has anti-oxidative effect on chronic kidney disease patients. We evaluated whether paricalcitol has renoprotective effect on CsA-induced renal injury using experimental model of chronic CsA nephropathy.

Male SD rats were divided 4 groups; vehicle, CsA, CsA+paricalcitol 50 ng/kg (P50) and CsA+paricalcitol 200 ng/kg (P200), respectivley. CsA (15 mg/kg/day) was injected daily for 28 days and paricalcitol was injected as the concentration of 50 ng/kg/day(low) and 200 ng/kg/day (high) for 28 days. The responses of paricalcitol were evaluated by measuring renal functional parameters and the degree of the fibrosis by Masson's trichrome stain and the number of ED-1 positive cells. We also assessed the mechanism of the effect on renal pathology by analyzing the expression of βig-h3, caspase-3 immunoblotting and 24-h urinary and tissue expression of 8-hydroxy-2'-deoxyguanosine (8-OHdG).

Increased oxidative stress in the CsA group was significantly decreased compared to the P50 or P200 groups. The number of ED-1 positive cells was also lower in the P200 group than CsA group ($36.8 \pm 1.6/0.5mm^2$, vs. $52.3 \pm 2.0/0.5mm^2$, $P < 0.05$). At molecular basis, increased βig-h3 expression in the CsA group was significantly decreased in the P200 compared to CsA group ($9750 \pm 101\%$ vs $6897 \pm 465\%$, $P < 0.05$). Increased caspase-3 expression in the CsA group protein level for caspase-3 was decreased in paricalcitol groups. But lower paricalcitol dosage group (P50) did not show the significant difference with CsA group. Four weeks treatment of CsA developed typical chronic CsA nephropathy, characterized by interstitial inflammatory cells infiltration and tubulointerstitial fibrosis(TIF). Quantification for TIF revealed lower TIF score in the P200 group than CsA group ($15.5 \pm 2.3\%$ vs. $23.5 \pm 0.9\%$, $P < 0.05$).

Paricalcitol attenuates CsA-induced interstitial fibrosis and inflammation by decreasing oxidative stress, and this effect was dose-dependent.

**Sympathetic Blockade Prevents the Decrease in Cardiac VEGF Expression and Capillary Supply in Experimental Renal Failure** Kerstin U. Amann,[1] Kerstin Benz,[2] Roland Veelken.[3] *[1]Pathology, University of Erlangen-Nürnberg, Erlangen, Germany; [2]Pediatrics, University of Erlangen-Nürnberg, Erlangen, Germany; [3]Hypertensiology and Nephrology, University of Erlangen-Nürnberg, Erlangen, Germany.*

**Background:** Uremic cardiomyopathy of men and rodents is characterized by lower myocardial capillary supply which in rats could be prevented by central and peripheral blockade of the sympathetic nervous system. The underlying pathomechanisms remain largely unknown. We investigated whether alterations of cardiac VEGF gene and protein expression were involved.

**Methods:** 1. Long-term experiment: We investigated whether VEGF gene and protein expression was altered in the heart of male Sprague-Dawley rats with either sham operation (sham, n=10) or subtotal nephrectomy (SNX, n=10). 2. Short term experiment (17 sham, 24 SNX):, The effect of a putative downregulation of sympathetic nervous activity by surgical renal denervation (interruption of renal afferent pathways) on cardiac gene expression of VEGF, flt-1 and flk-1 and on myocardial capillary supply was analysed.

**Results:** In the long-term study cardiac capillary supply (3484±532 vs 4258±829 mm/mm$^3$ and VEGF gene and protein expression were significantly lower in SNX than in sham. In the short-term experiment cardiac capillary supply (244.7±83.9 in SNX vs. 323.5±95.3 per mm$^2$ of myocardium in sham, $p<0.05$) and VEGF mRNA expression was significantly lower in untreated SNX (4258±2078 units) than in both sham groups (11709±4169 and 8998±4823 units); the decrease in capillarisation and VEGF expression was significantly prevented by renal denervation (8190±3889, $p<0.05$).

**Conclusion:** Cardiac VEGF gene and protein expression is reduced in experimental CRF and this may be considered as one potential reason for impaired myocardial adaptation under the situation of cardiac hypertrophy. The beneficial effect of sympathetic downregulation on cardiac structure and function in CRF may be at least in part explained by increased cardiac VEGF gene expression.

### Molecular Targets for FGF23 in a Mouse Model of Chronic Kidney Disease

Bing Dai, Valentin David, Leigh Darryl Quarles. *UTHSC, Memphis, TN.*

The Col4a3$^{-/-}$ mouse is an animal model of Alport's disease caused by intrinsic defects in basement membrane collagens. 12-week old mice display loss of renal function and show features of CKD-MBD, including increased FGF23 levels. Progression of CKD in Col4a3$^{-/-}$ might result from the primary defect or extrinsic factors, such as circulating hormones, that modulate renal damage. Indeed, the kidney is the principal target for FGF23, which regulates phosphate transport, vitamin D metabolism and independently predicts progression of CKD. To determine the intrinsic and FGF-23 dependent expression of renal genes in progressive CKD, we performed microarray expression profiling on kidneys derived from 12-week-old Col4a3$^{-/-}$ and WT mice and compared these data with previously published data from Hyp and Fgf23 transgenic mice. Based on a minimum 2-fold change in expression of significantly modified genes, Col4a3$^{-/-}$ mice showed a marked up-regulation of 904 genes and downregulation of 148 transcripts. Up-regulated transcripts included lipocalin2 (+53.8 fold), Timp1 (+23.7), amiloride binding protein 1 (+16.7) and Col1a1 (+13.5). Several protein families were up-regulated including tumor necrosis factor (38 transcripts) and metalloproteinases (20 transcripts for MMPs and ADAMs). Downregulated transcripts included Dnase1 (-8.4 fold), Hbb-b2 (-7.2), Hbb-b1 (-4.6) and Klotho (-2.3). Also, 55 proteins belonging to the solute carrier transporters and 10 members of the cytochrome P450 superfamily were downregulated in Col4a3$^{-/-}$ mice. We identified 30 FGF23-depedent genes in Col4a3$^{-/-}$ mouse kidneys (10 upregulated, including Vcam1 and Ramp2, and 20 downregulated genes, including Dnase1, Klotho and Ace2). Pathway analysis of FGF23-dependent genes identified networks enriched for "Cell Death, Connective Tissue Development" related functions and disease categories such as "Immunological Disease" and "Renal Nephritis", suggesting that FGF23 may be directly involved in the renal disease progression. Although additional analysis of Col4a3$^{-/-}$ mice with an FGF23 endocrine clamp is needed to verify the FGF23-reponsive genes, these data set the stage for identifying specific FGF23-dependent pathways and investigating their role in the development of CKD-MBD.

### The Expression of Glia Maturation Factor-β Promoted Aging Process of the Kidney by the Induction of an Aberrant Form of Lamin A

Masaru Takenaka,[1] Rika Imai,[1] Sungyun Choi,[1] Yoko Yasui,[2] Junichi Hanai.[3] *[1]Kobe Women's University, Kobe, Japan; [2]Osaka University Hospital, Suita, Osaka, Japan; [3]Renal Division & Division of Interdisciplinary Medicine and Biotechnology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.*

Glia Maturation Factor-β (GMF) is induced by proteinurea in the kidney (*KI* 2002) and its expression causes apoptosis in cultured renal proximal cells because of vulnerability to oxidative stress (*J. Biol. Chem.*, 2003). To get insights into this process, transgenic mice expressing GMF (GMF-TG) was constructed, indicating early aging phenotype, similar to those of laminopathies, the premature-aging diseases such as Hutchinson -Gilford progeria syndrome. As a mechanism for this, we identified an excess amount of prelaminA in the kidney, which might be caused through a decrease of cleaving enzyme (Face-1) for this aberrant protein.

C57BL/6 (WT) was used to construct transgenic mice (GMF-TG). After genotyping, we found the followings;. 1) Kaplan-Meier representation of the survival curves demonstrated that GMF-TG died earlier than WT mice. 2) The hair on GMF-TG appeared to be sparser, like alopecia than that of WT. Hair growth declines linearly as aging in mice, which was assessed by hair growth assay (*Nature*, 2002). We measured the amount of hair growth 14-21 days after removal of hair from a dorsal area. Hair regrowth of GMF-TG was decreased significantly at 60 weeks of age compared with that of WT. 3) We also found induction of senescence associated genes, e.g. TGF-β and CTGF, in GMF-TG kidney. 4) Western blot analysis revealed that abnormal form of the nuclear protein lamin A (prelamin A) was expressed in the kidney of GMF-TG, but not in WT. The accumulation of this aberrant form is known to cause laminopathy and this accumulation is also detected in physiological aging (*Science* 2006). 5) The gene expression of Face-1, a zinc-metalloprotease that cleaved prelamin A to lamin A, decreased significantly in the kidney of GMF-TG at 60 weeks comparing to control.

Conclusion: The expression of GMF induced an aberrant form of lamin A, resulting in the promotion of premature aging process of the kidney.

## TH-PO274

### Basic Fibroblast Growth Factor Reduces Renal Damage and Induces Repairing Nephrogenes and Angiogenes in Experimental Chronic Kidney Disease

Sandra Villanueva,[1] Felipe Contreras,[1] Cesar Vergara,[1] Carlos Cespedes,[2] Carlos P. Vio.[2] *[1]Department of Physiology, Universidad de Los Andes, Santiago, Chile; [2]Department of Physiology, Center for Aging and Regeneration, P. Universidad Catolica de Chile, Santiago, Chile.*

Chronic renal failure (CRF) is a clinical syndrome characterized for a progressive and irreversible structural damage of the nephron. Several therapies have been employed to retard the loss of renal function and reduce proteinuria, but have not been successful in limiting the progression of the disease. With the hypotheses that basic Fibroblast Growth Factor (bFGF) is involved in renal tissue repair, our objective was to study the evolution of CRF in animals treated with the repairing factor bFGF, an inductor of nephrogens, thus we expected that the damage induced in CRF could be decreased.

Male Sprague Dowley rats were submitted to nephrectomy 5/6 and were divided in two groups: injected with bFGF 30 mg/Kg or injected with saline that was used as control (Sham rats) (n = 7 per group). After 5 weeks, animals were sacrificed and the kidney was removed. The procedures were performed according with institutional and international standards for care and use of laboratory animals (PHS, NIH). The renal function was assessed by the serum creatinine levels; the morphological damage was evaluated by HE stain and the presence of damage markers ED-1 (macrophages) and interstitial α-SMA. Nephrogenes, angiogenes and transcriptional factors were analyzed by immunohistochemistry, Western blotting and RT-PCR.

Animals injected with bFGF had a significant reduction in serum creatinine levels, as well a reduction in the damage markers ED-1 and α-SMA compared to sham rats ($p<0.05$). Further, the animals injected with bFGF showed an important re-expression of nephrogenes BMP-7, LIM, bFGF, NOGGIN, and WNT-4. Also angiogenic proteins VEFG, TIE-2 and transcriptional factors HIF-1α, SMAD and p-SMAD were induced by bFGF ($p<0.05$).

These results indicate the potential therapeutic effect of bFGF on renal function in CRF by improving renal damage through the re-expression of nephrogenes and angiogenes (Fondecyt 11075029, Fondecyt 1080590, PFB 12-2007).

## TH-PO275

### Cysteamine Ameliorates Progressive Interstitial Fibrosis by Modulating Oxidative Stress and Attenuating Extracellular Matrix Synthesis during Chronic Kidney Injury

Daryl M. Okamura,[1] Nadia Bahrami,[1] Jon A. Gangoiti,[2] Jesus M. Lopez-Guisa,[1] Bruce A. Barshop,[2] Allison A. Eddy.[1] *[1]Center for Tissue and Cell Sciences, Seattle Children's Research Institute, Seattle, WA; [2]University of California San Diego, San Diego, CA.*

Few therapeutic options exist to slow or halt the relentless expansion of interstitial extracellular matrix (ECM) leading to nephron loss and progressive decline of kidney function. Cysteamine treatment has had a tremendous impact on the severity and progression of nephropathic cystinosis, however, the primary renoprotective mechanisms remain poorly understood. The effect of cysteamine on the degree of renal fibrosis was investigated in a model of unilateral ureteral obstruction (UUO) using two doses, 400 and 600 mg/kg/day, and compared to mice that received vehicle alone (n = 8/timepoint: days 3, 7, and 14). Both doses were well-tolerated and measured serum levels of cysteamine were appropriate. Total kidney collagen content was significantly reduced by 21% in both the 400 and 600mg/kg doses in cysteamine-treated mice at day 14. ECM gene transcription levels were significantly down-regulated in UUO kidneys of cysteamine-treated mice: procollagen I mRNA levels were 56% lower in the mice treated with 600 mg/kg at day 14; and at day 7, despite no difference in total collagen, there was a nearly 40% reduction in kidney fibronectin and procollagen III mRNA levels in mice treated with 400mg/kg and a nearly 60% reduction in fibronectin, procollagen I and procollagen III at higher doses of cysteamine (600mg/kg). There was a significant reduction in alpha-SMA positive myofibroblasts by nearly 30% in both doses at day 14 in cysteamine-treated mice. There was a significant reduction in interstitial macrophage infiltration by 34% in mice treated with 600mg/kg. Total kidney thiol content, a measure of antioxidant status, was significantly increased by 36% in high dose cysteamine-treated mice (600mg/kg) compared to controls. Taken together, these data suggest that cysteamine may affect both myofibroblast accumulation and interstitial macrophage infiltration by modulating oxidative stress within the intersitium during chronic kidney injury.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO276**

**Leucine Stimulates mTOR Anabolic Signal Transduction in Muscle of CKD Rats** Sumita Sood,[1,2] Yu Chen,[1,2] Kevin L. Mcintire,[1,2] Ralph Rabkin.[1,2] *[1]Nephrology, Stanford University School of Medicine, Palo Alto, CA; [2]Nephrology, Veterans Affairs Palo Alto Health Care System, Palo Alto, CA.*

There is recent evidence that the branched chain amino acid (BCAA) leucine (LEU), stimulates muscle protein synthesis in part by directly activating the mTOR signaling pathway, with phosphorylation of p70 ribosomal S6 kinase-1 ($p70^{S6K}$), S6 ribosomal protein (rpS6) and eukaryotic factor 4E-binding protein1 (4E-BP1). Since muscle wasting in CKD arises in part due to resistance to insulin/IGF-1 activation of the downstream PI3-kinase/Akt pathway and also low serum and tissue levels of BCAA, we tested whether LEU can effectively activate the mTOR anabolic signaling pathway in uremia. CKD and control (Con) rats were gavaged with LEU (L) or saline (S) and sacrificed 30 mins later. Western blot analysis showed that LEU loading did not affect AKT phosphorylation as anticipated, but did effectively stimulate down-stream phosphorylation of mTOR, $P70^{S6K}$ and rpS6 in both Con and CKD rats (fig 1). Of note, basal levels of phospho-rpS6 were depressed in CKD (saline treated) rats and following LEU gavage increased similarly in CKD and Con rats.

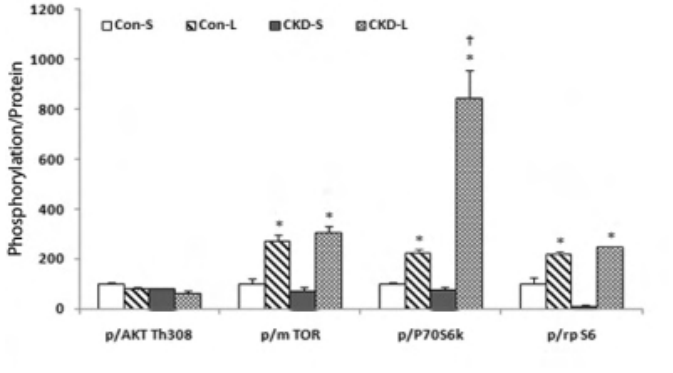

Fig 1. LEU (L) stimulated m TOR anabolic signal transduction down-stream of Akt in skeletal muscle of CKD and control rats. * - p<0.01 vs saline (S); † - p<0.0001 vs Con-L

Thus uremia appears to inhibit distal mTOR activated anabolic signaling, a significant defect that can be overcome by oral administration of LEU. Taken together these findings suggests that LEU supplements maybe of particular value in managing uremic muscle wasting, especially as serum LEU levels are commonly reduced in advanced CKD.

**TH-PO277**

**Fenofibrate Attenuates Proteinuria but Is Not Effective on Metabolic Parameters with Excess Dietary Salt Intake in SHR/NDmcr-cp** Junichi Yatabe,[1,2] Midori Sasaki Yatabe,[2,3] Pedro A. Jose,[4] Hironobu Sanada,[1] Tsuyoshi Watanabe.[2] *[1]Div. of Health Science Research, Fukushima Welfare Federation of Agricultural Cooperatives, Fukushima, Japan; [2]Dept. of Nephrology, Hypertension, Diabetology, Endocrinology and Metabolism, Fukushima Med. Univ., Fukushima, Japan; [3]Dept. of Pharmacology, Fukushima Med. Univ., Fukushima, Japan; [4]Center for Molecular Physiology Research, Children's National Medical Center, Washington, DC.*

While fenofibrate is used widely to manage dyslipidemia, whether its effects are influenced by salt intake has not been elucidated. This study aimed to determine the metabolic and renal effects of fenofibrate in metabolic syndrome model rats, SHR/NDmcr-cp (SHR-cp), on high-salt diet.

SHR-cp at 12 weeks of age (n=5 /group) were fed 0.3 % normal- or 4% high-NaCl chow and given oral fenofibrate (30 mg/kg/day) or vehicle for 4 weeks.

On normal-salt diet, fenofibrate significantly reduced fasting plasma glucose (control vs. fenofibrate; 124±0.4 vs 91±1.0 mg/dl, p<0.05), total cholesterol (131±6.7 vs 91±7.3 mg/dl, p<0.01), and proteinuria (27.3±3.2 vs 13.3±1.9 mg/g.crea, p<0.01) without changing blood pressure. However, with high-salt diet, fenofibrate rather elevated fasting plasma glucose (88.6±2.8 vs 101±4.9 mg/dl, p<0.05), postprandial glucose (176±16 vs 267±9 mg/dl, p<0.05) and plasma insulin (3.4±0.9 vs 5.7±1.9 IU/L, p<0.05). Total cholesterol, triglyceride, LDL cholesterol, free-fatty acid, BNP concentrations, systolic blood pressure and urinary sodium excretion were similar between fenofibrate and control groups on high-salt diet. However, body weight was less in the fenofibrate group (474±6 vs 424±5 g, p<0.01) with similar food intake. Moreover, the fenofibrate group showed significantly less urinary protein excretion (20.9±1.7 vs 15.0±2.2 mg/g.crea, p<0.05), and reduced renal cortical fibronectin protein (100±16.5 vs 35.4±10.8 %, p<0.05).

In conclusion, in SHR-cp on high-salt diet, fenofibrate decreased proteinuria and renal fibronectin expression without improving either glucose or lipid metabolism. The results of this study suggest that fenofibrate may be renoprotective while excess dietary NaCl may abrogate the metabolic benefits of fenofibrate.

**Investigation of Prevalence of Chronic Kidney Disease in 1031 Consecutive Cases with Coronary Angiography** Bi-Cheng Liu, Hong Liu, Kun Ling Ma. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China.*

**Objective** To investigate the prevalence of CKD in patients who had undergone coronary angiography with suspected coronary heart disease (CHD).

**Methods** Coronary angiography was performed in 1031 patients with suspected CHD in ZhongDa Hospital from December 2008 to November 2009. The definition of CKD was based on the estimated Glomercular filtration rate (eGFR) , which was estimated with the Modified Diet in Renal Disease (MDRD) equationand or proteinuria. Luminal narrowing at least one lesion ≥50% in the main branches of coronary artery was considered as CHD.

**Results** The mean age of patients were 64 ± 11 years. There were 543 males and 488 females, including 551 patients with CHD and 134 patients with CKD (13%). Patients with CHD had a significantly higher prevalence of CKD compared with patients without CHD (18.33% vs 6.88%, p < 0.001). With the increasing number of stenosed coronary vessels (n=0, 1, 2, 3), eGFR was declined significantly (84.25±19.00, 81.61±23.92, 75.16±20.99, 73.92±20.66ml/min per 1.73 $m^2$, p<0.001) significantly, and the percentage of proteinuria increased (0.42%, 0.82%, 1.96%, 3.25%; P=0.006), the prevalence of CKD increased accordingly (6.88%, 13.11%, 21.57%, 23.38%; P<0.001). Within the group of CHD patients, logistic regression analysis indicated that age (odds ratio, 1.106; 95% confidence interval, 1.075 to 1.139), hypertension (odds ratio, 2.248; 95% confidence interval, 1.156 to 4.372), systolic insufficiency (odds ratio, 4.541; 95% confidence interval, 2.452 to 8.412) and increasing numbers of stenosed coronary vessels (odds ratio=1.423; 95% confidence interval, 1.100 to 1.840) were the risk factors for the development of CKD.

**Conclusion** This study suggested a higher prevalence of CKD in patients with CHD diagnosed by coronary angiography, and it is closely related with the increasing number of stenosed coronary vessels. Aging, hypertension, low LVEF and elevated numbers of stenosed coronary vessels were important risk factors for angiographic CHD patients with CKD.

**TH-PO279**

**Effect of Nephrotic Syndrome (NS) on Homocysteine (Hcy) Metabolism** Mohammad A. Aminzadeh, Pavan Gollapudi, Nosratola D. Vaziri. *Medicine/ Nephrology, University of California, Irvine, Irvine, CA.*

Proteinuria and hyperhomocysteinemia are independently associated with increased risk of atherosclerosis and cardiovascular disease. The available data on plasma Hcy level in patients with NS are contradictory with increased, decreased and unchanged values reported by different investigators. The reason for the disparity among the reported studies is unknown and could be due to differences in severity of hypoalbuminemia, concomitant renal insufficiency or underlying systemic diseases among others. In this study we explored the effect of NS on plasma Hcy concentration, urinary Hcy excretion and hepatic expression of methylenetetrahydrofolate reductase (MTHFR) and cystathionine-β-synthase (CBS), the key enzymes in trans-methylation and trans-sulfuration of Hcy respectively. Sprague-Dawley rats were rendered nephrotic by IP injection of puromycin aminonucleoside. Compared to placebo-injected controls the nephrotic rats showed heavy proteinuria (691±70 vs. 56±6 mg/24hr, P=0.003), hypoalbuminemia (1.8±0.1 vs. 3.3±0.1 g/dl, P<0.001), hypercholesterolemia (496±28 vs. 95±8 mg/dl, P<0.001), normal plasma creatinine (0.74±0.08 vs. 0.75±0.04 mg/dl) and creatinine clearance (1.36±0.2 vs. 1.4±0.02 ml/min), reduced plasma Hcy (3.0±0.3 vs. 5.6±0.8 µmol/L, P<0.03), increased urinary Hcy (3.4±0.2 vs. 9.6±0.2 µmol/24 hr, P<0.03 ) and down-regulation of CBS but not MTHFR expression. Plasma Hcy correlated directly with plasma albumin (r =0.77, P=0.009) and inversely with proteinuria (r =-0.78, P=0.02) and urinary Hcy correlated directly with proteinuria (r =0.98, P<0.001). Thus heavy proteinuria results in significant reduction in plasma total Hcy concentration which is due to diminished protein-bound fraction as opposed to its biologically-active free fraction. Increased urinary Hcy is, in part, due to the loss of albumin which is a major Hcy-binding protein and increased Hcy pool occasioned by its reduced CBS-catalyzed trans-sulfuration.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO280**

**Renin-Angiotensin-Dependent and -Independent Antihypertensive Therapies Exhibit Similar Degrees of Cardio- and Renoprotection in 5/6-Nephectomized Ren-2 Transgenic Rats** Ludek Cervenka. *Department of Experimental Medicine, Institute for Clinical and Experimental Medicine, Prague, Czech Republic.*

Hypertension plays a critical role in the progression of chronic kidney disease (CKD) to end-stage renal disease (ESRD) and it has been postulated that antihypertensive drugs which block the renin-angiotensin system (RAS) exhibit class-specific renoprotective actions beyond their blood pressure (BP)-lowering effects. Since this notion has been recently questioned, the present study was performed to compare the effects of a RAS-dependent antihypertensive therapy, a combination of the angiotensin-converting enzyme inhibitor (ACEI) trandolapril and the angiotensin II (ANG II) receptor subtype 1A receptor antagonist losartan with a RAS-dependent antihypertensive therapy, a combination of the alfa- and beta-adrenoreceptor antagonist labetalol with the diuretics hydrochlorothiazide and furosemide, on the progression of CKD after 5/6 renal ablation (5/6 NX) in Ren-2 renin transgenic rats (TGR), a model of ANG II-dependent hypertension. Normotensive transgene-negative Hannover Sprague-Dawley (HanSD) rats with 5/6 NX served as controls.

The RAS-dependent and -independent antihypertensive therapies normalized BP and survival rate and prevented the development of cardiac hypertrophy and glomerulosclerosis to the same degree in 5/6 NX HanSD rats as in 5/6 NX TGR. Our findings indicate that the renoprotection, at least in rats after 5/6 NX animals, is predominantly BP-dependent. When equal BP-lowering effects leading to normotension were achieved the cardio- and renoprotective effects were equivalent independently of the type of antihypertensive therapy. This information derived from our present study should be considered in attempts for developing new therapeutical approaches and strategies to prevent the progression of CKD and lower the incidence of ESRD.

**New Biomarkers of CKD Progression Discovered with a Multiplexed Aptamer Proteomic Technology** Roxana M. Bologa,[1] Daniel Levine,[1] Thomas Parker,[1] Trudi Foreman,[2] Nebojsa Janjic,[2] Robert E. Mehler,[2] Alex Stewart,[2] Jeffrey J. Walker.[2] *[1]The Rogosin Institute and Weil Cornell Medical College, New York, NY; [2]SomaLogic, Boulder, CO.*

The progressive loss of renal clearance that occurs in chronic kidney disease (CKD) is expected to be accompanied with an overall increase in plasma concentration of small proteins. We have tested this hypothesis using a highly multiplexed, aptamer-based proteomics array technology that simultaneously measures large numbers of proteins ranging from very low (0.1pg/mL) to high (50mg/mL) abundance in plasma. Plasma, obtained from 11 subjects with early- (stages 1-2) and 31 with late-stage CKD (stages 3-5), was used to measure 614 human proteins simultaneously in a 15uL volume. We identified 60 proteins that varied significantly between the two groups, using the Mann-Whitney test statistic, with a q-value (FDR-corrected p-value) of 4.2 x 10-4. Cystatin C and β2-microglobulin, which are important known biomarkers of CKD, were found, but many of the remaining 58 proteins are newly discovered biomarkers of declining renal function. Nine of the 11 proteins with the most significant variation (q-values <3.5 x 10-7) are relatively small proteins (MW <25 kDa) with an inverse correlation between abundance and renal clearance: β2-Microglobulin (11.7kDa), Folistatin-like-3 (FSTL3, 25.0kDa), Pleotrophin (15.3kDa), TNF sR-I (extracellular domain, 21.2kDa), Complement Factor D (24.4kDa), IL-15 Rα (extracellular domain, 18.4 kDa), Matrilysin (19.1kDa), Cystatin C (13.3kDa), C-C motif chemokine 14 (HCC-1 small isoform, 8.7kDa), Coiled-coil domain containing 80 (Ccdc80 or URB small isoform 10.3kDa).

Accumulation in plasma of small proteins appears to be a major change in the plasma proteome in CKD. However, the fact that the biomarkers are not simply ranked according to their molecular weights shows that renal tissue injury and secondary systemic effects resulting from reduced renal function clearly also affect the proteome. This example demonstrates that we can recover known biomarkers and discover new biomarkers that can be used to build diagnostic signatures for measuring CKD progression.

**A Comparison of Comorbidity in CKD Patients Based on MDRD vs. CKD-EPI Equations** David T. Gilbertson,[1] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

Estimation of GFR is most commonly done using the MDRD equation published in 2006. Inaccuracies using this equation, particularly in pts with mild CKD, led to the search for better equations such as the CKD-EPI equation published in 2009. Estimation using this equation, which was developed on pts across wide ranges of GFR, better estimates actual GFR in patients with GFR > 60 mL/min/1.73 m2.

Using i3 Ingenix data on individuals with coverage in 2008 with ≥ 1 serum creatinine, we computed eGFR using both equations and compared comorbidity burdens across CKD stages, particularly for pts classified differentially. For pts with > 1 creatinine, we used the average. Since ACR data was mostly unavailable, we compared the following categories/ CKD stages: >=90, 60-90 (mL/min/1.73 m2), stage 3, 4 or 5.

We identified 786,348 persons with continuous insurance coverage and ≥ 1 serum creatinine during 2008. 49.7%, 45.4%, and 4.6% were identified as >=90, 60-90, and stage 3, respectively, by CKD-EPI. 28.3%, 63.2%, and 8.1% were similarly classified by MDRD. The table shows the comorbidity burden for those classified the same by both equations compared to those differentially classified by the 2 equations. For pts classified as lower eGFR by MDRD than CKD-EPI (lower half of table), the comorbidity burden was generally similar to the comorbidity burden of the higher eGFR group (top half of table). These results are consistent with other studies showing more accurate estimation of actual GFR with the CKD-EPI equation for pts with less severe CKD.

| | | **Comorbidity Burden of Patients Classified the Same by Both Equations** | | | | |
|---|---|---|---|---|---|---|
| **MDRD & CKD-EPI Agree** | | ASHD | Anemia | CHF | Cancer | DM |
| >= 90 | | 2.7% | 5.5% | 0.7% | 3.2% | 12.3% |
| 60 - 90 | | 5.7% | 4.6% | 1.3% | 4.8% | 13.1% |
| Stage 3 | | 13.4% | 11.6% | 5.7% | 8.5% | 28.9% |
| Stage 4 | | 21.4% | 48.5% | 17.9% | 9.3% | 49.9% |
| | | | | | | |
| **MDRD & CKD-EPI Disagree** | | **Comorbidity Burden of Patients Classified with Higher eGFR by CKD-EPI** | | | | |
| MDRD | CKD-EPI | ASHD | Anemia | CHF | Cancer | DM |
| 60 - 90 | >= 90 | 2.8% | 4.6% | 0.6% | 3.2% | 10.2% |

**Implications of the CKD-EPI GFR Estimation Equation in a Health Care System** Sankar D. Navaneethan,[1] Jesse D. Schold,[2] Stacey Jolly,[3] Susana Arrigain,[2] Welf Saupe,[4] John W. Sharp,[2] Emilio D. Poggio,[1] James F. Simon,[1] Martin J. Schreiber,[1] Anil K. Jain,[3,4] Joseph V. Nally.[1] *[1]Nephrology & Hypertension, Cleveland Clinic; [2]Quantitative Health Sciences, Cleveland Clinic; [3]Medicine Institute, Cleveland Clinic; [4]eCleveland Clinic eResearch, Cleveland Clinic.*

***Purpose:*** Chronic kidney disease (CKD) is a significant public health problem whose diagnosis and staging relies upon equations to estimate glomerular filtration rate (GFR), including the new CKD-EPI equation. CKD-EPI demonstrated superior performance compared to the existing MDRD equation during development and validation, but has not been applied to a population within a healthcare system.

***Methods:*** We identified 53,759 CKD patients based on either the MDRD or CKD-EPI equations using two eGFR measures <60 mL/min/1.73 m² greater than 90 days apart from an outpatient setting. We compared the prevalence, patient characteristics and time to inclusion using the two equations.

***Results:*** Prevalence of CKD decreased 10% based on the CKD-EPI equation. This change varied substantially by patient characteristics with a 35% decrease among patients <60 years and 10% increase among patients over 90 years. Females and non-African Americans had a greater decline in CKD identification.

| Patient Characteristics (n=53,759) | Method of CKD Classification | | | % Change in CKD patients based on the CKD-EPI Equation |
|---|---|---|---|---|
| | Both MDRD and CKD-EPI equations | MDRD equation only | CKD-EPI equation only | |
| Age 18-59 (n=33413) | 65% | 35% | 0% | -35% |
| Age 60-69 (n=12301) | 89% | 11% | 0% | -11% |
| Age 70-79 (n=5986) | 96% | 4% | 1% | -3% |
| Age 80-89 (n=2033) | 90% | 0% | 9% | 9% |
| Age 90+ (n=1726) | 91% | 0% | 9% | 10% |
| African American (n=6251) | 93% | 2% | 5% | 2% |
| Non-African American (n=47508) | 87% | 12% | 1% | -11% |
| Diabetes present (n=11004) | 91% | 7% | 1% | -6% |
| Diabetes absent (n=42755) | 86% | 12% | 2% | -11% |
| Male gender (n=23779) | 89% | 9% | 2% | -7% |
| Female gender (n=29980) | 86% | 13% | 1% | -12% |
| BMI < 20 kg/m² (n=1813) | 88% | 9% | 3% | -6% |
| BMI 20-24 kg/m² (n=13052) | 87% | 10% | 2% | -8% |
| BMI 25-29 kg/m² (n=17719) | 88% | 10% | 2% | -8% |
| BMI 30-34 kg/m²(n=10858) | 87% | 12% | 1% | -11% |
| BMI 35+ kg/m² (n=8133) | 85% | 13% | 1% | -14% |
| Overall – n (%) | 46985 (87%) | 3951 (13%) | 823 (2%) | 10% |

Adjusted for other characteristics, patients aged >70 had over two-fold hazard for time to inclusion in the registry with CKD-EPI relative to patients <60 (AHR=2.17, 95% C.I.2.11-2.23) as compared to a reduced hazard with MDRD (AHR=0.90, 95% C.I.0.88-0.93).

***Conclusions:*** Application of CKD-EPI equation resulted in a substantial decline in equation-based inclusion of CKD patients in our health care system. Further research is needed to determine whether widespread use of CKD-EPI based on current CKD classification guidelines could lead to delayed needed care among younger patients or excessive referrals among older patients.

**TH-PO284**

**Predicting ESRD and CVD Risk Using GFR Estimated by the CKD-EPI and MDRD Equations: Strong Heart Study (SHS)** Nawar M. Shara,[1,2] Hong Wang,[1] Elizabeth A. Carter,[1] Mihriye Mete,[1] Yaman Rai Balha,[1,3] Barbara V. Howard,[1,2] Jason G. Umans.[1,2] *[1]Biostatistics, MedStar Health Research Institute, Hyattsville, MD; [2]Georgetown University, Washington, DC; [3]School of Medicine, Damascus University, Syrian Arab Republic.*

**Background:** Estimated glomerular filtration rate (eGFR) is the best available kidney function measure. The CKD-EPI collaboration has published a new equation to improve GFR estimates. Whether the new equation is better than the MDRD equation in predicting ESRD and CVD in populations with diabetes and obesity has not been studied. **Methods:** We analyzed data from the SHS, a longitudinal study of CVD risk in 4549 American Indians ages 45-74y. We excluded those with missing serum creatinine (n=173); with ESRD (n=21) or with CVD (n=331), leaving 4024participants (40% male) for this analysis. ESRD was defined as eGFR<15 or incident kidney transplant or dialysis. Of the 4024 participants, 156 had incident ESRD during subsequent SHS phases, while 1249 had incident CVD during a 15-y median follow-up. Logistic regression models and Cox proportional hazards models, adjusted for age, gender, LDL-C, HDL-C, hypertension (yes/no), smoking (never, past, or current smoker), and albuminuria, were used to assess the association of baseline $eGFR_{MDRD}$ or $eGFR_{CKD-EPI}$ with subsequent ESRD or CVD seperately. We categorized eGFR measures into groups as follows: [120-90), [90-60), [60-30], and < 30 mL/min/1.73 m². **Results:** Risk, assessed by either eGFR measure was similar in models predicting ESRD

and CVD separately. Adjusted ORs for ESRD were identical using either eGFR measure for models with or without adjustment for albuminuria. HRs for CVD were also identical using either eGFR measure in models with or without adjustment for albuminuria. Harrell's C were identical for models including either eGFR measure. No substantial reclassification to different eGFR strata (NRI=0.01, p=0.2) was observed. **Conclusions:** In an American Indian population with a high prevalence of diabetes, $eGFR_{MDRD}$ or $eGFR_{CKD\text{-}EPI}$ was equally predictive of ESRD or CVD and provided similar discriminatory power, suggesting that eGFR as calculated by either equation may be used in risk stratification.

### TH-PO285

**Modification of the CKD-EPI Equation for Japanese: Accuracy and Use for Population Estimates** Masaru Horio,[1] Enyu Imai,[2] Yoshinari Yasuda,[2] Tsuyoshi Watanabe,[3] Seiichi Matsuo.[2] *[1]Functional Diagnostic Science, Osaka University Graduate School of Medicine, Osaka, Japan; [2]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]Third Department of Medicine, Fukushima Medical University, Fukushima, Japan.*

**Background:** We previously reported a Japanese-GFR equation and a coefficient-modified MDRD Study equation for use in Japan. Recently, the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) developed a new equation, the CKD-EPI equation, that is more accurate than the MDRD Study equation and yields a lower prevalence of CKD in the US than the MDRD Study equation. We modified the CKD-EPI equation and evaluated its accuracy. We compared the prevalence of CKD in Japan using the equations. **Subjects**: We used same data set from which the coefficient of MDRD Study equation was obtained. Total 763 Japanese patients (413 for development and 350 for validation) were included. GFR were measured by inulin renal clearance. Prevalence estimates were based on 574,024 participants from the annual health check program. **Results:** The Japanese coefficient of CKD-EPI equation was 0.813 (95% CI: 0.794 - 0.833). In validation dataset, bias (measured minus estimated GFR, SD) of the coefficient-modified CKD-EPI equation, the coefficient-modified MDRD Study equation and the Japanese-GFR equation was 0.4±17.8, 1.3 ±19.8 and 2.1±19.0 ml/min/1.73 m², respectively. The coefficient-modified CKD-EPI equation performed significantly better than the coefficient-modified MDRD Study equation overall and for subjects with mGFR≥60 ml/min/1.73 m². The modified CKD-EPI equation also performed significantly better than the Japanese GFR equation for subjects with mGFR≥60 ml/min/1.73 m², although the Japanese GFR equation was better for subjects with mGFR< 60 ml/min/1.73 m². Modified CKD-EPI equation yields a lower estimated prevalence of CKD than the MDRD Study equation (7.9% vs. 10.0%), primarily because of a lower estimated prevalence of stage 3 (5.2% vs. 7.5%). **Conclusion:** The coefficient modified CKD-EPI equation is more accurate than the coefficient modified MDRD Study equation for Japanese and leads to a lower estimated prevalence of CKD in Japan.

### TH-PO286

**Does Use of eGFR in Donor Screening Unnecessary Reduce the Donor Pool? Long Term Follow-Up of Donors with Pre-Donation eGFR<80** H. Tent, Mieneke Rook, Jaap Homan vd Heide, Gerjan Navis. *Internal Medicine Division of Nephrology, University Medical Center Groningen, Netherlands.*

Due to low costs and easy use, many centers rely on estimated GFR (eGFR) for initial living donor screening, with a cut-off of <80 mL/min/1.73m². Since eGFR tends to be imprecise and underestimates true measured GFR (mGFR) this may lead to unnecessary rejection of potential donors. Here we evaluate follow-up of donors with pre-donation eGFR<80 mL/min/1.73m².

Evaluated were 81 donors (38% male, mean age at follow-up 52±11) who donated at our center. Screening and follow-up were performed by mGFR ($^{125}$I-Iothalamate), 4 months prior and 2 months and 5.1±1.3 years post-donation. MDRD and CKD-EPI were determined from creatinine samples from the same days. Furthermore, a cohort of 291 living kidney donors (44% male, mean age 49±11) of whom only short term follow-up was available yet was analyzed.

Pre-donation mGFR, MDRD and CKD-EPI were 104±15, 83±18 and 88±14 mL/min/1.73m². 43 donors had pre-donation MDRD<80, 26 CKD-EPI<80 mL/min/1.73m². Renal function data is shown in the table. Long term mGFR of donors with pre-donation MDRD and CKD-EPI>80 was 77±11 and 75±11 mL/min/1.73m² respectively (both p<0.01 vs pre-donation value<80). In the larger group eGFR underestimated in similar extent: 170 donors had pre-donation MDRD<80, 96 CKD-EPI<80 mL/min/1.73m². In both groups, donors with eGFR<80 were older than those with eGFR>80 mL/min/1.73m².

Thus, both MDRD and CKD-EPI underestimate mGFR at screening which could potentially lead to rejection of a large proportion of potential donors (56% for MDRD and 33% for CKD-EPI). On follow-up, donors with pre-donation MDRD and CKD-EPI<80 had lower mGFR than donors with pre-donation value>80 mL/min/1.73m², mGFR was however stable and sufficient. To optimize the donor pool, we argue the use of more reliable methods for screening along with long term follow-up to ensure donor safety.

| | MDRD<80 | CKD-EPI<80 |
|---|---|---|
| Pre-Unx mGFR | 99±14 | 97±15 |
| Early post-Unx mGFR | 62±9 | 61±10 |
| Long term post-Unx mGFR | 68±9 | 67±9 |
| Pre-Unx eGFR | 70±6 | 74±5 |
| Early post-Unx eGFR | 46± | 48±6 |
| Long term post-Unx eGFR | 49±7 | 52±7 |

Unx: donation; mGFR and eGFR in mL/min/1.73m²

**Internal Standardization of Cystatin C Measurements in the Chronic Renal Insufficiency Cohort (CRIC) Study** Amanda Hyre Anderson, Dawei Xie, Kelvin Tao, J. Richard Landis, Daniel J. Rader, Harold I. Feldman. *University of Pennsylvania School of Medicine.*

One major limitation of widespread use of cystatin C to estimate GFR is the lack of standardization of laboratory procedures and assays. Owing to this fact, the International Federation of Clinical Chemistry and Laboratory Medicine working group for the standardization of cystatin C is working to disseminate secondary reference preparations of cystatin C. The NIDDK-sponsored Chronic Renal Insufficiency Cohort (CRIC) Study will track changes in kidney function over time among 3,939 participants, in part, by measuring cystatin C using the Siemens Diagnostics nephelometric assay at all study visits. All assays will be performed at the study's central biochemistry laboratory located at the University of Pennsylvania. To monitor for any drift in the Siemens cystatin C assay across testing batches in CRIC, a set of control specimens have been run repeatedly. In 2009, quality control checks identified a downward drift in cystatin C values of 19% over 1.5 years in these control samples (Table). This drift was verified at the central biochemistry laboratory for several large NHLBI studies. Potential sources of the assay drift were investigated across a range of cystatin C values from approximately 0.5-6.0 mg/L, and CRIC Investigators observed varied performance of the assay across reagent and calibrator lots. Cystatin C values were corrected to a specific Siemens reagent and calibrator lot combination using data from a subset of retested specimens and linear regression models to ensure longitudinal measures would not be confounded by downward assay drift. With the future achievement of international standardization of cystatin C, these corrected values will be able to be calibrated to gold standard materials ensuring the comparability of CRIC Study results to external groups.

Table. Mean uncorrected and corrected cystatin C values in N=30 control samples in the CRIC Study

| Calibrator lot | Reagent lot | Uncorrected mean cystatin C | Corrected mean cystatin C |
|---|---|---|---|
| 44 | 34 | 0.77 | 0.68 |
| 45 | 35 | 0.70 | 0.70 |
| 48 | 39 | 0.65 | 0.72 |
| 49 | 40 | 0.62 | 0.68 |
| 50 | 41 | 0.70 | 0.70 |

Disclosure of Financial Relationships: nothing to disclose

### TH-PO288

**Cystatin C Assay Calibration: An Important Determinant of Cystatin C Concentrations and GFR Estimation** Christine A. White,[1] Andrew D. Rule,[2] Ayub Akbari,[3] John C. Lieske,[2] Greg A. Knoll.[3] *[1]Dept. of Internal Medicine, Queen's University, Kingston, ON, Canada; [2]Division of Nephrology, Mayo Clinic, Rochester, NY; [3]Division of Nephrology, University of Ottawa, Ottawa, ON, Canada.*

Cystatin C has emerged as a promising new marker of glomerular filtration rate (GFR) and several prediction equations have been derived to estimate GFR from its serum concentration. Marked heterogeneity in the performance of these novel equations in similar populations exist even when the same methodology and reagents from the same manufacturer are utilized. This study was designed to examine differences in cystatin C assay calibration and its effect on GFR estimation using the common PENIA assay (Siemens). Cystatin C was measured in 97 split samples of frozen serum in the laboratories of the Mayo Clinic and of the Children's Hospital of Eastern Ontario (CHEO). GFR was estimated by the Mayo equation using cystatin C measured in both laboratories. The analysis was repeated after stratifying patients by cystatin C values greater than (n=45) and lesser than or equal to (n=52) the median Ottawa cystatin C value of 1.33 mg/L. For the whole cohort, the mean Ottawa cystatin C was 0.19 ± 0.32 mg/dL lower than the mean Mayo cystatin C (p<0.0001). For those with a cystatin C >1.33 mg/dL and cystatin C ≤ 1.33 mg/dL, the mean CHEO cystatin C value was 0.22 ± 0.38 mg/dL and 0.16 ± 0.23 mg/dL lower than the mean Mayo cystatin C value respectively (p<0.0001 for both). The results of the estimated GFRs using the 2 cystatin C assays are shown below.

| | eGFR (Mayo) ± SD (ml/min/1.73m²) | eGFR (CHEO) ± SD (ml/min/1.73m²) | Mean difference eGFR (CHEO) - eGFR (Mayo) ± SD (ml/min/1.73m²) |
|---|---|---|---|
| whole cohort (n=97) | 52.1 ± 22.1 | 60.5 ± 26.5 | * 8.4 ± 14.9* |
| Cystatin C ≤ 1,33 mg/L (n=52) | 67.2 ± 18.5 | 78.9 ± 22.3 | *11.7 ± 18.8 |
| Cystatin C > 1.33 mg/L (n=45) | 34.6 ± 9.1 | 39.3 ± 9.8 | *4.6 ± 6.7 |

*p<<0.0001

Significant differences in GFR estimation result from differences in assay calibration and this is more pronounced at higher GFRs. Cystatin C assay standardization should be a priority as this novel analyte becomes increasingly utilized.

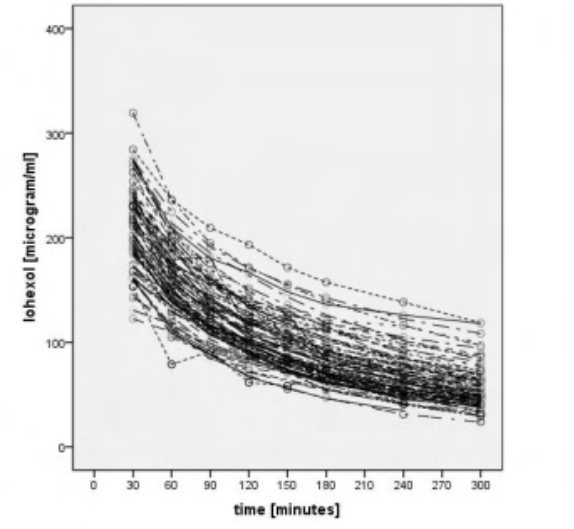
Disclosure of Financial Relationships: nothing to disclose

**TH-PO289**

**Iohexol Clearance Measurement in the Elderly – What Is the Better Protocol?** Natalie R. Ebert,[1] Peter Martus,[1] Jens Gaedeke,[1] Martin K. Kuhlmann,[4] Markus van der Giet,[1] Elke Schaeffner.[1] *[1]Nephrology, Charité, Berlin, Germany; [2]Nephrology, Klinikum im Friedrichshain, Berlin, Germany.*

Above the age of 70 no GFR formula has been validated. To construct a future estimation equation for the elderly we measured as goldstandard plasma clearance of iohexol which is known to be a safe and precise method. To find the ideal sampling protocol we compared several measurement points within the pilot of the *Berlin Initiative Study*.

Iohexol was measured every 30 min. with 8 measurements (30-300 min.). The analysis compares 4 (60, 120, 180, 240) vs. 8 measurement points (add. 30, 90, 150, 300). A half logarithmic linear model was applied in each of these analyses to the last three observations; slopes and correlation coefficients were compared and correlated to age, weight, height, BMI, and serum creatinine.



From 71 subjects one had to be excluded due to low correlations. 46 male (median 77ys, range 70-96) and 24 female (77 ys, 71-88) subjects entered the analysis. Creatinine (1.06±0.36 vs. 0.81±0.29, p = 0.004) was significantly different between males and females. The regression slope was –0.0042±0.0010 for 4 measurement points and –0.0036±0.0010 for 8 measurement points ($p<0.001$) with a non-significant steeper slope for females for each method of analysis ($p<0.15$). The slopes were highly correlated (r=0.825) and the linear fit was better for 8 (r=-0.995) compared to 4 measurements (r=-0.992, p =0.063 Wilcoxon signed rank test). Correlations of regression slope with creatinine and weight were higher for 4 (r=0.73, r=0.30) vs. 8 measurements (r=0.63, r = 0.23). Correlation to age and height was higher for 8 (r = 0.44, r= 0.25) vs. 4 measurement points r=0.35, r=0.18). BMI was not correlated with the slope parameters.

Measurements with 8 data points are feasible in the elderly. The later measurement points seem to be more adequate to determine a constant filtration rate.

**Accurate Prediction of True Glomerular Filtration Rate (GFR) by Both Immediate Post-Angiography Iodixanol Clearance, and Pre-Angiography Estimated GFR** Susie L. Hu,[1] Fatemeh Akhlaghi,[2] Shripad D. Chitnis,[2] Ritche C. Chiu,[3] Subil C. Go,[4] Preeti Rout,[5] Michael Steffes,[6] J. Dawn Abbott,[7] Lance D. Dworkin,[1] Andrew G. Bostom.[1] *[1]Div of Kidney Dis & HTN, Brown University, Providence, RI; [2]Biomed & Pharmaceutical Sciences, University of Rhode Island, Kingston, RI; [3]Nephrology Assoc of SW Ohio Inc, Cincinnati, OH; [4]N Valley Nephrology, Yuba City, CA; [5]Div of Nephrology, BI Deac Medical Center, Boston, MA; [6]Laboratory Medicine & Pathology, University of MN, Minneapolis, MN; [7]Div of Cardiology, Brown University, Providence, RI.*

**Introduction:** Creatinine-based GFR formulas may be inaccurate due to wide variability of creatinine among patients with relatively preserved GFR. GFR measurement by iodinated contrast media elimination at routine angiography (angiography GFR) has been internally validated. We evaluated whether the angiography GFR more accurately reflects true GFR compared to estimation equations on a day-to-day basis.

**Methods and Results:** Eighteen subjects had determination of **1)** GFR by iodixanol clearance at routine coronary angiography, and **2)** estimated GFR (eGFR) using pre-angiography creatinine. They were validated against an outpatient standard GFR measurement (with 5-ml intravenous iodixanol bolus) performed at a 2-week interval. Patients were selected from 4 GFR categories (30 to >75 ml/min/1.73m$^2$). Subjects with acute kidney injury were excluded. Precision of the measured angiography GFR with respect to the standard measurement of GFR was high with $R^2$ of 0.78 (R=0.88). $R^2$ of eGFR by the CKD-EPI (Chronic Kidney Disease Epidemiology Collaboration) equation using pre-catheterization creatinine levels was also 0.78. Precision by mean coefficient of variation was 13 and 12% respectively. Both methods of GFR determination had good accuracy with 83% of values ranging within 30% of the standard GFR, and 94% within 50% of the standard GFR.

**Conclusions:** GFR measurements using iodixanol elimination at routine coronary angiography and estimation equations using pre-catheterization creatinine are precise and accurate on a day-to-day basis. GFR measurement during routine angiography does not appear to be better than GFR determination with estimation equations.

**TH-PO291**

**Estimation of GFR from Cystatin C and Creatinine in the General Population – Results from the Renal Iohexol-Clearance Survey in Tromsø 6 (RENIS-T6)** Bjorn Odvar Eriksen,[1,2] Ulla Dorte Mathisen,[1,2] Toralf Melsom,[1,2] Marit D. Solbu,[2] Trond G. Jenssen.[1,3] *[1]Institute of Clinical Medicine, University of Tromsø, Tromsø, Norway; [2]Section of Nephrology, Clinic of Internal Medicine, University Hospital of North Norway, Tromsø, Norway; [3]Section of Nephrology, Department of Internal Medicine, Oslo University Hospital, Oslo, Norway.*

**Background** Although GFR estimated from cystatin C alone ($eGFR_{CYS}$) or combined with creatinine ($eGFR_{CYS\&CRE}$) predict cardiovascular mortality better than estimates from creatinine ($eGFR_{CRE}$), there is no evidence that existing cystatin C-based equations estimate GFR better than $eGFR_{CRE}$ in the general population. However, these equations were developed in patients with kidney disease. We studied the fit of regression models in the middle-aged general population to explore whether cystatin C can improve estimation of GFR.

**Method** A representative sample of 1593 persons (50 to 62 years) from the general population without diabetes, cardiovascular or kidney disease was studied with iohexol-clearance, enzymatically measured creatinine, and a turbidimetric cystatin C immunoassay. Non-linear methods were used to regress GFR on age, sex, height, weight, cystatin C and/or creatinine. Fit was measured as $R^2$ and root mean square error (RMSE) on the log-scale. The CKD-EPI equation is included for comparison.

**Results**

**Fit of models**

| Dependent variable | Independent variables | RMSE(95% CI) | | $R^2$(95% CI) | |
|---|---|---|---|---|---|
| Log(GFR) | Sex, log(age), log(creatinine) | 0.112 | 0.108, 0.116 | 0.387 | 0.349, 0.424 |
| Log(GFR) | Sex, log(age), log(cystatin C) | 0.114 | 0.110, 0.118 | 0.369 | 0.332, 0.406 |
| Log(GFR) | Sex, log(age), log(cystatin C), log(creatinine) | 0.103 | 0.099, 0.107 | 0.481 | 0.446, 0.516 |
| GFR* | Sex, height, weight, age, log(creatinine), cystatin C | 0.102 | 0.098, 0.106 | 0.494 | 0.458, 0.527 |
| CKD-EPI* | | 0.122 | 0.118, 0.126 | 0.296 | 0.259, 0.332 |

*fit measured on log-scale

**Conclusion** The fit of $eGFR_{CYS\&CRE}$ was superior to both $eGFR_{CYS}$ and $eGFR_{CRE}$. In the general population, equations combining both cystatin C and creatinine may improve GFR estimation.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO292**

**The Discrepancy between Two Reference GFR Measurements: Plasma Clearance of $^{99m}$Tc-DTPA Used in China and a Modified Renal Clearance of Insulin Used in Japan** Li Zuo, Shanshan Dai. *Renal Division, Peking University First Hospital, China.*

**Background and objective:**Racial coefficient added to the original Modification of Diet in Renal Disease (MDRD) equation by Chinese and Japanese study was 1.233 and 0.81, respectively. Our hypothesis is that different reference GFR methods may contribute to such a big racial coefficients difference. In this study,dual plasma sampling $^{99m}$Tc-DTPA plasma clearance (CL_DTPA)used in Chinese study and modified inulin renal clearance(CL_IN) used in Japan were compared.

**Methods:**Plasma clearance of $^{99m}$Tc-DTPA and a modified renal clearance of inulin were performed simultaneously on each subject according to the original Chinese and Japanese study protocol,a single dose of 37MBq $^{99m}$Tc-DTPA was bolus injected in the forearm and inulin solution was continuously administrated intravenously after oral hydration.Blood drawing,urine collection and GFR calculation were performed according to the original studies.Paired t test, correlation analyze and Bland-Altman plot were used to compare the discrepancy of two methods.

**Results:**Thirty-nine CKD patients and 2 healthy volunteers were enrolled (15 females),the average age was 42.59±11.88 years.There was a significant difference between CL_DTPA and CL_IN by paired t-test ($p < 0.01$).The mean CL_DTPA was 53.18±29.98ml/min/1.73m$^2$,CL_IN was 40.17±25.50ml/min/1.73m$^2$.All CL_DTPA correlated well with CL_IN, and spearman correlate coefficient r was 0.976 ($p < 0.01$).The discrepancy between two reference GFR methods was shown in Figure 1,mean difference between CL_DTPA and CL_IN was 13.00±7.63ml/min/1.73m$^2$,CL_DTPA exceed CL_IN by 10.60 to 15.41ml/min/1.73m$^2$ ($p<0.01$).

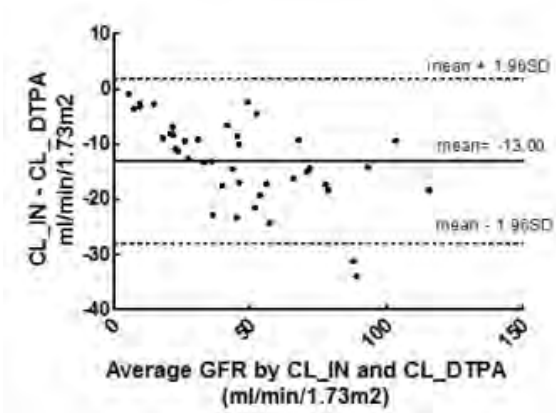

Figure 1 Bland-Altman plot of the CL-DTPA and CL-IN

**Conclusions:** Plasma clearance of $^{99m}$Tc-DTPA used in Chinese study was systemically higher than the modified inulin renal clearance used in Japanese study.This could partly explain why Chinese study got a higher racial coefficient.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO293

**Variation in the $^{125}$-I Iothalamate Glomerular Filtration Rate (GFR) Procedure in the Chronic Renal Insufficiency Cohort (CRIC) Study** Amanda Hyre Anderson, Wei Yang, J. Richard Landis, Dawei Xie, Valerie L. Teal, Harold I. Feldman. *University of Pennsylvania School of Medicine.*

In an effort to develop a more accurate GFR estimating equation for use in the NIDDK-sponsored Chronic Renal Insufficiency Cohort (CRIC) Study, approximately one-third of the cohort (i.e., the subcohort) was selected to have GFR measured using $^{125}$-I iothalamate clearance testing (iGFR). As part of the test, plasma and urine were collected during four 30-minute clearance periods after an initial equilibration period of 60 to 90 minutes. Period-specific iGFR was monitored to detect any systematic or large differences across testing periods as a quality control procedure given the stability of true GFR over the brief testing interval of 3 to 3.5 hours. Among subcohort members with four testing periods (N=1288; Table), iGFR was higher during the first period compared to the time-weighted average of periods 2 through 4 (delta = 3.97 mL/min/1.73m²; p-value = <0.001). Comparisons of time-weighted average iGFRs from all periods and from periods 2 through 4 revealed a mean (SD) difference of 1.15 (4.43) mL/min/1.73m². After developing two CRIC GFR estimating equations using; 1) data from all periods, and 2) data from all but the first testing period, a similar difference (SD) in estimated GFR of 1.11 (1.09) mL/min/1.73m² was observed. Using linear regression methods, several technical aspects of the iGFR test including time between saturated solution of potassium iodine administration and Glofil injection, time between Glofil injection and initiation of Period 1, and the discard urine volume were significant predictors of differences between average iGFRs before and after the exclusion of the first period. Exclusion of the first iGFR testing period provides an estimate of GFR that appears to more closely reflect true GFR within CRIC subcohort members.

Table. Description of iGFR testing periods for CRIC subcohort members (N=1288)

| | Period 1 | Period 2 | Period 3 | Period 4 | Overall time-weighted mean iGFR (Periods 1-4) | Time-weighted mean iGFR (Periods 2-4) |
|---|---|---|---|---|---|---|
| Mean (SD) iGFR, mL/min/1.73m² | 52.01 (25.66) | 49.11 (21.90) | 47.73 (20.80) | 47.59 (21.41) | 49.19 (20.91) | 48.04 (19.83) |

Disclosure of Financial Relationships: nothing to disclose

**New Adjusted Equations for Estimated GFR from Serum Creatinine in Korean** Beom Seok Kim,[1] Hoon Young Choi,[1] Ho Yung Lee,[1] Yong Kyu Lee,[1] Sung-Kyu Ha,[1] Sug Kyun Shin,[2] Seung-Ok Choi,[3] Ho-Jung Kim,[4] Kang Wook Lee,[5] Yang Wook Kim,[6] Yong-Lim Kim,[7] Yoshinari Yasuda,[8] Enyu Imai,[9] Masaru Horio,[9] Hirofumi Makino,[10] Seiichi Matsuo.[8] *[1]Yonsei Univ; [2]Ilsan Hospital; [3]Wonju Christian Hospital; [4]Hanyang Univ.; [5]Chungnam National Univ.; [6]Inje Univ.; [7]Kyungpook National Univ.; [8]Nagoya Univ.; [9]Osaka Univ.; [10]Okayama Univ.*

Introduction: Modification of Diet in Renal Disease (MDRD) Study equation is a standard method to estimate glomerular filtration rate (GFR). However, it's accuracy in Asians is often unsatisfactory. In this sub-study of the Asian Collaborative Study for Creation of GFR Estimation Equation (ACOS-CG-FREE) which is designed to develop the equation of estimated GFR (eGFR) for Asians, we focused on developing the modified eGFR for Korean population.

Methods: Patients with non-dialysis chronic kidney disease were enrolled. Measured GFR (mGFR) was computed from renal clearance of inulin (Cin). All the laboratory tests were performed at the central laboratory in Japan. The Korean coefficient was statistically determined by minimizing the sum of squared errors between eGFR and mGFR.

Results: Among 202 patients enrolled, 200 cases were analyzed as the development data set currently. Male to Female ratio was 56:44%. Mean age of the patients was 46.5 ± 16.7. The percentage of patients with diabetes mellitus and hypertension were 24.7% and 55.7%, respectively. From out data, modified eGFR equation in Korean was GFR (ml/min/1.73 m2) = 194 × Cr-1.094 × Age-0.287 (female × 0.739). With this equation, 30% accuracy was 57% (R = 0.907).

Conclusion: We showed that the eGFR equation obtained by this study is different from the standard MDRD study equation. Further study validating the accuracy of new eGFR equation should be considered to clinically apply this equation.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO295

**Equations To Estimate Creatinine Excretion Rate: The CKD Epidemiology Collaboration** Joachim H. Ix,[1,2] Christina Wassel,[2] Lesley A. Stevens,[3] Gerald J. Beck,[4] Marc C. Froissart,[5] Gerjan Navis,[6] Roger A. Rodby,[7] Vicente E. Torres,[9] Yaping Lucy Zhang,[3] Tom H. Greene,[9] Andrew S. Levey.[3] *[1]UC San Diego; [2]UC San Diego; [3]Tufts; [4]Cleveland Clinic; [5]Paris Descartes Univ.; [6]Univ. Med Center Groningen; [7]Rush; [8]Mayo Clinic; [9]Univ. of Utah.*

**Background:** Creatinine excretion rate (CER) can be used evaluate collection accuracy of timed urine specimens, but extremes of normal ranges vary by up to 100%, so collections may be deemed inaccurate only if grossly over -or under-collected. We aimed to develop and externally validate new CER equations using commonly available variables that mark muscle mass.

**Methods:** Individuals from 3 kidney disease studies (n=2466) were divided into development (random 2/3rd) and internal validation (1/3rd) datasets. Linear regression was used to develop new equations. Equation estimated CER was compared to measured 24-hr urine CER among 987 participants from 3 additional studies for external validation.

**Results:** Mean GFR was 60 ± 40 ml/min/1.73m², and measured CER (± SD) was 1400 ± 453 mg/day. Age, sex, race, weight, and serum phosphorus levels improved new equation fit in the development dataset. Because phosphorus is not always available in clinical practice we carried forward 2 equations (with or without serum phos). In external validation, the new CER equations showed little bias and moderate precision.

Performance of CER Estimation Equations in the External Validation Dataset (n=987)

| | % Difference (Measured-Estimated CER) | | Accuracy | | |
|---|---|---|---|---|---|
| | Median (95% CI) | IQR | $P_{15}$ (95% CI) | $P_{30}$ (95% CI) | RMSE (95% CI) |
| Equation without Phosphorus* | -0.7% (-2.6%, 1.0%) | 32% | 51% (47%, 54%) | 79% (76%, 81%) | 35.7 (33.1, 38.7) |
| Equation with Phosphorus** | 0.3% (-2.6%, 3.1%) | 27% | 54% (50%, 59%) | 81% (77%, 85%) | 33.9 (29.5, 37.8) |

* eCER = 880 + 12.5*weight - 6.2*age (+ 34.5 if black) (-379 if female)
** eCER = 1115 + 12*weight - 5.8*age - 60*phos (+ 53 if black) (- 368 if female)

Abbreviations: eCER=estimated CER; IQR=interquartile range; CI=confidence interval; P15=percent of estimated CERs within 15% of measured CERs; P30=percent of estimated CERs within 30% of measured CERs; RMSE=Root mean squared error

**Conclusions:** Common clinical variables can estimate expected CER, to which measured CER can be compared. The new equations may facilitate evaluation of accuracy of timed urine specimens.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO296

**Performance of Equations To Estimate 24-Hour Creatinine Excretion in Healthy Subjects and Renal Transplant Recipients** Steef Jasper Sinkeler,[1] Stephan J. L. Bakker,[1] Joachim H. Ix,[2] Gerjan Navis.[1] *[1]Nephrology, University Medical Center Groningen, Groningen, Netherlands; [2]Medicine, Division of Nephrology, University of California San Diego, San Diego, CA.*

24h urine allows assessment of renal function, proteinuria and dietary factors but is fraught with collection errors. As 24h creatinine excretion (CER) derives from muscle mass the appropriate 24h CER can be predicted from anthropometric data and thus serve to identify collection errors. Several formulas derived from CKD cohorts were proposed for CER estimation. We tested performance in renal transplant recipients (RTR) and healthy subjects.

595 RTR (mean age 52, 42% female, all Caucasian, mean GFR (iothalamate) 43 mL/min/1.73 m², mean time after transplantation 7 yr) and 263 healthy subjects (mean age 53, 52% females, all Caucasian, mean GFR 100 mL/min/1.73m²) were studied. The formula by Cockroft & Gault (eCERCG) (28 – 0.2*Age) *Body Weight (*0.85 if female) and 2 new equations by Ix et al. were used to estimate CER (eCER): eCERsimple=879.89+12.51*Weight–6.19*Age(-379.42 if female) and, when serum phosphorus was available, eCERphos = 1115.89+11.97*Weight–5.83*Age–(60.18*[Serum Phosphorus]) (-368.75 if female) .

In RTR median CER was 1267 [inter-quartile range (IQR) 532], eCERsimple 1434 [528], eCERphos1465 [519] and eCERCG 1266 [534] mg/day. R² for both eCERsimple and eCERphos was 0.43, and for eCERCG 0.41. Median bias was 7.0% [IQR 30.0%] for eCERsimple, 9.5% [31.1%] for eCERphos and 1% [31.2%] for eCERCG, and 15%-accuracy was 51, 48 and 49%; the 30%-accuracy 78, 75 and 83%, respectively.

In healthy subjects median CER was 1458 [628], eCERsimple 1375 [542], eCERphos 1391 [538] and eCERCG 1261 [470]. R² for both eCERsimple and eCERphos was 0.52 and for eCERCG 0.43. Median bias was -9.3% [19.4%] for eCERsimple and -8.3% [23.3%] for eCERphos, as compared to -14.7% [34.3%] for eCERCG, with 15%-accuracy of 51, 52 and 37%; the 30%-accuracy was 87, 87and 76%, respectively.

Thus, empirical equations estimate CER reasonably well in RTR and healthy subjects with precision corresponding to data in CKD. Their use can improve the suitability of 24h urine for monitoring of renal function and dietary factors.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO297

**Detection of Early Impairment of Glomerular Filtration Rate: Serum Creatinine Versus Low-Molecular Weight Proteins** Carlo Donadio,[1] Danika Tognotti,[1] Angeliki Kanaki,[1] Elena Donadio.[2] *[1]Internal Medicine, University, Pisa, Italy; [2]Biochemistry, University, Pisa, Italy.*

Serum creatinine is an efficient marker of GFR impairment only at CKD stages ≥3b (GFR<45 mL/min/1.73 m$^2$), while serum concentrations of low molecular weight proteins (LMWP) have been proposed as a more sensitive marker of GFR impairment.

Aim of this study was to assess the accuracy of serum levels LMWP (cystatin C, Cys; beta2-microglobulin, β2M; retinol-binding protein, RBP; beta-trace protein, BTP) as indicators of impairment of GFR, in comparison with serum creatinine (Creat) and urinary excretion of albumin (U-Alb).

Two hundred and ninety-five adult CKD patients (F 137), affected by different kidney diseases with various impairment of renal function (S-Creat 0.40-12.1 mg/dL), participated to this study. GFR was measured as the renal clearance of $^{99m}$Tc-DTPA. Creat, Cys, β2M, RBP, BTP and U-Alb were measured with standard laboratory methods.

Serum concentration of all markers increased with the reduction of GFR. The slight increases found at CKD stage 2 resulted already statistically significant versus the values found in the group of CKD at stage 1. Statistical significance was higher for S-Creat, S-β2M and S-BTP than for S-Cys and S-RBP. Some differences among the different markers were found according to the gender of patients. In any case, a very high correlation was found between GFR, and serum Creat (r=0.9254), Cys (r=0.9361), β2M (r=0.9381), and BTP (r=0.9251). The lowest correlation was that of RBP (r=0.6917). In general, the criterion values to screen the same GFR impairment were higher for male than for female patients. Furthermore, to screen patients with mild impairment in GFR, one must use criterion values lower than those necessary to screen patients with a more advanced impairment in GFR. All serum markers showed a similar accuracy as indicators of different degrees of GFR impairment, except RBP, which resulted significantly less accurate.U-Alb was inadequate as indicator of any level of GFR impairment.

In conclusion, serum levels of LMWP are probably not more sensitive or accurate than serum creatinine as an early indicator of GFR impairment. U-Alb gives no information on GFR impairment.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO298

**Cystatin C, Mortality Risk, and Clinical Triage in US Adults: Threshold Values and Hierarchical Importance** Robert N. Foley,[1,2] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

It has been suggested that cystatin C may be a superior measure of estimated glomerular filtration rate (eGFR) than creatinine-based methods. The utility of cystatin C for clinical triage in community-based settings, however, is unknown. Hence, we identified cystatin C thresholds that maximize sensitivity and specificity ($Max_{Sn+Sp}$) for predicting death, and subsequently applied classification tree methodology considering serum creatinine, creatinine-based eGFR, urinary albumin-creatinine ratio, and conventional modifiable risk factors to define subgroups, interactions, and hierarchical ranks in fasting US adults (National Health and Nutrition Examination Survey 1988-1994, followed through 2006). A threshold cystatin C value of 0.94 mg/L exhibited the best maximum combined value of sensitivity and specificity for predicting death ($Max_{Sn+Sp}$, Sn 0.64/Sp 0.78). When all variables were considered jointly in a classification tree, cystatin C and albumin-creatinine ratio were the primary mortality discriminators in subgroups that added up to 41% and 14% of the study population, respectively; serum creatinine and creatinine-based eGFR were non-discriminatory. Cystatin C may be useful for risk-based clinical triage in public health settings.

### TH-PO299

**UK Prevalence of Chronic Kidney Disease (CKD) and Associated Cardiovascular (CV) Co-Morbidities: The Baseline Data from the QI-CKD Study** Hugh Gallagher,[1] Charles Tomson,[2] Kevin P. G. Harris,[3] Simon de Lusignan.[4] *[1]St Helier Hospital; [2]Southmead Hospital; [3]Leicester General Hospital; [4]St George's University of London.*

**Background:**

The high quality of computerised medical records in UK family practice provides a rich source of data for use in quality improvement and research. Here we report the prevalence of CKD in the UK from a very large primary care dataset, using stringent criteria for case definition. We also compare the abilities of the four-variable MDRD and CKD-EPI formulae to identify those at higher risk of CV disease.

**Method:**

Analysis of routine data collected from 930,997 patients registered with 139 general practices across England. Data were extracted to enable the calculation of eGFR using the MDRD and CKD-EPI formulae. We took into account whether local creatinine assays were traceable to the reference IDMS method. CV co-morbidities were documented.

**Results:**

The UK prevalence of stage 3 to 5 CKD (defined using two measurements of eGFR <60 ml/min/1.73m$^2$ at least three months apart with no interim values >60 ml/min/1.73m$^2$) is 5.41% (7.34% in females and 3.48% in males) using MDRD. Assuming white ethnicity in all and ignoring interim values gives prevalence estimates of 5.49% and 5.55% respectively. Just using the latest eGFR (as in NHANES and NEOERICA) inflates the figure to 6.4%. Using CKD-EPI and the full case definition, the prevalence is lower at 4.76% (6.14% in women and 3.39% in men).

Ischaemic heart disease is recorded amongst 15.3% of patients with CKD3a (compared with 6.5% in those with eGFR>90 ml/min/1.73m$^2$), 26.9% in CKD3b, 29.2% in CKD4, and 28.5% in CKD5. A major increase in prevalence between CKD3a and 3b is also seen for other CV co-morbidities.

The prevalence of CV co-morbidities in stages 3a, 3b, and 4 is approximately 10% higher using CKD-EPI compared with MDRD.

**Conclusions:**

The application of strict case definition criteria to high quality routinely collected data results in a lower estimate of prevalence of stage 3 to 5 CKD than that previously reported in the UK, whether the MDRD or CKD-EPI is used. CV co-morbidities are far more prevalent in CKD3b than 3a. CKD-EPI identifies a smaller, higher-risk population as CKD3a.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO300

**Changes in Estimated Glomerular Filtration Rate (eGFR) in Apparently Healthy Adults with an Elevated High-Sensitivity C-Reactive Protein (hsCRP) Level in the JUPITER (Justification for the Use of Statins in Prevention: An Intervention Trial Evaluating Rosuvastatin) Trial** Michael D. Cressman,[1] Donald G. Vidt,[2] John Monyak.[1] *[1]AstraZeneca; [2]Cleveland Clinic Foundation.*

**Purpose:** The aim of this analysis was to assess changes in eGFR among a population of apparently healthy adults across a range of baseline eGFR levels. **Methods:** JUPITER subjects were apparently healthy men ≥50 or women ≥60 years of age with an hsCRP ≥2.0 and an LDL-C <130 mg/dL. Changes in eGFR were assessed using the Modification of Diet in Renal Disease (MDRD) and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations among 16 279 evaluable participants in JUPITER. Changes from baseline in eGFR were determined in all subjects in the placebo and rosuvastatin groups, and in subsets with baseline eGFR ≥90, 60–89, or <60 mL/min/1.73 m$^2$. **Results:** Mean (SD) serum creatinine increased 0.10 (0.16) mg/dL and 0.09 (0.18) mg/dL in the placebo and rosuvastatin groups, respectively, after a mean follow-up of 2.3 yr (p=0.0045). Reductions in eGFR (mL/min/1.73 m$^2$) were greater with placebo vs rosuvastatin based on both the MDRD (–8.4 [13.3] vs –7.9 [13.5], p=0.0007) and the CKD-EPI equation (–7.4 [12.1] vs –6.8 [12.2], p=0.0004). Reductions in eGFR (placebo and rosuvastatin groups) were apparent in study participants with a baseline eGFR ≥90 [MDRD: –22.6 (14.3) and –22.3 (14.5); CKD-EPI: –19.3 (11.2) and –18.7 (11.1)] or in those with a baseline eGFR 60–89 [MDRD: –7.0 (10.9) and –6.3 (11.3); CKD-EPI: –7.5 (11.2) and –6.7 (11.5)] but not in subjects with baseline eGFR <60 [MDRD: 0.2 (8.4) and 0.3 (8.5); CKD-EPI: 0.2 (8.4) and 0.3 (8.6)]. **Conclusions:** In JUPITER, reductions in eGFR based on the MDRD or CKD-EPI equation were greater than expected among individuals with baseline eGFR levels over 60 mL/min/1.73 m$^2$. Results of longitudinal studies that include individuals with higher eGFR levels may be misleading when eGFR is used to assess change in renal function.

### TH-PO301

**eGFR Variability in Primary Care: Normal Variation or Portending Increased Risk? Work in Progress** Christopher K. T. Farmer,[1] Jean Irving,[1] Edmund J. Lamb,[2] Adeera Levin,[3] Paul E. Stevens.[1] *[1]Kent Kidney Care Centre, East Kent Hospitals, Canterbury, Kent, United Kingdom; [2]Clinical Chemistry, East Kent Hospitals, Canterbury, Kent, United Kingdom; [3]Division of Nephrology, St. Paul's Hospital, University of British Columbia, Vancouver, BC, Canada.*

Introduction

Biological and analytical variability of serum creatinine (SCr) is ~ 5%, but in the real world may be greater as sampling is not standardised, leading to variation in reported eGFR and uncertainty in clinical decision making.

Aim

To describe the variability in a large primary care cohort with stable renal function over time.

Methods

Patients with ≥4 SCr tests and a rate of decline of eGFR <2 mL/min/1.73m$^2$/y over at least 2 y were identified from a primary care population of 279,000. Demographic, co-morbidity and prescription data were recorded. Patients were stratified by baseline eGFR. The number of excursions of SCr >26.4 μmol/L from baseline was the outcome of interest.

Results

47,191 of 128,370 pts with SCr tests fulfilled the entry criteria, 20% had DM and 68% hypertension, total number of SCr tests was 465,346 (mean 10/pt). 3111 (6.6%) of pts had significant excursions during follow up. DM, hypertension and medication were predictors of excursions (Table).

| GFR | Patients | Mean age | SCr excursions >26.4 umol/L | OR for excursions ( 95%CI) | | |
|---|---|---|---|---|---|---|
| (mL/ min/1.73m²) | (n) | (y) | Patients (number ) | Diabetes | Hypertension | Drugs* |
| All | 47971 | 59 | 3111 (6652) | 1.37 (1.29-1.45) | 1.15 (1.08-1.22) | 1.21 (1.14-1.30) |
| >90 | 9963 | 51 | 354 (534) | 1.08 (0.91-1.28) | 1.14 (0.97-1.33) | 1.13 (0.95-1.33) |

**Pre-CKD: A Novel Risk Factor for CKD in Older Adults** C. Barrett Bowling,[1,2] Ruth C. Campbell,[2] Marjan U. Mujib,[2] Arnold B. Alper,[4] George L. Bakris,[3] Richard M. Allman,[2,1] Wilbert S. Aronow,[5] L. Lee Hamm,[4] Paul W. Sanders,[2,1] Ali Ahmed.[2,1] *[1]Birmingham VAMC; [2]UAB; [3]UChicago; [4]Tulane; [5]NY Medical College.*

**Purpose**: To determine the prevalence and effect of pre-CKD, defined as eGFR 60–89 ml/min/1.73m² on incident CKD.

**Methods**: Of the 5125 community-dwelling older adults ≥65 yrs in the original Cardiovascular Health Study, 2878 had data on eGFR (CKD-EPI) at baseline (BL) and year 9 (Y9). Of these, 2270 had eGFR ≥60 ml/min/1.73m², of which 1804 had pre-CKD. Propensity scores for pre-CKD were used to assemble a cohort of 428 pairs with (w) and without (w/o) pre-CKD who were balanced on 62 BL characteristics. Logistic regression models were used to estimate the association of BL pre-CKD with incident CKD at Y9.

**Results**: Participants (n=856) had a mean age of 70 (±3) yrs and 79% women and 4% Afr. Amer. Incident CKD occurred in 34% and 8% of matched pts w and w/o pre-CKD respectively (OR, 6.28; 95%CI, 4.16–9.48; p<0.001; **Table**). Pre-CKD also predicted incident eGFR <45 (OR, 6.58; 95%CI, 2.27–19.06; p=0.001) which occurred in 6% and 1% of those w and w/o BL pre-CKD respectively. Pre-match associations and the dose-response association between pre-CKD and new-CKD are displayed in the **Table**.

**Conclusions**: Among older adults w/o CKD, pre-CKD (eGFR 60–89) is common and associated with increased risk of incident CKD.

Association of pre-CKD with incident CKD

| | Matched OR (95% CI) | Unadjusted OR (95% CI)* | MV-adjusted OR (95% CI)*† |
|---|---|---|---|
| No pre-CKD (eGFR ≥90 ml/ min/1.73 m²) | 1 | 1 | 1 |
| Pre-CKD (eGFR 60–89 ml/ min/1.73 m²) | 6.28 (4.16–9.48); p<0.001 | 6.05 (2.45–14.90); p<0.001 | 7.52 (5.13–11.02); p<0.001 |
| Dose-response | | | |
| eGFR 60–74 ml/min/1.73 m² | 14.01 (8.62–22.78); p<0.001 | 16.51 (11.37–23.95); p<0.001 | 20.06 (13.25–30.37); p<0.001 |
| eGFR 75–89 ml/min/1.73 m² | 3.84 (2.44–6.04); p<0.001 | 3.79 (2.61–5.51); p<0.001 | 4.25 (2.86–6.33); p<0.001 |

* Based on 2270 pre-match cohort, † Adjusted for all 62 baseline covariates used in the propensity model

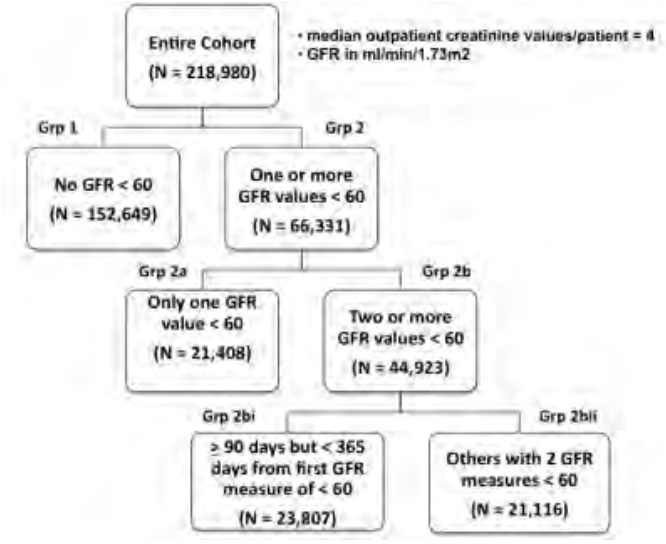
### TH-PO303

**Validity of Definition and Classification of Chronic Kidney Disease (CKD) in Observational Databases** Charuhas V. Thakar,[1,2] Christine Edie,[2] Kristen Schmitt,[2] Loretta Simbartl.[2] *[1]University of Cincinnati, Cincinnati, OH; [2]Cincinnati VA, Cincinnati, OH; [3].*

K/DOQI guidelines define CKD as estimated glomerular filtration rate (GFR) < 60 ml/min/1.73m2 measured > 90 days but < 365 days apart. Criteria to define CKD in a retrospective observational cohort are unclear.

We examined validity of classification of CKD in a multi-center cohort of 218,980 veterans seeking care across 5 Veterans Affairs healthcare systems in Ohio between 1/1/06 and 4/1/10. All outpatient creatinine values during the study were extracted, along with demographic information (age at first creatinine, gender, race). Primary outcome was all cause mortality. Estimated GFR was expressed in ml/min/1.73m2. Patients were classified into 5 groups based on number of GFR measures < 60, and compared to those with no GFR measures < 60 (Figure). Logistic regression models tested the association of GFR groups with mortality after adjusting for age, gender and race; results were expressed as odds ratios (OR) and 95% confidence intervals (CI).

The sample was 93% male, median age was 62 yrs. Prevalence of CKD was 30% defined as only one GFR measure < 60, 20.5% defined as any two GFRs < 60, and 11% when defined as two consecutive GFRs of < 60, > 90 but < 365 days apart.



Mortality was 4.4% in Grp 1 vs 13% in Grp 2 (Chi-square p < 0.0001). In multivariable models, the OR of mortality associated with different groups, with Grp 1 as a reference, were: Grp 2: 1.76 (95% CI, 1.70, 1.82); Grp 2a: 1.89 (95% CI, 1.80, 1.99); Grp 2b: 1.67 (95% CI, 1.61, 1.74); Grp 2bi: 1.44 (95% CI, 1.37, 1.51), and Grp 2bii: 1.88 (95% CI, 1.79, 1.97).

In an observational cohort, even a single measure of GFR < 60 is associated with increased risk of mortality; magnitude of mortality risk is comparable in patients with 2 GFR values < 60, regardless of timing of measurement.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO304

**Prevalence of Chronic Kidney Disease in the Chinese, South Asian and White Populations of Alberta, Canada** Joslyn D. Conley,[1] Sony Brar,[1] Hude Quan,[1] Braden J. Manns,[1] Marcello Tonelli,[2] Brenda Hemmelgarn.[1] *[1]University of Calgary, Alberta Kidney Disease Network; [2]University of Alberta.*

The reported prevalence of chronic kidney disease (CKD), eGFR < 60mL/min/1.73m², is highly variable among ethnic groups. The purpose of this study was to determine the prevalence of CKD for three ethnic groups in Alberta.

Using the Alberta Kidney Disease Network province-wide laboratory database we identified a cohort (n=777,354) of people with at least one out-patient measurement from January – December 2005 in Alberta, Canada. Chinese (4.09%) and South Asian (3.98%) populations were established using validated surname identification algorithms. eGFR was calculated using the MDRD equation, with the Alberta Health and Wellness registry file (n=2,397,981) used to determine the denominator.

The age and sex adjusted prevalence of CKD was highest in the white population (5.46%), followed by South Asians (3.65%) and Chinese (2.94%).

Table: Age and sex adjusted prevalence of CKD by eGFR stage and ethnicity

| eGFR | Total | White | South Asian | Chinese | P* |
|---|---|---|---|---|---|
| >60 mL/min | 94.74 | 94.53 | 96.34 | 97.06 | <0.01 |
| 46-60 mL/min | 3.81 | 3.97 | 2.62 | 2.05 | <0.01 |
| 30-45 mL/min | 1.11 | 1.15 | 0.77 | 0.62 | <0.01 |
| <30 mL/min | 0.34 | 0.35 | 0.26 | 0.27 | <0.01 |

* chi-square test of ethnic groups

The prevalence of CKD in South Asian and Chinese ethnic groups is lower than the white population, and similar to those reported from their countries of origin.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO305

**CKD among Disadvantaged Populations in Mexico** Guillermo G. Garcia,[1] Hector R. Perez,[1] Alfonso Gutierrez,[1] Martha Mendoza,[1] Librado De la Torre-Campos,[1] Karina Renoirte,[1] Marcello Tonelli.[2] *[1]Nephrology, Hospital Civil de Guadalajara, Guadalajara, Mexico; [2]Nephrology, University of Alberta, Edmonton, Canada.*

CKD is a major cause of morbidity and mortality in Mexico. In other nations, risk factors for CKD are disproportionally higher among individuals with low educational levels. Since lower education is itself a potentially reversible risk factor, this warrants further study.

Since September 2006, the Fundacion Hospitales Civiles de Guadalajara has used mobile units to screen for CKD in residents of poor communities in Jalisco, Mexico. Potential participants were informed of risk factors for CKD. We excluded individuals with known CKD and < 18 years of age. Trained personnel collected demographic and clinical data and collected blood and urine samples for selected tests. Between 09/2006 and 12/2009 9,619 were screened. The majority of participants (56%) had less than a primary school education. Findings were compared according to the level of education.

Results

| | ≤primary school or illiterate n= 5260 | ≥junior High School n= 4069 | p |
|---|---|---|---|
| Age (y) | 58.5 ±12.7 | 50.9 ±13.6 | 0.0001 |
| Male (%) | 1279 (24.3) | 1452 (35.7) | 0.0001 |
| Known DM (%) | 2409 (45.9) | 1510 (37.1) | 0.0001 |
| Blood glucose (mg/dL) | 148.2 ± 75.8 | 138.1 ± 71.2 | 0.0001 |
| >126 mg/dL (%) | 2249 (43.3) | 1432 (35.8) | 0.0001 |
| Known HTN (%) | 2866 (54.5) | 1921 (47.2) | 0.0001 |
| SBP≥140 or DBP≥90 (%) | 2894 (55.2) | 1888 (46.6) | 0.0001 |
| BMI (Kg/m²) | 29.5±5.3 | 29.3 ±5.4 | 0.039 |
| +dipstick proteinuria (%) | 969 (19.3) | 757 (20.8) | 0.081 |
| Current smoker (%) | 894 (17.0) | 802 (19.7) | 0.001 |
| eGFR (ml/min/1.73 m²) | 77.1 ±27.8 | 80.5 ±22.4 | 0.0001 |
| eGFR<60 ml/min/1.73 m²) (%) | 901 (17.1) | 487 (12.0) | 0.0001 |

We conclude that 1) the prevalence of CKD and its risk factors are higher among individuals with low level or no education. 2) Consideration should be given to target this high risk population in programs aimed to prevent CKD and its risk factors in Mexico.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO306

**A Nationwide Study of Mass Urine Screening Tests on Korean School Children and Implications for Chronic Kidney Disease Management**

Byoung-Soo Cho,[1] Won-Ho Hahn,[1] Jin-Soon Suh,[1] Hae Il Cheong,[2] Inseok Lim,[3] Cheol Woo Ko,[4] Tae-Sun Ha,[5] Su-Young Kim,[6] Dae-Yeol Lee.[7] *[1]Department of Pediatrics, Kyung Hee University Hospital; [2]Seoul National University Children's Hospital; [3]Yongsan Hospital, Chung-Ang University College of Medicine, Seoul; [4]Kyungpook National University Hospital, Daegu; [5]Chungbuk National University Hospital, Cheongju; [6]Pusan National University Hospital, Gyeongnam; [7]Chonbuk National University Hospital, Jeonju, Korea.*

We report the findings of a school urinary screening program that analyzed pediatric patients with proteinuria and/or hematuria. Between 1999 and 2008, 5,114 children were referred to pediatric nephrologists at 7 hospitals. These children had isolated hematuria (IH) (72.82%), isolated proteinuria (IP) (10.79%) or combined hematuria and proteinuria (CHP) (16.3%). Renal biopsies were performed on 1478 children (28.79% of total subjects; 26.77% in IH, 9.09% in IP and 51.19% of CHP) who showed abnormal renal function, persistent hematuria and/or proteinuria for more than 6 months, nephrotic-range proteinuria, or those with underlying systemic diseases. The most common findings in renal biopsies are IgA nephropathy in 38.97%, mesangial proliferative glomerulonephritis in 24.29%, and thin basement membrane nephropathy in 13.13%, respectively. Chronic kidney disease (CKD) was detected in 25.17% of all visiting subjects. Compared with the relative frequency of renal diseases associated with urinary abnormalities, the CHP group (46.9%) and nephrotic-range proteinuria group (69.96%) had more frequent CKD than the others. Abnormal findings on the renal ultrasound with or without Doppler scan were noted in 462 cases (suspected nutcracker phenomenon, 159; increased parenchymal echogenicity, 92; hydronephrosis, 75; simple cyst, 47). In conclusion, mass urine screening tests could detect asymptomatic CKD in its early stages. Initial aggressive diagnosis and treatment for CHP and nephrotic-range groups may prove helpful as interventions that delay CKD progression. These findings may inform the development of diagnostic and management guidelines for relatively mild urinary abnormalities, such as IH or low-grade IP.

## TH-PO307

**Measured *vs.* Estimated GFR in the Detection of Early GFR Decline in Type 1 Diabetes Patients**

Aleksandra Kukla, Maria Luiza A. Caramori, John H. Eckfeldt, Michael Mauer. *University of Minnesota.*

Early GFR decline is difficult to detect. Serum creatinine changes over time are commonly used, however, this may not be sufficiently sensitive. We assessed, whether creatinine and cystatin C based GFR estimates (eGFR) could detect early measured GFR changes in 244 normoalbuminuric (NA) normotensive type 1 diabetic patients (pts) in the Renin Angiotensin System Study (RASS).

**Methods**: Pts underwent iohexol GFR measurements (iGFR) at baseline and at 5 yrs. MDRD-IDMS [eGFR(MDRD)], Chronic Kidney Disease Epidemiology Collaboration (CKD-Epi) and cystatin C [eGFR(cysC)] eGFRs were also calculated at these times.

**Results**: eGFR(CKD-Epi) and eGFR(MDRD) underestimated while eGFR(cysC) overestimated (perhaps partially explained by methodological changes) iGFR (p<0.001 for each). Correlations with iGFR were: eCKD-Epi, r=0.49; eGFR(MDRD), r=0.49; eGFR(cysC), r=0.35 (p<0.001 for each). GFR declined by all 4 methods (p<0.001 for each; see table; *in ml/min/1.73m*).

| N=244 | iGFR | eGFR(CKD-Epi) | eGFR(MDRD) | eGFR(cysC) |
|---|---|---|---|---|
| Baseline | 128±19 | 119±15 | 116±27 | 139±22 |
| 5 years | 120±21 | 115±14 | 110±25 | 136±20 |
| baseline-5 years | -7.6±15.9 | -3.6±9.6 | -5.8±20 | -3.0±18 |

The decline, numerically greatest by iGFR, was not statistically different from that for eGFR(MDRD) but it was less for eGFR(CKD-Epi) and eGFR(cysC) *vs*. iGFR (p=<0.001 for both) and for eGFR(CKD-Epi) (p=0.008) and eGFR(cysC) (p=0.02) *vs*. eGFR(MDRD). The decline by iGFR was weakly correlated with those by eGFR(MDRD) (r=0.24, p<0.001), eGFR(CKD-Epi) (r=0.28, p<0.001) and eGFR(cysC) (r=0.39, p<0.001). A 2 arm clinical trial powered for an 80% probability to detect a 50% reduction in the observed GFR decline would require a total of 552 pts for iGFR, 896 for eGFR(CKD-Epi), 1,496 for eGFR(MDRD), and 4,524 for eGFR(cysC).

**Conclusions:**

All 4 methods detected GFR decline over 5 yrs in NA T1DM subjects. For detecting subtle GFR changes in individual patients eGFR(CysC) was most closely correlated with iGFR changes, but if iGFR is considered the gold standard, no eGFR method accurately predicted these early changes. For clinical trials aiming to slow early GFR loss, iGFR is far superior. ** for the RASS Group.

## TH-PO308

**Quantile Regression Better Estimates Effect of Diabetes on eGFR**

Mihriye Mete,[1] Nawar M. Shara,[1,2] Barbara V. Howard,[1,2] Jason G. Umans.[1,2] *[1]Medstar Health Research Institute, Hyattsville, MD; [2]Georgetown University, Washington, DC.*

**Background**: Estimated glomerular filtration rate (eGFR) is commonly associated with diabetes mellitus (DM) and other covariates using multiple linear regression models (MLRM). However, MLRM may obscure important associations when the covariates exert differential effects across the distribution of the outcome. Such differentiation would be expected for DM, which causes hyperfiltration at higher levels of GFR and accelerated chronic kidney disease (CKD) at lower levels. We quantified the impact of DM on eGFR (MDRD) using quantile regression (QR) and compared these results to those of an MLRM.

**Methods**:Data from 3,137 American Indians in the Strong Heart Family Study were used to examine relationships between DM and eGFR. MLRM provide a single set of coefficients estimating the mean response of eGFR to DM. In contrast, QR estimates the response in different locations across the eGFR curve, allowing varying covariate effects.

**Results**: Results of the MLR and QR models of eGFR on DM, adjusted for age, sex, hypertension, and protein intake, are shown (Table). MLRM estimate that eGFR is, on average, 14 mL/min/1.73m2 higher for participants with DM (p<0.001) than for those without DM. QR results show that the effect of DM varies across eGFR percentiles, revealing the expected negative effect of DM on eGFR (-30 to -0.5) at lower percentiles and suggesting diabetic hyperfiltration at higher percentiles. Indeed, at eGFR values ≥ the 25th percentile (eGFR≥ 83 in our sample), DM increased eGFR by 9-25. Both these positive and negative effects of DM were masked in the MLRM.

**Conclusions**: MLRM fail to capture the varying effects of DM on kidney function by masking differential impacts at the low and high ends of the eGFR distribution. QR reveals both hyperfiltration and accelerated CKD due to DM in our population and may improve mechanistic and genetic inferences from observational studies.

Effect of DM on eGFR estimated by MLRM vs. QR

| MLRM (95% CI) | QR estimates at different percentiles (95% CI) | | | | | | |
|---|---|---|---|---|---|---|---|
| | 1st | 5th | 10th | 25th | 50th | 75th | 95th |
| 14(11,16) | -30(-50,-9) | -8(-23,7) | -0.5(-6,5) | 9(5,12) | 14(11,17) | 18(14,21) | 25(22,28) |

## TH-PO309

**Repeat Testing Significantly Reduces the Estimated Prevalence of Chronic Kidney Disease and Identifies a Population with Increased Cardiovascular Risk**

Matthew O. Brook,[1] Matthew James Bottomley,[1] Alena Svistunova,[3] Aleh Kalachik,[3] Paul N. Harden.[1] *[1]Oxford Kidney Unit, Churchill Hospital, Oxford, United Kingdom; [2]Department of Biochemistry, John Radcliffe Hospital, Oxford, United Kingdom; [3]National Centre for Nephrology, Minsk, Belarus.*

**Purpose**

To investigate the impact of repeat testing of renal function on estimated prevalence of chronic kidney disease (CKD) and cardiovascular risk.

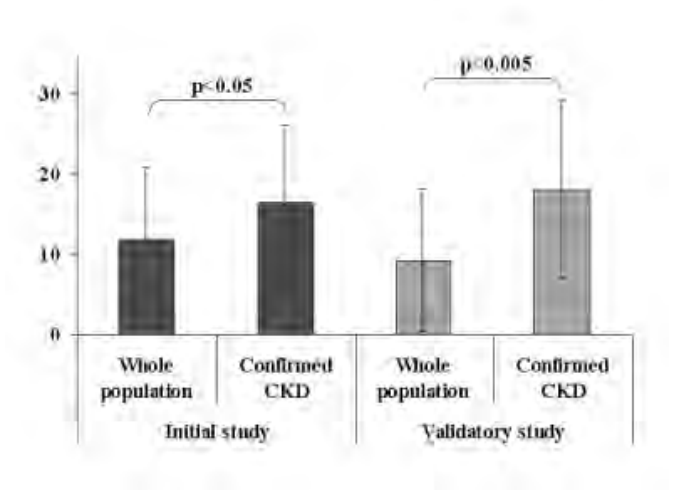
**Methods**

We carried out 2 observational studies in Minsk, Belarus. Blood and urine samples were taken with repeat testing 3 months later to confirm the diagnosis of CKD. 10-year general cardiovascular disease risk was calculated using criteria determined by the Framingham Study.

An initial study recruited 512 participants. Of these, 142 with abnormal or near abnormal results consented to repeat samples. A second validatory study recruited 528 individuals. 214 provided follow up samples 3 months later.

**Results**

Repeat testing reduced the estimated prevalence of CKD from 8.2% (initial study) and 10.8% (validatory study) based on single point testing to 4.1% and 4.2% respectively. Figure 1 demonstrates elevation of mean 10-year general cardiovascular risk in those with CKD confirmed by repeat testing over that of the whole population.



Importantly, cardiovascular risk in those individuals with only a single result indicating CKD was the same as the general population.

Finally, we identified a significant elevation in systolic hypertension in those with confirmed CKD in both studies (140 vs 148, p<0.05 and 133 vs 150, p<0.05).

**Conclusion**

We demonstrate that repeat testing reduces estimated prevalence of CKD and reveals a population with greatly increased cardiovascular risk likely related to systolic hypertension.

We conclude that studies based on a single test are likely to signficantly overestimate CKD prevalence and underestimate cardiovascular risk.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO310**

**High Prevalence of Undiagnosed Kidney Disease in Those Presenting with Troponin Positive Acute Coronary Syndrome** Christopher W. M. Horner, Sumith C. Abeygunasekara, Galil Rahman Ali. *Dept of Nephrology, Division of Medicine, Broomfield Hospital, Chelmsford, United Kingdom.*

*Aim*

The aim was to assess the prevalence of CKD in those presenting to a District General Hospital (DGH) with troponin positive acute coronary syndrome (ACS) as compared to a sample of the general population and determine the proportion of undocumented CKD in this patient group.

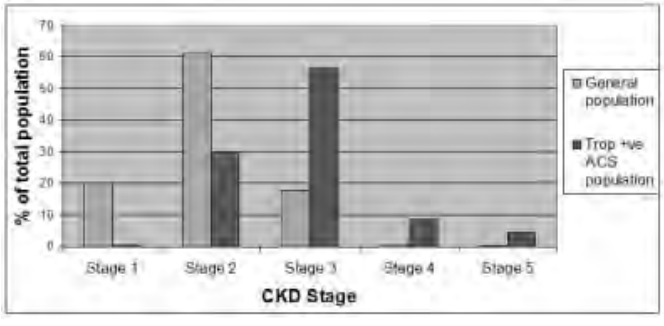
*Methods*

A retrospective observational study. Data was collected from proformas completed during the 18 month period from 01/11/07 to 30/04/09 for patients admitted to a large DGH for Troponin positive ACS. Demographic data, initial creatinine/eGFR and whether patient was documented to have CKD prior to admission were recorded.

Stage of CKD was calculated and the data was compared to that from de Lusignan *et al*. (2005). The t-test statistic was used to compare means. The proportion of undocumented CKD at presentation was also calculated.

*Results*

936 patients (600 men, 336 women) presented with troponin positive ACS, their mean CKD stage = 2.874 +/- 0.024. This was significantly different from the mean stage of CKD = 1.999 +/- 0.004 found in the general practice population (of similar demographics) sampled by de Lusignan *et al*. (2005) (p<0.001).



35.5% of patients with CKD stage 5, 65.7% of patients with CKD stage 4 and 92.7% of patients with CKD stage 3 had no knowledge or documentation of their renal impairment.

*Conclusions*

The management of patients with significant renal impairment should be optimised through the input of a nephrologist. Our data shows that the population of patients presenting to hospital with troponin positive acute coronary syndrome contains many patients with severe renal impairment who are unaware of their diagnosis, thus providing a useful starting point for the screening for renal disease and specialist nephrology input. Joint renal and cardiac clinics may offer better care for this group of patients.

Disclosure of Financial Relationships: nothing to disclose

**Association between Kidney Function and Coronary Artery Plaque on Computed Tomographic Angiography in Patients with Newly Diagnosed Coronary Artery Disease** Sejoong Kim, Jiyoon Sung, Jae Hyun Chang, Sun Young Na, Ji Yong Jung, Hyun Hee Lee, Wookyung Chung. *Internal Medicine, Gachon University Gil Hospital, Incheon, Gyeonggi, Korea.*

Cardiovascular disease (CVD) is the most frequent cause of morbidity and mortality in patients with chronic kidney disease (CKD). However, the association of kidney dysfunction with coronary atherosclerosis has not yet been fully elucidated. The purpose of this study was to evaluate the association of CKD and coronary artery plaque composition in a cohort of subjects without a previous diagnosis of coronary artery disease. A total of 1192 plaques from 470 patients (2.54 plaque/patient) with any coronary artery plaques on multislice computed tomographic angiography (CTA) were analyzed. Calcified plaque (CP), noncalcified plaque (NCP), and mixed plaque (MP) were identified on the CTA. The mean of eGFR was 80.6 ± 15.9 mL/min/1.73m$^2$, and the prevalence of CKD (defined as eGFR < 60 ml/min/1.73m$^2$) was 5.6%. Multivariate linear regression analysis was used to determine the association of clinical factors including CP, MP, NCP, and total plaque counts. CKD was associated with MP counts and total plaque counts ($r$=0.223, $P$<0.001; $r$=0.248, $P$<0.001, respectively). After the adjustment of covariables such as age, gender, diabetes mellitus, hypertension, smoking, anemia, albumin, calcium-phosphorus product, and lipid profiles, CKD was independently associated with MP counts and total plaque counts ($r$=0.132, $P$=0.01; $r$=0.15, $P$=0.002, respectively). The association was not significant between CKD and the CP or NCP counts. CKD was positively associated with coronary artery plaque counts, especially MP counts. These findings suggest that kidney function may play a role in the formation of coronary arterial plaques.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO312**

**The Presence of Ischaemic Heart Disease Magnifies the Risk of CKD in Patients with Essential Hypertension** Gavin Dreyer,[1] Sally Hull,[2] Ellena Badrick,[2] Alistair Chesser,[1] Magdi Yaqoob.[1] *[1]Nephrology, Royal London Hospital, London, United Kingdom; [2]Centre for Health Sciences, Queen Mary University, London, United Kingdom.*

Introduction:

Early identification of CKD reduces cardiovascular co-morbidity and delays progression to end stage kidney disease. Identifying high risk groups for developing CKD can direct screening services to identify and treat those most at risk for CKD. We studied a cohort of patients with essential hypertension (EH) to determine if a concomitant diagnosis of ischaemic heart disease (IHD) predicts an increase risk for CKD.

Methods:

Computer databases in 148 east London primary care practices were searched using Morbidity Information Query and Export Syntax software. 75,103 adults with a computerised diagnostic code for EH were identified. Patients with an eGFR measurement (MDRD 4 variable, n=29,749) during the study period (1/1/07 and 31/3/08) were included for analysis. Patients with diabetes mellitus were excluded from the analysis allowing us to evaluate the effect of EH in isolation.

Results:

The crude prevalence of EH was 9.5% and for CKD 3-5 was 22%. A diagnosis of IHD was present in 3,779 (12.7%) patients. The crude prevalence of CKD 3-5 in patients with EH and IHD is 30% compared to 19% in those without IHD (Chi$^2$ p<0.001). In a logistic regression analysis, the odds ratio for CKD 3-5 in patients with IHD compared to those without is 1.33, 95%CI 1.22-1.47 (adjusted for age, sex, systolic BP, smoking, cholesterol, ethnicity and clustered by practice). Severe CKD (stages 4-5) is more prevalent in patients with EH and IHD than those with EH alone (OR 1.37, 95%CI 1.03-1.82, adjusted as previously). Mean BP is lower in patients with CKD 3-5 and IHD than those without IHD (133/73 mmHg vs 137/76 mmHg, p<0.001). This may reflect greater use of anti-hypertensive medications in patients with CKD and IHD (2.36 vs 2.13 medications, p<0.001).

Conclusions:

CKD and particularly more severe CKD are significantly more prevalent in patients with EH and concomitant IHD despite a lower mean BP in this group. The public health implications of these findings should encourage clinicians to adopt an aggressive screening policy for CKD where EH and IHD co-exist.

**History of Nephrolithiasis Is Associated with Chronic Kidney Disease in Chinese General Population** Jianfang Cai, Xiaohong Fan, Hang Li, Xuemei Li, Xue-Wang Li. *Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China.*

**AIM** To explore the the association between history of nephrolithiasis and chrionic kidney disease (CKD) in Chinese general population.

**DESIGN AND METHODS:** In this cross-sectional study, a random sample of 6856 Chinese rural adults aged 30 to 75 years were selected in Beijing during 2008 to 2009. History of nephrolithiasis was assessed by asking:"Did a doctor ever say you had kidney stones?" Reduced eGFR was defined as eGFR <60ml/min/1.73m², albuminuria as albumin-creatinine ratio (ACR) ≥3.39 mg/μmol of first-void urine samples and CKD as the presence of reduced eGFR and/or albuminuria. The estimated marginal means (EMMs) of eGFR and the logarithm of urine ACR by history of nephrolithiasis were calculated and compared with generalized linear modelsThe odds ratios (ORs) of reduced eGFR, albuminuria and CKD associated with nephrolithiasis were obtained with logistic regression. Estimates of EMMs and ORs were adjusted for age, gender and other confounding factors (e.g. hypertension, diabetes, dyslipidemia, obesity, smoking).

**RESULTS:**History of nephrolithiasis had an overall prevalence of 7.41% and was more frequent in men than in women (9.12% vs. 5.71%, p<0.0001). There was significantly higher prevalence of reduced eGFR, albuminuria or CKD between persons with and those without nephrolithiasis (3.9% vs. 1.4%, p<0.0001; 14.4% vs. 10.4%, p=0.003; 15.7% vs 11.2%, p=0.002; respectively). The multivariate-adjusted EMM of eGFR was lower (90.09±0.89 vs. 91.26±0.74 ml/min/1.73m2, p<0.0001) and that of logarithm of ACR (0.316±0.026 vs. 0.267±0.022, p=0.002) was higher in the persons with than in those without history of nephrolithiasis. The multivariate-adjusted ORs of reduced eGFR, albuminuria, microalbuminuria and CKD associated with history of nephrolithiasis were 2.69 (95%CI 1.59-4.55, P<0.0001), 1.44 (95%CI 1.10-1.89, P=0.008), 1.51 (95%CI 1.15-2.00, p=0.003) and 1.44 (95%CI 1.11-1.87, P=0.006) respectively.

**CONCLUSIONS:** History of nephrolithiasis has a high prevalence and significant associations with reduced renal function, albuminuria and CKD in Chinese general population.

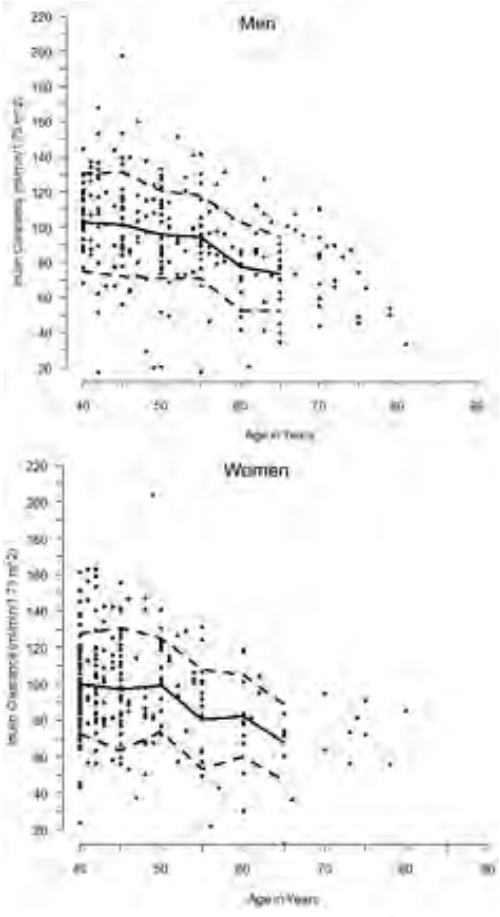
**Kidney Function in South Asians-Measured Glomerular Filtration Rate in the General Population** Tazeen H. Jafar,[1,3] Muhammad Islam,[1] Saleem Jessani,[1] Lesley A. Stevens,[3] Christopher R. Mariat,[2] Andrew S. Levey.[3] *[1]Nephrology, Medicine and Community Health Sciences, Aga Khan University, Karachi, Pakistan; [2]CHU de Saint-Etienne, Université Jean Monnet, Saint-Etienne, France; [3]Nephrology, Tufts Medical Center, Boston, MA.*

Background: South Asian population is at high risk of chronic kidney disease (CKD) due to increased exposure to conventional risk factors, social determinants and low birth weight. Some reports on potential South Asian kidney donors indicate low glomerular filtration rate (GFR) as their normal level, and lowering of GFR thresholds for defining CKD has been suggested for this population. However, the level of kidney function in general adult population of South Asian origin has not been studied.

Methods: We measured GFR using the gold standard of inulin clearance on 530 subjects aged 40 years and above. Participants were randomly selected from communities in Karachi, Pakistan, using multi-stage cluster sampling.

Results: The mean age of participants was 46.9 (9.5) years, 50% were men. About 34% had hypertension (blood pressure >=140/90 mm Hg on two separate days or on antihypertensive medications) and 31% had diabetes (fasting plasma glucose >= 126 mg/dl or on hypoglycemic drugs). The mean inulin clearance (SD) adjusted for BSA was 94.1 (28.6) ml/min/1.73m2: 93.3 (28.1) in men vs 94.9 (29.1) in women (p=0.50). The age specific inulin clearance in men and women are shown in figures below, respectively.



Conclusions: The measured GFR in adults from the general population is not dramatically lower than levels in European-origin counterparts, as suggested by previous reports. Our findings do not support lowering GFR thresholds for defining CKD in Pakistan. Further studies are needed to assess GFR levels across a wider age range, and any regional variation in GFR levels in South Asia.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO315**

**Determinants of Measured Glomerular Filtration Rate in Adults from General Population in Pakistan** Tazeen H. Jafar,[1] Saleem Jessani,[1] Christopher R. Mariat,[2] Andrew S. Levey.[3] *[1]Nephrology, Medicine and Community Health Sciences, Aga Khan University, Karachi, Pakistan; [2]CHU de Saint-Etienne, Université Jean Monnet, Saint-Etienne, France; [3]Nephrology, Tufts Medical Center, Boston.*

Background: Nutritional status and diet influence glomerular filtration rate (GFR) in patients with chronic kidney disease (CKD). South Asians are at high risk of CKD and have poor nutritional indicators. However, the determinants of GFR in unselected general population of South Asian origin have not been studied.

Methods: We assessed the sociodemographic, nutritional, and clinical factors associated with measured GFR (mGFR) in 530 subjects aged 40 years and above. GFR was measured using the gold standard of inulin clearance. Participants were randomly selected from communities in Karachi, Pakistan, using multi-stage cluster sampling. Multivariable models were built using linear regression analysis.

Results: The mean age of participants was 46.9 (9.5) years, 50% were men, 34% had hypertension, 31% had diabetes. The mean body mass index was 25.8 (5.1) kg/m2 and serum albumin was 3.7 (0.3) g/dl. The mean (SD) mGFR adjusted for BSA was 94.1 (28.6) ml/min/1.73m2: 93.3 (28.1) in men vs 94.9 (29.1) in women (p=0.50). In the multivariable model the factors (beta coefficient (SE) ml/min/1.73m2, p value) independently associated with mGFR were: increasing age (-1.90 (0.25) for each 10 year increase, P<0.001), fasting plasma glucose (0.90 (0.17), for each 10 mg/dl increase, p <0.001), serum albumin (5.03 (1.88), for each 0.5 g/dl increase, p=0.008), high vs medium to low dietary meat consumption (5.46 (2.6), (11 or more vs 5 or less servings per week), p=0.04), and urine urea nitrogen (2.03 (0.49), each 1 g/d increase, p<0.001)). Sex was not significant (0.30 (2.47) for men vs women), and no interaction was detected between age and sex on mGFR.

Conclusions: Higher dietary protein intake and better nutritional status are associated with higher mGFR levels in the South Asians from the general population in Pakistan. Further research is needed to determine whether these factors account for regional and ethnic variations in GFR levels among general populations.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO316**

**Inappropriate Use of Metformin in Nursing Home Diabetic Population with Renal Failure** Leah Balsam, Jignesh Shah, Ankita Patel. *Medicine/Nephrology, Nassau University Medical Center, East Meadow, NY.*

**Purpose:** Metformin use has been contraindicated in renal impairment or congestive heart failure and advanced age unless measurement of creatinine clearance shows that renal function is not reduced. Concern remains over the side effect of lactic acidosis, a condition with mortality of up to 50%. Our study was undertaken in a group of nursing home diabetic residents to assess if appropriate considerations with regard to renal function were made before prescribing metformin.

**Methods:** This was a retrospective observational study. It included 64 residents of an Extended Care Facility with history of Diabetes Mellitus type 2 on Metformin. Data regarding age, sex, race, height and creatinine was obtained. Creatinine clearance was calculated using the Cockcroft-Gault equation modified for ideal body weight based on height and gender. Based on prior studies a creatinine clearance more than or equal to 60 mL/min was used as a cutoff for appropriate use of Metformin.

**Results:** In our study 48.5 % (31) of residents were females and 51.5 % (33) were males. The group comprised 40.6 % (26) Caucasians, 37.5 %( 24) African Americans, 17.2 % (11) Asians and 3.1 % (2) Hispanics. The average age was 65.5 years. The average age of females was 71.1 years and that of males was 61.1 years. 17.2 % (11) of the patients had a creatinine of greater than 1.5 mg/dl. 56.3 % (36) patients had a calculated creatinine clearance of less than 60 ml/min.

**Conclusion:** Our study demonstrates that more than half of elderly diabetic nursing home residents were prescribed metformin without adequate consideration to creatinine clearance. Although only 17.2 % had a serum creatinine that would be considered out of the normal range, 56.3 % had significantly decreased renal function. Use of estimated creatinine clearance should be advocated instead of serum creatinine when prescribing metformin.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO317**

**Evaluation of MDRD and Cockroft-Gault Equations for Sitagliptin Dosing** Joanna Q. Hudson,[1] M. Shawn Mcfarland,[2] Brandon M. Markley,[2] Utpal P. Patel.[3] *[1]Dept of Clinical Pharmacy, University of TN, Memphis, TN; [2]Dept of Veterans Affairs, TN Valley Healthcare System; [3]Murfeesboro Medical Center, Murfeesboro, TN.*

The MDRD equation is now advocated along with the Cockcroft-Gault (CG) equation for drug dosing. Currently most dose recommendations by manufacturers are based on estimated creatinine clearance (eCrCl) determined by CG. Few studies have evaluated differences in dosing using MDRD and CG. Sitagliptin is a dipeptidyl peptidase IV inhibitor used for type 2 diabetes mellitus (T2DM) with dose adjustments based on eCrCl. We assessed discordance rates in initial sitagliptin doses recommended using MDRD and CG.

Adult patients with T2DM prescribed sitagliptin in the outpatient clinic Oct 2006-June 2009 were included. Estimated GFR (eGFR) and eCrCl were calculated by the 4-variable MDRD and CG equations, respectively. Sitagliptin dose based on manufacturer's labeling was determined. Discordance in doses recommended using MDRD and CG estimates were compared overall and by subgroup based on eCrCl category (eCrCl >50, 30-50, and <30 mL/min). Discordance in drug dosing between methods was compared using the $x^2$ test; alpha was set at 0.05 a priori with 80% power.

A total of 121 patients were included; 52% male; 90% Caucasian; mean age 61±12 yrs; weight 93±19 kg; ideal body weight 62±10 kg; BSA 2.0±0.22 $m^2$. Mean eGFR was 70±15 mL/min and eCrCl was 67±17 mL/min. Discordance in sitagliptin dose was observed in 17 patients (14%) with MDRD compared to CG ($p<0.001$). Discordance by subgroup was as follows: n=1/2 (50%) for eCrCl < 30, n=8/10 (80%) for eCrCl 30-50, and 8/109 (7%) for eCrCl > 50 mL/min. All patients with eCrCl ≤50 would have received a higher sitagliptin dose using MDRD while patients with eCrCl > 50 would have received a lower dose.

Overall there was agreement in initial sitagliptin dose using MDRD and CG. Discrepancies resulted in underestimation of dose at eClCr above 50 mL/min and overestimation of dose at lower eClCr. Clinical implications are the potential for excessive initial dosing for individuals with kidney dysfunction. Since many agents have similar dosing stratification by eCrCl, this pattern is likely for other renally eliminated agents.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO318**

**Defining "Normal" Kidney Function in Phase I Clinical Trials: An Emerging Issue** Suzanne K. Swan,[1] William B. Smith,[2] Thomas C. Marbury,[3] Harry Alcorn,[1] Mahesh Krishnan,[1] T. Christopher Bond.[1] *[1]DaVita Inc, Denver, CO; [2]New Orleans Center for Clinical Research, New Orleans, LA; [3]Orlando Clinical Research Center, Orlando, FL.*

Background: Though it is generally accepted that renal function declines with age, equations that estimate glomerular filtration rate (GFR) or creatinine clearance do not have defined age-adjusted normal ranges. This leads to problems identifying an appropriate "normal" kidney function, age-matched groups for phase I/II pharmacokinetic trials involving investigational pharmaceutical compounds, particularly in light of a new draft FDA guidance defining "normal" kidney function or eGFR as > 90 ml/min.

Methods: We reviewed pharmacokinetic trial data from 3 phase I clinical research sites (Orlando, New Orleans, and Minneapolis) within the U.S. Renal Network, which performs a large percentage of pharmacokinetic trials in renal impairment subjects annually in the U.S. "Normal" eGFR lab values from 478 age-matched subjects over the past 7 years were available. Simultaneous results for Cockcroft-Gault (CG), Modified Diet in Renal Disease Study (MDRD) equation, or 24 urine collections for creatinine clearance (Ccr) were compared.

Results: The average eGFR of trial participants (as measured by MDRD) was less than 80 ml/min among all men and women aged 40 to 80. In subjects between 50 and 79 years of age, mean eGFR value ranged between 69 and 76 ml/min. If "normal" kidney function is redefined as eGFR > 90 ml/min by the MDRD equation, few, if any, age-matched subjects with "normal" kidney function would be identified for renal impairment subjects. As expected, CG estimates of Ccr were higher on average, with the discrepancy between the methods declining with age of subjects.

Conclusions: A proposed revision of the current FDA guidance on conducting pharmacokinetic drug studies in renal impairment subjects defines normal kidney function > 90 ml/min. However, this standard, if adopted, would complicate the conduct of early phase trials thus delaying drug approval. A lower, or age-adjusted "normal" eGFR is warranted.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO319**

**Validation of Estimating Equations for Lean Body Mass in Morbidly Obese Females** Ion D. Bucaloiu,[1] G. Craig Wood,[2] Evan Norfolk,[1] James E. Hartle,[1] Christopher D. Still,[1] Robert M. Perkins.[1,2] *[1]Geisinger Medical Center, Danville, PA; [2]Center for Health Research, Danville, PA.*

Background: Accurate estimation of lean body mass (LBM) is essential for appropriate determination of creatinine clearance and drug dosing in morbidly obese (MO) individuals (BMI≥40 kg/m²). The validity of existing LBM estimating equations is unknown in this population. Methods: Six previously reported LBM estimating equations were compared with LBM determined by dual energy absorbtiometry body composition (DEXA) in female, MO, Caucasian patients. All were enrolled in a comprehensive weight management program at a tertiary medical center. Correlation and bias against measured LBM were assessed. Results: 70 female patients [mean (SD) age 43.0 (11.0), weight 128.1 (13.8) kg, body mass index (BMI) 48.3 (4.8) kg/m²] underwent DEXA.

Performance of LBM estimating equations among females with morbid obesity

| | | BMI Category, kg/m² | | |
|---|---|---|---|---|
| **Reference** | **LBM Estimating Formula** | **40-44.9** | **45-49.9** | **≥50** |
| | | n=20 | n=27 | n=23 |
| Measured LBM (DEXA), mean (SD), (kg) | NA | 59.3 | 62.4 | 68.0 (5.7) |
| | | r (bias) | | |
| Garrrow (1985) | 0.287 x TBW + 9.74 x Ht² | 0.868 (-0.1) | 0.782 (-0.7) | 0.865 (-1.4) |
| Dufful (2004) | 1.75 x TBW – 0.0242 x BMI x TBW – 12.6 | 0.765 (9.7) | 0.587 (0.6) | -0.013 (-8.0) |
| Janmahasatian (2005) | [9270 x TBW]/[8780 + 244 x BMI] | 0.865 (-3.8) | 0.774 (-5.3) | 0.808 (-7.9) |
| Boddi (1972) | 1.07 x TBW - 0.0148 x BMI x TBW | 0.765 (-9.4) | 0.586 (-6.2) | -0.014 (-9.7) |
| Benezet (1997) | (TBW – IBW)/2 | 0.867 (26.1) | 0.785 (27.5) | 0.871 (30.4) |
| Amato (1995) | IBW + 0.32 x (TBW - IBW) | 0.863 (15.2) | 0.777 (14.8) | 0.836 (14.5) |

IBW - ideal body weight; TBW - total body weight; LBM - Lean Body Mass; BMI - body mass Index; r - Pearson's correlation coefficient.

Conclusions: In this female population with BMI > 40 kg/m², not all previously reported LBM estimating equations performed well. The estimating equation of Garrow et al. best correlated with DEXA LBM and minimized bias.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO320**

**Morbid Obesity: A Common *Noxa* to Kidney and Liver** Sara Goncalves,[1] Mariana Machado,[2] Adília Costa,[3] Fátima Carepa,[4] João Coutinho,[4] Helena Cortez-Pinto.[2] *[1]Nephrology, HSM - CHLN, Lisbon, Portugal; [2]Gastroenterology, HSM - CHLN, Lisbon, Portugal; [3]Histopathology, HSM - CHLN, Lisbon, Portugal; [4]Surgery, HSM - CHLN, Lisbon, Portugal.*

**Introduction and aims**: Obesity is a risk factor for chronic kidney disease (CKD) and nonalcoholic fatty liver disease (NAFLD), suggesting common pathways of lesion. We sought to evaluate early changes in renal function in morbid obese patients with NAFLD.

**Methods**: Morbid obese patients submitted to bariatric surgery, with liver biopsy classified by NAFLD Activity Score. Insulin resistance (IR) was defined as HOMA ≥3. Evaluation of renal function with CKD-EPI (CKD-Epidemiology Collaboration) estimated glomerular filtration rate (eGFR). Determination of plasmatic adiponectin, ghrelin and leptin, by ELISA.

**Results**: 111 patients, 94 women, age 42±11 years old, body mass index (BMI) 46±7 kg/m², IR in 53% and metabolic syndrome in 45%, eGFR 105±17 mL/min/1.73 $m^2$ (<90 mL/min/1.73 $m^2$ in 19%). Liver biopsies were classified as: nonalcoholic steatohepatitis (NASH)/ significant lobular inflammation (≥2), in 23% of patients, and simple steatosis, in 77%. There were no associations between eGFR and lipid profile, presence of metabolic syndrome or IR. eGFR correlated negatively with AST and bilirubin (-0.193, p=0.043 and -0.374, p<0.001, respectively), and was lower in patients with arterial hypertension (99±16 *vs* 110±17 mL/min/1.73m²; p=0.001), in patients with NASH/ significant lobular inflammation as compared to simple steatosis (98±21 *vs* 107±16 mL/min/1.73m²; p=0.034) and in patients with any fibrosis (104±18 *vs* 113±8 mL/min/1.73m²; p=0.0018), with no relation with steatosis severity. eGFR <90 mL/min/1.73m² was associated with NASH/ significant inflammation (52% vs 17%, p=0.001), any lobular inflammation (71% vs 39%, p=0.007) and hepatocyte ballonization (19% *vs* 4%, p=0.04). Neither eGFR nor liver histology was associated with adiponectin, ghrelin or leptin levels.

**Conclusions**: In morbidly obese patients, NASH, and particularly lobular inflammation, is associated with early decreases in eGFR, suggesting a common inflammatory link between liver and renal lesion. Adipokines role seems to be blunted in this high metabolic risk group.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO321

**The Prevalence of Renal Disease and Risk Factors for Renal Disease in Australian HIV-Infected Patients in the Primary Care Setting** David M. Gracey,[1] Mark T. Coulson,[2] Derek Chan.[3] *[1]Renal Unit, Royal Prince Alfred Hospital, Sydney, NSW, Australia; [2]Gilead Sciences, East Melbourne, Victoria, Australia; [3]Albion Street Centre, Surry Hills, NSW, Australia.*

**Aim:** To assess the prevalence of renal disease in the Australian HIV-infected cohort and to evaluate current practices in the management of renal disease and risk factors for renal disease by HIV physicians.

**Methods:** Internet-based data collection undertaken as part of a program to assess the care of common co-morbidities in HIV-infected patients. Primary care physicians (n=51) reported information relating to the renal health of their HIV-infected cohort (n=512).

**Results:** Patients demonstrated a low proportion thoroughly assessed for renal disease. This is despite a high prevalence of kidney disease and a high burden of risk factors. In this study population 93% were male, 39% were smokers, 20% had known hypertension, 5% had diabetes, 5% were morbidly obese and 32% had dyslipidaemia. 83% were on HAART and 6% were coinfected with hepatits C. Of those tested for renal function (n=484), 4% demonstrated an eGFR <60 (n=19); 91% of these patients were proteinuric. 3 patients (0.5%) had an eGFR <15; none were on dialysis. Less than half of all patients had been screened for proteinuria (n=252); of those tested 11.5% had > +1 on urine dipstix (n=29). The majority of patients with proteinuria were not on an ACE inhibitor or ARB (76%). Despite a history of hypertension (n=103), 21% of hypertensive patients were not medicated (n=22); this group had an average blood pressure of 145/92mmHg. Those on antihypertensives (n=66) demonstrated average blood pressure readings of 137/83mmHg. Use of potentially nephrotoxic medications was reported in 16% (n=85). NSAIDs and antiretorvirals were the most commonly reported nephrotoxins. Despite the burden of risk for renal disease and its high prevalence in this population, none of these patients had ever been referred to a Renal Physician for review.

**Conclusions:** This study demonstrates a high burden of renal disease in the HIV-infected population. The current screening and management practices fall short of suggested guidelines. Specialist input from Renal Physicians appears underutilised.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO322

**Chronic Kidney Disease in Patients Alive More Than 10 Years after Allogeneic Hematopoietic Stem Cell Transplantation** Tatsunori Shimoi,[3] Minoru Ando,[1] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Nephrology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; [2]Internal Med IV, Tokyo Women's Medical University, Tokyo, Japan; [3]Hematology, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan.*

**Introduction:** Chronic kidney disease (CKD) is common in survivors of hematopoietic stem cell transplantation (SCT). However, evolution over time of kidney dysfunction and its association with peri-SCT acute kidney injury (AKI) are unclear.

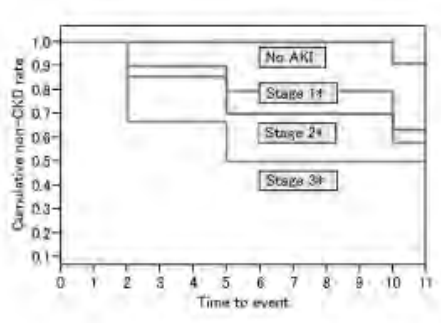
**Methods:** A retrospective cohort study was performed in 100 myeloablative allogeneic SCT patients who lived without relapse over 10 years after SCT. CKD was defined as a sustained decrease in estimated GFR (less than 60 ml/min/1.73 m$^2$) for a period more than 3 months. Prevalence of CKD was studied at 2, 5 and 10 years after SCT. Peri-SCT AKI was classified into three stages according to the AKIN criteria within 100 days after SCT. Cumulative CKD proportion was evaluated by the Kaplan-Meier analysis. The factors associated with 'CKD at 10 years' and 'mortality after 10 years' were examined, using Cox regression analysis.

**Results:** Prevalence of CKD after SCT is shown in **Table 1**. The cumulative CKD rate increased according to increasing AKI stages with significant difference between stages ≥1 and no AKI (**Figure 1**). Cox regression showed that each AKIN stage was a significant predictor of 'CKD at 10 years' [HR (95% CI): stage3, 19 (3.4-154); stage 2, 8.9 (2.0-64); stage 1, 7.8 (2.0-53)] and that CKD at 2 years was significantly associated with 'mortality after 10 years' [HR (95% CI): 11.6 (1.6-103)].

**Conclusions:** Prevalence of CKD increased during the 10-year follow-up period. Peri-SCT AKI, regardless of the AKIN stages, is significantly involved in presence of CKD. Early onset of CKD is potential risk for late mortality in patients alive without relapse.

Prevalence of post-SCT CKD

| Time after SCT | 2 years | 5 years | 10 years |
|---|---|---|---|
| Prevalence | 13% | 23% | 34% |



Disclosure of Financial Relationships: nothing to disclose

### TH-PO323

**Chronic Kidney Disease in Cancer Patients** Shin-Young Ahn,[1] Sewon Oh,[2] Dong Ki Kim,[1] Kook-Hwan Oh,[1] Ki Young Na,[2] Kwon Wook Joo,[1] Chun-Soo Lim,[1] Yon Su Kim,[1] Dong Wan Chae,[2] Curie Ahn,[1] Jin Suk Han,[1] Suhnggwon Kim,[1] Ho Jun Chin.[2] *[1]Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [2]Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul, Republic of Korea.*

Chronic kidney disease (CKD) may be a risk factor for cancer and also cancer can cause CKD. As well, CKD in cancer patients can influence both clinical eligibility for treatment and mortality. Therefore, we investigate the prevalence of CKD, elucidate the risk factors of CKD in cancer patients and assess the impact of CKD on cancer patient survival.

This retrospective study reviewed 3769 patients who were classified according to the diagnostic code, as C-code in ICD-10, and visited the Seoul National University Bundang Hospital at least once in 2004. Patients aged 18 years or more were included. Glomerular filtration rate (GFR) was calculated based on serum creatinine (sCr) using the MDRD formula. CKD was defined as an estimated GFR (eGFR) of less than 60 ml/min/1.73m$^2$.

The study sample consisted of 3716 patients (2078 males; mean age, 59.2 ± 14.1 yrs). Among the 3716 patients, 82.1% had sCr at the time of diagnosis. The prevalence of CKD in cancer patients was 12.6%. Patients with diabetes, dyslipidemia, acute coronary syndrome (ACS), and cerebrovascular accident (CVA) had significantly higher prevalence of CKD than those without such comorbidities. Age ≥60yrs, male gender, diabetes and ACS remained an independent risk factors for CKD in cancer patients after multivariate analysis. During the observational period, all cause mortality rate was 36% and mean follow up duration was 50.6 month. Patients with CKD showed poorer mortality rate than those without CKD (33.6% vs 46.7%, p<0.001). In multivariate analysis adjusted by age, gender, diabetes and cancer types, CKD remained an independent risk factor for all cause mortality (OR 1.562, 95% CI 1.244-1.962).

The prevalence of CKD in cancer patients is higher than general population (12.6% vs 5.1%). Age ≥60yrs, male gender, diabetes and ACS are risk factors for CKD in cancer patients. CKD is one of the major independent risk factors for survival outcome in cancer patients.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO324

**Proteinuria and Microalbuminuria as Predictors of Renal Dysfunction in a Cohort of Marfan Syndrome Patients** Enrique Morales,[1] Eduardo Gutierrez,[1] Alberto Forteza,[2] Raquel Bellot,[2] Violeta Sanchez,[3] Maria Paz Sanz,[1] Jose Cortina,[2] Manuel Praga.[1] *[1]Nephrology, Hospital 12 de Octubre, Madrid, Spain; [2]Cardiac Surgery; [3]Cardiology, .*

Proteinuria and microalbuminuria are considered predictors of renal dysfunction but also as cardiovascular risk indicators. There is no information in the literature on renal involvement in patients with Marfan syndrome (MS)

Objectives: To assess the prevalence of proteinuria and microalbuminuria as predictors of renal dysfunction in Marfan syndrome.

Methods: Forty-eight patients with MS according Ghent criteria have been evaluated to assess renal function. Mean age was 32,3 ± 8,7 and 54% were male. Urine samples of 24 hours were analyzed in each patient to determine proteinuria and microalbuminuria. Additional measures like serum creatinine, creatinine clearance, glomerular filtration, hematuria, presence of ANAs or immunoglobulin A levels were also considered.

Results: Significant proteinuria was found in 25% of patients (0,23 ± 0,03 g/24 hour) and two more patients (4%) presented isolated microalbuminuria. Seven patients had hypertension but only one had proteinuria. Seventeen patients were with drugs blocking renin-angiotensin system. Immunoglobulin A levels were increased in 8 patients (16,7%). The serum creatinine was 0,83 ± 0,19 mg/dL (0.5-1.3). Glomerular filtration rate was 106.2 ± 24.3 ml/min/m2 (66.4-177.2). None patient had GFR below 60 ml/min/m2.

Conclusions: Prevalence of proteinuria and microalbuminuria in MS patients are higher than in general population. Although renal function was not affected it could be an early renal dysfunction predictor. Immunoglobulin A levels were higher than expected, but its relevance is unknown.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO325**

**Fibroblast Growth Factor 23 Is Associated with Proteinuria** Marc G. Vervloet,[1] Arjan D. Van Zuilen,[2] Peter J. Blankestijn,[2] Pieter M. Ter Wee,[1] Jack F. Wetzels.[3] *[1]Nephrology, VU University Medical Center, Amsterdam, Netherlands; [2]Nephrology, University Medical Center Utrecht, Utrecht, Netherlands; [3]Nephrology, Radboud University Medical Cener, Nijmegen, Netherlands.*

Introduction:

Fibroblast Growth Factor 23 (FGF23) may be a risk factor for cardiovascular disease (CVD) in CKD-stages 3 and 4. However, its relation to other risk factors for CVD is ill-defined.

Methods:

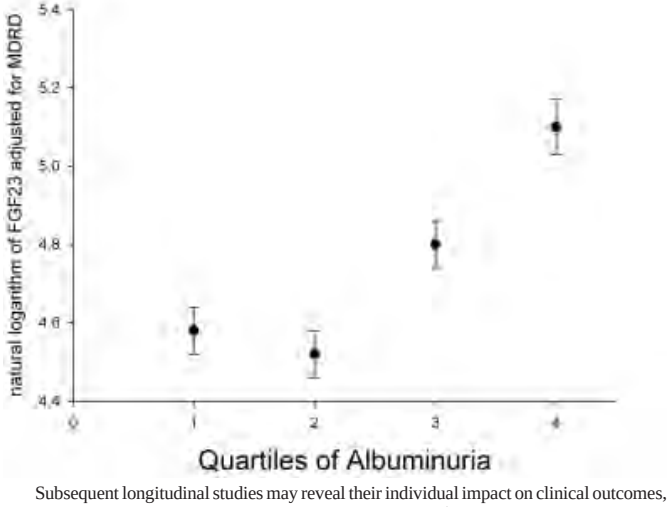
In a large cross-sectional cohort of patients with CKD stage 3 and 4 (The Masterplan Cohort) we assessed the correlation between c-terminal FGF23 levels and creatinine, eGFR, age, gender, race, history of cardiovascular disease, presence of diabetes, blood pressure, 24 hour proteinuria, presence of left ventricular hypertrophia (LVH), socioeconomic background, smoking habits, PTH and phosphate levels. Medications used were recorded. Several multivariate models were used, FGF23 was analyzed after log-transformation.

Results:

We evaluated 701 subjects, with an eGFR of 37 ± 14 ml/min; age 59 ± 13 years; 68% males; 92% Caucasians; 24% diabetics; 24% smokers; 29% with a history of CVD; and 14% with LVH. Blood pressure was 136/78 ± 21/11 mmHg; phosphate 1.09 ± 0.24 mmol/l and PTH 9 ± 9 nmol/l. Proteinuria median was 300 (100-700 IQR)mg/24 hrs. In univariate analysis females, diabetes, smoking, history of CVD, systolic blood pressure, phosphate, PTH, use of phosphate binders, proteinuria and active vitamin D usage were all significantly correlated with FGF23. Using multivariate modelling eGFR ($p<0.001$), PTH ($p<0.001$), phosphate ($p<0.006$), and proteinuria ($p<0.001$) were associated with FGF23.

Conclusion:

Both eGFR and proteinuria are highly significantly and independently associated with FGF23 in stage 3 and 4 CKD.



Subsequent longitudinal studies may reveal their individual impact on clinical outcomes, and may strengthen the hypothesis that FGF23 is a target of therapy.

**A Comparison of Prediction Equations for Estimating Glomerular Filtration Rate in Preeclampsia** Mahfuzur Rahman, Arnold B. Alper. *Nephrology & Hypertension, Tulane University Health Science Center, New Orleans, LA.*

**Background:**

Accurate estimation of the Glomerular Filtration Rate (GFR) in patients with preeclampsia is often difficult or impossible to accomplish. Measurement of the GFR either with Cockroft-Gault (CG) or the MDRD formula has not been validated in this setting.

**Objective:**

In a previous study, a newly created formula, the Preeclampsia GFR (PGFR) formula was proposed to accurately estimate GFR in preeclamptic patients. This study compared the utility of the CG, MDRD, and PGFR equations to predict the GFR in preeclampsia in a larger, more ethnically diverse population.

**Methods:**

This was a retrospective chart review study that compared the estimated GFR calculated from the above formulas with the creatinine clearance values (gold standard) obtained from a 24-hour urine collection in 515 preeclampsia patients from 5 large hospitals.

**Results:**

The Cockcroft-Gault formula provided the highest mean GFR (160 ml/min) and the MDRD formula provided the lowest (107ml/min). The PGFR formula provided an estimated GFR (131ml/min) that was very similar to that provided by the 24 hour Creatinine clearence (132 ml/min). The CG formula had the highest relative bias (19.5%) significantly overestimating GFR in all subjects, while the MDRD formula had smaller but significant relative bias (-12.1%) underestimating the GFR. The PGFR formula had the smallest relative bias (2.25%) and performed significantly better in predicting a GFR that was within 10% or 30% of the gold standard.

**Conclusion:**

Current GFR estimation equations based on serum creatinine values in non-pregnant patients are not reliable measures of renal function in patients with preeclampsia. The use of proposed PGFR formula is recommended.

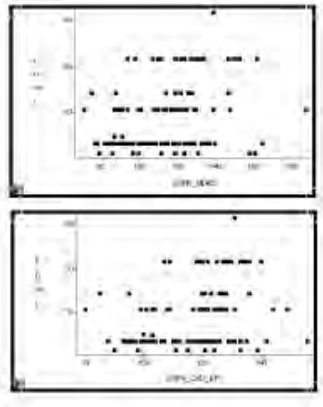
**Retrospective Review of Serum Creatinine and Creatinine-Based Measures of Estimated Glomerular Filtration Rate in an Amputee Population** Casey Cotant,[1] Molly A. Tilley,[1] Ian J. Stewart,[1] Ellen E. Im,[3] Kelly D. Heegard,[3] Kevin Chung.[2] *[1]Nephrology, Wilford Hall Medical Center, Lackland Air Force Base, TX; [2]Institute of Surgical Research, Brooke Army Medical Center, Ft Sam Houston, TX; [3]Internal Medicine, SAUSHEC, Lackland Air Force Base, TX.*

**Background:** The MDRD and CKD-EPI equations may be over estimating the renal function of the wounded warrior amputee population potentially leading to erroneous medication dosing and inadequate disease surveillance.

**Methods:** Serum creatinine levels obtained from chart review of 206 patients with a history of traumatic amputation at the Center for the Intrepid were analyzed and averaged. Patients with acute kidney injury (AKI), as defined by Acute Kidney Injury Network (AKIN) 1 criteria or greater, were excluded. Estimated percentage of body weight lost (EBWL) was calculated for each patient using a formula derived by Osterkamp that takes into account the location and type of amputation. Estimated GFR (eGFR) was calculated using the Modification of Diet in Renal Disease (MDRD) equation as well as the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation. The data was recorded as a scatter plot demonstrating the relationship between EBWL and eGFR by MDRD and CKD-EPI equations. Spearman correlation coefficients were calculated.

**Results:** Both MDRD and CKD-EPI were significantly positively correlated with EBWL, with r values of 0.32 and 0.27 and p values of 0.0001 and 0.0010, respectively.



**Conclusions:** In patients with decreased muscle mass secondary to amputations, both the MDRD and CKD-EPI equations over estimate GFR, as evidenced by weak but statistically significant increases in eGFR with greater percentages of lost muscle mass. Further research comparing estimating equations to gold standard methods of GFR measurement is needed in the amputee population.

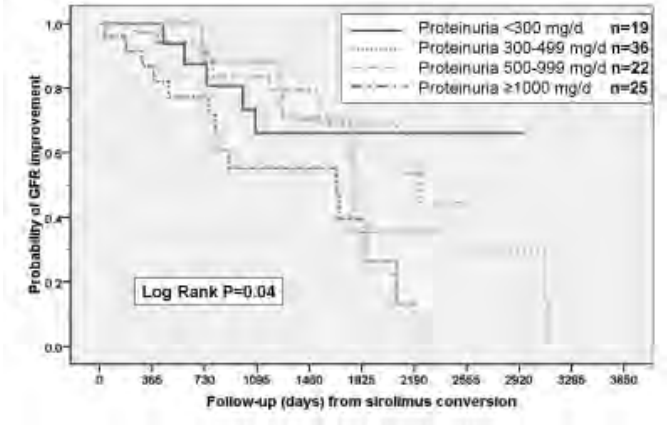
**Sirolimus Induced Proteinuria Is Associated with Deterioration in Kidney Function in Liver Transplant Recipients with Calcineurin Inhibitor Nephrotoxicity** Hani Wadei, Ziad S. Zaky, Barry Rosser, Andrew Keaveny, Thomas A. Gonwa. *Transplantation, Mayo Clinic, Jacksonville, FL.*

**Background:** Proteinuria develops following sirolimus conversion in liver transplant (LT) recipients with calcineurin inhibitor (CNI) nephrotoxicity but its effect on post-conversion improvement of kidney function is unknown. **Methods:** Data of 102 consecutive LT recipients with CNI nephrotoxicity who were converted from cyclosporine (n=3) or tacrolimus (n=99) to sirolimus and remained on sirolimus monotherapy for ≥4 months were retrospectively reviewed. Kidney function was assessed using serum creatinine (Cr) and MDRD eGFR at time of conversion and serially thereafter. 24-hr urine for protein excretion was collected annually or when clinically indicated. **Results:** The follow-up period from sirolimus initiation to death, sirolimus discontinuation or last Cr was 2.9 ± 2.0 years. Stabilization or improvement in kidney function was defined as ΔeGFR (eGFR at last followup-eGFR at conversion) of ≥0 ml/min and developed in 65 (64%) patients. Post-sirolimus proteinuria ≥300mg/d developed in 83 (81%) and had a graded negative impact on eGFR improvement post-conversion with the highest probability of eGFR deterioration in those with proteinuria ≥ 1gr/day. **Figure 1.**

**Figure 1:** Kaplan-Meier plot showing the relationship between proteinuria and probability of GFR improvement in LT recipients with CNI nephrotoxicity converted to sirolimus



Sirolimus was discontinued in 11 patients for proteinuria which subsequently improved in 9 (82%). eGFR changed from 35.8±7.7 to 44.2±9.0 ml/min (P=0.06) in 8 patients following sirolimus discontinuation while 3 remained dialysis dependent. **Conclusions:** 1) Proteinuria was common following sirolimus conversion in LT patients with CNI nephrotoxicty 2) Post-sirolimus proteinuria showed a graded negative impact on the probability of post-conversion kidney function improvement 3) Proteinuria and kidney function improved following sirolimus discontinuation.

## TH-PO329

**Vitamin D Deficiency and Cardio-Renal Risk Factors in Children: National Health and Nutrition Survey (NHANES) 1999-2004** Peter Chau,[1] Sheena Cecille Marie Go,[2] Dulcie Kermah,[4] Keith C. Norris,[1,4] Kamyar Kalantar-Zadeh,[1,2,3] Gangadarshni Chandramohan.[1,2,3] *[1]University of California, David Geffen School of Medicine, Los Angeles, CA; [2]Pediatrics, Harbor-UCLA Medical Center, Torrance, CA; [3]Los Angeles Bio-Medical Research Institute, Torrance, CA; [4]RCMI, Charles Drew University, Los Angeles, CA.*

Vitamin D deficiency is associated with poor cardiac and renal outcomes in adults. In children, prevalence of vitamin D (VitD) deficiency has been increasing. We analyzed the risk VitD deficiency based on gender, ethnicity and other risk factors in children. **Methods**: VitD deficiency (<15ng/ml), insufficiency (15-29ng/ml) and combined (vitDdef). High waist circumference (WC): >75th percentiles. Obesity: BMI >95$^{th}$ percentile. Dyslipidemia (Dyslip): abnormal lipid profile. Abnormal fasting blood sugar (abFS): > 100mg/dl. High blood pressure (HBP): >90th percentile. Metabolic syndrome (MetS): 3 or 4 components of MetS. **Results**: Analyzed 2202 children, 6 -17 yrs; 51% males, 66% White, 15% Black, 19% Hispanic, 11% obese, 27% with high WC, HBP 9%, Dyslip 52%, abFS 7% and MetS 3%. VitD deficiency found in 78% and was significantly high in females, Blacks, Hispanics, obese, those with high WC, Dyslip and MetS. Odd ratio for vitDdef was only high in females, Blacks, Hispanics, obese and with Dyslip.

Odds Ratio for Vitamin D Deficiency Associated with Various Risk Factors

| Variables | Odds Ratio | 95% Confidence Interval |
|---|---|---|
| Gender (Female=1) | | |
| Male | 0.6 | .39 - .82 |
| Races (White=1) | | |
| Black | 58.1 | 15 - 224 |
| Hipanic | 6.2 | 3.3 - 11.7 |
| Waist circumference (Normal=1) | | |
| *High | 1.6 | 1.0 - 2.5 |
| **Obesity (No=1) | | |
| Yes | 1.8 | 1.1 - 3.1 |
| Blood Pressure (Normal=1) | | |
| ^High | 0.6 | 0.3 - 1.0 |
| Dyslipidemia (No=1) | | |
| Yes | 1.5 | 1.0 - 2.3 |
| Fasting blood sugar (Normal=1) | | |
| Abnormal | 1.5 | 0.7 - 3.4 |
| Metabolic syndrome (No=1) | | |
| Yes | 1.4 | 0.3 - 7.0 |

*High waist circumference >75th percentile, **Obesity=BMI >95th percentile, ^Blood pressure - high=systolic and/or diastolic >90th percentile

**Conclusion**: Risk of Vitamin D deficiency was high in female, Black, Hispanic, obese and Dyslip children. Dietary factors perhaps the major culprit. Further studies needed to identify the mechanisms of development of vitDdef in children.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO330

**Cocaine Use and Chronic Kidney Disease in the United States** Ruchir Patel,[1] Ankit Rathod,[1] Apurva Badheka,[1] Zeenat Yousuf Bhat.[2] *[1]Internal Medicine, Wayne State University/Detroit Medical Center, Detroit, MI; [2]Division of Nephrology, Wayne State University/Detroit Medical Center, Detroit, MI.*

**Background:**

Epidemiologic data regarding cocaine associated chronic kidney disease (CKD) is lacking.

**Methods:**

All adults (>18years) in the publicly available dataset of the National Health and Nutrition Examination III (NHANES III) survey between 1988-1994 (n=11990) were analyzed. History and frequency of cocaine use was self reported. The two groups were analyzed on basis of lifetime cocaine use as present or absent. We excluded subjects with data missing regarding cocaine use, serum creatinine and BMI (n= 5090). Creatinine clearance (ml/min) was calculated using Cockcroft-Gault equation and GFR was calculated using MDRD equation. CKD was graded per established criteria. Other baseline variables included in the model were age, sex, race, lipid profile, diabetes, hypertension, smoking, BMI, stroke, myocardial infarction, peripheral arterial disease and homocysteine level. Beta parameter estimate and odds ratio were calculated using linear and logistic regression and considered significant for p<0.05. All analysis were performed using SAS 9.2.

**Results:**

Our cohort consisted of 6900 adults with 49% males, 5.1% MI, 3.9% stroke, 26% hypertensives, 7.8% diabetics and 26% smokers. Mean age, BMI and eGFR were 48 years, 25.9 kg/m$^2$ and 86 ml/min respectively. Cocaine use was not associated with decreasing eGFR or creatinine clearance (beta 0.14, p = 0.91) on multivariate analysis. Cocaine use was also not associated with worsening CKD stage as an ordinal variable(OR = 1.05, 95%C.I 0.86-1.24,p =0.70). Even in patients with >100 lifetime exposures to cocaine this relationship did not change.

**Conclusion:**

Cocaine use was not associated with CKD in this large cross sectional survey representative of the adult US population after controlling for race, hypertension and cardiovascular risk factors. This is in contrast to prior data from small case series or single center studies. It is unknown whether cocaine per se is causes pathologic changes and CKD. Our results indicate that CKD among cocaine users is secondary to cocaine associated cardiovascular co-morbidities.

## TH-PO331

**Role of Lean Body Mass in Estimating GFR in Alzheimer Disease** James B. Wetmore,[1] Jeffrey M. Burns.[2] *[1]Medicine, Division of Nephrology and Hypertension, University of Kansas Medical Center, Kansas City, KS; [2]Neurology, University of Kansas Medical Center, Kansas City, KS.*

**Introduction**

The association between estimated glomerular filtration rate (eGFR) and progression of Alzheimer Disease (AD), as measured by cognitive decline and brain atrophy, has not been systematically studied. Since AD is characterized by sarcopenia and other changes in body composition, determining the applicability of various eGFR equations, particularly those that account for lean mass (LM), is important.

**Methods**

Participants were drawn from a prospective longitudinal study of brain aging and AD in community-dwelling individuals. Control ($n$ = 60)and AD ($n$ = 61) participants had baseline and 2-year assessments of both cognitive function and brain volume. Estimated GFR was calculated using the 4-variable MDRD and Lean Mass (LM) GFR (eGFR = (2.4 * LM) - (0.75 * LM * creatinine)) equations. Association of eGFR and the outcomes was examined.

**Results**

Individuals with AD demonstrated a paradoxical finding in which lower baseline MDRD eGFR was associated with lower rates of both cognitive decline ($p$ =0.04) and brain atrophy ($p$ = 0.02), a phenomenon not observed in non-AD controls. This finding was abolished in the AD individuals when the LM GFR equation was used. While significant group-by-eGFR interactions were present for cognitive decline ($p$ = 0.006) and brain atrophy ($p$ = 0.001) when MDRD was used, no group-by-eGFR interactions were present when LM GFR was used ($p$ = 0.92 and $p$ = 0.52 for cognitive decline and brain atrophy, respectively).

**Conclusions**

Accounting for LM in GFR estimation appears to significantly mitigate counterintuitive relationships between measures of AD progression and eGFR as calculated by more traditional measures of renal function. This suggests that consideration of lean mass in eGFR calculations may be important in the AD population.

**TH-PO332**

**Recognition of Chronic Kidney Disease: Prevalence and Predictors** Rajyalakshmi Gadi,[1] Lakshmi Venkitachalam,[2] John Spertus,[2] John Powers,[3] Paul S. Chan.[2] *[1]Nephrology, Univ of Kansas Med Ctr, KS; [2]CV Research, Saint Lukes' Mid America Heart Inst., MO; [3]Kaiser Permanente Inst. of Research, CO.*

**Background:** Because chronic kidney disease (CKD) is associated with significant cardiovascular (CV) morbidity and mortality, early recognition of incident cases would facilitate appropriate care. However, it is unknown whether the introduction of the new ICD-9-CM codes by CKD stages in early 2006 has increased physician recognition rates of this disease entity.

**Methods:** Within the Kaiser Permanente Colorado hypertension registry of 186,195 patients enrolled from 2000-2007, we identified 16,833 patients with incident CKD, defined as 2 consecutive estimated glomerular filtration rate's (eGFR) below 60ml/min/1.73m$^2$ and which were 3-12 months apart. The primary outcome, clinician recognition of incident CKD was defined as documentation of CKD with an ICD-9 code within 1 year of the second eGFR. Using multivariable logistic regression, we compared CKD recognition rates before and after 2006.

**Results:** Overall, CKD was recognized by physicians in 1446 (8.6%) patients, in 7.5% (1218/16122) with moderate CKD (eGFR 30-59) and 32.0% (228/711) with severe CKD (eGFR 15-29). The CKD recognition rate increased from 6.9% (969/13847) before 2006 to 15.9% (477/2986) after 2006. After multivariable adjustment, the likelihood of CKD recognition increased by more than 3-fold after 2006 (Adjusted odds ratio of 3.30, P<.0001).

Independent Predictors of CKD Recognition

| Covariate | Adjusted OR | P value |
|---|---|---|
| Age | 0.99 | <0.0001 |
| Male sex | 3.10 | <0.0001 |
| Black race | 2.56 | <0.0001 |
| Diabetes | 1.50 | <0.0001 |
| CHF | 2.05 | <0.0001 |
| Albuminuria | 1.10 | 0.75 |
| CKD stages 4-5 | 7.99 | <0.0001 |
| Introduction of new CKD ICD codes[a] | 3.30 | <0.0001 |

[a] After 2006 vs. Before 2006

**Conclusion:** While CKD recognition rates remain low, they have increased 3-fold since the new CKD ICD coding system has heightened awareness about CKD. Future studies need to examine whether improved CKD recognition resulted in more intensive CV risk factor modification and avoidance of nephrotoxic medications.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO333**

**BMP7 Maintains Nephron Progenitor Population and Determines Nephron Number** Mayumi Tomita,[1] Itsuro Kazama,[2] Nariaki Asada,[1] Atsuko Y. Higashi,[1] Shuichiro Endo,[1] Toru Kita,[3] Atsushi Fukatsu,[1] Aris N. Economides,[4] Elizabeth Robertson,[5] Jordan A. Kreidberg,[6] Motoko Yanagita.[1] *[1]Graduate School of Medicine, Kyoto University, Japan; [2]Tohoku University, Sendai, Japan; [3]Kobe City Medical Center, Hyogo, Japan; [4]Regeneron Pharmaceuticals, Inc., NY; [5]University of Oxford, United Kingdom; [6]Division of Nephrology, Children's Hospital Boston, MA.*

The number of nephrons varies between individuals, and low nephron number associates with the risk of hypertension and progression of renal insufficiency. However, the molecular mechanisms determining nephron number has not been clarified. Bone morphogenic protein 7 (BMP7) knockout mice demonstrate aplastic kidneys with few nephrons, however, the precise mechanism has not been clarified, because the nephrogenesis is arrested at the early stage of kidney development. Systemic knockdown of BMP7 after the initiation of kidney development enabled us to observe the prominent apoptosis and accelerated epithlialization and maturation of metanephric mesenchyme, which is known to include nephron progenitor population. Knockdown of BMP7 in kidney explants resulted in the accelerated epithelialization of metanephric mesenchyme. Inhibition of Smad1/5/8 in wild-type kidney explants similarly demonstrated the accelerated epithelialization. We also examined the inhibitory effect of BMP7 on epithelialization in colony-forming assay, in which metanephric mesenchymal cells epithelialize and form sheet-like colonies. Administration of BMP7 to this culture system dose-dependently prevented colony formation. Taken together, BMP7 inhibits apoptosis and differentiation of nephron progenitors through Smad signaling. In conclusion, BMP7 seems to maintain nephron progenitors and regulate nephron number at birth.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO334**

**Inhibitory Effect of Mesenchymal Stem Cells on the Progression of Experimental Peritoneal Fibrosis in a Rat Model** Toshinori Ueno,[1,2] Ayumu Nakashima,[2] Yoshihiko Taniguchi,[4] Takeshi Kawamoto,[3] Yukio Kato,[3] Noriaki Yorioka.[2] *[1]Department of Molecular and Internal Medicine; [2]Department of Advanced Nephrology; [3]Department of Dental and Medical Biochemistry, Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima, Japan; [4]Department of Pharmaceutical Science, Hiroshima International University, Kure, Japan.*

**Background:** Recent studies have suggested that mesenchymal stem cells (MSCs) can be employed for various types of tissue damage because of their regenerative capacity and immunoregulatory properties, but the involvement of MSCs in peritoneal fibrosis is not clear.

**Methods:** Using male SD rats or Fisher 344 rats, a peritoneal fibrosis model was created by intraperitoneal injection of 0.1% chlorhexidine gluconate in 15% ethanol dissolved in saline, while 15% ethanol in saline was injected as a control. MSCs were obtained from the bone marrow of GFP transgenic rats and cultured. Then MSCs ($1\times10^7$ cells) suspended in 1 mL of PBS or vehicle were injected intraperitoneally into the peritoneal fibrosis model rats and control rats. At 7 and 14 days after injection of MSCs, the peritoneal tissues were taken for immunohistochemical analysis. In a separate in vitro investigation, we cultured human peritoneal mesothelial cells (HPMCs) with a high concentration of D-glucose (4%) and co-cultured HPMCs with human MSCs by using a trans-well system. To clarify the effect of MSCs, TGF-β mRNA expression by HPMCs was evaluated with RT-PCR.

**Results:** We found GFP-positive MSCs on the peritoneal surface in MSC-treated rats with fibrosis, but GFP-positive MSCs were not seen in MSC-treated control rats. Injection of MSCs suppressed myofibroblast accumulation (α-SMA), macrophage infiltration (ED-1), and the expression of TGF-β and MCP-1 in the peritoneum. TGF-β mRNA expression by HPMCs was increased 4.3-fold after exposure to a high concentration of D-glucose compared with the control (P<0.01), while there was 0.65-fold suppression by co-culture with human MSCs (p<0.05).

**Conclusions:** Our findings suggest that MSCs were mobilized to sites of peritoneal damage and that these cells may have anti-inflammatory and anti-fibrotic effects against peritoneal fibrosis.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO335**

**Effect of hMSCs Microvesicles on Cystine Content of *CTNS* Mutant Human Fibroblasts** Reyhan El-Kares,[1] Francesco Emma,[2] Nicoletta Eliopoulos,[3] Paul R. Goodyer.[1] *[1]Pediatrics, McGill University, Montreal, QC, Canada; [2]Nephrology and Urology, Bambino Gesù Children's Hospital, Rome, Italy; [3]Experimental Medicine, McGill University, Montreal, QC, Canada.*

Cystinosis is caused by mutations in the *CTNS* gene, encoding a cystine transporter in the lysosomal membrane. In affected children, cystine accumulates within lysosomes, causing progressive multi-organ dysfunction and a need for renal replacement therapy in the second decade of life. Recently, Syres *et al* reported that an infusion of heterologous wildtype bone marrow stem cells dramatically reduced pathologic cystine accumulation and reversed renal dysfunction in *Ctns* knockout mice. However, there was little evidence of replacement of the mutant tissue by transdifferentiation of wildtype stem cells. We hypothesized, therefore, that human mesenchymal stem cells (hMSCs) might correct the primary defect by shedding microvesicles (MVs) that transfer wildtype cystinosin to the mutant tissue.

Cystinotic fibroblasts derived from a patient with homozygous deletion (57kb) of the *CTNS* gene were co-cultured with hMSCs (in a 4:1 ratio) for 96 hours. Cystine level of the mixed cell population was 50% of the baseline level in mutant fibroblasts alone.

To test our hypothesis, we isolated MVs by ultracentrifugation from hMSC-conditioned medium and added them to human cystinotic fibroblasts. After 24 hours, we noted a MVs dose-dependent reduction of cystine content in the mutant fibroblasts. Exposure to 1700μg/ml of MVs reduced cystine content to the level in control non-cystinotic fibroblasts.

These observations indicate that the powerful effect of stem cells to reverse the pathologic cystine accumulation in *CTNS*$^{(-/-)}$ tissue is conferred by microvesicle transfer and cannot be explained by other postulated paracrine effects of stem cells such as stem cell transdifferentiation, suppression of inflammation or stimulation of endogenous cell proliferation. We speculate that microvesicle transfer of wildtype protein and/or mRNA may be relevant to stem cell therapy for cystinosis and other inherited renal diseases.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO336**

**Mesonephric Development and Regeneration in Transgenic Zebrafish** Weibin Zhou,[1] Rudrick Casey Boucher,[1] Christoph Englert,[3] Friedhelm Hildebrandt.[1,2] *[1]Pediatrics and Human Genetics, University of Michigan, Ann Arbor, MI; [2]Howard Hughes Medical Institute; [3]Leibniz Institute for Age Research, Fritz Lipmann Institute, Jena, Germany.*

Zebrafish represents a valuable vertebrate model for kidney research. The majority of previous studies were focusing on the pronephros of zebrafish, which consists of only two nephrons. It is structurally and functionally simpler than the mesonephros of adult fish and the metanephros of mammals. To evaluate the zebrafish system for studies of kidney development and regeneration, we investigated the development and post-injury regeneration of mesonephros in adult zebrafish.

Utilizing two transgenic zebrafish lines (wt1b::GFP and Pod::NTR-mCherry), we characterized the developmental stages of individual mesonephric nephron and the temporal-spatial pattern of mesonephrogenesis. We found the mesonephrogenesis continues throughout the life of zebrafish, with a rapid growth phase during the juvenile period and a slower phase in adulthood. Interestingly, the total nephron number of juvenile and adult fish linearly correlates with the body mass.

Following gentamicin-induced renal injury, the zebrafish mesonephros can undergo *de novo* regeneration of mesonephric nephrons, known as neo-nephrogenesis. We here used transgenic zebrafish to investigate the initialization of neo-nephrogenesis. As early as 48 hours post injury *wt1b* expression was induced in individually dispersed cells in the mesonephric mesenchyme. This was followed by aggregation of *wt1b*-expressing cells and nephron formation, suggesting that *wt1b* may serve as an early marker of fated renal progenitor cells. The gentamicin-induced injury causes overly synchronized mesonephrogenesis, useful for developmental studies of nephrons.

With the inducible podocyte injury model we have generated, we characterized the repair process initiated after podocyte injury in mesonephros and found that *wt1b* expression expands into Bowman's capsule. This indicates a podocyte-specific repair mechanism in zebrafish mesonephros, a process also known to occur in metanephros following podocyte injury. Thus zebrafish mesonephros may serve as a suitable animal model for studies of glomerular repair.

**Clonal Analysis, Sphere-Formation and Cell Sorting Identify Human Adult Kidney Cells Capable of Enhanced Tubular Regeneration *In Vivo*** Ella Buzhor,[1] Orit Harari-Steinberg,[1] Dorit Omer,[1] Michal Mark-Danieli,[1] Tzahi Noiman,[2] Ronald S. Goldstein,[2] Benjamin Dekel.[1] *[1]Pediatric Stem Cell Research Institute, Sheba Medical Center, Tel Hashomer, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [2]Mina and Everard Goodman Faculty of Life Sciences, Bar-Ilan University, Ramat Gan, Israel.*

Human adult kidney (hAK) stem/progenitor cells are ideal targets for gene therapy, cell transplantation and tissue engineering. However, their identity remains elusive. Cells from dissociated human tissues that express tissue-specific stem cell markers are clonogenic and form spheres *in vitro* and capable of tissue regeneration *in vivo* often represent progenitor cells. Based on these assays we have now analyzed expanded heterogeneous cultures of kidney epithelial cells retrieved from nephrectomy samples and sorted cell subpopulations for progenitor potential.

Clonal analysis of individual cells in cultures from 5 hAK samples revealed clone frequency of 1-4% and clonogenic expansion, indicative of self-renewal, mostly up to passage 3-5, with a single clone expanded to P10. The addition of human fetal kidney culture conditioned media (hFKCM) to hAK cells augmented clonogenic frequency and self-renewal. When switched to low-attachment conditions 'nephrospheres' developed in hAK cultures resulting in up-regulation of renal progenitor markers. Although, human nephrospheres were not entirely clonally-derived, sphere cells grafted in the chick embryo displayed enhanced regenerative capacity of the entire tubular spectrum. Finally, fractionation of hAK cells according to *NCAM1* expression, an embryonic renal progenitor surface antigen that re-appeared in culture, selected a cell subpopulation that overexpressed renal 'stemness' genes (*Six2/Sall1/Pax2/Wt1*) and proximal tubule markers (*aquaporin1, aminopeptidaseA*), exclusively formed well-defined 'nephrospheres' and was highly clonogenic when seeded on matrigel with FKCM. When grafted into the chick embryo NCAM1+ cells showed preferential reconstruction of proximal tubules.

Thus, we have identified hAK growth conditions and specific cell subsets that harbor progenitor potential and promote renal regeneration.

### TH-PO338

**Expression of Receptor-Type Tyrosine Phosphatases VE-PTP and PTPμ in Developing and Adult Renal Endothelium** Keiko Takahashi,[1] Colette R. Hunt,[1] Rebecca S. Weller,[1] Hiroki Fujita,[1] Dietmar Vestweber,[2] Nicholas W. Gale,[3] Takamune Takahashi.[1] *[1]Nephrology, Vanderbilt University Medical Center, Nashville, TN; [2]Max Planck Institute for Molecular Biomedicine, Muenster, Germany; [3]Regeneron Pharmaceuticals, Tarrytown, NY.*

Renal vascular development is a coordinated process which requires ordered endothelial cell proliferation, migration, intercellular adhesion, and morphogenesis. In recent decades, extensive efforts have defined the pivotal role of endothelial receptor tyrosine kinases (RPTKs) in the development of renal vasculature. However, the role of receptor tyrosine phosphatases (RPTPs), counter enzymes of RPTKs, remains unknown. Therefore, here we evaluated the expression of endothelial RPTPs, VE-PTP and PTPμ, in developing (from E12.5 to P7) and adult renal vasculature using the heterozygous LacZ knock-in mice as well as the specific antibodies. In adult kidney, both RPTPs are abundantly expressed in arterial and glomerular endothelial cells. They are also expressed in segments of vasa recta, whereas their expression is limited or absent in peritubular capillaries (PTCs) and venous circulations. In developing kidneys, VE-PTP is expressed in branching renal arteries, developing glomerular endothelium (as early as S-shaped stage), and medullary vessels (from E15.5 stage). Its expression becomes prominent as the vasculatures mature. Interestingly, substantial VE-PTP expression was observed in the PTCs of P3 and P7 kidneys, whereas it is down-regulated in adult PTCs; the finding indicates that VE-PTP expression is strictly controlled during the development of PTCs. Compared with VE-PTP, PTPμ protein expression is highly limited in embryonic and neonatal renal vasculature, although the promoter activity is observed in developing renal arteries and glomerulus. Its protein expression in renal vasculature is remarkably increased from P3 stage. Thus, compared to RPTKs, VE-PTP and PTPμ are expressed at later stage of renal vascular development and the differences in their expression timing suggest distinct role of these RPTPs in maturation and maintenance of the renal endothelium.

**Angiotensin (Ang) II-Dependent Ureteric Bud (UB) Branching Morphogenesis Is Mediated by UB Cell Movements** Renfang Song, Graeme James Preston, Ihor V. Yosypiv. *Pediatrics, Tulane University School of Medicine, New Orleans, LA.*

Directional UB cell migration represents an important cellular mechanism of UB branching morphogenesis. Here, we tested the hypothesis that Ang II-induced UB cell migration is essential for UB branching morphogenesis. Quiescent UB cells were grown overnight on top of transwell filters (8-μm-pore size, Corning, Acton, MA) the bottom side of which was precoated with 2 μg/ml fibronectin at 370 C and 5% CO2. Ang II ($10^{-5}$ M) or media (control) were added to the bottom of the well. The cells on the upper surface of the filter were removed with a cotton swab, the membrane was fixed, stained with hematoxylin-eosin, and mounted on a slide. The mean number of cells that migrated through each membrane was determined by counting the number of cells in 5 high-power fields (x400)/well (n=4 wells/treatment group). Ang II increased the number of cells that migrated through the filter compared with control (336±5.1 vs. 301±4.4, $p<0.05$). To determine whether Ang II can directly stimulate UB morphogenesis, E11.5 HoxB7-GFP+ intact UBs were suspended in Matrigel and grown at 37° C for 5 days on transwell filters located on top of DMEM/F12 medium containing GDNF (120 ng/ml) and FGF (100 ng/ml) (n=6) or GDNF/FGF and Ang II (10-5 M, n=6). Ang II increased the number of UB tips on day 5 compared to control (20.0±2.1 vs. 12.1±0.7; $p<0.01$). To identify UB cell-autonomous genes expression of which is altered by Ang II signaling, we examined the effect of Ang II (10-5 M) or media (control) on global gene expression in intact UBs after overnight culture using Agilent mouse GE4X44K microarray. 19 transcripts were upregulated by Ang II by four-fold or more and 68 by two-fold. Ang II downregulated 14 transcripts by four-fold or more and 52 by two-fold. Detailed analysis is underway to identify gene and signal transduction networks downstream of Ang II. In summary, Ang II stimulates UB cell migration and directly induces morphogenetic response in intact UBs. We hypothesize that: 1) Ang II-dependent cell movements play an important role in UB branching morphogenesis, and 2) Gene networks downstream of Ang II mediate the effects of Ang II on UB branching.

**Use of the E2F1 Transgenic Suicide-Inducible Mice Permit Regeneration of Completely Human Kidneys** Kei Matsumoto,[#1] Takashi Yokoo,[#1] Shinya Yokote,[#1] Tetsuya Kawamura,[#1] Toya Ohashi,[#1] Tatsuo Hosoya,[#1] Osahiko Tsuji,[#2] Hirotaka James Okano,[#2] Hideyuki Okano,[#2] Eiji Kobayashi.[#3] *[1]The Jikei University School of Medicine, Tokyo, Japan; [2]Keio University School of Medicine, Tokyo, Japan; [3]Jichi Medical University, Tochigi, Japan.*

Introduction: We have grown a chimeric kidney using human mesenchymal stem cells (MSCs) that produces urine and erythropoietin (EPO) but is derived from both the human MSCs and the host animal cells. To remove the animal component from the chimera we have established a novel system, in which the xeno-tissue component can be eliminated during development.

Methods:

We have established the transgenic ER-E2F1 suicide-inducible mice, which express estrogen receptor-E2F1 fusion protein. E2F1 is a transcription factor which regulate cell proliferation and its ectopic expression induces apoptosis in differentiated cells, therefore cells fate from ER-E2F1 mouse can be eliminated on demand by tamoxifen administration. Metanephroi from ER-E2F1 mice (E2F1 group) and C57BL/6 mice (control group) were cultured with and without tamoxifen for 14 days. Cell fate was observed by fluorescence microscopy. Metanephroi were transplanted to Splague-Dawley rats (N=10 in both groups), and FK506 and tamoxifen were administered daily for two weeks. The average weight of the grown transplants was recorded and any changes were observed histologically. The expression of EPO was assayed by q-PCR using species-specific primers.

Results: In vitro tamoxifen treatment of metanephros cells derived from ER-E2F1 mice successfully eliminated these cells whereas wild-type cells remained viable. The percentage of the grown transplants in vivo, was 32% in the E2F1 group versus 56% in control group ($P=0.045$). The final weight of transplants was 2.4±0.8 mg in the E2F1 group versus 8.7±1.3 mg in the control group ($P=0.035$). Histological analysis showed that kidney tissue is replaced by fibrous tissue in the E2F1 group. qPCR revealed that rat EPO was produced from grown metanephros in both groups and that there was no significant difference between the two groups.

Conclusion: Metanephroi derived from ER-E2F1 mice are a powerful tool to regenerate completely human-derived kidney tissue.

**The Epigenetic Signature of the Developing Nephron** Nathaniel J. D. Mclaughlin, Fenglin Wang, Zubaida R. Saifudeen, Samir S. El-Dahr. *Pediatrics, Tulane University School of Medicine, New Orleans, LA.*

Kidney development is orchestrated by intricate regulatory networks of pioneer transcription factors. However, how distinct gene expression domains and cell fate decisions are propagated and maintained faithfully throughout generations of cell divisions is not completely understood. We postulate that epigenetic inheritance of combinatorial histone modifications (signature) play a key role in "imprinting" and maintenance of cell fate decisions during nephrogenesis. Cell lineages and fates were co-immunolocalized with histone marks and corresponding enzymes and examined by confocal microscopy. At E11.0, the Wolffian duct, ureteric bud (UB) and uninduced metanephric mesenchyme (MM) are decorated with a broad epigenetic landscape composed of both activating (H3-K4me3, K36me3, R17me2; H4-K16ac) and repressive marks (H3-K9me3, K27me3; H4-R3me2, K20me3). Quantitative analysis further indicated that certain repressive marks, e.g., H3K27me3 and H4R3me2, are domain-enriched in MM and UB, respectively. On E15.5, Six2/Pax2$^+$ MM cap cells are highly enriched with repressive marks/enzymes (H3K9me3/G9a, K27me3/EzH2) but also express activating marks/enzymes (H3K4me3/Ash2l and R17me2/Carm1), suggesting that the genome remains poised in nephron progenitors. The progeny of Six2$^+$ cells give rise to Lhx1$^+$ renal vesicles, which are now decorated predominantly with activating marks. Proximal K-cadherin$^+$ tubules are rich in H3K4me3, whereas distal E-cadherin$^+$ segments are enriched in H3K79me3 and its enzyme, Dot1l. Unlike other marks, H3K79me3/Dot1l increase in abundance with maturation. WT1$^+$ podocyte progenitors possess a repressive signature characteristic of terminally differentiated cells and are also enriched with H3K79me3. In summary, differentiation along the nephric lineage is characterized by dynamic changes in the epigenome. Renal progenitors possess a "bivalent" epigenetic signature, allowing for plasticity of gene expression in their progeny during nephrogenesis and differentiation. Our data support the hypothesis that epigenetic inheritance plays an important role in the generation and maintenance of cell fate decisions during kidney development.

**Distinct Epigenomic Landscapes of Renal Developmental Regulators** Nathaniel J. D. Mclaughlin, Jiao Liu, Zubaida R. Saifudeen, Samir S. El-Dahr. *Pediatrics, Tulane University School of Medicine, New Orleans, LA.*

According to the histone code hypothesis, combinatorial modifications of histone tails create an epigenetic landscape, recognized by specific effector protein complexes facilitating either activation or repression of gene transcription. In the embryo, pluripotent progenitor cells have a high number of "bivalent" or "poised" promoters marking important developmental regulators compared to differentiated cells, as indicated by the repressive H3K27me3 and the active chromatin mark H3K4me3. To explore whether this model applies to cellular differentiation during organogenesis, we compared the epigenetic landscapes of three renal developmental regulators, Six2, Pax2 and Lhx1, in two lines of immortalized mouse E11.5 metanephric mesenchyme cells, utilizing ChIP-PCR and ChIP-Seq. mK3 cells express Six2 but lack Pax2 and Lhx1; in contrast, mK4 cells express Pax2 and Lhx1 but lack Six2. The results demonstrate that in mK4 cells, the Pax2 promoter is enriched with H3K4me3 and phosphorylated form of RNA PolII; in contrast, occupancy of H3K27me3 is much higher in mK3 cells. Other repressive marks, H3K9me3 and H3R2me2, are not different. The Lhx1 promoter harbors two active marks, H3K4me3 and H3K79me3, in mK4 cells, but is enriched in two repressive marks, H3K9me3 and H3K27me3 in mK3 cells. The Six2 promoter harbors the active mark, H3K4me3, in mK3 cells, and two repressive marks H3R2me2s and H3K27me3 in mK4 cells. Overexpression of the H3K4 histone methyltransferase, Ash2l, in mK4 cells, stimulated H3K4me3 accumulation and induced endogenous *Six2* mRNA; in contrast, expression of the H3K27 methyltransferase, EzH2, stimulated H3K27me3 accumulation and further suppressed *Six2* gene expression. Ash2l and EzH2 had no effect on *GDNF* expression. Our data demonstrates that renal developmental regulators possess distinct epigenetic landscapes, which correlate strongly with gene expression patterns. While the three developmental genes share H3K4me3 as a common activation mark, they diverge in their repressive marks, lending support to the idea that distinct epigenetic signatures play a role in differential gene regulation during cellular differentiation.

**Reduced Six2 Expression Compromises Nephron Development** Suwit Jack Somponpun, Nora Matutino, Thomas Hynd, Scott Lozanoff. *Anatomy, Uni of Hawaii, Honolulu, HI.*

Suboptimal kidney development resulting in an in-born deficit in nephron number is associated with cardio-renal disease in later life. We identified a heritable mutation affecting embryonic expression of sine oculis 2 (six2) in Brachyrrhine (Br) mice who display renal hypoplasia, indicating critical role of six2 in nephrogenesis. In this study, we determine whether six2 is involved in establishing nephron number during development. E12.5 kidney explants from wild-type, Br/+, and Br/Br were cultured in DMEM for 72h and stained for six2 and calbindin. In subsequent experiment siRNA was used to inhibit six2 transcription in developing cultures and its effect on ureteric bud (UB) branching examined. Explants were incubated with 3μM of six2-siRNA and after 72h, stained for six2 and calbindin or processed for qPCR for six2 and other factors' mRNA. Six2-ir and number of UB tips were determined. Cultured kidney rudiments from Br/+ and Br/Br mice were substantially smaller and exhibited fewer UB tips, suggesting disruption of kidney growth in the absence of six2. In wild-type tissue, six2 was expressed in metanephric mesenchymes, typical of developing kidneys. Expression of six2 corresponds with branching pattern and number of UB, indicating successful kidney development in our preparation. Conversely, six2 was markedly reduced in Br/+ explants and absent from Br/Br. Correspondingly, number of UB tips decreases in Br/+ and are least amongst Br/Br kidneys. Explants exposed to six2-siRNA exhibit a substantial reduction in six2+ cells and a marked depletion of UB tips over 72h. qPCR demonstrated decreases in six2, PAX2, and Cited1 mRNA, whereas WT1 was elevated in response to six2-siRNA. Based on the degree and pattern of six2 and the number of UB tips among wild-type, Br/+, and Br/Br kidneys, results indicate that reduced six2 expression is associated with reduced UB branching and deficient nephron number in developing kidneys. This is further supported by a knockdown of six2 with siRNA, leading to a reduction in six2-expressing cells and UB branching morphogenesis. Our results implicate the role of six2 in early nephrogenesis and suggest that six2 may constitute the genetic basis for renal nephron endowment.

**Epigenetic Reprogramming of Mouse Hematopoietic Stem and Progenitor Cells for Treatment of Acute Kidney Injury** Ling Li, Fangming Lin. *Pediatrics, University of Texas Southwestern Medical Center, Dallas, TX.*

The objective of this study is to develop stem cell-based therapy for treatment of acute kidney injury. Hematopoietic stem and progenitor cells were isolated from mice with renal epithelial-specific expression of EYFP (KspCre;R26R-EYPF mice) and treated with protein factors in culture. After one week of treatment, a large number of reprogrammed cells were generated with 6.3% expressing EYFP. The cells expressed a panel of renal developmental genes and proteins, and exhibited an epithelial-like phenotype. The cells did not express embryonic stem cell marker Oct-4 or revert to a pluripotent state. Our results indicate the activation of a renal program in treated cells. An increased level of histone acetylation was detected on the promoters for cadherin 6 and 16. Further treatment of the cells with a histone deacetylase inhibitor trichostatin A resulted in a 6-fold increase in EYFP-expressing cells and in renal gene expression. These results suggest the importance of histone acetylation in reprogramming. Reprogrammed cells integrated into developing tubules of the embryonic kidney organ cultures whereas mouse embryonic fibroblasts failed to integrate. To test the therapeutic effect of reprogrammed cells, we transplanted the cells into mice with renal ischemic injury and detected improved renal function, increased proximal tubular proliferation, and decreased tubular injury. Subcapsular injection of the cells did not form teratomas, supporting the safety of cell treatment. However, only a small number of transplanted cells were founded in the regenerating tubules, indicating that cell replacement by the transplanted cells is not the main mechanism of renal protection. Instead, reprogrammed cells may offer beneficial effects in a paracrine and/or endocrine fashion. This possibility was confirmed by renal functional improvement seen after the injection of conditioned medium and the detection of renotrophic factors from reprogrammed cells. In conclusion, our studies demonstrate that hematopoietic stem and progenitor cells can be reprogrammed to generate a large number of therapeutically valuable cells in a short period of time to treat acute kidney injury.

**Validation of a New Developmental Cre Driver Strain for Kidney Development** Yoshiro Maezawa,[1] Matthew Binnie,[2] Chengjin Li,[1] C. C. Hui,[4] Susan E. Quaggin.[1,2,3] *[1]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; [2]Department of Medicine and Division of Nephrology, St Michael's Hospital, Toronto, ON, Canada; [3]Institute of Medical Science, University of Toronto, Toronto, ON, Canada; [4]Endocrine Research, Hospital for Sick Children, Toronto, ON, Canada.*

Cell type-/tissue-specific gene targeting strategies have provided enormous insights for the development of various organs. The Cre-loxP system is most widely used and requires introduction of loxP sites around an essential region of the gene of interest followed by cell type-specific Cre recombinase-mediated gene excision. To study renal development, a number of Cre-driver mouselines have been created, including Six2-Cre, HoxB7-Cre, and Pax2-Cre. Here, we report a new Cre driver mouse line, which, under control of the endogenous Pod1(Tcf21)-promoter, directs Cre recombinase expression in metanephric mesenchyme and its derivatives, including interstitial cells and all the epithelial components of the nephron from podocytes down to distal tubules of the developing kidney. This Pod1-Cre line also expresses Cre throughout the embryonic mesenchyme, including lung, heart, gastrointestinal tract and pancreas. We tested the utility of the Pod1-Cre line using four floxed lines. Pod1-Cre line bred with floxed VEGF-A mice resulted in striking loss of mesangial cells. When crossed to the beta-catenin floxed line, this mouseline generated hydroureter, hydronephrosis and hypoplastic kidneys. A conditional gain of function model of beta-catenin resulted in fused kidneys as well as a striking poorly differentiated sarcoma that is spread throughout the mesenchyme of multiple organs of the embryo. Finally, a conditional knockout of the gene encoding Patched-1, a receptor for sonic hedgehog signaling, resulted in cyst formation and lack of medullary space in the kidney. Surprisingly, these Pod1-Cre/ Patched-1 mice also developed an aggressive embryonic sarcoma, which is virtually identical to that seen in the conditional gain of function model of beta-catenin. These results demonstrate that the Pod1-Cre mouse is a powerful tool to study the development and function of the kidney in transgenic mice.

**High Salt Intake in Pregnancy Alters Maturation of Glomeruli in the Rat Offspring** Nadezda Koleganova,[2] Grzegorz Piecha,[2] Eberhard Ritz,[1] Marie-Luise Gross.[2] *[1]Dept. of Internal Medicine, University of Heidelberg, Heidelberg, Germany; [2]Institute of Pathology, University of Heidelberg, Heidelberg, Germany.*

Faulty fetal programming leads to alterations in kidney morphology in the offspring. A low number of glomeruli is known to cause high blood pressure later in life. It was the purpose of the present study to clarify whether high salt intake in pregnancy alters kidney development in the offspring.

Sprague-Dawley rats were fed normal (0.15%), medium (1.3%), or high (8.0%) salt diet during pregnancy and weaning. The number of glomeruli (mature, immature, and S-shape bodies) was assessed at 1 week postnatally. The expression of proteins involved in kidney development was assessed (by western blotting) at term and at 1 week postnatally.

At age 1 week the number of S-shaped bodies was significantly lower (405±308) and the number of mature glomeruli (818±405) and layers of developing glomeruli (7.1±0.6) was higher in the offspring of mothers on high-salt compared to the other groups (1044±490, 460±304, and 5.9±0.9 respectively). As a net result total number of glomeruli was significantly lower in the offspring of mothers on high-salt (9476±1264) compared to the other groups (11175±1920). At 1 week of age in the offspring of mothers on high salt the glomeruli were bigger compared to lower salt intake. The expression of Pax-2 (54±23% vs. 100±28%) and FGF-2 (72±33% vs. 100±30%) was significantly lower in the offspring of mothers on high-salt consistent with their causative role. There was no difference between the groups with respect to litter size, birth weight, and placenta size

We conclude that high maternal salt intake during pregnancy accelerates maturation of glomeruli in the offspring, but reduces the final number of glomeruli.

**Postnatal Overnutrition Brings Lifelong Obesity and Renal Impairment in Adult Male Rats** Hyung Eun Yim, Kissu Ha, In Sun Bae, Young Sook Hong, Joo Won Lee, Kee Hwan Yoo. *Pediatrics, Korea University Guro Hospital, Seoul, Korea.*

Accelerated growth in early infancy has been associated with later cardiovascular and metabolic diseases. We recently showed that postnatal overnutrition led to hyperleptinemia, obesity and the acquired reset of key intrarenal hormone systems in the juvenile male rats. In this study, we investigated the influence of overnutrition during neonatal periods on the development of lifelong renal pathophysiological changes in adult offspring rats. Three or 10 male pups per mother from rat pup litters were assigned to either the overnutrition or control groups during the first 21 days of life. The effects of early postnatal nutrition excess on body weight, blood pressure, blood glucose and potential renal changes related to obesity were measured by 3 and 6 months of age, respectively. Smaller litter male pups persistently weighed heavier than controls between 7 days and 6 months of age ($P < 0.05$). By 3 and 6 months of age, there were no differences of kidney weight per body weight ratio, blood glucose and plasma leptin levels between the two groups. However, increased systolic, diastolic and mean blood pressure levels were observed in obese 6 month-old rats ($P < 0.05$). Serum creatinine was increased in each 3 and 6 month-old obese rats ($P < 0.05$). ED-1 positive macrophages and glomerulosclerosis were also increased by overnutrition at 3 and 6 months of ages ($P < 0.05$). Apoptotic cortical renal cells increased in neonatally overfed 6 month-old rats ($P < 0.05$). In immunoblots and immnnohistochemistry, matrix metalloproteinase (MMP)-9 protein expressions decreased and tissue inhibitor of MMP-1, tumor necrosis factor-α, osteopontin and adiponectin expressions increased in obese 3 month-old rats ($P < 0.05$). In contrast, increased MMP-9 and osteopontin expressions were found in obese offsprings of 6 months old ($P < 0.05$). Renin, angiotensin II type (AT) 1 and AT2 receptor expression was not changed. Our data demonstrates that postnatal overfeeding leads to lifelong obesity and renal dysfunction. Obesity induced by early postnatal overnutrition may have a detrimental impact on kidney structure, function and intrarenal inflammatory cytokines.

**TH-PO348**

**Genome-Wide Identification of Target Genes of the Distal Nephron Transcription Factor CP2-Like 1 (Tcfcp2l1)** Kai M. Schmidt-Ott,[1,2] Melanie Viltard,[3] Jonathan M. Barasch.[3] *[1]Max-Delbrueck Center for Molecular Medicine, Berlin, Germany; [2]Experimental and Clinical Research Center, Charité-Universitätsmedizin Berlin, Berlin, Germany; [3]Department of Medicine, Columbia University College of Physicians and Surgeons, New York, NY.*

Transcription factors of the CP2 family control aspects of epithelial differentiation across species from Drosophila to man. Two transcription factors of this family are specifically expressed in the ureteric bud and in the distal nephron of the developing and adult kidney, grainyhead-like 2 (Grhl2) and transcription factor CP2-like 1 (Tcfcp2l1). We have set out to understand genomic target gene regulation by these factors in the kidney. We conducted chromatin immunoprecipitation (ChIP) coupled with massively parallel sequencing (ChIP-seq) in postnatal day 2 kidneys using a specific Tcfcp2l1 antibody and compared to rabbit IgG as a control. Sequence alignment to the mouse genome produced 3,171,121 aligned matches and the top 5000 clusters (representing genomic windows covered by at least 6 reads) were selected for further characterization. 50 of these Tcfcp2l1-binding peaks were randomly selected and 41 of these were confirmed independently by ChIP-PCR experiments corresponding to a validation rate of 82%. We combined data on the genomic localization of Tcfcp2l1 binding sites with respect to genes with expression profiles of the ureteric bud we had previously obtained. We identified genes that contained at least one Tcfcp2l1 binding site within 2000 bp of the transcriptional start site and found a highly significant overrepresentation of ureteric bud genes ($p<0.0001$). Tcfcp2l1 target genes constituted several key constituents of distal nephron epithelia, including cytokeratin 7 (Krt7), aquaporin 3 (Aqp3), and cadherin 6 (Cdh6). Remarkably, overexpression of Tcfcp2l1 in isolated rat metanephric mesenchyme using adenoviral gene transfer resulted in an upregulation of several of these genes and, ultimately, induced the appearance of epithelial tubules. These data indicate that Tcfcp2l1 is sufficient to drive an ectopic distal nephron-specific epithelial gene program in non-epithelial progenitor cells.

**TH-PO349**

**An NCAM1$^+$ Cell Enriched for Aldehyde Dehydrogenase Activity and Possessing Renal Stem Cell Characteristics Is the Wilms' Tumor Initiating Cell** Naomi Pode Shakked,[1] Sarit Bahar,[1] Peter Tsvetkov,[2] Orit Harari-Steinberg,[1] Benjamin Dekel.[1] *[1]Pediatric Stem Cell Research Institue, Sheba Medical Center, Israel; [2]Department of Molecular Genetics, Weizmann Institute of Science, Rehovot, Israel.*

Wilms' tumor (WT), the most common pediatric renal malignancy is suggested to arise from malignant transformation of abnormally persistent renal stem cells which retain proliferative potential but also undergo partial differentiation to form the heterogeneous mature cell populations seen in this tumor. We have previously suggested NCAM1 as a marker for WT stem/progenitor cell based on in vitro assays which demonstrated this cell fraction as highly clonogenic, proliferative and overexpressing the WT "stemness" genes.

Complicating WT in vivo cellular analysis is the inability of fresh or cultured WT cells to form tumors in immunodeficient mice. Here, we have established WT xenografts (Xn) that are characteristically highly proliferating tumors that can be rapidly propagated and sustained by individual cells and are enriched for early renal lineage markers (OSR1/SIX2), poor WT prognostic markers (TOP2A, N-MYC and CRABP2) and the surface marker NCAM1. We utilized this WT reservoir to isolate tumor-initiating cells that recapitulate the entire tumor morphology in immunodeficient mice. Accordingly, sorting experiments of Xn–derived cells and injection to mice at serial dilutions, revealed that the tumor-initiating capacity is solely contained within the NCAM1$^+$ cell population (as few as 500 cells), which gives rise to NCAM1$^-$ tubular cells and can further induce tumors when transplanted into secondary and tertiary recipients, indicative of self-renewal and differentiation capacities.

We go on to show that within the NCAM1 population, CD44 and especially ALDH1 but not PSA-NCAM greatly enrich for the tumor-initiating cells (as few as 200 cells). Importantly, the expression of nephric patterning, stemness and poor prognostic genes in these cell fractions was intimately linked with their tumor forming ability.

In summary, this study definitely identifies a renal stem cell as the cellular origin of WT and affords a novel in vivo system for vast pre-clinical drug studies on WT.
